doi: 10.3389/fphys.2021.662029

This study analyzed whether 100- and 200-m interval training (IT) in swimming differed regarding temporal, perceptual, and physiological responses. The IT was performed at maximal aerobic velocity (MAV) until exhaustion and time spent near to maximalVO ${ }_{2}$ peak oxygen uptake ( $\mathrm{VO}_{2}$ peak), total time limit ( $\mathrm{L}_{\mathrm{Lim}}$ ), peak blood lactate [La-] peak, $\stackrel{\mathrm{VO}}{2}$ kinetics $\left(\stackrel{\rightharpoonup}{ } \mathrm{O}_{2} \mathrm{~K}\right)$, and rate of perceived exertion (RPE) were compared between protocols. Twelve swimmers (seven males $16.1 \pm 1.1$ and five females $14.2 \pm 1$ years) completed a discontinuous incremental step test for the second ventilatory threshold $\left(\mathrm{V}_{2}\right), \dot{\mathrm{V}} \mathrm{O}_{2}$ peak, and MAV assessment. The swimmers subsequently completed two IT protocols at MAV with 100- and 200-m bouts to determine the maximal $\dot{\mathrm{VO}}_{2}\left(\right.$ peak- $-\mathrm{V}_{2}$ ) and time spent $\geq \mathrm{V}_{2}, 90$, and $95 \%$ of $\dot{\mathrm{V}} \mathrm{O}_{2}$ peak for the entire protocols ( $\mathrm{I} \mathrm{T}_{100}$ and $\mathrm{I} \mathrm{T}_{200}$ ) and during the first 800-m of each protocol ( $\mathrm{I}_{8 \times 100}$ and $\mathrm{IT}_{4 \times 200}$ ). A portable apparatus (K4b²) sampled gas exchange through a snorkel and an underwater led signal controlled the velocity. RPE was also recorded. The Peak- $\dot{\mathrm{V}} \mathrm{O}_{2}$ attained during $\mathrm{T}_{8 \times 100}$ and $\mathrm{I}_{4 \times 200}(57.3 \pm 4.9 \mathrm{vs}$. $57.2 \pm 4.6 \mathrm{ml} \cdot \mathrm{kg}^{-1} \cdot \mathrm{~min}^{-1}$ ) were not different between protocols $(p=0.98)$ nor to $\dot{\mathrm{V}} \mathrm{O}_{2}$ peak ( $59.2 \pm 4.2 \mathrm{ml} \cdot \mathrm{kg}^{-1} \cdot \mathrm{~min}^{-1}, p=0.37$ ). The time constant of $\dot{\mathrm{V}} \mathrm{O}_{2} \mathrm{~K}(24.9 \pm 8.4 \mathrm{vs} .25 .1 \pm 6.3-\mathrm{s}$, $p=0.67$ ) and $\left[\mathrm{La}^{-}\right]$peak ( $7.9 \pm 3.4$ and $8.7 \pm 1.5 \mathrm{mmol} \cdot \mathrm{L}^{-1}, p=0.15$ ) also did not differ between $\mathrm{T}_{100}$ and $\mathrm{I} \mathrm{T}_{200}$. The time spent $\geq \mathrm{V}_{2}, 90$, and $95 \% \mathrm{VO}_{2}$ peak were also not different between $I T_{8 \times 100}$ and $I T_{4 \times 200}\left(p=0.93,0.63\right.$, and 1.00, respectively). The RPE for $I T_{8 \times 100}$ was lower than that for $\mathrm{IT}_{4 \times 200}$ ( $7.62 \pm 2$ vs. $9.5 \pm 0.7, p=0.01$ ). Both protocols are considered suitable for aerobic power enhancement, since $\dot{\mathrm{V}_{2}}$ peak was attained with similar $\dot{\mathrm{V}_{2} \mathrm{~K}}$ and sustained with no differences in $t_{\text {Lim }}$. However, the fact that only the RPE differed between the IT protocols suggested that coaches should consider that $\mathrm{n} \times 100-\mathrm{m} / 15-\mathrm{s}$ is perceived as less difficult to perform compared with nx200-m/30-s for the first $800-\mathrm{m}$ when managing the best strategy to be implemented for aerobic power training.

[^0]
## INTRODUCTION

Interval training (IT) has been considered an effective exercise plan to improve endurance performance and maximal aerobic velocity (MAV, i.e., the velocity corresponding to the peak oxygen uptake, $\dot{\vee} \mathrm{O}_{2}$ peak; Billat and Koralsztein, 1996; Billat et al., 2000; Dalamitros et al., 2016), and, therefore, has been proposed as a successful way to enhance cardiovascular and muscle adjustments needed to optimize performance during middle-distance racing in different sports, e.g., running and swimming (Billat, 2001; Libicz et al., 2005; Reis et al., 2012a,b; Espada et al., 2015, 2021). The time sustained with $\dot{\mathrm{V}} \mathrm{O}_{2}$ responses closer to the maximal rates ( $90-100 \%$ of $\dot{\vee} \mathrm{O}_{2}$ peak) is considered an important factor to maximize aerobic training benefits ( $\stackrel{\mathrm{V}}{2}$ peak, $\mathrm{O}_{2}$ transport, and mitochondrial density) and avoid high oxygen deficits and fast metabolite accumulation, which can contribute to an increase in endurance capacity and tolerance at severe and maximal intensities (Billat and Koralsztein, 1996; Millet et al., 2003a,b; Bentley et al., 2005; Sousa et al., 2017).

The IT planning requires the organization of several parameters, such as work intensity, distance and duration, rest mode (active or passive) and duration, number of bouts to be performed ( $n$ repetitions), number of sets, and the duration of recovery between sets (Buchheit and Laursen, 2013a,b). When IT is planned to increase the time limit at MAV or/and to ensure an increase in time exercising closer to $\dot{\mathrm{V}} \mathrm{O}_{2}$ peak response, workouts have been designed with repeated bouts lasting 2-4 min, which is characterized as long-term work intervals (Buchheit and Laursen, 2013b; Wen et al., 2019). However, performing short-duration work intervals ( $<60 \mathrm{~s}$ ) could allow the athlete to complete longer IT sessions with greater oxidative demands and lower anaerobic glycolytic contribution than long work intervals, despite the similarities between short and long work intervals regarding the time spent at $\dot{\vee} \mathrm{O}_{2}$ peak (Zuniga et al., 2011; Rønnestad and Hansen, 2016) and the effectiveness for improving $\dot{\mathrm{V}} \mathrm{O}_{2}$ peak (Wen et al., 2019). Hence, the planning of work interval duration must consider the energetic balance that matches the specificity of the race to be performed.

When performing continuous exercise at MAV, the time limit approximates to $\sim 5 \mathrm{~min}$ for different exercise modes (running, cycling, swimming, and paddling; Billat et al., 1996a). However, IT has been reported to increase significantly the time limit and time spent at high $\dot{\vee} \mathrm{O}_{2}$ when designed either with short- or long-distance work intervals at 1:1 ratio (30:30 or $120: 120 \mathrm{~s}$ ) but with higher blood lactate accumulation ( $>3 \mathrm{mmol} \cdot \mathrm{L}^{-1}$ ) and oxygen deficit ( $>\sim 5 \mathrm{ml} \cdot \mathrm{kg}^{-1}$ ) when using the latter (Billat, 2001; Zuniga et al., 2011; Buchheit and Laursen, 2013b). In swimming, short-distance work intervals ( $n \times 100-\mathrm{m}$ ) performed at submaximal or maximal velocities ( $\leq 95$ or $100 \%$ MAV) have been shown to induce higher (absolute) time limit and time spent at submaximal or maximal $\dot{\mathrm{V}} \mathrm{O}_{2}$ ( $>90$ or $100 \%$ $\dot{\mathrm{V}} \mathrm{O}_{2}$ peak) than a single trial performed at same velocities (Bentley et al., 2005; Libicz et al., 2005; Sousa et al., 2017). Although the literature is not extensive, the temporal and $\dot{\mathrm{V}} \mathrm{O}_{2}$ responses during IT in swimming, seems to point out that using 60 - 120 -s work intervals at velocities $\geq 95 \%$ of MAV is recommended to stimulate improvements in aerobic power and
endurance in high swimming intensity (Dalamitros et al., 2016; Sousa et al., 2017).

However, there are still doubts on how to define the IT to provide the best combination of aerobic and anaerobic responses in swimming, especially considering the requirements for successful performance in middle-distance events, as proposed for running and cycling (Billat, 2001; Spencer and Gastin, 2001; Buchheit and Laursen, 2013b). In swimming, performing IT at MAV with $1: 1$ or 1:1/2 ratios for work:rest elicits only moderate blood lactate accumulation, clearly lower values than those reported for running and cycling (Billat et al., 2000; Zuniga et al., 2011), which is probably attributed to the clearance mechanism during long rest periods (Bentley et al., 2005; Libicz et al., 2005). Therefore, we could expect that longer work intervals or decreases in the rest periods would lead to higher anaerobic glycolic energy release (Buchheit and Laursen, 2013b). However, this has not been studied in swimming.
$\dot{\mathrm{V}} \mathrm{O}_{2}$ kinetics $\left(\dot{\mathrm{VO}}_{2} \mathrm{~K}\right)$ has been associated with endurance performance (Jones and Burnley, 2009; Reis et al., 2012b; Espada et al., 2015; Almeida et al., 2020) and time spent at $\dot{\mathrm{V}} \mathrm{O}_{2} \max$ (Millet et al., 2003a,b; Sousa et al., 2018), since faster kinetics can represent an accelerated oxidative rate. It has been reported that athletes with faster $\dot{\mathrm{V}} \mathrm{O}_{2} \mathrm{~K}$ can reach $\dot{\mathrm{V}} \mathrm{O}_{2}$ peak faster and present lower oxygen deficits (Millet et al., 2003b). However, Bentley et al. (2005) did not find any influence of faster kinetics with the time spent near $\dot{\mathrm{V}} \mathrm{O}_{2}$ maximal values on swimmers when performing IT with $400-\mathrm{m}$ bouts. Furthermore, Sousa et al. (2015) reported that swimmers seem to have slower $\dot{\mathrm{V}} \mathrm{O}_{2} \mathrm{~K}$ than runners and cyclists, which can indicate that IT in swimming could require longer work intervals to induce near maximal $\dot{\mathrm{V}} \mathrm{O}_{2}$ responses.

Considering that different combinations of the IT parameters truly induce different acute physiological responses (time spent closer to maximal $\dot{\vee} \mathrm{O}_{2}$ ), it is crucial to investigate different types of IT. Therefore, to understand whether different combinations of IT produce different but high aerobic and anaerobic responses, while exercising at MAV, this study compared the $\dot{\mathrm{V}} \mathrm{O}_{2}$, blood lactate accumulation, oxygen deficit, and rate of perceived exertion (RPE) responses during two different ITs, designed with $100-\left(\mathrm{IT}_{100}\right)$ and $200-\mathrm{m}\left(\mathrm{IT}_{200}\right)$ swimming bouts, until exhaustion. The first 800 m of each IT session was also considered for analysis in order to allow a direct comparison between training sets $\left(\mathrm{IT}_{8 \times 100}\right.$ vs. $\left.\mathrm{IT}_{4 \times 200}\right)$. We chose this format for IT in an attempt to represent the usual intermittent bouts in the daily training routine and therefore expected an analysis that is more ecological.

We hypothesize that both ITs will elicit the achievement of $\dot{\mathrm{V}} \mathrm{O}_{\text {2peak; }}$; however, $\mathrm{IT}_{100}$ will present longer times to exhaustion and consequently longer times spent near swimmers $\dot{\mathrm{V}} \mathrm{O}_{2}$ maximal values, and swimmers with faster $\dot{\mathrm{V}} \mathrm{O}_{2} \mathrm{~K}$ will also present longer times to exhaustion and times spent near $\dot{\vee} \mathrm{O}_{2}$ peak.

## MATERIALS AND METHODS

## Experimental Design

To analyze the physiological and temporal responses during two different intermittent swimming (IT) protocols, the peak
oxygen uptake ( $\stackrel{\mathrm{V}}{2} \mathrm{O}_{2}$ peak), second ventilatory threshold $\left(\mathrm{VT}_{2}\right)$, and MAV were assessed by a discontinuous incremental step test performed until a maximal $200-\mathrm{m}$ pace or to volitional exhaustion. In a randomized order, the swimmers performed two different IT protocols until exhaustion at MAV, consisting of 100 or $200-\mathrm{m}$ repetitions, to compare the ventilatory and physiological responses between the two IT formats. All the swimmers performed the three testing protocols in front crawl swimming with in-water starts and open turns without underwater gliding (in a $25-\mathrm{m}$ swimming pool), with gas exchange analysis recorded by a portable gas analyzer ( ${\mathrm{K} 4 \mathrm{~b}^{2} \text {, }}^{\text {, }}$ Cosmed ${ }^{\circledR}$, Rome, Italy) connected to the swimmers by a respiratory snorkel and a valve system (new-AquaTrainer ${ }^{\circledR}$, Cosmed, Rome, Italy). The transportation of this system along the swimming pool can be watching in the Supplementary Material.

The participants were instructed to report to the swimming pool well hydrated, fed, and to abstain from caffeine, alcohol, and strenuous exercise in the 24 h preceding the testing protocols. The same environmental conditions (time of day $\pm 2 \mathrm{~h}$, water temperature $\sim 28^{\circ} \mathrm{C}$, and relative humidity $\sim 50 \%$ ) and same pre-test warm up protocol were ensured for all tests in order to minimize the effects of circadian rhythms and differences in prior exercise. The sessions were performed in the beginning of the preparatory period of the second macrocycle of competitive season of the swimmers, after a period of 2 weeks for training adaptation and were separated by at least 48 h .

## Participants

Twelve well-trained young swimmers (seven males and five females) were informed about the procedures and experimental risks of the study and signed a written informed consent (and their legal guardians when under 18 years old). All the swimmers were fully familiarized with the equipment and procedures before the beginning of the tests. The recruited swimmers had to be regularly competing in state or national championships for a minimum of 3 years prior to the beginning of the study, as a criterion to participate in this study. This study was approved by the local University Ethical Committee (CEFMH: 39/2015) and was conducted in accordance with the 1964 Declaration of Helsinki (Harriss et al., 2017). The descriptive characteristics of the swimmers are presented in Table 1.

## Incremental Step Test and Interval Training Protocol

The discontinuous incremental step test was structured with $6 \times 250$ and $1 \times 200-\mathrm{m}$ steps performed with 30 -s rest for blood lactate sampling (Espada et al., 2015; Almeida et al., 2020). The velocity started at $50 \%$ of the velocity at $200-\mathrm{m}$ (v200-m)

TABLE 1 | Anthropometric (mean $\pm$ SD) characteristics of the participants.

| Variables | Male $(\boldsymbol{N}=\mathbf{7})$ | Female $(\boldsymbol{N}=\mathbf{5})$ | Group (N=12) |
| :--- | :---: | :---: | :---: |
| Age $(\mathrm{yrs})$ | $16.1 \pm 1.1$ | $14.2 \pm 1.0$ | $15.3 \pm 1.4$ |
| Height $(\mathrm{m})$ | $1.76 \pm 0.1$ | $1.58 \pm 0.1$ | $1.69 \pm 0.1$ |
| Total body mass (kg) | $64.8 \pm 7.8$ | $50.6 \pm 5.1$ | $58.9 \pm 9.8$ |

maximal performance, which was performed 48 h before the execution of the incremental step test and ensured the similar swimming mode (in water starting, open turns and no underwater gliding). The following steps were incremented at $55,60,70$, 80,90 , and $100 \%$ rates of v200-m, aiming to ensure a narrow rest-to-work transition for the three initial steps and therefore enabling ideal warming with no metabolism compromise (premature acidosis and glycogen depletion) for the remaining steps (Espada et al., 2015; Almeida et al., 2020).

In a randomized order, the swimmers performed two different IT swimming protocols at MAV 48 h after the incremental test and 48 h apart from each other. The IT was performed until voluntary exhaustion, following the protocols: (1) $n$ repetitions of $100-\mathrm{m}$ interspersed by $15-\mathrm{s}$ of rest $\left(\mathrm{IT}_{100}\right)$, and (2) $n$ repetitions of $200-\mathrm{m}$ interspersed by $30-\mathrm{s}$ of rest $\left(\mathrm{IT}_{200}\right)$. The comparison between each IT protocol considered the first $800 \mathrm{~m}\left(\mathrm{IT}_{8 \times 100}\right.$ and $\mathrm{IT}_{4 \times 200}$, respectively for the $\mathrm{IT}_{100}$ and $\left.\mathrm{IT}_{200}\right)$, as well as the entire $\mathrm{IT}_{100}$ and $\mathrm{IT}_{200}$ protocols, analyzing temporal, perceptual, and physiological responses.

For the control of swimming velocity during each step of the incremental test and during each $n$ repetition of $\mathrm{IT}_{100}$ and $\mathrm{IT}_{200}$, an underwater visual pacer was employed, which was designed with 26 led lights that subsequently signaled the pacing (Pacer2Swim ${ }^{\circledR}$, KulzerTEC, Santa Maria da Feira, Portugal), and was used to provide the swimmers an accurate notion of the correct velocity for each test. Figure 1 depicts an overall view of the IT protocols.

## Measurements and $\stackrel{\vee}{ } \mathrm{O}_{2}$ Kinetics

For the gas exchange analysis, a telemetric portable gas analyzer
 by a respiratory snorkel and a valve system (new-AquaTrainer ${ }^{\circledR}$, Cosmed, Rome, Italy), allowing breath-by-breath pulmonary gas collection (Reis et al., 2010; Baldari et al., 2013). The system was moved alongside the swimmers by a member of the research team. Before the start ( 10 min of resting), during, and after each protocol (at $1,3,5$, and 7 -min in the recovery phase) capillary blood samples $(25 \mu \mathrm{l})$ were collected from the earlobe (carefully dried before each sampling) for blood lactate $\left[\mathrm{La}^{-}\right]$analysis (YSI, 2300 STAT $^{\circledR}$, Yellow Springs, Ohio). Exceptionally during the IT protocols, the blood samples were collected before (at rest) and after (at recovery) only. The peak of $\left[\mathrm{La}^{-}\right]$concentration ( $\left[\mathrm{La}^{-}\right]$peak) was measured in the recovery phase after the incremental step test and each IT protocol. The RPE was recorded through the CR-10 scale of Borg (1990).

During the incremental step test, the $\dot{\mathrm{VO}_{2}}$ peak was measured as the highest 30 -s (moving) averaged $\dot{\mathrm{VO}_{2}}$ in each step, and MAV was considered as the velocity corresponding to the step where $\dot{\vee} \mathrm{O}_{2}$ peak occurred (Billat and Koralsztein, 1996). $\mathrm{VT}_{2}$ was determined by gas analysis in the incremental test according to the recommendations of Filho et al. (2012), and was examined visually using the responses from the $\mathrm{V}_{\mathrm{E}} / \mathrm{VCO}_{2}$, $\mathrm{V}_{\mathrm{E}} / \stackrel{\mathrm{VO}_{2}}{ }, \mathrm{P}_{\mathrm{ET}} \mathrm{CO}_{2}$, and $\mathrm{P}_{\mathrm{ET}} \mathrm{O}_{2}$ parameters. The criterion was the continuous increase in $\mathrm{V}_{\mathrm{E}} / \stackrel{\mathrm{VO}_{2}}{ }$ and $\mathrm{V}_{\mathrm{E}} / \mathrm{VCO}_{2}$ ratio curves related to the reduction in $\mathrm{P}_{\mathrm{ET}} \mathrm{CO}_{2}$. The point of $\mathrm{VT}_{2}$ localization was observed by two independent experts. Swimming velocity at $\mathrm{VT}_{2}$ corresponded to the incremental testing step at which

FIGURE 1 | Overview of experimental design for 200-m performance (A), discontinuous incremental step test (B), $\mathrm{I}_{8 \times 100}$ (C), and IT Ix200 (D). The total time limit ( $t_{\text {Lim }}$ ) indicates $n$ repetitions until exhaustion during IT100 and IT200, respectively (A,B).
$\mathrm{VT}_{2}$ occurred. Maximal exertion during the incremental step test was ensured by analyzing secondary criteria, as [ $\mathrm{La}^{-}$]peak ( $\geq 8 \mathrm{mmol} \cdot \mathrm{l}^{-1}$ ) and respiratory exchange ratio (RER $>1$; Baldari et al., 2013). The maximal $30-\mathrm{s}$ (moving) averaged $\dot{\mathrm{V}} \mathrm{O}_{2}$ attained during each IT protocol was considered the Peak- $\dot{\vee} \mathrm{O}_{2}$, and the MPeak- $\dot{\vee} \mathrm{O}_{2}$ was the average of the maximal $\dot{\mathrm{V}} \mathrm{O}_{2}$ (30-s moving average) attained during each bout of the IT protocols. Both Peak- $\dot{\mathrm{V}} \mathrm{O}_{2}$ and MPeak- $\dot{-} \mathrm{O}_{2}$ were calculated in $\mathrm{IT}_{8 \times 100}$ and $\mathrm{IT}_{4 \times 200}$, as well as for the entire $\mathrm{IT}_{100}$ and $\mathrm{IT}_{200}$.

The time spent (in seconds) with $\dot{\mathrm{VO}_{2}}$ above the $\mathrm{VT}_{2}(\mathrm{t} @$ $\left.\mathrm{VT}_{2}\right), 90 \%$ ( $\mathrm{t} @ 90 \%$ ), and $95 \%$ ( $\mathrm{t} @ 95 \%$ ) of $\dot{\mathrm{V}} \mathrm{O}_{2 \text { peak }}$ and the corresponding percentage (\%) for the total duration of each IT were determined, as well as the time to exhaustion ( $\mathrm{t}_{\text {Lim }}$ ) and distance performed by each swimmer.

For the $\dot{\mathrm{VO}_{2} \mathrm{~K} \text { analysis, the outliers (exclusion of values lying }}$ over three SDs from the local mean) were previously excluded from the analysis, and the breath-by-breath data were interpolated into 1 -s values. Only the first bout of each IT protocol
(100 and $200-\mathrm{m}$ ) was used for the determination of the $\dot{\mathrm{VO}_{2} \mathrm{~K}}$ parameters [time delay (TD), time constant ( $\tau$ ), and amplitude (A)]. The cardiodynamic phase of the $\dot{\mathrm{VO}_{2}}$ response at the onset of the exercise was discharged by removing the first 20 s of the $\dot{\mathrm{V}} \mathrm{O}_{2}$ response (Filho et al., 2012). As described by Reis et al. (2010), an individual "snorkel delay" (ISD) that corresponded to the difference between the onset of exercise and the time when the following breaths summed up a tidal volume superior to the outlet tube volume was calculated for each test. The ISD was adapted to the specific characteristic of the snorkel device used in this study and then integrated into the time delay of the $\dot{\mathrm{V}} \mathrm{O}_{2}$ response. The $\dot{\mathrm{V}} \mathrm{O}_{2}$ vs. time mono-exponential adjustments were analyzed through an iterative procedure by minimizing the sum of the mean squares of the differences between the modeled and the measured $\dot{\mathrm{V}} \mathrm{O}_{2}$ values, according to the following equation:

$$
\dot{\mathrm{V}} \mathrm{O}_{2(\mathrm{t})}=\dot{\mathrm{V}} \mathrm{O}_{2 \text { base }}+\mathrm{A} \cdot\left(1-\mathrm{e}^{-(\mathrm{t}-\mathrm{TD}) / \tau}\right)
$$

where $\dot{\mathrm{V}} \mathrm{O}_{2(t)}$ represents the relative $\dot{\mathrm{V}} \mathrm{O}_{2}$ at a given time; $\dot{\mathrm{V}} \mathrm{O}_{2}$ base represents the $\dot{\mathrm{V}} \mathrm{O}_{2}$ at rest, which was calculated as the average of the first $30-\mathrm{s}$ of the last minute before the start of the exercise (after $10-\mathrm{min}$ of passive rest); TD, $\tau$, and A represent the time delay, time constant, and amplitude of the primary phase of the $\dot{\mathrm{VO}_{2} \text { response, respectively (Rodríguez et al., 2003; }}$ Sousa et al., 2013; Almeida et al., 2020). The oxygen deficit $\left(\mathrm{O}_{2 \text { Def }}\right)$ at the onset of the first 100 and $200-\mathrm{m}$ of each IT protocol was measured as the product between mean response time (MRT) and A, where the MRT is TD $\times \tau$ (Whipp et al., 2005).

## Statistical Analysis

Initially, normality and homogeneity of data were accessed by the Shapiro-Wilk and Levene tests. The comparison of the temporal, perceptual, and physiological responses between the two IT protocols was performed considering all the samples with the $t$-test for unpaired samples, or with the Mann-Whitney test when the assumptions for parametric tests were not met. The Kruskal-Wallis test compared $\dot{\mathrm{VO}_{2}}$ peak and $\left[\mathrm{La}^{-}\right]$peak responses during the incremental step test vs. Peak- $\dot{\mathrm{V}} \mathrm{O}_{2}$ during $\mathrm{IT}_{8 \times 100}$ and $\mathrm{IT}_{4 \times 200}$, and vs. Peak- $\dot{\mathrm{V}} \mathrm{O}_{2}$ during the entire $\mathrm{IT}_{100}$ and $\mathrm{IT}_{200}$ protocols. The Spearman coefficient (ro) tested the rank-order correlation between physiological, perceptual, and temporal responses during the IT protocols. The effect sizes (ES) were calculated by Cliff's $\delta$, considering the $n$ and $p$ values for the differences analyzed by the Mann-Whitney test, which was interpreted as 0.2 weak, 0.36 medium, 0.52 strong, and 0.76 very strong (Sheskin, 2011). The ro was interpreted as $<0.2$ (trivial), $0.2-0.49$ (small), $0.5-0.8$ (medium), and $>0.8$ (large; Ferguson, 2009). All statistical analyses were performed with the Statistical Package for the Social Sciences (version 25.0; SPSS ${ }^{\circledR}$, Chicago, IL, United States), and statistical significance was accepted at $p \leq 0.05$.

## RESULTS

The physiological responses of the swimmers during the incremental step test are shown in Table 2. The $\left[\mathrm{La}^{-}\right]$peak

TABLE 2 | Measurements (mean $\pm$ SD) during the incremental step test for the entire groups of participants $(N=12)$.

and RER reached values corresponding to the maximal exertion, and the entire sample of participants (male and female) exhibited no large variance for maximal and submaximal indexes of aerobic conditioning level [coefficient of variation (CV) $<10 \%$ for $\dot{\mathrm{V}} \mathrm{O}_{2}$ peak and $\mathrm{VT}_{2}$ ]. An individual response of $\dot{\mathrm{V}} \mathrm{O}_{2}$ increasing during the incremental step test and the profile of gas-exchange variable $\left(\dot{\mathrm{V}}_{\mathrm{E}}, \dot{\mathrm{V}} \mathrm{CO}_{2}, \dot{\mathrm{~V}}_{\mathrm{E}} / \mathrm{VO}_{2}\right.$, and $\left.\dot{\mathrm{V}}_{\mathrm{E}} / \dot{\mathrm{V}} \mathrm{CO}_{2}\right)$ matching $\mathrm{VT}_{2}$ criteria are illustrated in Figure 2.

The physiological and perceptual responses during the IT protocols and $\dot{\mathrm{V}}_{2} \mathrm{~K}$ analysis are shown in Table 3. Typical responses of $\dot{\mathrm{V}} \mathrm{O}_{2}$ in $\mathrm{IT}_{8 \times 100}$ and $\mathrm{IT}_{4 \times 200}$ are illustrated in Figure 3 for the male (panels A and B) and female (panels C and D) swimmers. The velocities while performing $\mathrm{IT}_{100}$ and $\mathrm{IT}_{200}$ did not differ from MAV ( $p=0.89$ and $p=0.39$, respectively) or between each other ( $p=0.44$ ). When comparing $\dot{\mathrm{V}} \mathrm{O}_{2}$ peak vs. Peak- $\dot{\mathrm{V}} \mathrm{O}_{2}\left(\mathrm{IT}_{8 \times 100}\right)$ vs. Peak- $\dot{\mathrm{V}} \mathrm{O}_{2}\left(\mathrm{IT}_{4 \times 200}\right)$, no significant differences were observed ( $p=0.37$ ). However, differences were observed for the comparison of $\dot{\mathrm{V}} \mathrm{O}_{2}$ peak vs. MPeak- $\dot{\mathrm{V}} \mathrm{O}_{2}$ $\left(\mathrm{IT}_{8 \times 100}\right)$ vs. MPeak- $\dot{\vee} \mathrm{O}_{2}\left(\mathrm{IT}_{4 \times 200} ; p=0.01\right)$. Similar results were observed when comparing the $\mathrm{IT}_{100}$ and $\mathrm{IT}_{200}$ protocols. Therefore, there were no significant differences for $\dot{\mathrm{V}} \mathrm{O}_{2}$ peak vs. Peak- $\dot{\mathrm{V}} \mathrm{O}_{2}\left(\mathrm{IT}_{100}\right)$ vs. Peak- $\dot{\mathrm{V}} \mathrm{O}_{2}\left(\mathrm{IT}_{200} ; p=0.32\right)$, but significant differences were observed for $\dot{\mathrm{V}} \mathrm{O}_{2}$ peak vs. MPeak- $\dot{\mathrm{V}} \mathrm{O}_{2}\left(\mathrm{IT}_{100}\right)$ vs. MPeak- $\dot{\vee} \mathrm{O}_{2}\left(\mathrm{IT}_{200} ; p<0.01\right)$. Additionally, no significant differences were observed for $\left[\mathrm{La}^{-}\right]$peak responses after the incremental step test vs. $\mathrm{IT}_{100}$ vs. $\mathrm{IT}_{200}(p=0.15)$. Regarding the RPE, differences were observed when comparing $\mathrm{IT}_{8 \times 100}$ vs. $\operatorname{IT}_{4 \times 200}(p=0.012 ; \delta=0.36)$ but no differences for IT100 vs. IT200 $(p=0.55)$. The measurements of $\mathrm{A}_{1}(p=0.38)$, TD $(p=0.89), \tau(p=0.67)$, and $\mathrm{O}_{2 \mathrm{Def}}(p=0.98)$ did not differ between $\mathrm{IT}_{100}$ and $\mathrm{IT}_{200}$.

The values of distance, time limit, and time spent above $\mathrm{VT}_{2}, 90$, and $95 \%$ of $\dot{\mathrm{V}} \mathrm{O}_{2}$ peak during the IT protocols are shown in Table 4. The comparison between the percentage of $\mathrm{t} @ \mathrm{VT}_{2}$, $\mathrm{t} @ 90 \%$, and $\mathrm{t} @ 95 \%$ of $\dot{\mathrm{V}} \mathrm{O}_{2}$ peak during each IT protocol are illustrated in Figure 4. There were no significant differences in distance $(p=0.09)$ and $\mathrm{t}_{\mathrm{Lim}}(p=0.16)$ between $\mathrm{IT}_{100}$ and $\mathrm{IT}_{200}$. No significant differences were observed when comparing $\mathrm{IT}_{8 \times 100}$ vs. $\mathrm{IT}_{4 \times 200}$ with regard to $\mathrm{t} @ \mathrm{VT}_{2}(p=0.72)$, $\mathrm{t} @ 90 \%(p=0.63)$, and $\mathrm{t} @ 95 \%(p=1)$. Similarly, $\mathrm{IT}_{100}$ vs. $\mathrm{IT}_{200}$ did not differ regarding $\mathrm{t} @ \mathrm{VT}_{2}(p=0.22)$, $\mathrm{t} @ 90 \%(p=0.29)$, and $\mathrm{t} @ 95 \%(p=0.16)$. However, $\mathrm{t} @ \mathrm{VT} \mathrm{T}_{2}$ was higher than $\mathrm{t} @ 95 \%$ during $\operatorname{IT}_{8 \times 100}(p<0.01)$ and $\operatorname{IT}_{4 \times 200}(p<0.01)$.

TABLE $3 \mid$ Mean $\pm$ SD of the physiological and perceptual responses during the IT protocols, and $\dot{\mathrm{V}} \mathrm{O}_{2}$ kinetics ( $\dot{\mathrm{V}} \mathrm{O}_{2} \mathrm{~K}$ ) during the first bout of $\mathrm{IT}_{100}$ and $\mathrm{IT}_{200}(N=12)$.

Peak- $\dot{\mathrm{V}} \mathrm{O}_{2}$ and $\%$ Peak- $\dot{\mathrm{V}} \mathrm{O}_{2}$ : maximal $\dot{\mathrm{VO}_{2}}$ achieved in the test and corresponding percentage of $\dot{\mathrm{V}} \mathrm{O}_{2}$ peak; $M P e a k-\dot{\mathrm{V}} \mathrm{O}_{2}$ and $\% M P e a k-\dot{\mathrm{V}} \mathrm{O}_{2}$ : average value and corresponding percentage of the Peak- $-\mathrm{V}_{2}$ achieved during the performance of each bout of IT protocols; [La-]peak: peak blood lactate concentration after each IT protocol performance; velocity: the actual velocity while performing each IT protocol.
*Statistical difference between IT protocols (IT $T_{8 \times 100}$ Vs. $I T_{4 \times 200}$ or $I T_{100}$ Vs. $I T_{200}$ ) at $p \leq 0.05$.

The correlation between the IT protocols with regard to the temporal, physiological, and perceptual responses is shown in Table 5. The total distance and $\mathrm{t}_{\text {Lim }}$ attained during $\mathrm{IT}_{100}$ and $\mathrm{IT}_{200}$ did not associate the protocols with each other ( $p=0.11$ and $p=0.27$ ) regarding performance. However, the [La-]peaks after $\mathrm{IT}_{100}$ and $\mathrm{IT}_{200}$ are positively correlated ( $p<0.01$ ), as well as $\tau$ and $\mathrm{O}_{2 \text { Def }}$ for $\dot{\mathrm{O}_{2} \mathrm{~K}}$ during the first bout of $\mathrm{IT}_{100}$ and $\mathrm{IT}_{200}(p=0.03$ and $p=0.05)$, despite Peak$\dot{\mathrm{V}} \mathrm{O}_{2}$ not being associated when analyzing $\mathrm{IT}_{100}$ vs. $\mathrm{IT}_{200}(p=0.53)$ and $\mathrm{IT}_{8 x 100}$ vs. $\mathrm{IT}_{4 \times 200}(p=0.6)$. Therefore, the IT protocols are associated with each other only with regard to some features of anaerobic contribution and initial $\dot{\mathrm{V}} \mathrm{O}_{2}$ response. The $\mathrm{t}_{\mathrm{Lim}}$ at $\mathrm{IT}_{100}$ and $\mathrm{IT}_{200}$ correlated with RPE at the strong ( $p<0.01$ ) and poor ( $p=0.08$ ) levels, respectively, but the distance swam at $\mathrm{IT}_{100}$ and $\mathrm{IT}_{200}$ correlated both with RPE ( $p<0.01$ and $p=0.04)$. The [ $\mathrm{La}^{-}$]peak after $\mathrm{IT}_{100}$ showed no correlation with $\mathrm{t}_{\text {Lim }}$ in $\mathrm{IT}_{100}(p=0.09)$, and negative correlation with total distance in $\mathrm{IT}_{100}(p=0.03)$. Additionally, the [ $\left.\mathrm{La}^{-}\right]$peak after $\mathrm{IT}_{200}$ positively correlated with $\mathrm{@} 90 \%$, $\mathrm{@} 95 \%$, and $\mathrm{O}_{2 \text { Def }}$ during $\mathrm{IT}_{4 \times 200}(p=0.03 ; p=0.05 ; p<0.01) . \dot{\vee} \mathrm{O}_{2}$ peak and MAV correlated negatively with $\left[\mathrm{La}^{-}\right]$peak after $\mathrm{IT}_{100}[r o=-0.8$, $p<0.01$, (medium); ro $=-0.71, p=0.01$, (medium)]. MAV correlated negatively with $\mathrm{@} 95 \%$ during $\mathrm{IT}_{200}$ ( $r o=-0.59$, $p=0.04$ ), while $\dot{V}_{2}$ peak had a positive correlation with total distance in $\mathrm{IT}_{100}(r o=0.55, p=0.07)$, as well as $\dot{\vee} \mathrm{O}_{2}$ peak correlating significantly only with Peak- $\mathrm{VO}_{2}$ during $\mathrm{IT}_{4 \times 200}$ [ $r o=0.64, p=0.02$, (medium)] but showed a tendency with Peak- $\mathrm{VO}_{2}$ during $\mathrm{IT}_{8 \times 100}(r o=0.52, p=0.09)$.

## DISCUSSION

This study analyzed the $\dot{\vee} \mathrm{O}_{2}$ response, as well as the blood lactate concentration and oxygen deficit induced by different intermittent training protocols. The findings support that the two IT formats studied ( $100-\mathrm{m} / 15-\mathrm{s}$ and $200-\mathrm{m} / 30-\mathrm{s}$ performed at MAV) were able to stimulate the exertion level close to maximal $\stackrel{\stackrel{V}{2}}{2}$, as well as moderate to high anaerobic stimulation when considering blood lactate accumulation and oxygen deficit.

Therefore, both training protocols showed to elicit physiological responses that were typical of middle-distance swimming performance. Moreover, the analysis of the first 800 m allowed the comparison between both training protocols ( $\mathrm{IT}_{8 \times 100}$ vs. $\mathrm{IT}_{4 \times 200}$, , highlighting that the perception of exertion level differed, while performing each IT, with a significantly higher RPE at $\mathrm{IT}_{4 \times 200}$.

Other important findings to be highlighted are (i) the Peak$\mathrm{VO}_{2}$ attained during both IT protocols did not differ from the $\dot{\vee} \mathrm{O}_{2 \text { peak }}$ attained during the incremental step test, which suggests that independently of the IT protocol ( $n \times 100-\mathrm{m} / 15-\mathrm{s}$ and $n \times 200-\mathrm{m} / 30-\mathrm{s}$ ) a maximal demand upon aerobic contribution was imposed; and (ii) the features of the stimulus upon [ $\mathrm{La}^{-}$] peak and $\mathrm{O}_{\text {2Def }}$ denoted a moderate to high reliance on anaerobic contribution, which was similar between the IT protocols and therefore reproduce the energetics required in middle-distance events. In perceptual terms, these IT protocols differed regarding the sensation of exertion, with $\mathrm{IT}_{\text {8x100 }}$ perceived as a less exhaustive exercise, despite no physiological difference between the IT protocols.
To the best of the knowledge of the authors, only two studies analyzed the $\dot{\vee} \mathrm{O}_{2}$ response in swimming during IT protocols. Libicz et al. (2005) reported that well-trained triathletes spent double the time above $95 \%$ of $\dot{\mathrm{V}_{2} \max }$ ( $\sim 145 \mathrm{vs}$. $\sim 69-\mathrm{s}$ ) in $8 \times 100-\mathrm{m} / 30-\mathrm{s}$ than in $16 \times 50 \mathrm{~m} / 15$-s repetitions, despite the large variability observed in the $\stackrel{\mathrm{V}}{2}$ data constraining the level of statistical significance between each IT. Another study measured time sustained closer to $\dot{\mathrm{V}} \mathrm{O}_{2} \max \left(>90 \% \dot{\mathrm{~V}} \mathrm{O}_{2}\right.$ max) during two different IT protocols ( $16 \times 100$ vs. $4 \times 400 \mathrm{~m}$ ) performed at submaximal intensity ( $\Delta 25 \% \mathrm{LT}-\mathrm{v}^{2} \mathrm{O}_{2 \max }$; Bentley et al., 2005). Similar to this study, the authors reported no influence of the work interval duration on time sustained above $90 \%$ of $\dot{\mathrm{V}} \mathrm{O}_{2}$ max ( $\sim 564$ vs. $341-\mathrm{s}$ ) nor on the maximal $\dot{\mathrm{V}} \mathrm{O}_{2}$ ( $\sim 93$ vs. $92 \%$ ) reached during each IT, as well as reporting no correlation between faster $\dot{\mathrm{V}_{2} \mathrm{~K}}(\tau \sim 17$-s during $400-\mathrm{m}$ ) and longer times spent closer to $\mathrm{VO}_{2}$ max. The lack of significance for the differences was attributed to the large variability, which is therefore corroborated to the current data for either total time-limit or time spent at a high $\stackrel{\mathrm{V}}{2}{ }_{2}$ in swimming, which

FIGURE $2 \mid$ Pulmonary $\dot{\mathrm{V}}_{2}$ and other gas-exchange responses during the incremental step test for a male participant. The vertical dashed line indicates $\mathrm{VT}_{2}$ occurrence and the inclined dashed line illustrates isocapnic disturbance and ventilatory compensation. The progression for this male swimmer ranged from 67 to $100 \% \dot{\mathrm{~V}} \mathrm{O}_{2}$ peak, and time performance range was $265-161-\mathrm{s}$, respectively, from the first to the seventh step.
was higher than $30 \%$ and even larger at higher exercise intensity ( 90 and $95 \% \dot{\mathrm{~V}} \mathrm{O}_{2}$ peak) for both IT.

Notwithstanding, the variability in time-limit performance sounds not to be a matter of sex-related differences in the sample, since other studies including only males or combining male and female participants also reported large temporal variability (Billat et al., 1999; Zuniga et al., 2011), despite sex differences regarding the time limit in intermittent swimming performance remaining to be investigated. For continuous performance in swimming at paces demanding high $\dot{\mathrm{V}}{ }_{2}$, there are no differences in time limit between male and female swimmers, regardless of conditioning level (Fernandes et al., 2006). Indeed, the exercise tolerance (the endurance performance) during $\dot{\mathrm{V}} \mathrm{O}_{2}$ sustained closer to $\dot{\mathrm{V}} \mathrm{O}_{2}$ peak is determined by the
ability of the muscle system to attenuate the reliance on anaerobic sources at the onset of exercise, as well as the accumulation of metabolites, which are processes often analyzed through oxygen deficit, blood lactate accumulation, and $\dot{\mathrm{V}} \mathrm{O}_{2}$ on-kinetics (Murgatroyd et al., 2011), with responses to specific exercise but not constrained to sex differences (Billat et al., 1996b; Carter et al., 2006; Reis et al., 2017).

Therefore, the decrease or increase in anaerobic reliance during intermittent exercise relies on the modification of the ratio of work and rest intervals (Billat, 2001; Buchheit and Laursen, 2013b). Interval training has been proposed to increase the time exercising with high $\dot{\vee_{O}}$ demand, which is not attained without a high stimulus on anaerobic glycolysis metabolism (Billat et al., 2000). However, according to

TABLE $4 \mid$ Mean $\pm$ SD of the distance and time performance during the IT protocols $(N=12)$.

${ }^{+}$Statistical difference between IT protocols ( $I T_{8 \times 100}$ vs. $I T_{4 \times 200}$ or $I T_{100}$ Vs. $I T_{200}$ ) at $p \leq 0.05$.

Zuniga et al. (2011) and Rønnestad and Hansen (2016), short work intervals ( $30-\mathrm{s}$ ) compared with longer ones (3-min) may allow athletes to complete longer IT exercise sessions with greater metabolic demands and lower [ $\mathrm{La}^{-}$]. Despite the study of Libicz et al. (2005), which argued that short work interval IT in swimming fails to induce longer time spent near $\dot{\mathrm{V}} \mathrm{O}_{2 \max }$, while inducing an excessive muscular fatigue or acidosis for an effective improvement in endurance and middle-distance performance, this study was the first to evidence this combination.

With regard to the ability of the IT protocols to elicit maximal $\dot{\vee} \mathrm{O}_{2}$, this study observed that $\mathrm{t} @ \mathrm{VT}_{2}$ (exercise in a severe domain, encompassing time spent at or above $\mathrm{VT}_{2}$ ) is higher than $80 \%$ of $\mathrm{t}_{\text {Lim }}$ to perform either the first $800-\mathrm{m}$ or the entire $\mathrm{IT}_{100}$ and $\mathrm{IT}_{200}$ protocols, while $\mathrm{t} @ 90 \%$ comprised $40-50 \%$ of time for the first $800-\mathrm{m}$ or $\mathrm{t}_{\mathrm{Lim}}$ for the entire protocols. Despite that the $\mathrm{VT}_{2}$ was attained $\sim 88 \% \dot{\mathrm{~V}}{ }_{2}$ peak in this study, swimming at or above $\mathrm{VT}_{2}$ leads to an appreciable increase in $\mathrm{VO}_{2}$ (Pessôa Filho, 2012). Hence, the protocols studied enabled the increase in the time spent closer to $\stackrel{\rightharpoonup}{\vee} \mathrm{O}_{2}$ peak, when compared with the findings reported by Sousa et al. (2017) for continuous swimming performance at or above $90 \% \dot{\mathrm{~V}} \mathrm{O}_{2}$ peak at 90 and $100 \%$ of MAV ( $\sim 78$ and $\sim 72 \%$ ). Moreover, even considering time at or above $90 \% \dot{\mathrm{~V}_{2}}$ peak for this study in absolute terms ( $\sim 300-450-\mathrm{s}$ ), it was longer than those reported by Sousa et al. (2017; $\sim 268-s)$. However, in the study of Libicz et al. (2005), the time spent above $95 \%$ of maximal $\dot{\mathrm{V}} \mathrm{O}_{2}$ was $\sim 22 \%$ of total time during IT planned with $8 \times 100-\mathrm{m} / 30-\mathrm{s}$, which percentage is higher than the $\sim 12-15 \%$ of total time observed for $\mathrm{t} @ 95 \%$ during both IT8x100 and IT4x200 in the present study. It is likely that the mode of performance (continuous vs. intermittent) and rest interval between $100-\mathrm{m}$ bouts ( 30 vs. $15-\mathrm{s}$ ) accounts for the differences between these studies and this study. In spite of the fact that this study only analyzed the effect of velocity at $100 \%$ of MAV on $\dot{\mathrm{V}} \mathrm{O}_{2}$ demand, the $\dot{\mathrm{V}} \mathrm{O}_{2}$ elicited during $\mathrm{IT}_{100}$ and $\mathrm{IT}_{200}$ has satisfactory high similarity to those reported for continuous or intermittent efforts in swimming (Libicz et al., 2005) and other sports modalities (Billat, 2001; Buchheit and Laursen, 2013b).

Nevertheless, total distance swam and $\mathrm{t}_{\text {Lim }}$ are not correlated between IT protocols, as well as $\mathrm{t} @ \mathrm{VT}_{2}, \mathrm{t} @ 90 \%$, and $\mathrm{t} @ 95 \%$, which means that the IT protocols are independent in those measures. Also, the protocols did not correlate regarding the peak of $\dot{\mathrm{V}} \mathrm{O}_{2}$ reached during the performance of each IT protocol, although temporal $\dot{\vee} \mathrm{O}_{2} \mathrm{~K}$ and anaerobiosis stimulus $\left(\mathrm{O}_{2 \text { Def }}\right.$ and $\left[\mathrm{La}^{-}\right]$peak) correlated with each other between protocols.

Therefore, both the protocols are suitable to match middledistance specificity regarding energetic contribution, which approaches $\sim 25-26 \mathrm{ml} \cdot \mathrm{kg}^{-1}$ and $\sim 12 \mathrm{mmol} \cdot \mathrm{L}^{-1}$ for swimming (200- and $400-\mathrm{m}$; Campos et al., 2017). Indeed, the values observed for $\mathrm{O}_{2 \text { Def }}$ and $\left[\mathrm{La}^{-}\right]$peak in this study are also quite similar to the values reported for IT performed at $100 \% \mathrm{v} \dot{\mathrm{V}} \mathrm{O}_{2 \text { max }}$ in running and cycling ( $\sim 20-31 \mathrm{ml} \cdot \mathrm{kg}^{-1} ; \sim 5-7 \mathrm{mmol} \cdot \mathrm{L}^{-1}$; Billat, 2001; Scott, 2006; Panissa et al., 2018).

However, the IT protocols showed particular correlations with anaerobic variables as follows: (i) negative coefficients between $\left[\mathrm{La}^{-}\right]$peak vs. $\dot{\vee} \mathrm{O}_{2}$ peak, MAV, $\mathrm{t}_{\mathrm{Lim}}$, and total distance for $\mathrm{IT}_{100}$; and (ii) positive coefficients between $\left[\mathrm{La}^{-}\right]$peak vs. $\mathrm{t} @ 90 \%$, $\mathrm{t} @ 95 \%$, and $\mathrm{O}_{2 \text { Def }}$ for $\mathrm{IT}_{200}$. These results suggest that swimmers with the highest $\dot{\vee} \mathrm{O}_{2}$ peak and MAV had the tendency to perform $\mathrm{IT}_{100}$ with low [ $\mathrm{La}^{-}$]peak and, hence, tolerate more distance at MAV, which seems to account for the influence of lower perceived exertion reported (less uncomfortable) by those swimmers. In contrast, swimmers with higher MAV had spent less time at or above $90 \% \dot{\vee} \mathrm{O}_{2}$ peak during $\mathrm{IT}_{200}$, suggesting that the improvements of the time at high rates of $\dot{\mathrm{V}} \mathrm{O}_{2}$ are related to high $\dot{\mathrm{V}} \mathrm{O}_{2}$ peak (wide range to $\dot{\mathrm{V}} \mathrm{O}_{2}$ adjustments) and anaerobic capacity (enable to support high $\mathrm{O}_{2 \text { Def }}$ and $\left[\mathrm{La}^{-}\right]$peak), and, therefore, perceived as harder to perform. Hence, the performance during $\mathrm{IT}_{200}$ exhibits a typical inverse relationship between MAV and $\mathrm{t}_{\mathrm{Lim}}$ at rates closer to $\dot{\mathrm{V}} \mathrm{O}_{2} \max$ (Billat et al., 1996a). Additionally, the combination of long exercise bouts ( $>2 \mathrm{~min}$ ), high intensity ( $100 \%$ MAV), and short rest intervals ( $\leq 30 \mathrm{~s}$ ), as designed for $\mathrm{IT}_{200}$, are difficult to manage with no acidosis because of the reduction in phosphocreatine stores replacement and the increasing reliance on the anaerobic glycolytic contribution (Billat, 2001; Buchheit and Laursen, 2013b).

These dynamics between phosphocreatine nadir and greater glycogen utilization can be more relevant to explain $\mathrm{t}_{\text {Lim }}$ than microvascular blood flow and muscle oxygen extraction (temporal parameters of $\left.\dot{\mathrm{V}} \mathrm{O}_{2} \mathrm{~K}\right)$. The assumption that $\mathrm{t}_{\text {Lim }}$ is related to $\dot{\mathrm{V}} \mathrm{O}_{2} \mathrm{~K}$ considers that fast $\mathrm{VO}_{2}$ response until the targeted muscle $\mathrm{O}_{2}$ requirements would reduce $\mathrm{O}_{2}$ deficit and metabolite accumulation and, therefore, attenuate phosphocreatine and glycogen stores depletion (Millet et al., 2003b; Bailey et al., 2009). For example, the increase in $\mathrm{O}_{2}$ availability induced by prior heavy exercise could be higher for subjects with a slower time constant, improving the time spent above $90 \% \dot{\mathrm{~V}} \mathrm{O}_{2 \text { max }}$ when performing at 100 or $105 \%$ of MAV (Millet et al., 2003b). For Bailey et al. (2009), the analysis of $\dot{\vee} \mathrm{O}_{2} \mathrm{~K}$ has the potential to demonstrate the enhancement of exercise tolerance after

FIGURE $3 \| \dot{\mathrm{VO}_{2}}$ response during $\mathrm{I}_{8 \times 100}(\mathbf{A}, \mathbf{C})$ and $\mathrm{I}_{4 \times 200}(\mathbf{B}, \mathbf{D})$ for male $(\mathbf{A}, \mathbf{B})$ and female $(\mathbf{C}, \mathbf{D})$ swimmers. The yellow, orange, and red shadow areas highlight the t @ $\mathrm{T}_{2}$, $\mathrm{t} 90 \%$, and $\mathrm{t} @ 95 \%$ of $\stackrel{\mathrm{V}}{2 \text { 2paek, }}$, respectively.
interval training through a substantial increase in oxidative energy contribution and a reduced reliance on anaerobiosis stimulus. Despite these authors not finding a correlation between the magnitude of changes in tolerance with time constant of $\dot{\mathrm{V}} \mathrm{O}_{2} \mathrm{~K}$ and aerobic conditioning indexes, this could be further explored in future studies trying to gather information on what adjustments in $\dot{\mathrm{V}} \mathrm{O}_{2} \mathrm{~K}$ ensure aerobic capacity enhancement, while training with the protocols proposed in this study.

Additionally, the better explanation for the $\mathrm{t}_{\mathrm{Lim}}$ in $\mathrm{IT}_{200}$ is that superior performance was obtained by swimmers with high $\dot{\mathrm{V}} \mathrm{O}_{2}$ peak, which would delay the attainment of maximal $\dot{\mathrm{V}} \mathrm{O}_{2}$ and thus a tendency to reduce the accumulation of metabolites, whereas during $\mathrm{IT}_{100}$ the short exercise interval attenuates anaerobic stimulus with no impairment on $\stackrel{\mathrm{VO}_{2}}{ }$ response. This is in agreement with Zuniga et al. (2011) who reported that short work intervals (30-s) compared with longer ones (3-min) may allow athletes

TABLE 5 | Spearman rank-order coefficients for the responses of temporal, physiological, and perceptual variables between the IT protocols.

to complete a longer IT session with greater metabolic demands and lower $\left[\mathrm{La}^{-}\right]$accumulations. The findings of this study might be useful for coaches to decide on the work interval (100- or $200-\mathrm{m}$ bouts) that match the needs for aerobic power of the team. In this study, the inclusion of male and female swimmers is a limitation when considering differences in muscle mass and blood perfusion in the upper limbs (Koons et al., 2019), but how sex differed with regard to $\dot{\mathrm{V}} \mathrm{O}_{2}$ increase and tolerance during different work:rest ratio interval training still remains to be answered. Furthermore, swimming with a snorkel and open turns may be a constraint to free swimming training.

## CONCLUSION

This study concluded that both the IT protocols performed at MAV showed similar physiological and temporal responses whatever the distance ( 100 or $200-\mathrm{m}$ ) utilized for exercise bouts. Additionally, the protocols can be considered suitable to improve middle-distance swimming performance, since both stimulated
the exertion level close to maximal $\dot{\mathrm{V}} \mathrm{O}_{2}$, as well as moderate to high blood lactate concentrations and oxygen deficit, which is the finding to be highlighted for IT in swimming, as first demonstrated in this study. The fact that only the perceived exertion level differed between the IT protocols suggested that coaches should consider that $n \times 100-\mathrm{m} / 15-\mathrm{s}$ is perceived as less difficult to perform than $n \times 200-\mathrm{m} / 30-\mathrm{s}$ for the first $800-\mathrm{m}$ when managing the best strategy to be implemented for aerobic power enhancement. Finally, the $\dot{\vee} \mathrm{O}_{2} \mathrm{~K}$ parameters (time constant and amplitude) were not associated to tolerance in each IT protocol, suggesting that $\mathrm{t}_{\text {Lim }}$ during IT is not related to the parameters of $\stackrel{\mathrm{V}}{2} 2 \mathrm{~K}$ that characterize oxidative contribution and anaerobiosis reliance, but this analysis should be considered to evaluate the potential of aerobic power enhancement with IT.

## DATA AVAILABILITY STATEMENT

The raw data supporting the conclusions of this article are fully available without restriction when required to the authors.

## ETHICS STATEMENT

This study was approved by the local University Ethical Committee of the Faculdade de Motricidade Humana (UL-CEFMH: 39/2015). Written informed consent to participate in this study was provided by the participants' legal guardian/ next of kin.

## AUTHOR CONTRIBUTIONS

TA, DP, and FA conceived and designed the study. TA, DP, ME, JR, AS, DM, and FS conducted the experiments and analyzed the data. TA, DP, ME, JR, and FA wrote the manuscript. All authors contributed to the article and approved the submitted version.
