Background

Iron is an essential micronutrient required by all living organisms including malaria parasites (*Plasmodium* spp.) for many biochemical reactions, especially growth and multiplication processes. Therefore, the malaria parasites needs to take up the iron from outside or/and inside the parasitized red blood cells (PRBC). Iron chelators are widely used for treatment of thalassemia-related iron overload and also inhibit parasite growth at levels which are non-toxic to mammalian cells.

Materials and methods

The inhibitory effect of 1-(N-acetyl-6-amino-hexyl)-3-hydroxypyridin-4-one (CM1) and green tea extract (GTE) on the growth of malaria parasite *P. falciparum* was investigated compared with standard chelators including desferrioxamine (DFO), deferiprone (DFP) and deferasirox (DFX). A flow cytometric technique was used to enumerate the PRBC stained with SYBR Green I fluorescent dye. Labile iron pool (LIP) was assayed using calcein-acetomethoxy (Calcein-AM) fluorescent method.

Results

The IC₅₀ values of DFO, GTE, CM1, DFX and DFP against *P. falciparum* were 14.09, 21.11, 35.14, 44.71 and 58.25 μM, respectively. Importantly, CM1 was more effective in reducing LIP level in the *P. falciparum* culture than DFP ($P < 0.05$).

Conclusions

CM1 and GTE exhibit anti-malarial activity. They could interfere with uptake of exogenous iron or deplete intracellular labile iron in malaria parasites, leading to inhibition of their growth.
