---

A 47-year-old, otherwise healthy woman presented with multiple deep ulcers located primarily on her lower extremities that presented 6 days ago as blisters. A biopsy revealed livedoid vasculopathy, without any evidence of vasculitis. Extensive laboratory workup was positive only for type II cryoglobulins.

Type II cryoglobulinemia is caused by monoclonal rheumatoid factors. Cutaneous manifestations are nearly always present in cryoglobulinemia. Lesions have a predilection for dependent areas and include erythematous macules and purpuric papules (90–95%), as well as ulcerations (10–25%). Livedo reticularis, Raynaud phenomenon, and nailfold capillary abnormalities are also noted. Presentation with deep ulcers may lead to a misdiagnosis of pyoderma gangrenosum.
