

Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.

Rapid transitional response to the COVID-19 pandemic by opioid agonist treatment programs in Ukraine

ABSTRACT

On March 16, 2020, Ukraine's Ministry of Health issued nonspecific interim guidance to continue enrolling patients in opioid agonist therapies (OAT) and transition existing patients to take-home dosing to reduce community COVID-19 transmission. Though the number of OAT patients increased modestly, the proportion receiving take-home dosing increased from 57.5% to 82.2%, which translates on average to 963,952 fewer clinic interactions annually (range: 728,652–1,016,895) and potentially 80,329 (range: 60,721–84,741) fewer hours of in-person clinical encounters. During the transition, narcologists (addiction specialists) expressed concerns about overdoses, the guidance contradicting existing legislation, and patient dropout, either from incarceration or inadequate public transportation. Though clinicians did observe some overdoses, short-term overall mortality remained similar to the previous year. As the country relaxes the interim guidance, we do not know to what extent governmental guidance or clinical practice will change to adopt the new guidance permanently or revert to pre-guidance regulations. Some future considerations that have come from COVID-19 are should dosing schedules continue to be flexible, should clinicians adopt telehealth, and should there be more overdose education and naloxone distribution? OAT delivery has improved and become more efficient, but clinicians should plan long-term should COVID-19 return in the near future. If the new efficiencies are maintained, it will free the workforce to further scale up OAT.

The first reported COVID-19 case in Ukraine was on March 3, 2020, with the first person dying 15 days later. By March 16, when there were 5 reported cases (Statistica, 2020), the Ministry of Health issued nonspecific interim guidance to Chief Narcologists (the administrative addiction treatment expert in each region) to 1) encourage continued access for starting new patients on OAT to reach national targets that the Ministry of Health (MoH) recommended and 2) provide physicians more flexibility with take-home dosing (range: 3–10 days) to safely transition as many patients as possible to reduce patient contact with clinical staff, exposure to others in the community when using public transportation, and clustering in the clinic during the limited hours of medication administration. We describe the consequences of this interim guidance for managing patients with opioid use disorder (OUD) who are treated with opioid agonist therapies (OAT) in the Ukrainian

context. We focus on OAT delivery during two 60-day time periods in 2020: a) pre-COVID guidance from January 1 to March 1; and b) post-COVID guidance from April 1 to June 1.

Ukraine introduced OAT in 2004 (Bruce et al., 2007); yet scale-up has been slow, constrained by patient, clinic, and policy factors (Bojko et al., 2016; Carroll, 2019; LaMonaca et al., 2019; Madden et al., 2017; Zelenev et al., 2018). Ukraine introduced treatment of OUD using OAT primarily for HIV prevention, and Order 200 highly regulates OAT (LaMonaca et al., 2019). The Network for Improvement of Addiction Treatment (NIATx) model for behavioral health (McCarty et al., 2007), an evidence-based implementation strategy, started in November 2014 to scale-up OAT. Four trained NIATx coaches (AM, IP, TF, MF) meet weekly with the Chief Narcologist from each administrative region, except Crimea, to facilitate rapid cycle change projects; we used notes

from calls to contextualize data. We also analyzed data from the national OAT registry (SYREX) to monitor patient census, entry, attrition (including death), type of OAT, and whether a patient receives take-home dosing (Farnum et al., 2020; Tan et al., 2020).

Order 200 changed in late 2016, guided by NIATx change projects, to allow take-home dosing every 3, 7, or 10 days if clinicians documented sobriety for 6 consecutive months; a change reflecting the narcologists' recommendations to reduce demand on patients (Madden et al., 2017). During 2019, OAT increased by 9% (11,385 to 12,411), resulting in 4.4% coverage for the estimated 284,022 people who inject drugs (PWID) with OUD; 40–45% of OAT patients have HIV (Mazhnaya et al., 2018). OAT scale-up in 2019 occurred despite 2,067 patients discontinuing treatment, with 538 deaths (annualized mortality = 4.3%) among them (cause unknown).

Before interim COVID-19 guidance, 7,381 (57.5%) of the 12,837 OAT patients at 214 sites received take-home dosing. Thereafter, OAT clinics focused mostly on transitioning patients to take-home dosing. By June 1, 10,766 (82.2%) of 13,097 OAT patients were receiving take-home medications (3-, 7- or 10-day supply; mostly 10 days), a 45.9% net increase in take-home dosing. Using a mid-point of 7-day take-homes and 5 minutes per clinical encounter, this translates into a reduction in 963,952 direct annual clinical contacts (range: 728,652–1,016,895 if take-homes were every 3 and 10 days, respectively) and 80,329 (range: 60,721–84,741) fewer hours (Fig. 1). OAT scale-up increased by 1,272 patients from January through May with fewer ($N = 360$) during the post-COVID guidance period. Though complete mortality data are not available yet (death certificates required), annualized mortality during this period did not change appreciably (5.0%–4.2%).

Both scale-up and take-home dosing varied geographically (Fig. 1). Six regions (Kyiv city, Odesa, Ivano-Frankivsk, Ternopil, Rivne, Luhansk) reduced the number of OAT patients during COVID-19 restrictions. Most regions increased their number of patients, with two regions doing so by more than 30% (Cherkasy, Dnipro). These two regions had increased their number of patients in 2019 by more than 70% and 20%, respectively. Take-home dosing increased from 53.4% to 82.2%, with 13 regions that increased the proportion of OAT patients on take-home dosing to > 90%: only two regions had < 50% on take-homes (Lviv, Zakarpattya).

We have learned several important lessons, with some questions still unanswered. The country quickly responded to COVID-19 guidance by modestly expanding treatment coverage, but also safely transitioned a substantial number of patients to take-home dosing. Chief Narcologists expressed major concerns during weekly NIATx collaborative calls, including concerns about overdoses, the guidance's contradiction with Order 200 (take-home dosing despite not meeting 6-month sobriety requirements), and patient drop-out, either from decreased or no public transportation. Before COVID-19, most Chief Narcologists felt Order 200 sobriety requirements were too stringent, and the order provided no clear guidance about “which patients” should transition to take-home dosing. Chief Narcologists were concerned that shelter-in-place restrictions would increase stress among patients and may facilitate overdose and polysubstance use. They also recognized that the police, who often extract bribes from patients coming for OAT, may arrest patients who were coming less often for OAT or had less money; research has documented such practices previously (Izenberg et al., 2013; Kutsa et al., 2016; Meteliuk et al., 2020).

Though clinicians increased telephone contact with patients to provide support, they felt it was insufficient because COVID-19 came just as a new national healthcare service started, which had substantially increased reporting requirements. With their heightened concerns, Chief Narcologists reported 15 fatal overdoses among OAT patients after the COVID guidance. Although the circumstances surrounding these overdoses have not been reported, they underline the need to strengthen overdose education and naloxone distribution (OEND) to patients and families. Naloxone is inexpensive in Ukraine,

but harm reduction using naloxone has traditionally been the purview of nongovernmental organizations (NGOs) and not medical providers.

Our findings here align with OAT scale-up strategies elsewhere (Bachireddy et al., 2015; Madden et al., 2018; Strang et al., 2010), where reduced demand and supervision of patients can create more efficient program delivery, promote scale-up, and not contribute to mortality. As a consequence of COVID-19, both clinicians and patients have markedly adapted their professional and personal lives. A major lesson that we have learned is that allowing more take-home medications is extraordinarily efficient. The time saved in clinical encounters and for supervised dosing could be used to scale-up OAT by allowing clinicians to enroll new patients who may need more time for stabilization and focus more on telehealth for counseling. Though a closer review is required, initial mortality data suggest that transitioning to take-home dosing appears safe despite observations of some fatal overdoses. As the country begins to relax shelter-in-place guidelines, to what extent governmental guidance or clinical practice will change in response to relaxation of pandemic restrictions is unclear. A crucial strategy for clinicians will be to identify patients at highest risk for overdose and either reduce the amount of take-homes or shift clinical time to telehealth to assist with patient coping and provide ongoing counseling support. Potentially more challenging will be how narcologists interpret Order 200 regarding take-home dosing. Officially, the order states that no patient may receive take-home dosing until that patient has demonstrated sobriety for 6 months. It does not, however, state that patients who have successfully transitioned to take-home dosing (e.g., during this pandemic and at the request of the government) must be returned to daily supervision once clinicians have transitioned them. In the absence of governmental guidance, narcologists often yield to a very stringent legal framework. Their most conservative interpretation is that all patients previously on daily supervision must return, irrespective of how well they have done clinically, because police may demand to review urine drug testing results to confirm Order 200 compliance. A more liberal interpretation, however, is that if patients have been successfully transitioned to take-home dosing, there is no need to return them to daily supervision unless clinically indicated. Last, we do not know the extent to which narcologists will learn about and use telehealth and opioid overdose education and naloxone distribution to manage patients with take-home medications. Telehealth principles are nascent in Ukraine, but could optimize patient care and keep patients and communities safe. Learning from COVID-19 in Ukraine could reform healthcare, especially for OAT patients, and may help advance OAT scale-up efforts by improving efficiencies in treatment delivery while keeping both patients and the broader community safe.
