In the title metal–organic framework,  $[\text{Fe}(\text{C}_4\text{H}_3\text{BrN}_2)_2\{\text{Cu}(\text{CN})_2\}_2]_n$ , the  $\text{Fe}^{\text{II}}$  cation is located on an inversion center and has a slightly elongated octahedral coordination environment  $[\text{FeN}_6]$ , ligated by two pyrazine N atoms of symmetry-related bridging 2-bromopyrazine molecules in the axial positions and by four N atoms of pairs of symmetry-related cyanido groups in the equatorial positions. The  $\text{Cu}^{\text{I}}$  center has a fourfold coordination environment  $[\text{CuC}_3\text{N}]$ , with an almost perfect trigonal–pyramidal geometry, formed by three cyanido C atoms and an N atom of a bridging 2-bromopyrazine molecule. Copper(I) centers related by a twofold rotation axis are bridged by two carbon atoms from a pair of  $\mu\text{-CN}$  groups, resulting in  $\text{Cu}_2(\text{CN})_2$  units. Each  $\text{Cu}_2(\text{CN})_2$  unit is linked to six  $\text{Fe}^{\text{II}}$  cations via a pair of linear CN units, the pair of  $\mu\text{-CN}$  groups and two bridging 2-bromopyrazine ligands, resulting in the formation of a metal–organic framework, which is additionally stabilized by the short  $\text{Cu}\cdots\text{Cu}$  contacts of 2.4450 (7) Å.

## 1. Chemical context

The rational design and synthesis of cyanide-based coordination materials is of key interest today. By using different approaches for their design and tunable structures, composition and porosity, various exciting properties of these compounds, such as catalytic, photoluminescent, magnetic, electrical and other can be achieved (Zhang *et al.*, 2015; Catala & Mallah, 2017). The cyanide anion is an important ligand in coordination chemistry as it can be used for stabilization of coordination materials formed by diverse transition metals. Cyanide-containing coordination materials of very different topologies have been proposed, although attention is frequently paid to heterometallic complexes.

Symmetry codes: (i)  $-x + 1, y, -z + \frac{3}{2}$ ; (ii)  $x, y - 1, z$ ; (iii)  $-x + 1, -y, -z + 1$ ; (iv)  $x, -y, z + \frac{1}{2}$ ; (v)  $-x + \frac{3}{2}, -y + \frac{1}{2}, -z + 1$ .

The first class of cyanide-based metallic complexes emerged in the 18th century with the discovery of Prussian blue. Later its analogues containing two types of metals were synthesized. The inclusion of different metals instead of iron resulted in the occurrence of various attractive physical properties of these materials, which allowed their use as molecular sieves, for nanoscale devices, for hydrogen storage, etc. (Newton *et al.*, 2011). Prussian blue analogues form networks with general formula  $AM_A[M_B(\text{CN})_6]$  ( $A$  = alkali metal ion,  $M_A$  and  $M_B$  = transition metal ions) (Keggin & Miles, 1936). These complexes have a cubic structure in which the metallic centers are bridged in an  $M_A\text{—C}\equiv\text{N—}M_B$  fashion, forming three-dimensional frameworks.

Another class of heterometallic cyanide coordination compounds that has attracted much attention is represented by *f-d* complexes composed of lanthanide(III) ions and *d*-block cyanometallates. This type of materials has been shown to have exceptional photoluminescent properties (Chorazy *et al.*, 2017). In addition, polynuclear octacyanides form a different family of cyanide-based heterometallic complexes.

**Figure 1**  
A fragment of the crystal structure of the title compound, with atom labelling. Displacement ellipsoids are drawn at 50% probability level [symmetry codes: (i)  $-x + \frac{3}{2}, -y + \frac{1}{2}, -z + 1$ ; (ii)  $-x + 1, -y, -z + 1$ ; (iii)  $-x + 1, y, -z + \frac{1}{2}$ ; (iv)  $x, -y, z + \frac{1}{2}$ ].

**Figure 2**

A view of the coordination environment of the Cu atoms in the title compound, with atom labelling [symmetry codes: (i)  $-x + 1, -y, -z + 1$ ; (iii)  $x, -y, z + \frac{1}{2}$ ; (iv)  $x, -y, z + \frac{1}{2}$ ].

Compounds of this class can adopt very different geometries creating 0, 1, 2 or 3D assemblies. These materials are known for photomagnetism, molecular magnetism, and the ability to create chiral networks (Sieklucka *et al.*, 2011).

The Hofmann clathrate analogues of the general formula  $[M_A(L)_x\{M_B(\text{CN})_y\}]$  constitute another prominent example of bimetallic cyanometallates (Hofmann & Küspert, 1897), which are famous for their switchable magnetic properties (Muñoz & Real, 2011). Here we describe the crystal structure of a new Hofmann clathrate analogue of general formula  $[\text{Fe}(\text{Brpz})_2\{\text{Cu}(\text{CN})_2\}_2]_n$ .

## 2. Structural commentary

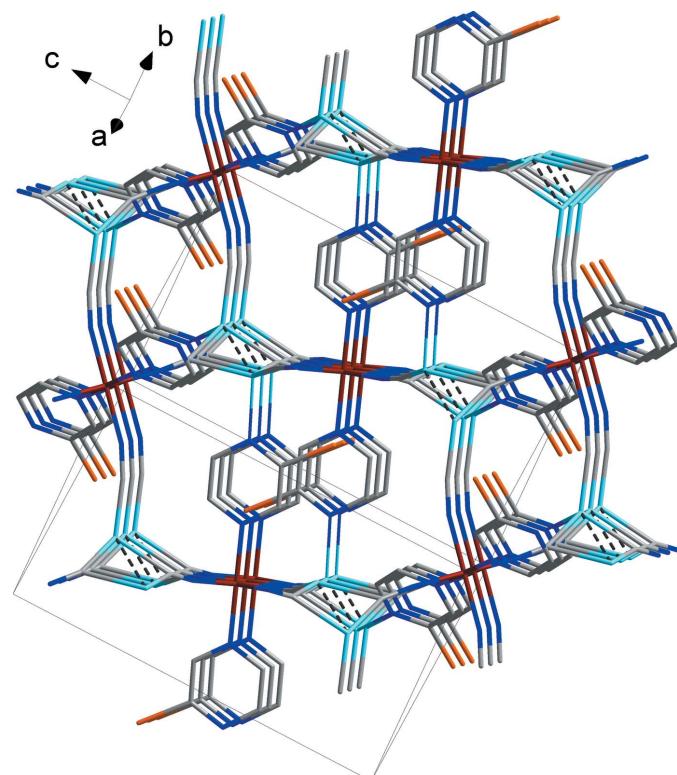

A fragment of the structure of the title compound, illustrating the sixfold coordination environment of atom Fe1, is shown in Fig. 1. Selected geometrical parameters are given in Table 1. The Fe<sup>II</sup> ion is located on an inversion centre and has a slightly elongated  $\text{FeN}_6$  octahedral coordination environment. It is ligated by two N atoms of symmetry-related 2-bromopyrazine molecules in axial positions [ $\text{Fe1—N3} = 1.980 (2) \text{ \AA}$ ] and by four N atoms of symmetry related cyanido groups in the equatorial positions [ $\text{Fe1—N1} = 1.958 (2)$  and  $\text{Fe1—N2} = 1.952 (2) \text{ \AA}$ ]. The Fe—N bond lengths clearly indicate that the Fe<sup>II</sup> center is in the low-spin state at the temperature of the experiment, *i.e.* 296 K. The deviation from an ideal octahedron of the Fe<sup>II</sup> center can be described by the octahedral distortion parameter  $\Sigma|90 - \theta| = 23.36^\circ$ , where  $\theta$  is a *cis*-N—Fe—N angle. Notably, this sum is higher than that expected for a low-spin Fe<sup>II</sup> ion. It is important to note, and should always

be taken into account, that the octahedral distortion value cannot always be used to judge the spin state of a metallic center, it is rather a characteristic of the order level in the structure, the measurement temperature, etc.

Atom Cu1 has a fourfold  $\text{CuC}_3\text{N}$  coordination environment (Fig. 2, Table 1) with a  $\tau_4$  descriptor of 0.82, close to that for a perfect trigonal-pyramidal geometry ( $\tau_4 = 0.00$  for square-planar, 1.00 for tetrahedral and 0.85 for trigonal-pyramidal; Yang *et al.*, 2007). It is ligated by three C atoms of the cyano groups and an N atom of a bridging 2-bromopyrazine molecule [ $\text{Cu1}-\text{C}1 = 1.924$  (3),  $\text{Cu1}-\text{C}2^{\text{iv}} = 2.181$  (3),  $\text{Cu1}-\text{C}2^{\text{iii}} = 2.049$  (3),  $\text{Cu1}-\text{N}4^{\text{ii}} = 2.152$  (2) Å]. Notably, the coordination to atom Fe1 occurs only via the more sterically accessible atom N3 of the pyrazine ring, while atom Cu1 binds to atom N4 of the pyrazine ring.

### 3. Supramolecular features

The crystal packing of the title compound is shown in Fig. 3. The coordination framework is made up of bridging 2-bromopyrazine ligands and  $\text{Cu}_2(\text{CN})_2$  moieties (Fig. 2). The latter are formed by a pair of copper atoms, centered about a twofold rotation axis, being bridged by two carbon atoms from a pair of  $\mu$ -CN groups. Each  $\text{Cu}_2(\text{CN})_2$  unit is linked to six  $\text{Fe}^{\text{II}}$  cations via a pair of linear CN units, the pair of  $\mu$ -CN groups and two bridging 2-bromopyrazine ligands, resulting in the formation of a metal-organic framework (Fig. 3). The

**Figure 3**

A view normal to plane (110) of the crystal structure of the title compound, showing the  $\text{Cu}\cdots\text{Cu}$  contacts as dashed lines. H atoms have been omitted for clarity. Colour code: Fe dark red, Cu light blue, C grey, N blue, Br orange.

framework is additionally stabilized by the short  $\text{Cu1}\cdots\text{Cu1}^{\text{i}}$  contact of 2.4550 (7) Å, which is significantly shorter than the sum of the corresponding van der Waals radii, *viz.* 2.8 Å. Additionally, within the framework there are weak  $\text{Br}\cdots\pi$  contacts of 3.8298 (6) Å, that are of lone-pair $\cdots\pi$  origin.

### 4. Database survey

A search of the Cambridge Structural Database (CSD, version 5.39, last update August 2018; Groom *et al.*, 2016) gave 15 hits for  $\text{Fe}-\text{N}\equiv\text{C}-\text{Cu}$  bimetallic structures supported mainly by substituted pyridines and pyrimidines. These include a number of variable temperature measurements of certain compounds in order to study their spin-crossover behaviour; for example, the two-dimensional coordination polymer catena-[bis( $\mu^3$ -cyano- $C,C,N$ )( $\mu^2$ -cyano- $C,N$ )]tetrakis(3-cyanopyridyl)dicopper(I)iron(II)] (VEHHOG, VEHHOG01; Galet *et al.*, 2006), and the framework structures catena-[tetrakis( $\mu^2$ -cyano- $C,N$ )-bis( $\mu^2$ -pyrimidine- $N,N'$ )dicopper(I)iron(II)] (EHOQOH01, EHOQOH03; Agustí *et al.*, 2008) and catena-[octakis( $\mu^2$ -cyano)octakis(3-chloropyridine)tetracopper(I)diiron(II)] (YUBRET, YUBRET03; Agustí *et al.*, 2009).

A search of the CSD for the bridging  $\text{Cu}_2(\text{CN})_2$  unit gave 27 hits. The majority of these are monometallic copper(I) metal-organic frameworks (MOFs). The  $\text{Cu}\cdots\text{Cu}$  distances vary from *ca* 2.31 Å in the two-dimensional network structure catena-[bis( $\mu_3$ -cyano)tetrakis( $\mu_2$ -cyano)tris( $N,N,N',N'$ -tetramethylethylenediamine)hexacopper(I)] (HIWHUQ; Stocker *et al.*, 1999) to *ca* 2.72 Å in the MOF catena-[tris( $\mu$ -cyano)-tris( $\mu$ -cyano)diamminepentacopper] (OPODAA; Grifasi *et al.*, 2016). Two particular compounds resemble the title MOF, namely catena-[bis( $\mu_3$ -cyano- $C,C,N$ )( $\mu_2$ -cyano- $C,N$ )( $\mu_2$ -2,3-dimethylpyrazine- $N,N'$ )tricopper(I)] (FERWUV; Greve & Nather, 2004), which involves a bridging 2,3-dimethylpyrazine ligand, and catena-[ $(\mu_3\text{-cyano})(\mu_2\text{-}4,4'\text{-bipyridine})\text{tris}(\mu_2\text{-cyano})\text{hexamethyldicopper(I)ditin(IV)}$ ] (NUMRUI; Ibrahim *et al.*, 1998), which is a bimetallic MOF with a bridging 4,4'-bipyridine ligand. The respective  $\text{Cu}\cdots\text{Cu}$  distances are *ca* 2.49 and 2.62 Å, compared to 2.4550 (7) Å in the title MOF.

### 5. Synthesis and crystallization

Crystals of the title compound were obtained by slow diffusion within three layers in a 3 ml glass tube. The first layer was a solution of  $\text{K}[\text{Cu}(\text{CN})_2]$  (7.8 mg, 0.05 mmol) in 1 ml of water; the second layer was a water/ethanol mixture (1:1, 1 ml); the third layer was a solution of  $\text{Fe}(\text{ClO}_4)_2 \cdot 6\text{H}_2\text{O}$  (9.1 mg, 0.025 mmol) and 2-bromopyrazine (8.0 mg, 0.05 mmol) in 0.5 ml of ethanol. After two weeks, brown crystals were formed in the middle layer. The crystals were kept under the mother solution prior to measurement.

### 6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 2. All the hydrogen atoms were

placed geometrically and refined as riding; C—H = 0.93 Å with U<sub>iso</sub>(H) = 1.2U<sub>eq</sub>(C).

*Special details*

**Geometry.** All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
