Observations on Mr Baynton's Method of Treating Ulcers on the Legs. By Mr W. Simmons, Member of the Corporation of Surgeons in London, and Senior-Surgeon to the Manchester Infirmary.

LD ulcers on the legs often come un der the review of the hospital-furgeon, and are a fource of much mifery to the lower orders of the people. The methods of treating this complaint have been defective, and fometimes the endeavours of the furgeon have been frustrated by the patient. Hofpitals are crowded with cafes of this kind, unless reftrictive regulations be adopted; and they furnish a ready cause of Imposition on fuch charities. After twice admiffion into the Manchefter Infirmary, they receive its benefits as out or home patients only. For, previous to this rule, a let of these was a burden to the charity every winter.

Y 2

Ulcers

Ulcers thus fituated, have received different appellations, indicative of their peculiar nature, as, carious, fcrophulous, fcorbutic, venereal, or cancerous, from being combined with caries, fcrophula, fcurvy, cancer, or the venereal poifon. Or, from being attended with fungus, finus, callous edges, or a varicofe ftate of the veins, they have been termed the fungous, callous, varicofe, or finuous ulcers. Their defcription and appropriate treatment will be found detailed in chirurgical writers, as governed by the prevailing opinions, at the refpective periods of heir publi ations.

It not uncommonly happens, that a combination of the different kinds of ulcer takes place, and that the callous is attended with a fpecific morbid action. The latter may be removed, and yet the ulcer may be intractable, from affuming the former character. Whatever plan of treatment be adopted, it appears evidently the intention to reduce it to the flate of a fimple ulcer. And in this form, or when attended with callous edges, the plan of treatment recommended by Mr Baynton, will, I apprehend, be extremely proper.

proper. The author has not referred it to any particular fpecies of ulcer.

For fome years I have been endeavouring to form a ground of preference, in the choice of remedies applicable to this common kind of ulcer; and after a trial of all of them, the plan of Wifeman, of applying precipitate and light bandages, has gained a decided preference. When the granulations rife above the level of the skin, the vitriol of copper has been fubflituted as repreffing them, and leaving the furface more difpofed for cicatrization. Rhubarb, fo ftrongly recommended by Mr Home, is feeble in its powers when compared with precipitate. But the admirable plan of applying adhefive plafters, as directed by Mr Baynton, frees the furgeon from farther difficulty in his choice of means. The principle of their operation is exemplified in the application of fheet-lead, as approved by the late Mr Elfe; which, from nicety in its application, has fallen into difufe.

Mr Baynton obferves, that the efficacy of this plan depends on the endeavour to bring

bring the divided parts nearer together. But whoever attends to its effect, on an extenfive old ulcer, on the anterior part of the leg for example, will fee the impoffibility of bringing the original fkin to approximate. Admitting his facts, the benefit may be produced in two ways, first, by acting as a bandage, giving tone and removing induration; and, fecondly, by keeping the ulcerated furface level with the furrounding fkin. The utility of bandaging is generally allowed, and it would feem that a bandage of fuch materials is preferable, by making a more fleady and uniform preffure than a common roller. The process of fkinning refembles the freezing of water, or the cryftallization of falts, both of which are facilitated by an even furface, which is effential to the due configuration of the cryftals. On the fame principle it is, that the adhefive plafters are fo efficacious.

In an old hollow ulcer, with hard callous edges, the cure is accomplifhed by the filling up of the cavity with new granulations, and the fubfidence of the neighbouring parts. Whilft the former is going on, the latter

ter is effected by preffure inducing the abforption of the thickened and indurated integuments, occafioned by interftitial depo-Thefe two points being attained, fition. cicatrization, or the cryftallization of fkin, will be greatly affifted by keeping the furface level. This ftage of the healing procefs takes place, in a beautiful and rapid manner, under this treatment. But should the granulations be fuffered to rife above the level of the adjoining fkin, an immediate obstacle prefents itself, and the skinning is impeded. That there is an extensive production of new fkin, may be afcertained by an admeasurement from day to day.

Viewing the introduction of this practice, as one of the greateft improvements in modern furgery, I have thus attempted an explication of the principle on which it acts, in a manner fomewhat different from its inventor, hoping thereby to extend its utility. I now apply it in all cafes where there has been a deftruction of common integument, and I find that it does more in one week, than could be accomplifhed in feveral, ac-
