Abstract: The COVID-19 pandemic and its continuing emerging variants emphasize the need to discover appropriate treatment, where vaccines alone have failed to show complete protection against the new variants of the virus. Therefore, treatment of the infected cases is critical. This paper discusses the bio-guided isolation of three indole diketopiperazine alkaloids, neoechinulin A (1), echinulin (2), and eurocristatine (3), from the Red Sea-derived *Aspergillus fumigatus* MR2012. Neoechinulin A (1) exhibited a potent inhibitory effect against SARS-CoV-2 M^{pro} with IC$_{50}$ value of 0.47 μM, which is comparable to the reference standard GC376. Despite the structural similarity between the three compounds, only **1** showed a promising effect. The mechanism of inhibition is discussed in light of a series of extensive molecular docking, classical and steered molecular dynamics simulation experiments. This paper sheds light on indole diketopiperazine alkaloids as a potential structural motif against SARS-CoV-2 M^{pro}. Additionally, it highlights the potential of different molecular docking and molecular dynamics simulation approaches in the discrimination between active and inactive structurally related M^{pro} inhibitors.

Keywords: SARS-CoV-2 M^{pro}; neoechinulin A; *Aspergillus fumigatus*; molecular docking; steered molecular dynamics simulation

1. Introduction

For approximately two years, the global pandemic caused by the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) has cost many lives and put the world economy on hold in 2020, with extreme consequences. In December 2021, the number of confirmed SARS-CoV-2 cases worldwide reached around 350 million, with more than 5.5 million reported deaths [1]. The world's focus suddenly shifted to the scientific community, which has diligently delivered several vaccines that positively impacted the new cases and hospitalization. However, apparent imbalances in the world economy are causing a delay in the rolling out of the vaccines, especially in low-income countries, delaying the

end of the epidemic and costing thousands of lives each day [2]. Moreover, infections have occurred in some cases despite vaccination, and the continuous announcement of new viral variants that could be resistant to the current vaccines represents an obvious challenge. Hence, finding an effective treatment as a weapon besides the vaccination campaign is still relevant and crucial in tackling the virus.

Generally, corona viruses' main proteases occur in dimeric forms, and their activity decreases profoundly if this conserved dimerization is inhibited by mutations. Each monomer consists of three domains (domains I, II, and III), where the catalytic binding site occurs between domains I and II, while domain III is responsible for the enzyme dimerization (Figure 1). The enzyme active site has a conserved HIS-41-CYS-145 catalytic dyad that is essential for peptide cleavage. Hence, any alteration in these catalytic key residues will lead to a complete loss of enzyme activity. A number of covalent inhibitors (i.e., covalent bonding to CYS-145) have been previously reported, while non-covalent competitive inhibitors are much less investigated [3].

Figure 1. (**A**) Monomeric structure of SARS CoV-2 M^{pro} (PDB code: 7LTJ) showing its three main domains (I, II, and III; blue, cyan, and green, respectively) along with the catalytic dyad (HIS-41:CYS-145). (**B**) The dimeric active form of SARS CoV-2 M^{pro}.

Virtual screenings by means of advanced computer-aided programs that perform molecular docking have enabled the screening of thousands of compounds in a short time span, accelerating the discovery of new drug leads [4]. The identification of new drug targets supersedes the development and licensing of new medicines. For example, from 2012 to 2017, only 12 new antivirals were approved by the FDA, of which eight are pre-scribed for the treatment of hepatitis C virus (HCV), and two are used in combinations with other drugs against the human immunodeficiency virus (HIV). However, the WHO and governments are recurrently challenged by (re)emerging viruses, which cause pandemics with no specific treatment, such as Zika virus (ZIKV), Ebola virus (EBOV), Middle East respiratory syndrome coronavirus (MERS-CoV), and SARS-CoV-2 [5]. Although drug repurposing is one of the main strategies for quick discovery of such treatments, remdesivir was the only antiviral drug approved by the FDA to treat SARS-CoV-2 patients who need hospitalization [6]. Additionally, the European Medicine Agency (EMA) has also approved remdesivir and three other medications [7]. Recently, molnupiravir (Merck Lagevrio®) was FDA-approved for oral treatment of COVID-19 non-hospitalized patients with mild-to-moderate symptoms [8] with a note from the European Medicine Agency (EMA) that,

although not authorized in the EU, it could be prescribed for adults with COVID-19 who do not need supplemental oxygen or at increased risk of developing severe COVID-19.

Given the crucial role of SARS-CoV-2 M^{pro} in viral replication in addition to the absence of spike protein variant resistance challenges, SARS-CoV-2 M^{pro} inhibition is considered an attractive target for approach for small-molecule oral antiviral therapeutics to treat COVID-19 [9]. Using this target for drug discovery, PF-07321332, an orally bioavailable SARS-CoV-2 M^{pro} inhibitor, showed promising anti-SARS-CoV-2 oral activity in vivo in mouse model as well as excellent oral plasma concentrations in a phase 1 human clinical trial [9]. Moreover, Pfizer's oral anti-SARS-CoV-2 M^{pro} drug paxlovid showed significant reduction in hospital admissions and deaths among people with COVID-19, when compared with placebo [10], hence it is approved by the FDA and recommended with conditional marketing by the EMA.

Due to their eminent chemical and biological diversity, natural products are considered a promising source for different structural motifs and drug leads. Out of the 1881 new chemical entities (NCEs) approved by the FDA between 1980 and 2019 covering all sources and diseases, approximately 55% are natural products, analogs, or natural product mimics. In the anti-infective areas (including antibacterial, antifungals, and antivirals), 60% of the 415 agents currently available on the market are naturally derived or originated from natural products [11]. Recently, the microbial-derived FDA-approved anti-parasitic drug ivermectin, pentacyclic lactone derived from the soil bacterium *Streptomyces avermitilis*, proved to be effective as an in vitro inhibitor of SARS-CoV-2 replication [12]. Clinical trials assessing ivermectin for the treatment of COVID-19 patients are ongoing.

Our group has reacted immediately with the pandemic, putting every effort to screen our available extracts, fractions, and pure compounds obtained from plants, endophytes, and microorganisms of marine and terrestrial origin for the discovery of antiviral hits against SARS-CoV-2 or its main protease (M^{pro}) as a potential target [13–18]. In the current study, we report the discovery of a previously reported indole diketopiperazine alkaloid neoechinulin A (**1**), as a promising SARS-CoV-2 M^{pro} inhibitor through bioguided screening. Despite the structural similarity between the isolated compounds, only **1** showed a promising effect. The mechanism of inhibition and the significant difference in the activity are discussed using classical and steered molecular dynamics simulation experiments.

2. Results

2.1. Bioguided Isolation and Structural Identification

Screening of our in-house total of 100 extracts comprising 20 marine and 15 terrestrial fungal extracts cultured on different culture media against SARS-CoV-2 M^{pro} pinpointed the extract of the Red Sea-derived *Aspergillus fumigatus* MR2012 as a potential to follow. Large scale fermentation, extraction, and fractionation with organic solvents with different polarities followed by SARS-CoV-2 M^{pro} screening, indicated the dichloromethane (DCM) as an active fraction. Purification of the HPLC fraction on semi-preparative RP-HPLC led to the isolation of four major compounds (Figure 2). Structure elucidation of the isolated molecules was based on HRESIMS analysis together with ^{1}H, ^{13}C, and multiplicity-edited HSQC spectra using SMART 2.1 database [19] and The Natural Products Atlas 2.0 [20], in addition to comparison with the literature data. This analysis led to the identification of the isolated metabolites as two prenylated indole diketopiperazines (DKP) neoechinulin A (**1**) [21] and echinulin (**2**) [22], the indole DKP dimer eurocristatine (**3**) [23], and the isocoumarin derivative eurotiumide G (**4**) [24]. The structures of the isolated compounds were further confirmed by COSY and HMBC correlations.
Figure 2. Compounds isolated from *Aspergillus fumigatus* MR2012 and the M^{pro} co-crystalized inhibitor.

2.2. In Vitro Screening against SARS-CoV-2 M^{pro}

Based on our initial SARS-CoV-2 M^{Pro} screening, the total methanolic extract and the DCM fraction showed good inhibition when subjected to an in vitro evaluation on the SARS-CoV-2 M^{Pro} using FRET assay with the known inhibitor GC376 as a positive control (data not shown). Evaluation of the four isolated metabolites indicated that only neoechinulin A (**1**) had significant SARS-CoV-2 M^{pro} inhibitory effects with IC_{50} value 0.47 μM compared to GC376 as a positive control with IC_{50} value of 0.36 μM (Figure 3). Echinulin (**2**) showed weak inhibition with an IC_{50} at 3.90 μM, while eurocristatine (**3**) showed weak enzymatic inhibition of less than 50% inhibition at 5 μM concentration, hence its IC_{50} was not calculated. The isocoumarin derivative eurotiumide G (**4**) showed no activity.

Figure 3. Dose-response curves of compounds **1** and **2**, and the positive control GC376 against SARS-CoV-2 M^{pro}.

2.3. Docking and Molecular Dynamics Simulations

To find out how these indole-based natural products can interact and inhibit M^{pro}, they were subjected to a series of docking and molecular dynamics simulation-based experiments. Looking into previously reported non-covalent inhibitors, YD1 (i.e., the co-crystalized inhibitor of M^{pro} with PDB code: 7LTJ) was observed to be the inhibitor with the most structural similarities to compounds **1** and **2**. Accordingly, this structure was selected for all of the subsequent in silico-based analyses. Despite using it as a reference inhibitor in the in vitro assays, GC376-contatining M^{pro} model was not selected for the in silico analysis due to its covalent interaction with CYS-145 inside the enzyme active site.

First (docking step), the three compounds were docked into the M^{pro} active site to estimate their fitting score inside this binding pocket. Before initiating docking experiments, we made sure that the docking method would be efficient and produce reliable binding poses. To do so, the co-crystalized ligand was re-docked inside the M^{pro} active site. The resulting top-ranked pose was almost identical to that of the co-crystallized one with an RMSD of 1.1 Å (Figure S12).

The resulting binding poses of the three compounds were then visually investigated. All generated poses for the three compounds showed docking scores between −5.0 and −8.3 kcal/mol (Figure S13). Only poses with scores < −7 kcal/mol were selected for subsequent in silico investigation that was also convergent in their orientations inside the M^{pro} active site.

Second (∆G_{bind} estimation step), these selected poses were subjected to molecular dynamic simulations (MDS)-based binding free energy estimation (∆G_{bind}) to select the best binding pose in terms of affinity towards M^{pro} active site. The ∆G_{bind} values of the best-ranked poses of compounds **1–3** were −8.1, −8.0, −3.2 kcal/mol, respectively. These results clearly explain why compound **3** displayed the least in vitro enzyme inhibitory activity. However, it is not sufficient to discriminate between **1** and **2** that were significantly different in their in vitro inhibitory activities against M^{pro} (IC$_{50}$ = 0.47 and 3.9 μM, respectively).

In the third step (MDS step), the binding pose of each compound was subjected to long MDS experiments carried out in duplicates to efficiently evaluate their stability inside the enzyme active site and investigate their mode of interaction. As shown in Figure 4, eurocristatine (**3**) was the least stable structure inside the M^{pro} active site, where it started to significantly deviate from the starting binding pose to reach RMSD > 7 Å at the end of the MDS. Regarding neoechinulin A (**1**) and echinulin (**2**), they both achieved stable binding inside the M^{pro} active site with average RMSDs of 2.16 Å and 2.21 Å, respectively. The dynamics of these two related structures (i.e., compounds **1** and **2**) over the course of the simulation were also convergent to that of the reported co-crystallized ligand (RMSD ~2 Å) [25] (Figure 4B).

To investigate the hotspot amino acid residues that contributed to the binding stability of each compound, including the co-crystalized inhibitor (i.e., YD1), the most populated poses of each simulated ligand were extracted (Figure 5). Additionally, the ligand–protein interaction pattern was extracted during the whole MDS runs (Figure 6). As revealed in Figures 5 and 6, neoechinulin A (**1**) and echinulin (**2**) binding poses populated 35% and 29% over their MDS, and both revealed stable H-bonds between the two compounds and LEU-141, ASN-142, GLY-143, and GLU-166 in addition to significant hydrophobic interaction with HIS-41. The main difference between the interactions of both compounds was that neoechinulin A (**1**) established the four H-bonds via its diketopiperidine moiety, while echinulin (**2**) established three H-bonds (i.e., with LEU-141, ASN-142, GLY-143) via its diketopiperidine moiety and the last H-bond with GLU-166 was established via its indole NH. Water bridges with ASN-142, GLY-143, and GLU-166 were also established, however, they showed low contribution in the binding stability of both compounds (Figures 4 and 5).
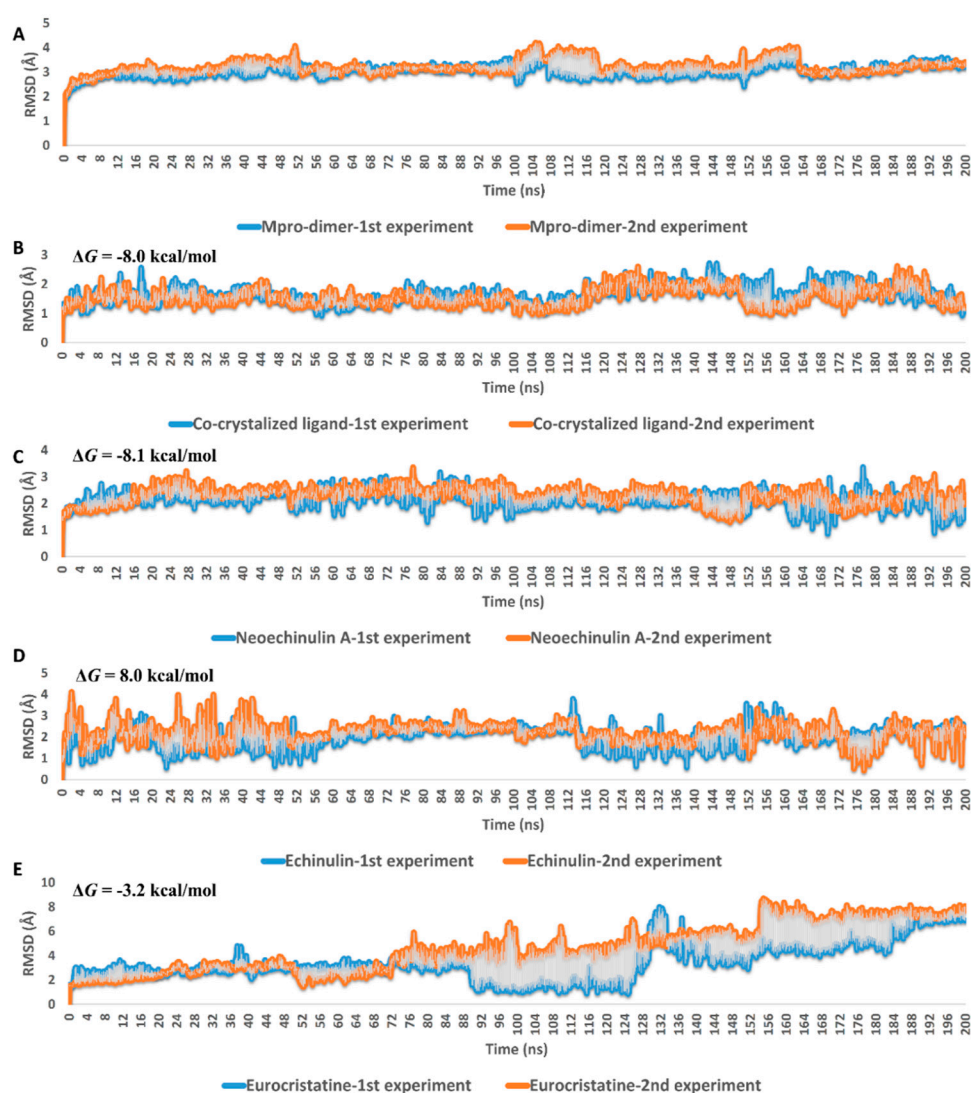

Figure 4. RMSDs of neoechinulin A (**1**), echinulin (**2**), and eurocristatine (**3**) (**C**–**E**) inside the M^{pro}-dimer active site over the course of MDS. (**A**,**B**) are the RMSDs of the free dimeric form of M^{pro} and co-crystalized inhibitor over the course of MDS. The MDS experiments were carried out two times for 200 ns. The blue color indicates the 1st experiment, while the orange color indicates the 2nd one.

The co-crystallized inhibitor YD1 also established two strong H-bonds with GLY-143 and GLU-166 as did both compounds **1** and **2**, in addition to further H-bond with HIS-163. Moreover, it also formed stable hydrophobic interactions with HIS-41 as in both compounds.

In regard to eurocristatine (**3**), its most populated pose (11%) revealed transient H-bonds with ASN-142, HIS-164, and GLU-166 in addition to a number of unstable hydrophobic interactions with LEU-27, HIS-41, MET-49, MET-165 (Figures 4 and 5).
Figure 5. The most populated binding poses of neoechinulin A (**1**), echinulin (**2**), and eurocristatine (**3**) (cyan color) in addition to the co-crystalized inhibitor YD1 (orange color) (**A–D**, respectively) inside the M^pro-dimer active site over the course of MDS.
Figure 6. Protein–ligand contacts inside the M^pro active sites over 200 ns of MDS: (**A,B**) M^pro-neoechinulin A (**1**) contacts derived from two independent MDS experiments, (**C,D**) M^pro-echinulin (**2**) contacts derived from two independent MDS experiments, and (**E,F**) M^pro-eurocristatine (**3**) contacts derived from two independent MDS experiments.

The fourth step, steered molecular dynamics (SMD), was carried out to determine the relative binding affinity of the investigated compounds, particularly neoechinulin A (**1**) and echinulin (**2**), that the calculated ΔG_{bind} were too convergent (−8.1 and −8.0 kcal/mol, respectively). However, **1** was eight times more active than **2** towards M^{pro} in vitro (Figure 3). For each, compound-protein complex (i.e., docking pose) and external force were applied to the compound (i.e., ligand) to steer it out of the M^{pro} active site. The exerted forces could be monitored over the course of the simulation. As shown in Figure 7, the unbinding of eurocristatine (**3**) (i.e., the inactive compound) was achieved by a force not higher than ~108 pN, while active compounds neoechinulin A (**1**) and echinulin (**2**) along with the co-crystalized inhibitor YD1 required an unbinding force ranging from 399 pN to 909 pN. The force profile plotted in Figure 7 clearly indicated that neoechinulin A (**1**) (IC$_{50}$ = 0.47 μM) has the highest binding stability inside the M^{pro} active site (i.e., needed unbinding force ~909 pN), followed by the co-crystalized inhibitor YD1 (Ki = 2.9 μM) [25] (i.e., needed unbinding force ~685 pN) followed by echinulin (**2**) (IC$_{50}$ = 3.9 μM) (i.e., needed unbinding force ~399 pN). These differences in the unbinding forces between neoechinulin A (**1**), echinulin (**2**), and the co-crystalized inhibitor YD1 may be attributed to the degree of ligand–protein H-bonds' stability during the unbinding process in addition to the degree of hydrophobic interactions with hydrophobic residues inside the enzyme active site, particularly with HIS-41, where neoechinulin A (**1**) was able to establish a significant stable hydrophobic interaction with this hydrophobic residue (Figure 6A). Accordingly, these SMD-based findings clearly explain the significant difference in the activity of neoechinulin A (**1**) in comparison with echinulin (**2**) depending on revealing how tightly each ligand was bound to the enzyme's active site.

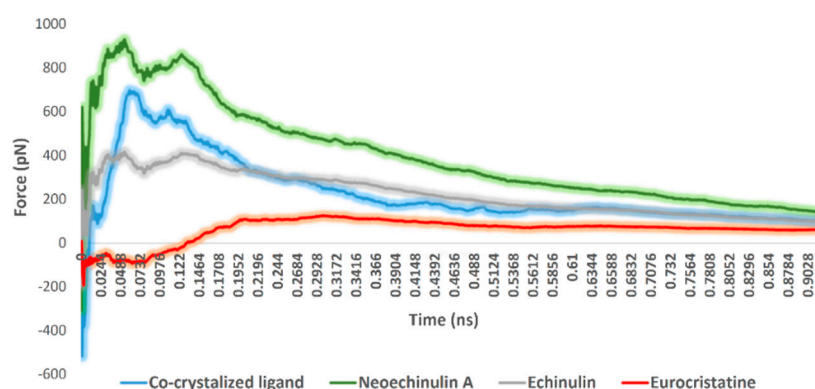

Figure 7. Comparison of the unbinding force profiles of neoechinulin A (**1**), echinulin (**2**), and eurocristatine (**3**) along with the co-crystalized ligand YD1. The plots show the resulting mean values from averaging the force profiles from three different SMD runs.

3. Discussion

The unprecedented pandemic of SARS-CoV-2 emerged in late 2019 is associated with significant mortality globally. Although several vaccines were developed, drug discovery campaigns are still crucial as vaccines alone were not sufficient for complete protection against the virus and its emerging variants. The SARS-CoV-2 M^{pro} is considered a promising drug target, as it is dissimilar to human proteases [26]. SARS-CoV-2: M^{pro} is a key enzyme in coronaviruses as it possesses an essential role in mediating viral replication and transcription. This made it attractive as a drug target for SARS-CoV-2, which has been used through different computer-assisted programs to discover medications that could modulate it and hence show good antiviral potential [3,27].

Although the computer-aided drug discovery process is very promising during pandemics, the standard bioguided isolation approach can quickly discover active hits. The marine fungal isolate *Aspergillus fumigatus* MR2012 was recovered from the Red Sea in 2011 and proved to be one of the "talented" strains in terms of drug discovery. Its initial large-scale fermentation on malt extract sea salt medium led to the isolation of nine

diketopiperazine alkaloids that showed antibacterial activity against Gram-positive bacteria [28]. When *Aspergillus fumigatus* MR2012 was co-cultured with the hyper-arid desert bacterial isolate *Streptomyces leeuwenhoekii* strain C34 on ISP2 medium, it produced the two new metabolites luteoride D and pseurotin G. Using OSMAC approach and screening the strain against three different media led to the isolation of the new metabolite brevianamide X [29].

Herein, bioguided screening to discover potential SARS-CoV-2 M^{pro} inhibitors led to the selection of *Aspergillus fumigatus* MR2012 as its extract on a medium supplemented with mannitol, and showed good inhibition of SARS-CoV-2 M^{pro} in vitro. The large-scale fermentation of the fungus on this medium led to the isolation of three indole diketopiperazines and one isocoumarin derivative which were not traced before in the previous fungal fermentation studies. In vitro screening of the isolated metabolites highlighted that neoechinulin A (**1**) had significant SARS-CoV-2 M^{pro} inhibitory effects with IC$_{50}$ value comparable to the positive control GC376. Neoechinulin A (**1**) has previously shown diverse biological effects such as antioxidant [30], neuroprotective [31], anti-inflammatory [32], and memory enhancer [33]. Although neoechinulin A has never been reported with antiviral effect, its closely related analogue neoechinulin B displayed potent inhibition against a panel of drug-resistant influenza clinical isolates by targeting the influenza envelope haemagglutinin and disrupting its interaction with the host cells [34].

Molecular modeling and simulation approaches became able to afford a very good explanation about the ligands' mode of actions at the molecular level. After predicting the binding modes of neoechinulin A (**1**), echinulin (**2**), and eurocristatine (**3**) inside the M^{pro} active site via running multiple docking and ΔG_{bind} calculation trials, we initiated a number of MDS-based experiments to explain the reasons behind eurocristatine (**3**) being inactive and why neoechinulin A (**1**) was significantly more active than echinulin (**2**).

MDS-derived findings clearly showed that eurocristatine (**3**) had a low affinity toward M^{pro} active site. This conclusion came from (i) its significantly low calculated ΔG_{bind} value, (ii) its high average RMSD over the MDS runs, (iii) and its low calculated unbinding force. Additionally, the extracted binding behavior revealed its transient molecular interactions inside the enzyme's active site.

Accordingly, the second question about the difference in the in vitro activity between the structurally related neoechinulin A (**1**) and echinulin (**2**) was explained by calculating their relative binding stabilities inside the M^{pro} active site by estimating the force needed to pull each compound out of the active site via running a number of SMD experiments. To the best of our knowledge, this is the first non-classical MDS-based experiment (i.e., SMD) in the relative affinity estimation of potential SARS CoV-2 M^{pro} inhibitors.

Depending on the previous discussion, it is important to emphasize the following concluding points that should be taken into consideration in dealing with the M^{pro}-related in silico investigation: (i) long multiple classical MDS runs (>150 ns long) produce sufficient data regarding the binding stability of the proposed ligands inside the M^{pro}'s active site. Shorter single runs (<50 ns) might be misleading on some occasions and unable to differentiate between active and inactive ligands [35]; (ii) MDS experiments should be carried out using the M^{pro} dimeric model to get more accurate and realistic results [36]; (iii) absolute binding free energy estimation and MDS experiments in some cases are not sufficient to discriminate between structurally similar scaffolds. Hence, using different non-classical MDS experiments could be the best solution in such cases [37].

It is worth noting that both neoechinulin A (**1**) and echinulin (**2**) have good drug-like properties according to Lipinski's rules [38] in contrast to that of eurocristatine (**3**) which has poor drug-like properties. Hence, these diketopiperazine derivatives, particularly neoechinulin A (**1**), are considered a very promising non-covalent M^{pro} inhibitors that can be developed as natural product-based COVID-19 medication.

4. Materials and Methods

4.1. Chemicals

All solvents used for extraction and processing were purchased from Fisher Chemical UK while HPLC grade solvents were obtained from Rathburn Chemicals Ltd. (Walkerburn, UK). Column chromatography was performed on Acros Organics 0.03–0.20 mm mesh size silica gel. Thin layer chromatography (TLC) technique was used for preliminary identification and performed on pre-coated TLC sheets POLYGRAM® SIL G/UV$_{254}$, Macherey-Nagel GmbH & Co., and samples were spotted using 5 μL micropipettes (Drummond Scientific Company, Broomall, PA, USA). Silica plates were visualized under UVGL Handheld UV lamp and para-Anisaldehyde (99% pure, Acros Organics, 2440 Geel, Belgium). Deuterated DMSO (Cambridge Isotope Laboratories, Inc., Tewksbury, MA, USA) was used for NMR measurements. The ingredients used to prepare fungal culture media were purchased from Oxiod, Hampshire RG24 8PW, UK.

4.2. Instruments

For compound purification, Agilent 1100 series HPLC system connected to Diode Array Detector was used. HRESIMS data were obtained using a Thermo LTQ XL/LTQ Orbitrap Discovery MS system coupled with an HPLC system (PDA detector, PDA autosampler and pump) run under the following conditions: capillary voltage of 45 V, capillary temperature of 260 °C, auxiliary gas flow rate of 10–20 arbitrary units, sheath gas flow rate of 40–50 arbitrary units, spray voltage of 4.5 kV, and mass range of 100–2000 amu (maximal resolution of 30,000). A Sunfire C$_{18}$ analytical HPLC column (5 μm 4.6 mm × 150 mm) was employed with a mobile phase of 0 to 100% MeOH over 30 min at a flow rate of 1 mL/min for the liquid chromatography analysis. Structure characterization of compounds was based on 1D and 2D NMR data, using Bruker Advance III spectrometer 600 MHz (Bruker UK Ltd., Durham, UK).

4.3. Fungal Isolation and Identification

The fungal isolate MR2012 was recovered from the marine sediment collected from Hurgada, the Red Sea, at the end of 2011. Sequence analysis of the ITS regions of rDNA showed 99% identity with *Aspergillus fumigatus* [28].

4.4. Small- and Large-Scale Fermentation and Extraction

The pure fungal culture was grown in ISP2 agar media (supplemented with 25 g/L sea salt) and incubated at room temperature for 5–7 days. Approximately 5 × 5 mm size agar pieces with the fungus were aseptically introduced into ten 3 L conical flasks containing 800 mL of fermentation broth containing 10 g/L of malt extract, 10 g/L of yeast extract, 4 g/L of mannitol, and supplemented with 25 g/L sea salt, under static fermentation for 28 days at room temperature. Then, the mycelial bed in each flask was combined and extracted by sonication with methanol (MeOH) (3 × 500 mL) for 1 h each. The MeOH extract was evaporated under vacuum to get 3.8 g of the crude extract. This extract was resuspended in 200 mL of 1:1 distilled water and MeOH and subsequently fractionated with 3 × 250 mL of *n*—hexane, DCM, and EtOAc, which were also evaporated under vacuum. TLC analysis confirmed different patterns in all fractions.

4.5. Isolation of Fungal Metabolites

The biologically active DCM fraction (1.1 g) was further purified through its injection into RP–HPLC (Phenomenex RP–C$_{18}$ analytical column (Luna 5 μm, 250 × 4.60 mm, L × i.d.)) using a gradient of 25–100% of MeCN in H$_2$O for 30 min and 100% MeCN for 5 min at a flow rate of 2 mL/min. This method afforded the four major compounds 1 (4.2 mg), 2 (1.1 mg), 3 (2.4 mg), and 4 (2.7 mg).

Neoechinulin A (**1**): white powder; $[\alpha]^{25}_{D}$ − 66.65 (c 0.15, CH$_3$OH); UV (MeOH) λ_{max} (log ε): 225 (3.95), 288 (3.15), 326 (2.90); ^{1}H (600 MHz, DMSO–d_6): δ 1.38 (3H, d, J = 6.5), 1.48 (6H, s), 5.05 (2H, s), 6.08 (1H, m), 2.55 (2H, s), 8.67 (1H, s), 4.17 (1H, d, J = 7.0), 6.89 (1H,

s), 7.42 (1H, d, J = 8.0), 7.01 (1H, t, J = 7.0, 7.8), 7.09 (1H, t, J = 8.0, 7.0), 7.19 (1H, d, J = 8), 11.06 (1H, s); ^{13}C NMR (150 MHz, DMSO–d_6): 20.0 (C-30), 28.0 (C-18/19), 112.1 (C-17), 145.6 (C-16), 40.9 (C-15), 166.9 (C-13), 51.0 (C-12), 160.4 (C-10), 125.3 (C-9), 110.7 (C-8), 135.6 (C-7a), 112.0 (C-7), 119.8 (C-6), 121.2 (C-5), 119.4 (C-4), 126.5 (C-3a), 103.9 (C-3), 144.4 (C-2); HR–ESIMS: [M + H]$^+$ at m/z 324.1719 $C_{19}H_{22}N_3O_2$ (calcd. 324.1707).

Echinulin (**2**): yellow powder; [α]$^{25}_D$ − 26.15 (c 0.2, CH$_3$OH); UV (MeOH) λ$_{max}$ (log ε): 218 (4.10), 284 (2.95); ^{1}H (600 MHz, DMSO–d_6): δ 1.33 (3H, d, J = 7), 1.69 (6H, s), 1.74 (6H, s), 5.38 (1H, t, J = 7.0, 7.5), 3.56 (2H, d, J = 7.6), 1.69 (6H, s), 1.74 (6H, s), 5.30 (1H, t, J = 7.0, 7.5), 3.29 (2H, d, J = 6.7), 1.50 (6H, d, J = 7.4), 1.50 (6H, d, J = 7.4), 5.05 (2H, m), 6.21 (1H, dd, J = 17.5, 10.6), 8.17 (1H, s), 3.81 (1H, dd, J = 2.8, 3.1), 7.43 (1H, s), 3.91 (1H, m), 3.01 (2H, dd, J = 9.4, 10), 6.63 (1H, s), 7.04 (1H, s), 9.70 (1H, s); ^{13}C NMR (150 MHz, DMSO–d_6): 21.3 (C-30), 18.2 (C-28/29), 130.8 (C-27), 123.3 (C-26), 29.5 (C-25), 26.0 (C-23/24), 132.0 (C-22), 125.3 (C-21), 34.6 (C-20), 28.5 (C-18/19), 111.5 (C-17), 147.3 (C-16), 40.9 (C-15), 168.4 (C-13), 50.8 (C-12), 167.9 (C-10), 56.1 (C-9), 31.8 (C-8), 141.9 (C-7a), 132.7 (C-7), 121.4 (C-6), 124.0 (C-5), 115.1 (C-4), 129.7 (C-3a), 105.6 (C-3), 145.9 (C-2); HR–ESIMS: [M + H]$^+$ at m/z 462.3119 $C_{29}H_{40}N_3O_2$ (calcd. 462.3115).

Eurocristatine (**3**): white powder; [α]$^{25}_D$ + 295.50 (c 0.02, CH$_3$OH); UV (MeOH) λ$_{max}$ (log ε): 212 (4.15), 244 (3.95), 304 (3.60); ^{1}H (600 MHz, DMSO–d_6): δ 0.69 (3H, d, J = 7), 0.81 (3H, d, J = 7), 1.95 (1H, m), 3.39 (1H, t, J = 5, 4.9), 8.26 (1H, d, J = 4.3), 3.14 (2H, s), 2.39 (2H, m), 4.12 (1H, t, J = 8.8, 8.8), 6.60 (1H, d, J = 7.7), 7.03 (1H, t, J = 7.5, 7.7), 6.64 (1H, t, J = 7.5, 7.5), 7.40 (1H, d, J = 7.5), 4.90 (1H, s), 6.74 (1H, s); ^{13}C NMR (150 MHz, DMSO–d_6): δ 18.5 (C-19), 19.5 (C-18), 32.5 (C-17), 167.9 (C-16), 62.8 (C-15), 168.8 (C-13), 37.7 (C-12α), 56.2 (C-11), 149.6 (C-9), 109.4 (C-8), 129.2 (C-7), 118.4 (C-6), 124.9 (C-5), 130.9 (C-4), 60.2 (C-3), 79.5 (C-2); HR–ESIMS: [M + H]$^+$ at m/z 569.2871 $C_{32}H_{37}N_6O_4$ (calcd. 569.2871).

Eurotiumide G (**4**): yellow oil; [α]$^{25}_D$ 0 (c 0.10, CH$_3$OH, suggesting a racemic mixture); UV (MeOH) λ$_{max}$ (log ε): 220 (3.25), 263 (0.90), 335 (1.2); ^{1}H (600 MHz, DMSO–d_6): δ 9.13 (1H, d, J = 2.2), 3.31 (3H, s), 3.38 (3H, br s), 1.30 (3H, br s), 1.30 (3H, br s), 5.75 (1H, d, J = 9.5), 6.32 (1H, d, J = 9.7), 0.89 (3H, t, J = 6.7, 6.6), 1.33 (6H, s), 1.32 (6H, s), 1.50 (2H, m), 1.39 (2H, m), 1.64 (2H, m), 1.70 (2H, m), 6.53 (1H, s), 4.11 (1H, d, J = 2), 3.87 (1H, br s), 5.35 (1H, s); ^{13}C NMR (150 MHz, DMSO–d_6): δ 58.0 (4-OCH3), 55.6 (1-OCH3), 27.7 (C-5″), 27.5 (C-4″), 75.7 (C-3″), 132.6 (C-2″), 122.4 (C-1″), 14.6 (C-5′), 22.6 (C-4′), 31.7 (C-3′), 25.5 (C-2′), 30.7 (C-1′), 123.4 (C-8a), 142.3 (C-8), 121.5 (C-7), 112.4 (C-6), 149.2 (C-5), 117.8 (C-4a), 69.3 (C-4), 70.5 (C-3), 95.0 (C-1); HR–ESIMS: [M + H]$^+$ at m/z 363.2160 $C_{21}H_{31}O_5$ (calcd. 363.2166).

4.6. In Vitro Assay against SARS-CoV-2 Main Protease

The fungal extract, fractions, and the isolated compounds (**1**–**4**) were assessed for their in vitro enzyme inhibition activities using 3CL Protease, tagged (SARS-CoV-2) Assay Kit (Catalog #: 79955-1, BPS Bioscience, Inc., Allentown, PA, USA), according to manufacturer's protocol [15]. The in vitro FRET assay was monitored at an emission wavelength of 460 nm with excitation at 360 nm, using a Flx800 fluorescence spectrophotometer (BioTek Instruments, Winooski, VT, USA).

4.7. Docking and Molecular Dynamics Simulations

The in silico-based investigation was carried out in four steps:

Step1 (docking step): the compounds under investigation were docked into the M^{pro} active site using Autodock Vina [39]. The resulting top-ranked pose was almost identical to that of the co-crystallized one with an RMSD of 1.1 Å (Figure S12). The generated binding poses were then visually investigated using Pymol software [13,39].

Step 2 (ΔG$_{bind}$ estimation step): Top-scoring poses resulted from the docking step were subjected to molecular dynamic simulations (MDS)-based binding free energy estimation (ΔG$_{bind}$) using the Free Energy Perturbation (FEP) method [40]. MDS experiments carried out to calculate ΔG$_{bind}$ were performed by NAMD software [41], and all input files required for simulation by NAMD were prepared by using the online website Charmm-GUI (https://charmm-gui.org/?doc=input/afes.abinding, accessed on 15 February 2022) [40,41].

Step 3 (MDS step): Top-scoring poses resulted from the docking step were subjected to 200 ns MD simulations carried out in duplicates. MDS runs were performed and analyzed by Desmond software [14,15,42,43].

Step 4 (SMD step): steered molecular dynamics (SMD), was carried out to determine the relative binding affinity of the investigated compounds. All SMD experiments were carried out by NAMD software as described previously [41].

The detailed procedures for each step are described in the Supplementary file.

5. Conclusions

Herein, we have fermented our in-house marine fungal strains on different media using the OSMAC approach. Through bio-guided screening, we have discovered the indole diketopiperazine alkaloid neoechinulin A as a potential structural motif against SARS-CoV-2 M^{pro}. By applying a number of different modeling and biophysics-based simulation experiments, the binding mode of this promising natural product along with its congeners was putatively elucidated. Additionally, we introduced SMD as a simple and powerful MDS-based method to discriminate between active and inactive structurally related motifs.
