Purpose: The synergistic effects of a trunk orthosis and an ankle–foot orthosis (AFO) in stroke patients with a hemiplegic gait are unclear. We previously developed a trunk orthosis with joints providing resistive force (TORF) to modify malalignment of the trunk and pelvis and confirmed its positive effects in stroke patients during level walking without an AFO. The aim of the present study was to determine if this trunk orthosis and an AFO have synergistic effects during level walking in community-dwelling patients with chronic stroke.

Methods: Twenty-eight community-dwelling stroke patients performed level walking at a self-selected speed with an AFO and again while wearing a TORF (TORF group) or a corset (control group). Spatiotemporal, kinematic, and kinetic data were recorded using a three-dimensional motion analysis system.

Results: When compared with the control group, the TORF group showed significant increases in walking speed, number of steps on the paretic leg per minute, and peak ankle plantar flexion moment during the single stance phase.

Conclusion: The TORF increased the ankle joint plantar flexion moment at the end of the single stance phase during level walking in stroke patients, leading to an increase in their gait speed because of the modified trunk and pelvis alignment.

Keywords: biomechanics, orthosis, gait, stroke, joint moment, motion analysis

Background

Hemiplegia is a typical symptom after the onset of stroke and causes a significant decrease in walking ability.¹ The paralysis in patients with hemiplegia tends to be more severe distally, and a number of ankle–foot orthoses (AFOs) can be used to improve gait in these patients.² It has been shown that AFOs improve the gait pattern and energy efficiency in patients with hemiplegia and improve spatiotemporal parameters, including walking speed, cadence, and step length.^{3–6} However, even though AFOs are easy to wear and remove, they can only help at a single joint, so their effect is localized.⁷ Therefore, researchers have sought ways of supporting the other joints in the lower extremities simultaneously to augment the effect of AFOs.

Hemiplegic patients are likely to experience hyperextension and buckling of the knee. Therefore, knee–ankle–foot orthoses are often used to assist the function of the knee joint.⁸ Further, several studies have reported on devices that support the hip joint in hemiplegic patients. Maguire et al demonstrated that an elasticated strap had an immediate effect of increasing hip abductor muscle activity in hemiplegic patients.⁹ In another study, Thijssen et al used an elastic strap to guide the major joints of the affected limb (ie, the hip, knee, and ankle) and reported both an immediate effect and

an effect after familiarization for 3 weeks on the energy cost and spatiotemporal parameters of level walking.¹⁰ Further, Carda et al reported immediate improvement in scores on the 6-min and 10-m walk tests in patients wearing an orthosis designed to assist hip flexion.¹¹

As described above, there are already some devices other than AFOs that can assist paretic lower limb joints in the hemiplegic patient. However, there is increasing emphasis on rehabilitation of the trunk in hemiplegic patients because trunk performance contributes to gait performance.^{12,13} Unfortunately, there has been little progress in development of trunk orthoses to supplement the function of the torso in patients with hemiplegia. Katsuhira et al developed a trunk orthosis with joints providing resistive force (TORF; Trunk Solution Co., Ltd, Tokyo, Japan) and investigated its effect on kinetic and kinematic parameters of the hemiplegic gait, reporting many effects in the paretic lower limb.¹⁴ However, in that study, the hemiplegic subjects walked without an AFO while wearing the TORF and no control group was included. If a combination of an AFO and a trunk orthosis could improve gait performance in hemiplegic patients, it might be useful as a rehabilitation intervention. In this study, a synergetic effect was defined as two different types of interventions providing a positive effect. A previous study reported that tibial nerve blockade and an AFO had a synergetic effect on hemiplegic gait,¹⁵ but the synergetic effect of two different orthotic strategies has not been studied.

The aim of this study was to compare the immediate effect on hemiplegic gait of wearing a trunk orthosis in addition to an AFO. We hypothesized that wearing a TORF as the trunk orthosis would stabilize the upper trunk and pelvis, thereby supplementing trunk function and improving hemiplegic gait performance.

Methods

Features of the TORF

The design and features of the TORF have been described previously.¹⁴ Briefly, a pelvic and upper support is positioned on the ilium and sternum, respectively, and the joints are connected with a silicon pad to an upper support made of stainless steel and to a pelvic support (Figure 1). The joints produce resistive force via extension springs, and a link mechanism translates the spring-generated tension into resistive force on the chest. Although anterior bending of the trunk is restricted by the resistive force, the upper support allows 40° of movement in the anterior direction. However, there is no restriction of movement of the upper trunk in the mediolateral direction. While wearing the TORF, the upper support initially inclines backward to exert resistive force

on the chest. The TORF has release mechanics produced by tension levers whereby resistive force is released by pulling the tension levers downward. Adjustable screws control the magnitude of spring-generated resistive force.

We previously reported that our prototype TORF could enhance the forward tilt of the pelvis and upright posture of the trunk, thereby increasing the flexion moment exerted by the abdominal muscles and decreasing the extension moment exerted by the back muscles during level walking in community-dwelling elderly people.¹⁶

Patients

The participants comprised 28 patients residing in Kanagawa Prefecture (n=13) or Fukuoka Prefecture (n=15) in Japan who were in the chronic phase of stroke. Patients in this phase of stroke were selected because the recovery curve plateaus and the gait performance reaches a steady state at ~6 months after onset.¹⁷ The inclusion criteria were a diagnosis of hemiparesis and the ability to walk at least 10 m. The exclusion criteria were nonconcurrent pathology affecting the neuromuscular or central nervous system, communication problems, severe spasticity, and proprioceptive sensory impairment. We randomly allocated the 28 patients to a TORF group or a control group (Figure 2). One patient from Fukuoka was found to be ineligible for inclusion because of missing markers, leaving data for 27 patients (TORF group, n=13; control group, n=14). Table 1 shows the participants' demographic and clinical characteristics. The study protocol was approved by the institutional ethics committees at the International University of Health and Welfare (14-Io-102) and Seiai Rehabilitation Hospital (14-1225) and followed the tenets of the Declaration of Helsinki. Written informed consent was obtained from all subjects prior to their participation in the study.

Study protocol

The participants were randomly allocated to the study groups by a statistician using a computerized random number generator. A physical therapist informed the participants of their allocation numbers. The study protocol has been published elsewhere.¹⁴ We recorded the gait data using a three-dimensional (3D) motion capture system consisting of 8 or 12 cameras (VICON Mx; VICON, Oxford, UK) and four or six force plates (AMTI, Watertown, MA, USA) arranged in two or three rows of two. The tests were performed at two separate institutions. The patient stepped onto the right-hand force plates with the right foot and the left-hand force plates with the left foot. Thirty-nine reflective markers were attached using the marker model developed by Helen Hayes. An ankle-joint marker was placed on the mechanical joint

Figure 1 Trunk orthosis with joints providing resistive force.

Figure 2 Flow of patients through the trial.

Note: One patient was excluded after measurements were taken because of missing markers.

Abbreviation: TORF, trunk orthosis with joints providing resistive force.

of the AFO. Markers for the trunk and pelvis were placed on the participant’s skin. An additional marker was placed on the center of the sacrum. Bilateral markers for the anterior superior iliac spine were removed to prevent interference when both trunk orthoses were worn but were reapplied on the posterior superior iliac spine bilaterally during walking and on the center of the sacrum during static standing when the trunk orthoses were not being worn. We measured the trajectories of the markers and the force plate data at a sampling frequency of 100 Hz in both laboratories. All patients were wearing an AFO (Gait Solution Design; Kawamura Gishi, Daito, Japan) and used canes as needed during all measurement sessions. Patients in the control group wore a lumbosacral orthosis (Damen Corset; Pacific Supply, Osaka, Japan) and those in the TORF group wore a TORF. First, we measured gait when the patient was wearing an AFO without any trunk orthosis at the patient’s selected speed and repeated these measurements three times. Next, we measured gait when the patient was wearing an AFO with their allocated trunk orthosis (TORF or corset).

Abbreviations: BrS, Brunnstrom recovery stage; TORF, trunk orthosis with joints providing resistive force.

Before starting measurements, all subjects practiced walking on the floor of the laboratory at a self-selected speed for 10 min to become accustomed to wearing their AFO and allocated trunk orthosis while holding a break. Before measuring gait, we set the magnitude of the resistive force to 20 N during static standing while wearing the TORF based on the results of the preliminary experiments. We measured the adjustments to the resistive force with a strain gauge embedded in the upper support of the TORF and transferred the measurement to a personal computer using Bluetooth technology. The pressure between the lumbosacral orthosis and the abdomen was set to 10 mmHg under all measurement conditions.¹⁸ Measurements were recorded for all patients in both groups with and without their trunk orthosis (TORF or lumbosacral corset).

Data processing

We processed the physical coordinates and ground reaction force (GRF) data using a 6- and 18-Hz low-pass filter,

respectively. The data were analyzed using Visual 3D version 6 analytical software (C-motion, Inc., Germantown, MD, USA). The link segment model consisted of 13 segments (head, trunk, pelvis, upper arms, forearms, thighs, shanks, and feet). We calculated joint kinematics and kinetics according to Winter's technique.¹⁹ From these data, we detected the spatiotemporal parameters and the peak values for triaxial joint angles, joint moments, and GRF per gait cycle in each patient under each condition; the reason for doing this was that a previous study investigating the effects of the TORF on hemiplegic gait used the same parameters¹⁴ and another study by Yamamoto et al used the same AFO and reported on the same parameters.²⁰ However, those studies reported kinetic and kinematic parameters mainly in the sagittal plane and neither reported on the alignment of the pelvis and trunk. A further study had investigated the effect of the TORF on alignment in healthy elderly subjects. Therefore, we decided to analyze GRF, triaxial lower joint kinetic and

kinematics, and triaxial movements of the trunk and pelvis. Joint moments and GRF were normalized by body mass. The peak values for paretic kinetic and kinematic parameters at the time of 1) initial contact, 2) loading response (LR), 3) pre-swing (PSw), 4) single stance (SS), and 5) swing were extracted for analysis. We defined these phases using the vertical component of GRF.

Statistical analysis

Gait parameters were determined and averaged for at least two of three measured trials without missing markers under each of the two experimental conditions. The spatiotemporal, kinetic, and kinematic parameters were not normally distributed according to the Shapiro–Wilk test, so a non-parametric statistical analysis was performed. First, the Wilcoxon signed-rank test was used to identify any significant differences between wearing and not wearing a trunk orthosis. When a significant difference was found, further comparisons were made between baseline and wearing a trunk orthosis using the Mann–Whitney *U*-test. A *p*-value of 0.05 was considered to be statistically significant. All statistical analyses were performed using SPSS for Windows version 21 software (IBM Corp., Armonk, NY, USA).

Results

No significant difference in patient height ($p=0.451$), weight ($p=0.133$), or age ($p=0.576$) was found between the two groups (Table 1).

Comparison with and without a trunk orthosis

There were statistically significant differences in values for all spatiotemporal gait parameters between when patients were wearing and not wearing a trunk orthosis (Table 2). Walking speed and number of paretic steps per minute

increased significantly, and the number of paretic steps decreased significantly in the TORF condition but not in the corset condition. Significant changes in spatiotemporal parameters were observed only on the paretic side.

Some kinetic and kinematic parameters showed significant changes under the TORF condition but not under the corset condition (Table 3). In addition, there were significant differences in angles at all joints of the lower extremities, pelvis, and thorax and GRF values between the TORF condition and the non-TORF condition. In the TORF group, the peak mediolateral component of the GRF during the LR phase and the vertical component of the GRF in the PSw phase increased significantly in the paretic limb when the trunk orthosis was worn compared to those when it was not. The peak ankle plantar flexion moment during the SS phase and the dorsiflexion moment during the swing phase increased significantly in the TORF condition when compared with the non-TORF condition. The peak knee abduction moment during the PSw phase also increased significantly in the TORF condition when compared with the non-TORF condition. The peak hip extension moment in the swing phase and the extension angle in the SS and PSw phases also increased significantly in the TORF condition when compared with the non-TORF condition.

The angles of the pelvis and thorax during one gait cycle of the paretic limb are shown in Table 4. The peak pelvic tilt angle in the LR phase increased significantly in the TORF condition when compared with the non-TORF condition. Peak thorax bending angles over one gait cycle in the paretic limb decreased significantly in both the TORF condition and the corset condition, except during the LR phase. The peak thorax lateral bending angle during the SS, PSw, and swing phases decreased significantly in the TORF condition when compared with the non-TORF condition but not in the corset condition when compared with the non-corset condition.

Comparison of changes from baseline between the TORF and corset groups

All changes in parameters from baseline are compared between the TORF and corset groups in Table 5. In the TORF condition, we observed significant increases in walking speed, paretic steps per minute, peak ankle plantar flexion moment during the SS phase, and dorsiflexion moment during the swing phase, as well as a significant decrease in paretic step time. The ankle plantar flexion moment increased at the end of the SS phase, which is the terminal stance phase shown in Figure 3.

Discussion

Our results demonstrate that wearing a TORF and an AFO at the same time can improve gait performance in hemiplegic patients by significantly increasing their gait speed and ankle-joint plantar flexion moment toward the end of the SS phase to a greater extent than is possible wearing a corset and an AFO. Further, the TORF significantly modified the malalignment commonly seen in hemiplegic patients.

Changes from baseline

We hypothesized that wearing both a TORF and a corset would augment gait performance by improving trunk function. However, subjects in the TORF group showed greater functional improvement in their hemiplegic lower limb because of the stabilizing effect on the upper trunk of the resistive force applied to the chest. In addition, significant changes from baseline were observed only in the TORF condition. The spatiotemporal parameters of gait speed and number of paretic steps per minute significantly increased and the paretic step time significantly decreased in the TORF condition. A previous study investigating the effect of a TORF on hemiplegic patient did not show significant improvement of gait speed compared with that before wearing a TORF¹⁴ because no AFO was applied. It is reported that AFOs are able to facilitate weight-bearing on the paretic limb and increase stability during stance in stroke patients,²¹ and thus might contribute to a decrease in the compensatory trunk movements seen in patients with a hemiplegic gait.²² The synergistic effect of wearing a TORF to stabilize the trunk and

an AFO might contribute to this decrease in compensatory trunk movements, leading to significant changes in spatiotemporal parameters.

The most interesting change in the TORF condition was the significant increase in ankle plantar flexion moment during the SS phase. Nadeau et al reported that weakness of the plantar flexors should be considered as a factor limiting gait speed.²³ Further, Yamamoto et al emphasized the importance of the plantar flexion moment as an indicator of the ankle rocker function relating to forward progression of the center of pressure in hemiplegic patients.²⁰ Yamamoto et al used an AFO similar to the one used in the present study and reported that their device increased the ankle plantar flexion moment after gait training for 3 weeks but not immediately after application.²⁰ In the present study, the ankle plantar flexion moment increased after only 10 min of familiarization with wearing the TORF and AFO. Moreover, this significant increase in ankle plantar flexion moment could have led to significant changes in spatiotemporal parameters, including gait speed. Accordingly, using a TORF might enhance the

effect of gait training wearing the AFO. Further, the slight increase in ankle dorsiflexion moment during the swing phase, which helps to prevent foot drop, was observed in the TORF condition; this increase in moment might have been caused by an increase in inertial force as a result of a faster gait speed, but this was too small to determine if there was an effect on gait or not.

Differences in gait parameters with and without a trunk orthosis

Parameters that showed a significant change from baseline also showed a significant difference between the TORF and non-TORF conditions. These differences may help to explain the beneficial effect of a TORF in hemiplegic stroke patients.

More significant differences were observed between the TORF and non-TORF conditions than between the corset and non-corset conditions. No significant differences were observed between the corset and non-corset conditions except for a significant decrease in the trunk

forward bending angle in the corset condition. The trunk forward bending and mediolateral bending angles were also significantly decreased in the TORF condition when compared with the non-TORF condition. A systematic review of trunk movement in patients with a hemiplegic gait after

stroke reported that gait performance was related to trunk movement not only in the sagittal plane but also in the frontal plane.²² A decrease in trunk movement in both planes while wearing a TORF could have contributed to the improvement in gait parameters. Interestingly, the TORF restricts

only forward but not mediolateral bending of the thorax with resistive force. Modified alignment in the sagittal plane and activation of the abdominal muscles by resistive force on the chest might have contributed to modified alignment even in the frontal plane. However, there was a significant increase in the mediolateral component of the GRF during the LR phase and in the internal abduction moment of the knee during the PSw phase. These increases might be caused by the restricted movement of the mediolateral trunk. An increase in the mediolateral component of the GRF provides stability in the same direction. However, it is well known that an increase in knee abduction moment is a cause of osteoporosis in the knee,²⁴ so consideration might need to be given to increasing the load on the paretic knee joint while wearing a TORF.

There was no significant change in the trunk bending angle during the LR phase or in the pelvic tilt angle over one gait cycle in the corset condition. In contrast, there was a significant change in the trunk bending angle over one gait cycle and in the pelvic tilt angle during the LR phase in the TORF condition. Further, a significant change in hip extension angle in the SS and PSw phases was only observed in the TORF condition. These differences might be key to understanding the kinetic and kinematic differences observed between wearing the TORF and wearing a corset. As shown in Figure 4, an upright posture with a pelvic forward tilt is important when rotating the body using the ankle joint as the fulcrum from the LR phase to the terminal stance phase, which constitutes the second rocker phase,²⁵ suggesting that this movement is accompanied by extension of the hip joint. Assisting the ankle joint using an AFO could be needed to achieve this movement, although a previous study designed to confirm the effect of the TORF in hemiplegic patients

did not apply any AFO and did not report an increase in ankle plantar flexion moment or gait speed.¹⁴ In contrast, this moment increased significantly during the SS phase and gait speed also increased significantly because of the upright posture with pelvic forward tilt during the LR phase in the TORF condition. The TORF might enable an effective second rocker phase to be achieved easily using the ankle-joint moment. Use of a TORF and an AFO might not only assist the trunk and pelvis but also the ankle joint, so it might be a good combination therapy for improving gait in hemiplegic patients.

This study has several limitations. First, we only investigated the immediate effects of wearing a TORF on hemiplegic gait, so further research is needed to confirm the longer term effects after familiarization with the device. Second, there was some variation in the severity of hemiplegia in our study population, with some patients needing to use a cane while walking but not others. Further research is needed to determine whether use of a cane in addition to wearing a TORF and AFO has further synergetic effects in hemiplegic stroke patients. Third, we used only one type of AFO, so the synergistic effects that might exist for other combinations of AFOs and the TORF are as yet unknown. Finally, although this study underscores the importance of a systemic approach using different types of orthoses, more studies are required to confirm whether this strategy has a beneficial effect on motor control and coordination at the systemic level.

Conclusion

We have demonstrated that a TORF can enhance the effects of an AFO and that the synergistic effects of these devices can improve gait performance in hemiplegic patients by significantly increasing their gait speed and ankle-joint

plantar flexion moment toward the end of the SS phase. Further, the TORF significantly modified the malalignment commonly seen in hemiplegic patients. We plan to conduct randomized controlled trials in the future to confirm the effect of continuous use of the TORF for gait training.

Acknowledgments

This study was supported by KAKENHI Grants-in-Aid (Nos 23700619 and 16K01516) from the Japan Society for the Promotion of Science. The funding source had no role in study design, data collection, and data analysis.

Clinical Interventions in Aging

Publish your work in this journal

Clinical Interventions in Aging is an international, peer-reviewed journal focusing on evidence-based reports on the value or lack thereof of treatments intended to prevent or delay the onset of maladaptive correlates of aging in human beings. This journal is indexed on PubMed Central, MedLine,

CAS, Scopus and the Elsevier Bibliographic databases. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
