# Crystal structure of a binuclear mixed-valence ytterbium complex containing a 2-anthracene-substituted phenoxide ligand

David J. Berg<sup>a\*</sup> and Brendan Twamley<sup>b</sup>

<sup>a</sup>Department of Chemistry, University of Victoria, PO Box 1700 Stn CSC, Victoria, BC, V8W 2Y2, Canada, and <sup>b</sup>School of Chemistry, Trinity College Dublin, University of Dublin, Dublin 2, Ireland. \*Correspondence e-mail: djberg@uvic.ca

Reaction of 2-(anthracen-9-yl)phenol ( $\text{HOPhAn}$ , **1**) with divalent  $\text{Yb}[\text{N}(\text{SiMe}_3)_2]_2 \cdot 2\text{THF}$  in THF–toluene mixtures affords the mixed-valence  $\text{Yb}^{\text{II}}\text{--Yb}^{\text{III}}$  dimer  $\{[2\text{-}(anthracen-9-yl)phenolato-\kappa O]\text{bis(tetrahydrofuran)}\text{ytterbium(III)}\}\text{-tris}[\mu\text{-}2\text{-}(anthracen-9-yl)phenolato]-\kappa^4O\text{:}O;\kappa O\text{:}1,2\text{-}\eta,\kappa O\text{-}\{[2\text{-}(anthracen-9-yl)phenolato-\kappa O]\text{ytterbium(II)}\}$  toluene trisolvate,  $[\text{Yb}_2(\text{C}_{20}\text{H}_{13}\text{O})_5(\text{C}_4\text{H}_8\text{O})_2]\text{-}3\text{C}_7\text{H}_7$  or  $[\text{Yb}^{\text{III}}(\text{THF})_2(\text{OPhAn})](\mu\text{-OPhAn})_3[\text{Yb}^{\text{II}}(\text{OPhAn})]\text{-}3\text{C}_7\text{H}_7$  (**2**), as the major product. It crystallized as a toluene trisolvate. The  $\text{Yb}\text{--O}$  bond lengths in the crystal structure of this dimer clearly identify the  $\text{Yb}^{\text{II}}$  and  $\text{Yb}^{\text{III}}$  centres. Interestingly, the formally four-coordinate  $\text{Yb}^{\text{II}}$  centre shows a close contact with one anthracene C–C bond of a bridging OPhAn ligand, bringing the formal coordination number to five.

## 1. Chemical context

One of the classical methods for introducing ligands into the metal coordination sphere in lanthanide chemistry is by a protonolysis or acid–base reaction that eliminates a suitable protonated ligand from the coordination sphere. The advantage of this method is that it avoids the formation of additional complexes ('ate' salt complexes) often favoured during metathesis reactions (Fig. 1) (Evans, 2000; Volker *et al.*, 2019). However, in the case of divalent ytterbium, the metal is a relatively good reducing agent that can lead to competing redox chemistry with the formation of unexpected trivalent

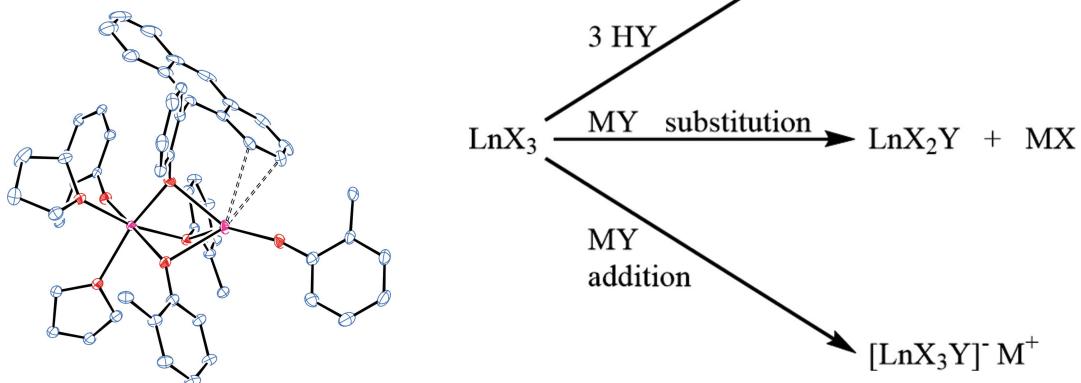

Figure 1

A comparison of the typical outcomes of metathesis with  $\text{MY}$  (e.g.  $\text{M} = \text{Na}^+$  and  $\text{Y} = \text{anionic ligand}$ ) versus protonolysis with  $\text{HY}$  (where  $\text{HY}$  is a stronger acid than  $\text{HX}$ ) in lanthanide reactions.

ytterbium products (Kagan & Namy, 1984). We have observed that these redox reactions become more problematic the more acidic the incoming ‘acid’ is. In the case of alcohols and phenols, reduction of the O–H bond is sometimes observed but there are also instances where the product remains divalent (Delbridge *et al.*, 2007; Binda *et al.*, 2008). In the case of

2-(anthracen-9-yl)phenol (HOPhAn) discussed here, partial O–H reduction is observed, resulting in a mixed-valence Yb<sup>II</sup>–Yb<sup>III</sup> dimer featuring bridging aryloxides.

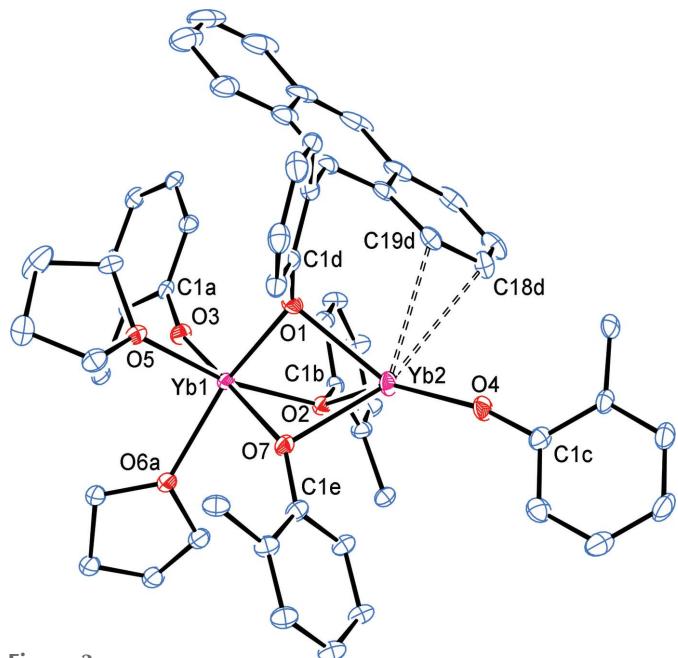

## 2. Structural commentary

The structure of complex **2** (without the three toluenes of solvation) is shown in Fig. 2. The inner coordination environment is depicted in Figs. 3 and 4. In Fig. 3, the anthracene groups have been removed for clarity, except for the 9-anthracene C atoms. In Fig. 4, the structure has been further

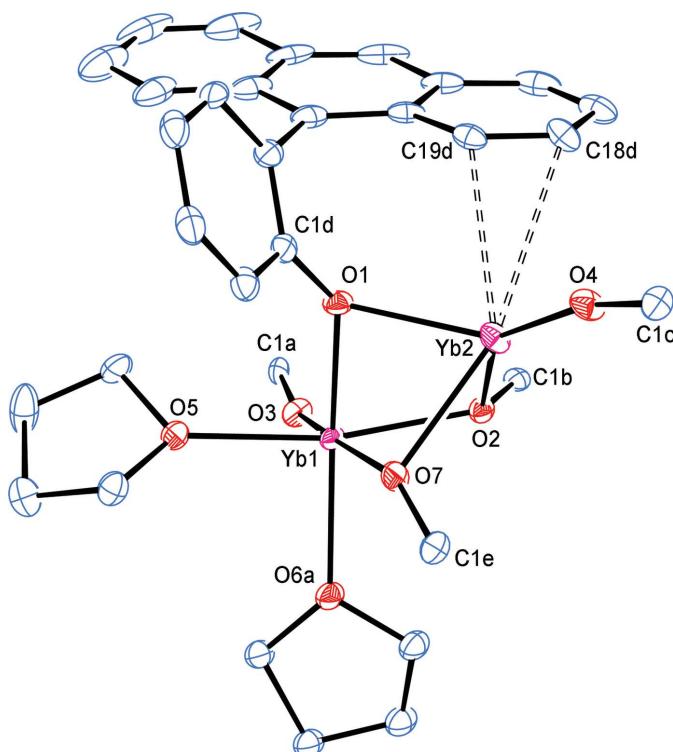

**Figure 2**

The molecular structure of complex **2**, with partial atom labelling and displacement ellipsoids drawn at the 30% probability level (as also for Figs. 3 and 4). For clarity, the toluene molecules of solvation and H atoms have been omitted in this and other figures. Only the major-disorder partner is shown for THF molecule O6a/C21a–C24a and the OPhAn ligand C1e–C20e.

**Figure 3**

A simplified view of complex **2**, removing all anthracene C atoms except those attached to the phenyl rings or part of the weakly interacting anthracene unit.

**Figure 4**

A view of the inner coordination sphere of complex **2**. Only the phenoxide C atom attached to an O atom is shown for all ligands, except for that of the coordinated anthracene group.

simplified by removing all of the PhAn C atoms except that directly attached to the phenoxide O atom. In both Figs. 3 and 4, all the C atoms of the PhAn ligand that show close contacts with Yb2 through atoms C18d and C19d are depicted.

The two Yb centres in **2** are connected [ $\text{Yb}_1 \cdots \text{Yb}_2 = 3.2587(7)$  Å; Table 1] by three bridging OPhAn aryloxides and each Yb atom is also bound to two terminal aryloxides. Atom Yb1 is further coordinated by two THF ligands, bringing the coordination number to 6, while Yb2 shows the aforementioned close contacts with C18d and C19d for a coordination number of 5 (taking the C18d–C19d bond as occupying the fifth coordination site). Based on the stoichiometry, **2** is expected to be a  $\text{Yb}^{\text{II}}/\text{Yb}^{\text{III}}$  mixed-valence complex. Selected bond lengths and angles and close contacts between Yb2 and the C atoms of one anthracene group are listed in Table 1. The substantially shorter terminal and bridging Yb1–OPhAn distances [terminal: 2.077 (3) Å; bridging: 2.191 (3)–2.236 (3) Å] compared to Yb2–OPhAn [terminal: 2.165 (3) Å; bridging: 2.352 (3)–2.416 (3) Å] indicate that Yb1 is trivalent, while Yb2 is divalent.

For ytterbium, the Cambridge Structural Database (CSD, Version 5.38, last update November 2018; Groom *et al.*, 2016) lists 10 bridging and 88 terminal structures containing nonchelating aryloxides. These structures represent both  $\text{Yb}^{\text{II}}$  and  $\text{Yb}^{\text{III}}$  oxidation states but there is only one structure containing a bridging aryloxide that contains both  $\text{Yb}^{\text{II}}$  and  $\text{Yb}^{\text{III}}$  in a mixed-valence complex (Deacon *et al.*, 2009). The supporting information (CSD search S1) lists the CSD

refcodes and references of structures containing Yb terminal and bridging nonchelating aryloxides used in the structural discussion below.

The terminal and bridging distances for Yb1 compare well with other six-coordinate trivalent Yb aryloxides (terminal: 2.023–2.258, median 2.077 Å; bridging: 2.215–2.246, median 2.240 Å).

The terminal and bridging distances for Yb2 also agree fairly well with other five-coordinate divalent Yb aryloxides (terminal: 2.168–2.233, median 2.215 Å; bridging: 2.245–2.356, median 2.309 Å).

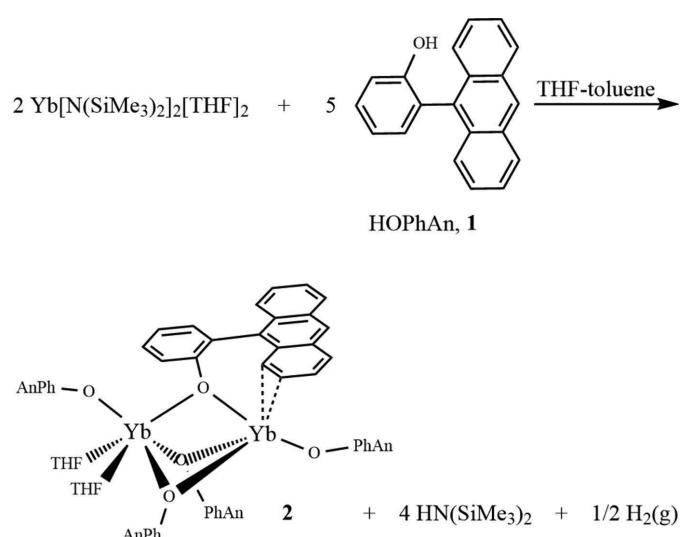

The terminal Yb2–OPhAn distance is at the short end of the observed range, while the bridging distance is somewhat longer than expected based on literature comparisons (see S1 in the supporting information).

The Yb1–O(THF) distances [2.306 (3) and 2.309 (6) Å] are typical of six-coordinate  $\text{Yb}^{\text{III}}\text{–O(THF)}$  bond lengths (2.251–2.509 Å; median 2.342 Å) and indicate that the Yb centre is not overly crowded (see CSD search S1 in the supporting information). The most noteworthy feature in the structure of **2** is the presence of a close contact between two anthracene C atoms of one bridging OPhAn ligand and Yb2 [ $\text{Yb}_2\text{–C}18\text{d} = 3.190$  (3) Å and  $\text{Yb}_2\text{–C}19\text{d} = 2.970$  (3) Å]. This is well within the wide range recognized for weak  $\text{Yb}^{\text{II}}\text{–arene}$  interactions (2.795–3.651 Å, median 2.98 Å) after correction to five-coordination.

It appears that the  $\text{Yb}^{\text{II}}$  centre prefers to satisfy its electron deficiency by coordination of an anthracene π-bond (or the anthracene C–H bonds) rather than coordinating a further molecule of THF.

### 3. Supramolecular features

The only noteworthy interactions observable in the crystal structure of complex **2** are C–H· · ·π interactions, both intra- and intermolecular (see Table S2 in the supporting informa-

tion). Interstitial space is filled with three toluene molecules of solvation (all disordered over two positions; see §5, *Refinement*).

## 4. Synthesis and crystallization

### 4.1. Materials and instrumentation

All solvents were purchased from Sigma–Aldrich Chemicals and dried by distillation from sodium under nitrogen. The 2-(anthracen-9-yl)phenol was purified by recrystallization from hot toluene, while Yb[N(SiMe)<sub>3</sub>]<sub>2</sub>(THF)<sub>x</sub> was prepared by analogy to the procedure of Hitchcock *et al.* (2002) using NaN(SiMe)<sub>3</sub> and YbI<sub>2</sub>(THF)<sub>x</sub>, and recrystallized from hot hexane. NMR spectra were recorded on a Bruker AV III 300 MHz Spectrometer in sealable Teflon-valved tubes and were referenced to residual solvent resonances. The line widths at half maximum (*v*<sub>1/2</sub> in Hz) were measured for all paramagnetic resonances and are reported below. Elemental analyses were performed by Canadian Microanalytical Ltd.

### 4.2. Synthesis of complex 2

The reaction scheme for the synthesis of complex **2** is illustrated in Fig. 5. A solution of 2-(anthracen-9-yl)phenol (0.100 g, 0.370 mmol) in THF (10 ml) was prepared in a glove-box and added by Pasteur pipette to a vigorously stirred solution of Yb[N(SiMe)<sub>3</sub>]<sub>2</sub>(THF)<sub>x</sub> (0.078 g, 0.12 mmol) in

toluene (10 ml). The deep-orange solution darkened to red on stirring overnight. The solution was filtered through Celite on a sintered glass frit and the filtrate was evaporated to dryness under reduced pressure. The red solid was recrystallized from a mixture of toluene and hexane at 143 K, yielding deep-orange crystals (yield 0.079 g, 62%). <sup>1</sup>H NMR (C<sub>6</sub>D<sub>6</sub>, 300 MHz, 296 K): δ 88.4 (6H, *v*<sub>1/2</sub> = 700 Hz), 49.4 (3H, overlaps next resonance), 47.9 (6H, *v*<sub>1/2</sub> = 350 Hz, overlaps previous resonance), 12.86 (2H, *v*<sub>1/2</sub> = 9 Hz), 11.70 (4H, *v*<sub>1/2</sub> = 12 Hz), 10.93 (4H, *v*<sub>1/2</sub> = 12 Hz), 10.00 (4H, *v*<sub>1/2</sub> = 25 Hz), 9.30 (4H, *v*<sub>1/2</sub> = 70 Hz), 1.26 (2H, *t*), 0.96 (2H, *t*), -2.77 (3H, *v*<sub>1/2</sub> = 100 Hz), -3.89 (2H, *v*<sub>1/2</sub> = 14 Hz), -5.38 (2H, *v*<sub>1/2</sub> = 20 Hz), -11.2 (6H, *v*<sub>1/2</sub> ~ 150 Hz, overlaps next resonance), -11.4 (6H, *v*<sub>1/2</sub> ~ 300 Hz, overlaps previous resonance), -16.0 (3H, *v*<sub>1/2</sub> = 140 Hz), -24.4 (3H, *v*<sub>1/2</sub> = 800 Hz), -77.2 (3H, *v*<sub>1/2</sub> = 600 Hz). Analysis calculated for C<sub>129</sub>H<sub>105</sub>O<sub>7</sub>Yb<sub>2</sub> (%): C 73.30, H 5.01; found: C 72.55, H 4.87.

## 5. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 2. The C-bound H atoms were included in calculated positions and treated as riding atoms: C—H = 0.95–0.99 Å, with *U*<sub>iso</sub>(H) = 1.5*U*<sub>eq</sub>(C) for methyl H atoms and 1.2*U*<sub>eq</sub>(C) for other H atoms.

One bridging ligand, O7/C1e–C20e:O7/C1f–C20f, was disordered and modelled in two positions, with an occupancy ratio of 0.533 (3):0.467 (3), using rigid groups and restraints. A metal-coordinated THF molecule, O6a/C21a–C24a:O6b/C21b–C24b, is also disordered and was modelled in two positions, with an occupancy ratio of 0.542 (9):0.458 (9), using restraints. Three toluene solvent molecules are also present and are all disordered over two positions; they were modelled with rigid groups and restraints; the C29 and C43 toluene molecules were modelled at 50% occupancy each and the C36 toluene molecule was modelled with an occupancy ratio of 0.682 (9):0.318 (9).

The largest peak in the final difference electron density synthesis is near atom Yb1 and the largest hole is near atom C19d; the r.m.s. deviation is 0.11 e Å<sup>-3</sup>.

$w = 1/[\sigma^2(F_o^2) + (0.046P)^2 + 19.2482P]$   
where  $P = (F_o^2 + 2F_c^2)/3$

$(\Delta/\sigma)_{\max} = 0.002$

$\Delta\rho_{\max} = 2.20 \text{ e } \text{\AA}^{-3}$  $\Delta\rho_{\min} = -0.93 \text{ e } \text{\AA}^{-3}$ *Special details*

**Experimental.** The data collection nominally covered a full sphere of reciprocal space by a combination of 5 sets of  $\omega$  scans each set at different  $\varphi$  and/or  $2\theta$  angles and each scan (5 s exposure) covering  $-0.3^\circ$  degrees in  $\omega$ . The crystal to detector distance was 5.035 cm.

**Geometry.** All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

**Refinement.** One bridging ligand O7-C1E-C20E/O7-C1F-C20F was disordered and modelled in two positions with occupancies 53:47% using rigid groups and restraints (SADI, SIMU). A metal coordinated THF is also disordered and modelled in two positions with occupancy 54:46% using restraints (SADI, SIMU). Three toluene solvent molecules are also present and they are all disordered over two positions and modelled with rigid groups and restraints (SIMU). C29 and C43 toluene molecules were modelled at 50% occupancy each and the C36 toluene was modelled at 68:32%.
