ABSTRACT

BACKGROUND/OBJECTIVES: This study aimed to evaluate how breastfeeding and complementary nutrition practices of mothers of 0–24-month-old children comply with the World Health Organization (WHO) recommendations for infant and young child feeding and to compare the results with selected demographic parameters related to the mother and child.

SUBJECTS/METHODS: The research sample comprised mothers (n = 250) with children less than 2 years old. Data were obtained via questionnaire and were analyzed using SPSS 20.0 package program. The Pearson χ^2 or Fisher's exact tests were used for assessing relationships between categorical variables. The one-sample t-test was used for comparisons with reference values.

RESULTS: Most mothers (97.2%) breastfed their babies immediately after birth. The mean time to breastfeeding after delivery was 47.8 ± 14.8 minutes, and 40.8% of the mothers complied with the WHO recommendation. Furthermore, 59.8% of the mothers exclusively breastfed their children for 6 months (mean 5.2 ± 1.5 months). The mean duration to the start of providing complementary food was 5.8 ± 0.6 months, and 76.1% of mothers who complied with the WHO recommendation. Only 12.3% of mothers breastfed their children for at least 12 months (mean 7.7 ± 3.3 months). On average, mothers gave cow milk to their children for the first time at 10.1 ± 1.7 months and honey at 11.8 ± 2.3 months. The mothers' rates of compliance with the WHO recommendations on cow milk and honey feeding were 32.0% and 71.6%, respectively. The rate of mothers who complied with the WHO minimum meal frequency recommendation was 88.3%.

CONCLUSIONS: We suggest that the WHO recommendations on this subject will be realized more fully by emphasizing the importance of the positive effects of breastfeeding until the age of 2 years and of a timely start of complementary food provision. Such changes will affect child health over the long term.

Keywords: Breastfeeding; complementary feeding; infant; food

INTRODUCTION

A healthy source of nutrition has an important role in the healthy growth and development of newborns and young children [1]. Breast milk is the most critical food contributing to the healthy growth and development of children [2]. Exclusive breastfeeding (EBF) for the first

analysis: Demir G, Yardımcı H; Investigation: Demir G, Yardımcı H; Methodology: Yardımcı H, Demir G; Supervision: Yardımcı H, Özçelik AÖ, Çakıroğlu FP; Writing - original draft: Demir G, Yardımcı H; Writing - review & editing: Yardımcı H, Demir G.

six months postpartum and complementary feeding in conjunction with breastfeeding for infants in the age range of 6–24 months are recommended by the World Health Organization (WHO) [3]. The type and duration of feeding in infants have important roles in biological and behavioral developments and affect subsequent growth and health [4]. The ability of breast milk to meet infants' macronutrient and micronutrient requirements diminishes with age [5].

The WHO, the United Nations International Children's Emergency Fund, and the Global Strategy on Infant and Young Child Feeding have recommended the practice of EBF for the first six months postpartum, beginning from the first hour of life with EBF continuing until the sixth month. Subsequently, appropriate semi-solid and solid complementary food can be provided in the sixth month, but breastfeeding should continue until, at least, the end of the first year [6,7]. Most countries, including Turkey, have adopted these recommendations. The study evaluated how breastfeeding and complementary feeding practices of mothers of 0–24-month-old children in Turkey comply with the WHO recommendations and to compare the results with selected demographic parameters related to the mother and child.

SUBJECTS AND METHODS

Study design

This study had a cross-sectional, descriptive research design. The planning phase of the study began in January 2017, and data were collected from June to August 2017. Data evaluation was completed in March 2018.

Study setting and sample selection

The research population consisted of mothers and their children living in Aksaray province in the Central Anatolia region of Turkey. The mothers had children between the ages of 0 and 24 months. The mothers and children were enrolled at one of two governmental family health centers in the city center, met the research criteria, and agreed to participate in the study. To determine the appropriate sample size for this study, the results of a Turkey Nutrition and Health Survey (TNHS) performed in 2010 were used as a reference. According to the 2010 TNHS, 59.1% of mothers initiated breastfeeding in the first hour after birth [8]. The sample size of this study was then calculated using the G*Power 3.1.9.4 program with the known rate of 59.1%, an assumed deviation of 5%, and a desired power of 90%; the result indicated a minimum sample size of 248 mothers (Faul *et al.*, 2007) [9]. The data obtained from two additional subjects were included, resulting in a total of 250 mothers and their children in the study sample.

The inclusion criteria for the mothers in the study were: having a 0–24-month-old child, no mental or communication problems, literate, and a volunteer. The inclusion criteria for the study children were: a birth weight over 2,000 g, no malnutrition or congenital anomalies, and no health problems. The subjects participated voluntarily after being fully informed about the objectives and methods of the study. They signed an informed consent form and filled in questionnaires that adhered to the Declaration of Helsinki protocols (World Medical Association). Ethical approval for this study was obtained by the Institutional Review Board of Ankara University (No:18/304/2016). Permissions from the administrative bodies of the two governmental family health centers were obtained.

Data collection and procedures

Data were obtained via a questionnaire, which was prepared by the authors after a review of relevant literature [7]. The research questions were based on the WHO recommendations for infant and young child feeding practices. These recommendations include the early initiation of breastfeeding (in the first hour after birth), EBF for 6 months, continued breastfeeding for at least one year, the introduction of solid, semi-solid, or soft foods at the 6th month, and a minimum meal frequency. For breastfed infants, the WHO recommends a minimum of two complementary food meals between the 6th and 8th months postpartum and three such meals between the 9th and 23rd months postpartum [7]. In addition, two more time markers were identified in accordance with the WHO recommendations: introduction of cow's milk into the diet at 12 months or later and introduction of honey into the diet at 12 months or later. To obtain responses to questions, mothers and children were taken into a quiet room and the questions administered via face-to-face interviews. Also, various demography-related questions were asked of the mother. The child's time of birth, birth weight, and birth length were obtained from the records of the Family Health Center at which they were registered.

Statistical analysis

Data were analyzed using SPSS 20.0 package program. The Kolmogorov-Smirnov one-sample test was used to determine the normality of the data. Quantitative data were summarized by presenting mean (\bar{X}), standard deviation (SD), and minimum and maximum values. Categorical data were summarized by presenting number and percentage (%) values. The one-sample t-test was used for comparison of results with reference values. Pearson's χ^2 or Fisher's exact tests were used to examine relationships between categorical variables. Any test result with a *P*-value less than 0.05 was accepted as a significant result.

RESULTS

General characteristics of mothers and children

The mean age of the mothers enrolled in the study was 28.5 ± 5.4 years. The mean age at first marriage was 20.5 ± 3.7 years. Of the participating mothers, 66.4% were graduates of high school, and 88.0% were housewives. The majority (91.2%) of the mothers were from nuclear families, which averaged 4.0 ± 1.0 members (**Table 1**).

Among the children in the study, 48.4% were female, and 51.6% were male. Furthermore, 34.4% were 0–6 months old, 29.6% were 7–12 months old, 22.4% were 13–18 months old, and 13.6% were 19–24 months old. Moreover, 73.2% of the children were born between gestational weeks 38 and 42. Of the children, the average birth weight was $3,260.3 \pm 491.4$ g; and the average birth length was 49.9 ± 2.2 cm. The children in the study were, on average, the mother's second child (**Table 2**).

Child feeding practices of mothers based on WHO recommendations

The initial breastfeeding time after birth was within the recommended range (47.8 ± 14.8 minutes). However, EBF duration, total breastfeeding duration, the month in which the children were given solid and semi-solid food, and the month in which the children were first given cow's milk significantly deviated from the WHO reference values by -0.8 , -4.3 , -0.2 , -1.9 months, respectively, $P < 0.001$). Furthermore, the number of meals was higher than the WHO recommendation and significantly deviated from the reference values (mean differences for the 6 to 8-month-old breastfed children: 1.2 meals, for the 9 to 23-month-old

age of 12 months or later, and 71.6% complied with the WHO recommendation to introduce honey at 12 months or later (**Table 4**).

Mothers' compliance with WHO recommendations on child feeding practices

There was a significant relationship between the early initiation of breastfeeding and the mother's educational level and the child's sex ($P < 0.05$). The EBF status of mothers was related to the mother's nutritional information source ($P < 0.05$). A significant relationship was also detected between the mothers' status of giving complementary food at the sixth month and their information sources ($P < 0.05$). Significant relationships were also detected between the minimum meal frequency and the mother's educational level, working status, information sources, the infants' birth weight, and the number of living siblings ($P < 0.05$). The times of the initial provision of cow's milk and honey were significantly related to the mothers' educational level ($P < 0.05$), and there was a relationship between the timing of honey provision and the mothers' information sources ($P < 0.05$, **Table 5**).

DISCUSSION

In many countries, including Turkey, there are health policies and health implementation programs regarding EBF in the first 6 months of a child's life and the provision of solid food along with breast milk starting at the sixth month of life. However, studies have shown that recommendations made by various authorities, such as WHO, may not be fully implemented. Recent data has shown that the EBF rate at 6 months of age is only 25.0% in the European

region and 43% in the South-East Asia region. Despite the high breastfeeding initiation rates at birth in many countries, EBF rates have been reported to gradually decline over time, resulting in rather low EBF rates at 6 months of age, particularly in the European region [10]. Data presented in the latest available Turkey Demographic and Health Survey (TDHS) show that the rate of EBF in Turkey was 41.0% [11]. The TDHS showed that the rate of exclusively breastfed children decreases rapidly with age to 14.0% in 4–5-month-old children. Moreover, the breastfeeding rate of children in the first hour after birth was 71.0%, while the percentage starting complementary foods at 6th months was 85.0%, and the rate of breastfeeding during the first year was 66.0% [11]. These results reveal that the targeted rates have not yet been reached in Turkey.

In the present study, it was observed that 97.2% of the mothers breastfed their children. This rate is similar to the rate for all of Turkey (98%) [11]. Carletti *et al.* [12] reported that 98.0% of women breastfed their children after birth. It is encouraging that the first food provided by mothers to their babies is breast milk because the content of breast milk is important in initiating a metabolic adaptation of the baby after birth, and it has features indicating it is the most suitable food. However, the rate of initiating breastfeeding within one hour after birth of the baby was 40.8% (**Table 4**). This low rate may be because some mothers do not have sufficient knowledge about the importance of early breastfeeding or that health personnel did not adequately inform the mother of that importance.

The WHO has reported that the EBF rate is below the globally targeted rate (at least 50.0%) by 2025 [13]. Globally, EBF status is about 40.0% [14],

The WHO/UNICEF have reported that the EBF rate is below the globally targeted rate (at least 50.0%) by 2025 [13]. Globally, EBF status is about 40.0% [14], and the rate of EBF in Turkey is 41.0% [11]. In the 2010 TNHS, the EBF duration was reported to average 5.3 months [8]. Similarly, in the present study the mean duration of EBF was 5.2 ± 1.5 months (**Table 3**), and 59.8% of the mothers in this study complied with the WHO recommendation of EBF for 6 months (**Table 4**); results that agree with the results reported by Carletti *et al.* [12]. However, the average duration of mothers' breastfeeding in the present study was 7.7 ± 3.3 months. This outcome is significantly lower than the recommended duration ($P < 0.001$, **Table 3**). Moreover, the percentage of mothers who breastfed their babies for one year or more was only 12.3% (**Table 4**). Interestingly, this is notably higher in developing countries. For example, Kimani-Murage *et al.* [15] reported this rate was about 85.0% in Nairobi-Kenya, while Lauer *et al.* [16] reported it as 91.8% in Africa, 87.5% in Asia (including Japan), and 59.9% in Latin America and the Caribbean. The differences between our study and these studies may be related to differences between countries' policies on breastfeeding. On the other hand, such differences are often considered to be caused by cultural differences among countries and by socio-economic factors. Changes in socio-economic factors are considered to affect breastfeeding. For example, in the poorest countries, late initiation of breastfeeding and low EBF rates are common, with fewer than 40% of children under 6 months being breastfed only. A short overall breastfeeding duration poses additional challenges, especially in middle- and high-income countries, where less than one in five children are breastfed during the first 12 months [17].

Nutritious food is vital in children 0 to 24 months of age because it is a determinant of both childhood and adulthood health [18]. Infant deaths can be decreased by 1/3 by providing complementary food in a timely fashion [19]. However, a previous study indicated that starting complementary feeding before the recommended time increases the frequency of food allergies, allergic rhinitis, and asthma [20]. Moreover, a decrease in the duration of breastfeeding is associated with childhood obesity, which is an increasing global health problem. For example, Gubbels *et al.* [21] reported that infants who were breastfed until the end of the first 12 months of life had lower body weights and BMI z-scores. Monasta *et al.* [22] reported that the absence of or a short breastfeeding period was one of five factors associated with overweight status and obesity in children and adults.

Starting the provision of complementary food before the sixth month of life is a common mistake made by mothers. Many factors can affect a mothers' decision to provide complementary foods. For example, mothers may believe that when they give their babies

various foods (especially liquids) before the sixth month, it will be good for colic, gas, gastroesophageal reflux, and thirstiness in babies, and if they continue to breastfeed simultaneously, mothers may assume they are exclusively breastfeeding, even if in reality they are not [23,24]. In addition, the problematic practice of providing complementary foods too early can result in decreased breast milk production.

In the present study (**Table 3**), mothers started giving complementary food before the sixth month (5.8 ± 0.6 months), which is not compatible with the WHO recommendation. However, the difference was slight (mean difference: 0.2 month). In addition, 76.1% of mothers started providing complementary foods at the 6th month (**Table 4**). In a previous study, only 33.2% of the mothers started complementary feeding in compliance with WHO recommendations [25]. In another study, it was reported that 60.5% of the mothers started complementary feeding at the recommended time [19]. Mothers who started complementary feeding early stated the reason for this as insufficient breast milk [19,26], lack of knowledge, and the difficulty in accessing a health center [19]. In this study, the rate of mothers who started complementary feeding at the recommended time (6th month) was high, which is beneficial because complementary feeding is crucial in preventing health problems. In another study, about 2/3 of the mothers (77.0%) started complementary food later than recommended [27]. Such differences may be caused by cultural differences in the countries in which these studies were conducted. Regardless, some results may be considered evidence that mothers fail to understand the importance of EBF, or they may present such behaviors because of difficulties in achieving EBF.

In this study, the time at which cow's milk was provided as a complementary food was 1.9 months earlier than the recommended time ($P < 0.001$, **Table 3**). Only 32.0% of the mothers fed the infants with cow's milk for the first time at the recommended 12th months or later. In their study Carletti *et al.* [28] reported that 63.0% of mothers gave cow's milk to their babies for the first time at 12 months or later. The American Academy of Pediatrics does not recommend providing cow's milk before 12 months of age [29], and supplementary feeding with cow's milk before the recommended age is an independent risk factor for iron deficiency anemia [30], which may deteriorate cognitive and emotional development of infants [31]. Cow's milk is one of the first food types typically used in infant feeding [32] and can result in a food allergy. The estimated prevalence of cow's milk allergy is reported to be between 2% and 7% [33]. On the other hand, excessive protein consumption in the first 12 months can increase the incidence of chronic diseases, such as obesity, Type 2 diabetes, and kidney diseases [34]. Therefore, starting cow's milk in the recommended month or later should contribute significantly to the health of children throughout their lives.

Honey, another food often provided as part of a child's diet, can act as a reservoir for *Clostridium botulinum* spores, which are associated with the development of infant botulism. Thus, it is inappropriate to feed honey to infants before they reach an age of 12 months [35]. In the present study, the average month when honey was given to babies for the first time (11.8 ± 2.3 months) was in accordance with the recommended start time. Furthermore, 71.6% of mothers gave honey to their babies for the first time at or after the 12th month, in accordance with the WHO recommendation. Carletti *et al.* [28] reported that 80.0% of mothers gave honey to their babies for the first time at the 12th month or later.

In this study, mothers provided the minimum number of meals to their infants in accordance with the recommendations based on age (**Table 3**). Most (88.3%) mothers fed their babies at

frequencies that complied with the WHO recommendations (**Table 4**). Aggarwal *et al.* [27] reported that infants were provided complementary food two (52.4%) or three times (31.5%) a day, but the results were not classified by months. These results show that mothers are sensitive to their child's feeding times. Some of that sensitivity is due to cultural practices.

Maternal age is associated with infant breastfeeding practices [36]. In some studies, it was determined that older mothers are less likely to breastfeed [36,37]. In contrast, other studies revealed that young mothers have an increased risk of early cessation of EBF compared to older mothers [38,39]. In this study, it was observed that younger mothers had higher rates of compliance with the WHO recommendations than those of older mothers. Although there was no statistical significance to that difference, it is notable that the younger mothers had a higher rate of compliance, which may be explained by the relationship between the educational level and age of the mothers. That relationship showed that most young mothers (71.2%) had a higher level of education than that of older mothers (67.3%) ($P < 0.05$). In addition, the results indicate that the educational status of mothers is associated with compliance to the WHO recommendations.

In this study, compared to mothers with a lower education level, mothers with a higher level of education started breastfeeding significantly earlier (59.8%, $P < 0.05$), and more than half of them (69.2%) continued EBF (though not statistically significant). As well, 84.6% of them continued breastfeeding until the end of 12 months of age. In addition, the number of women with a higher level of education who started providing complementary food at the 6th month was greater than that of primary school graduate mothers. Moreover, mothers with a higher education level complied to a greater extent with the WHO recommendations on the number of meals (77.1%) and the times to start giving cow milk (75.8%) and honey (75.9%) ($P < 0.05$, **Table 5**). Based on the results, it can be concluded that the mothers with a high school or better level of education exhibit better compliance with recommendations on baby nutrition. Various studies have shown that education level is positively correlated with compliance with EBF and complementary feeding practice recommendations [40,41].

It has been reported that a mother's working status can affect her breastfeeding behavior; in particular, full-time work has a strong negative effect on the duration of breastfeeding [42]. That study confirms Kumar *et al.*'s [42] thesis that the rates of working mothers complying with the WHO recommendations are quite low. Mothers should be encouraged to work during the postpartum period, but measures to continue breastfeeding should also be encouraged.

Some studies have shown that mothers will obtain information on child nutrition from family elders, health staff, and mass media [43,44]. In this study, nearly half of the mothers stated that they obtained information on child nutrition from health personnel (43.6%), as well as from family elders and mass media. This result parallels those in the 2010 TNHS [8]. In addition, our study revealed that the compliance rates of mothers were highest among those who used health personnel as an information source ($P < 0.05$, **Table 5**).

In the study, it was determined that most mothers with a high school and above educational level (73.4%) used health personnel as the source of nutrition information, whereas mothers with a primary school education (46.0%) asked their parents for such information ($P < 0.05$). In addition to the result showing that mothers' compliance with WHO recommendations increased as the mothers' level of education increased, it was also observed that education level affected the choice of information source and therefore affected the compliance rate.

In a previous study, complementary foods were started on time 2.5 times more in boys than in girls [19]. In the present study, the rate of providing complementary food in boys was higher than that in girls, but the difference was not statistically significant (51.8% and 48.2%, respectively) (**Table 5**), which may be due to a lack of sex-based discrimination among the mothers in this study. Most babies with a birth weight between 2,500 and 4,199 g were first given complementary food at the sixth month (92.0%). In addition, adherence to the minimum frequency of meals was significantly higher (88.7%) in 2,500–4,199 g babies, than in low birth weight (< 2,500 g) babies ($P < 0.001$).

Some studies have shown that breastfeeding behaviors differ between mothers with one child and mothers with more than one child. As well, some studies have shown that mothers who had two and more children were better at meeting recommendations on breastfeeding practices [45,46]. However, other studies detected no significant relationship between the number of children and breastfeeding practices [47,48]. In this study, compared to mothers with one child, mothers with more than one child exhibited higher compliance with WHO recommendations. This result is thought to be related to the mother's previous childcare associated with their first child.

In this study, almost all mothers breastfed their babies for some period after birth. However, the observed rates of initiation of breastfeeding, EBF, and duration of breastfeeding were less than the recommended levels. About two-thirds of the mothers in this study started complementary food on time. In addition, the recommended frequency of meals was provided by the majority of the mothers. However, most started cow's milk earlier than recommended. In this regard, mothers should be supported by providing more information about the WHO recommended child feeding practices. In order to provide such support, more intensive efforts are needed to develop policies that encourage the implementation of the WHO recommendations. Regulations could be made to facilitate the implementation of these policies in workplaces, especially among working women. We think that recommendations on breastfeeding and early childhood nutrition will be realized more fully by emphasizing the positive effects of breastfeeding until the age of two and the benefits of a timely start of complementary food provision on health in the long run.

This research is important because it reveals the compliance of mothers living in a less developed central Anatolian city in Turkey with the WHO child feeding recommendations, as well it has detected relationships between the feeding practices of mothers and various socio-demographic factors.

However, only two family health centers and only two months were available to carry out the study, thus restricting the size of the study. Further research with larger sample sizes will be needed to clarify the association between compliance with WHO recommendations and various socio-cultural and socio-economic variables. Such expanded studies will help identify problems in implementing the WHO recommendations. In this context, we view the results of this study as preliminary data that will form a basis for future studies into factors affecting the nutrition of children. Furthermore, the results contribute to the literature on this globally important subject.
