**Abstract:** The reaction of the V-shaped linker molecule 5-hydroxyisophthalic acid ( $H_2L^0$ ), with Al or Ga nitrate under almost identical reaction conditions leads to the nitration of the linker and subsequent formation of metal–organic frameworks (MOFs) with CAU-10 or MIL-53 type structure of composition  $[Al(OH)(L)]$ , denoted as Al-CAU-10- $L^{0,2,4,6}$  or  $[Ga(OH)(L)]$ , denoted as Ga-MIL-53- $L^2$ . The Al-MOF contains the original linker  $L^0$  as well as three different nitration products ( $L^2$ ,  $L^4$  and  $L^{4/6}$ ), whereas the Ga-MOF mainly incorporates the linker  $L^2$ . The compositions were deduced by  $^1H$ NMR spectroscopy and confirmed by Rietveld refinement. In situ and ex situ studies were carried out to follow the nitration and crystallization, as well as the composition of the MOFs. The crystal structures were refined against powder X-

ray diffraction (PXRD) data. As anticipated, the use of the V-shaped linker results in the formation of the CAU-10 type structure in the Al-MOF. Unexpectedly, the Ga-MOF crystallizes in a MIL-53 type structure, which is usually observed with linear or slightly bent linker molecules. To study the structure directing effect of the in situ nitrated linker, pure 2-nitrobenzene-1,3-dicarboxylic acid ( $m$ - $H_2BDC$ - $NO_2$ ) was employed which exclusively led to the formation of  $[Ga(OH)(C_8H_3NO_6)]$  (Ga-MIL-53- $m$ - $BDC$ - $NO_2$ ), which is isorecticular to Ga-MIL-53- $L^2$ . Density Functional Theory (DFT) calculations confirmed the higher stability of Ga-MIL-53- $L^2$  compared to Ga-CAU-10- $L^2$  and grand canonical Monte Carlo simulations (GCMC) are in agreement with the observed water adsorption isotherms of Ga-MIL-53- $L^2$ .

**Introduction**

Over the past years, metal–organic frameworks (MOFs) have been one of the most intensively studied classes of materials in inorganic chemistry.<sup>[1]</sup> The typically crystalline solids, are constructed from inorganic (metal ions or metal-oxygen clusters)

and organic building units (ligands or linkers). The modularity leads to materials which can assemble into various framework topologies.<sup>[2]</sup> Inorganic and organic components are often selectively chosen in order to create materials with defined pore networks and desired properties.<sup>[3]</sup> Through this approach MOFs have become a well-studied class of porous materials for applications in fields such as heat transformation,<sup>[4]</sup> drug delivery,<sup>[5]</sup> gas storage<sup>[6]</sup> and catalysis.<sup>[7]</sup>

Al-MOFs like CAU-10<sup>[8]</sup>  $[Al(OH)(m$ - $BDC)]$  (with  $m$ - $H_2BDC$  = isophthalic acid), among others, have been studied intensively in the last decade due to the availability of aluminium, their high chemical and thermal stability and outstanding sorption properties,<sup>[9]</sup> but compounds with the heavier homologue gallium have rarely been reported.<sup>[10]</sup> Synthesis conditions of Al- and Ga-MOFs are largely similar and the probability to acquire isorecticular frameworks is very high, for example in the prominent MIL-53 type structure  $[M(OH)(p$ - $BDC)]$  ( $M = Al^{3+}$ ,  $Ga^{3+}$ )<sup>[11]</sup> with  $p$ - $H_2BDC$  = terephthalic acid or  $[M(OH)(fum)]$  ( $M = Al^{3+}$ ,  $Ga^{3+}$ ,  $In^{3+}$ )<sup>[12]</sup> with  $H_2fum$  = fumaric acid.<sup>[10]</sup> Hence, there are only a few examples of unique structures reported for Ga-MOFs, although they are known to exhibit interesting properties, therefore showing the need for further investigations.<sup>[10,13]</sup>

The in situ formation of ligands during MOF synthesis under solvothermal reaction conditions is a powerful tool in the assembly of unique frameworks and can open up new strategic routes for MOFs that may be inaccessible via direct preparation.<sup>[14]</sup> Classical reactions include for example hydrolysis,<sup>[15]</sup> hy-

droxylation,<sup>[16]</sup> alkylation,<sup>[17]</sup> decarboxylation,<sup>[18]</sup> acylation<sup>[19]</sup> or nitration. Decarboxylation and nitration of 5-hydroxyisophthalic acid ( $H_2L^0$ ) during the synthesis of homo- and heterometallic coordination polymers have been reported previously.<sup>[20]</sup> Nitration of  $H_2L^0$  with nitrating acid leads to mixtures of mono-nitrated compounds in the 2- and 4-position at lower temperatures. Higher temperatures favour di- or trinitrated product mixtures. In addition decarboxylation of  $H_2L^0$  can occur.<sup>[20b,21]</sup>

Here we report our latest results on the systematic investigation of Al- and Ga-MOFs employing the linker 5-hydroxyisophthalic acid under solvothermal reaction conditions. In situ nitration and assembly into CAU-10 and MIL-53 type structures for Al and Ga, respectively, is demonstrated, showing the direct influence of the metal source on the framework formation and functionalization.

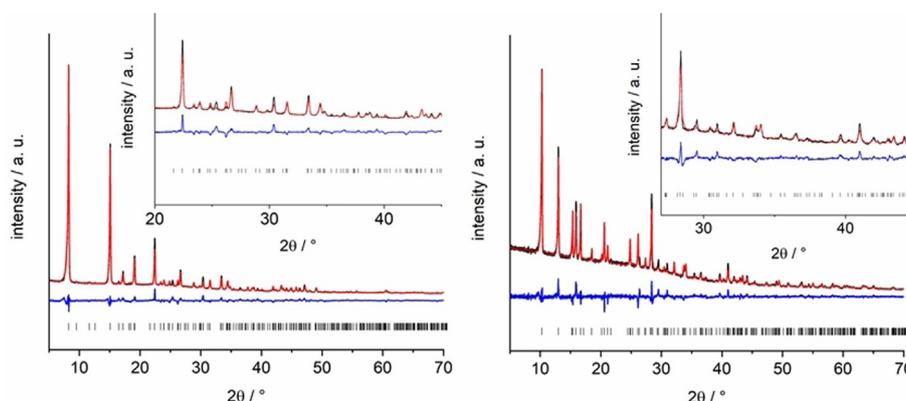

## Results and Discussion

The reaction of 5-hydroxyisophthalic acid ( $H_2L^0$ ) with  $Al(NO_3)_3$  or  $Ga(NO_3)_3$  in a mixture of water/acetic acid resulted in the formation of two different MOFs crystallizing in the well-known CAU-10 and MIL-53 type structures.<sup>[22]</sup> The reaction products were obtained as microcrystalline powders and PXRD data had to be used for the structure refinement (Figure 1). Crystal structure data are summarized in Table 1. In the following section, the framework structures of the parent Al-MOFs

are briefly described (Figure 2). Both frameworks are composed of 1D inorganic building units (IBUs) that are connected to four other chains by the dicarboxylate ions. While in MIL-53 chains of *trans* corner sharing polyhedra are found, *cis* corner sharing of the polyhedra leads to the helical IBU in CAU-10.

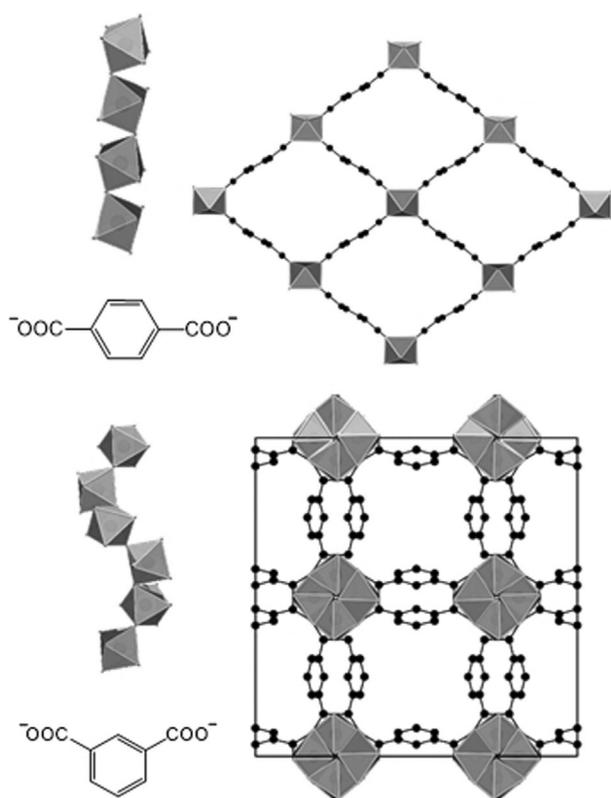

The linker shape is typically the major factor determining the connectivity of the  $AlO_6$  polyhedra. Linear linker molecules usually result in the formation of MIL-53 type structures, while V-shaped linkers form the CAU-10 type structure. Surprisingly in this study, the two framework structures are obtained from V-shaped linker molecules. To the best of our knowledge, until now no MIL-53 type structure containing a V-shaped linker with an angle of  $120^\circ$  between the carboxylate groups of the linker has been reported. Only 2,5-thiophendicarboxylic acid ( $H_2TDC$ ,  $148^\circ$ ) and (+)-camphoric acid ( $H_2CAM$ ,  $139^\circ$ ) have been shown to yield MIL-53 type frameworks ( $[M(OH)(TDC)]$   $M = Al^{3+}$ ,  $Ga^{3+}$ ,  $In^{3+}$  and  $[Ga(OH)(CAM)]$ ).<sup>[23]</sup> The two title compounds were obtained under almost identical solvothermal synthesis conditions depending on the metal ion employed.

The use of  $Al(NO_3)_3$  and  $Ga(NO_3)_3$  as reactants resulted in compounds of composition  $[Al(OH)(C_8H_{2.08}O_5(NO_2)_{0.92})]$  and  $[Ga(OH)(C_8H_2O_3(NO_2))]$  crystallizing in the CAU-10 and MIL-53 type structure, respectively. Since nitrated linkers are found in the final reaction products, in situ nitration of the linker  $H_2L^0$  must take place. Therefore the synthesis of the two MOFs was

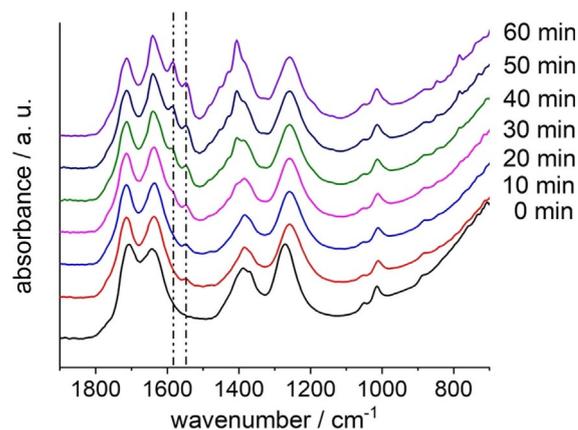

**Figure 2.** IBU and framework structure of [Al(OH)(*p*-BDC)] and [Al(OH)(*m*-BDC)] crystallizing in the MIL-53 (top) and CAU-10 (bottom) structures, respectively.<sup>[8,11a]</sup> Al(OH)<sub>2</sub>O<sub>4</sub>-polyhedra in grey, oxygen in red and carbon as well as the unit cell edges in black.

studied in more detail by in situ IR spectroscopy combined with light scattering (Figure S1–S4 in Supporting Information).

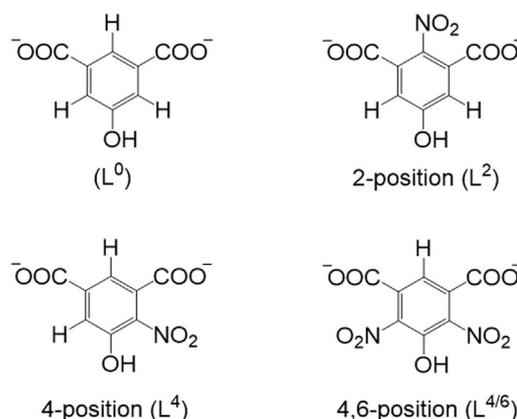

The data confirms the nitration of the ligand H<sub>2</sub>L<sup>0</sup> prior to the framework formation (Figure 3). The ligand is completely dissolved within 1 min and 20 seconds at a reaction temperature of 120 °C and a clear, transparent solution was formed, which started to turn slightly yellow after 2 min (Figure S2). After 5 min the solution turned intensively yellow and a band at 1550 cm<sup>-1</sup>, which can be assigned to the anti-symmetric stretching vibration of the aromatic nitro group, is clearly observed (Figure 3, Figures S3 and S4). The intensity of this band increases with reaction time and after 30 min the vibrational band of the anti-symmetric stretching vibration of the carboxylate group becomes visible. This is in agreement with the Faraday–Tyndall effect first observed after 30 min, triggered by colloidal particles in solution, showing the start of product formation (Figure S2).<sup>[24]</sup>

<sup>1</sup>H NMR spectroscopy was used to quantitatively determine the reaction products formed during the nitration reaction (Figure S5) and the nitrated ligands incorporated into the final framework structures. Electrophilic aromatic substitution at different positions of the aromatic ring resulting in the formation of the nitrated linker molecules as shown in Figure 4 was revealed.

The linker distribution in the two MOFs was also determined by NMR spectroscopy. Ex situ analyses of reactions quenched

**Figure 3.** In situ IR spectra of the reaction mixture for the synthesis of Al-CAU-10-L<sup>0,2,4,6</sup> after 0, 10, 20, 30, 40, 50 and 60 min at 120 °C. The vibrational bands which can be assigned to the antisymmetric -NO<sub>2</sub> stretching and the antisymmetric -CO<sub>2</sub><sup>-</sup> stretching vibrational bands are marked by dashed lines at 1550 and 1580 cm<sup>-1</sup>, respectively.

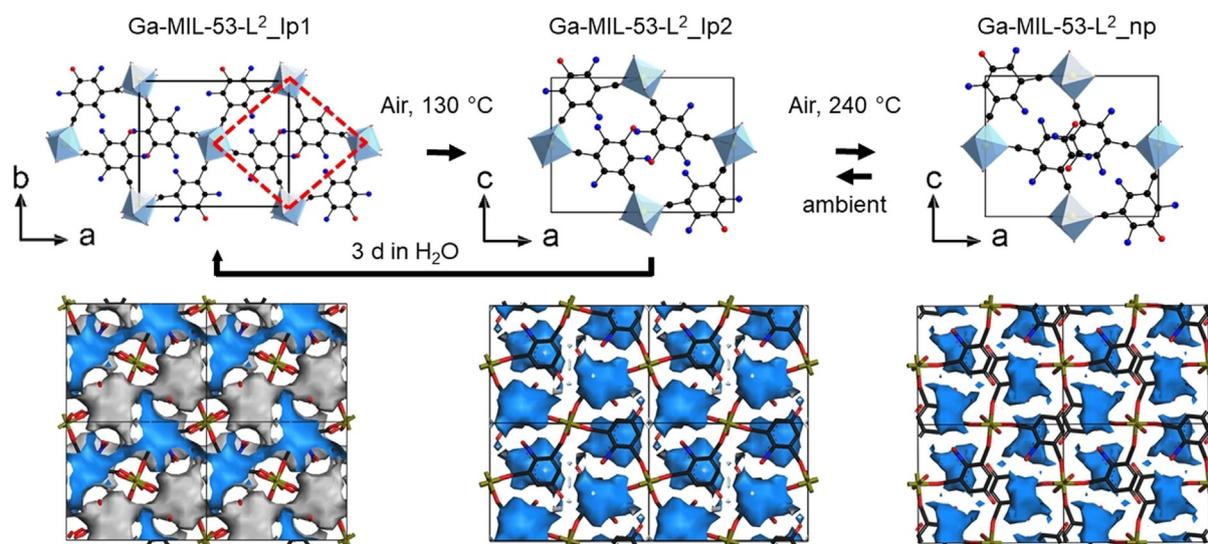

**Figure 4.** 5-Hydroxyisophthalic acid (H<sub>2</sub>L<sup>0</sup>, top left) and nitration products of 5-hydroxyisophthalic acid (H<sub>2</sub>L<sup>0</sup>) observed in our investigation. The position of the nitro group indicated in the superscript L<sup>x</sup>, x = 2, 4, 6.

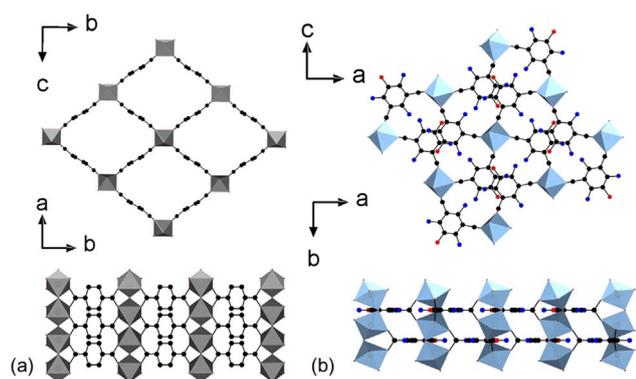

after 1, 2 and 24 h were carried out. The reaction products were dissolved in a mixture of NaOD/D<sub>2</sub>O and <sup>1</sup>H NMR as well as <sup>1</sup>H<sup>13</sup>CHMBC NMR spectra of the Ga- and Al-MOFs were recorded (Figure S6 and S7). The detailed evaluation demonstrated the incorporation of the different dicarboxylate molecules L<sup>0</sup>, L<sup>2</sup>, L<sup>4</sup> and L<sup>4/6</sup> into the framework of Al-CAU-10 while mainly the linker L<sup>2</sup> was observed in Ga-MIL-53. Hence the compounds are denoted as Al-CAU-10-L<sup>0,2,4,6</sup> and Ga-MIL-53-L<sup>2</sup>, respectively. Whereas the relative intensities of the differently nitrated ligands did not change with reaction time in Al-CAU-10-L<sup>0,2,4,6</sup> (Figure S8), an increase in the amount of incorporated linker L<sup>2</sup> from 47% after 1 h to 92% after 24 h is observed for Ga-MIL-53-L<sup>2</sup> (Figure S9 and Table S1). This is most likely related to the higher lability and faster ligand exchange rate of Ga<sup>3+</sup> ions as well as the steric hindrance in the 2-position when forming the MIL-53 type framework.

The Rietveld refinements confirm the incorporation of the different nitrated linker molecules. For Al-CAU-10-L<sup>0,2,4,6</sup> the

DRIFT measurements. According to the TG curve guest molecules in Al-CAU-10- $L^{0,2,4,6}$  and the two Ga compounds Ga-MIL-53- $L^2$ \_lp1/\_lp2 are desorbed up to 170 °C (Figures S15, S16, S17 and Table S2). A plateau is observed and the decomposition of the frameworks takes place above ca. 300 °C resulting in the formation of  $\beta$ -Ga $_2$ O $_3$  or X-ray amorphous Al $_2$ O $_3$  (Figure S18).<sup>[28]</sup> TD DRIFT measurements allow to follow the removal of incorporated guest molecules and changes of the local structure. The results for Al-CAU-10- $L^{0,2,4,6}$  and Ga-MIL-53- $L^2$ \_lp1 are presented in Figure S19 and S20. Similar changes of band intensities are observed for both compounds. Water molecules are desorbed between 40 and 140 °C, which is clearly visible in the changes in band intensities and shape. At around

100 °C, the band of the -OH stretching vibration of the aromatic hydroxyl group at 3060  $\text{cm}^{-1}$  becomes clearly visible. Simultaneously, at 2870  $\text{cm}^{-1}$  a band of low intensity can be assigned to intramolecular H-bonding between the hydroxyl and some nitro groups as evidenced in the DFT optimized geometries of the  $L^4$  linker (Figure S19 and S20, band 2 and band 3).<sup>[29]</sup> After the decomposition of the compounds ( $T > 360$  °C) to their respective metal oxides, a prominent band of adsorbed CO is found at higher temperatures (Figure S19 and S20, band 4). The ability of metal oxides, such as Al $_2$ O $_3$  or Ga $_2$ O $_3$  to adsorb CO, leading to the characteristic vibrational band at 2250  $\text{cm}^{-1}$ , has been previously reported.<sup>[30]</sup>

### Sorption properties

Compounds with MIL-53 and CAU-10 framework types are known to exhibit porosity with respect to N $_2$  and H $_2$ O. Therefore, sorption experiments were conducted. Prior to the experiments, samples of Al-CAU-10- $L^{0,2,4,6}$  and Ga-MIL-53- $L^2$ \_lp1 were activated under reduced pressure ( $p < 10^{-2}$  mbar) at 180 °C for 16 h and 230 °C for 4 h, respectively. Nitrogen sorption isotherms of type I for Al-CAU-10- $L^{0,2,4,6}$  and type III for Ga-MIL-53- $L^2$  were observed, indicating typical microporous and non-porous sorption behaviour, respectively (Figure 8). For Al-CAU-10- $L^{0,2,4,6}$  a BET surface area of  $a_{\text{SBET}} = 380 \text{ m}^2 \text{ g}^{-1}$  and a micropore volume of  $V_{\text{mic}} = 0.17 \text{ cm}^3 \text{ g}^{-1}$  were determined. Ga-MIL-53- $L^2$  does not show any uptake due to the small pores, that is, smaller than the kinetic diameter of N $_2$ , and weak host-guest interactions. The experimental water adsorption isotherms of Ga-MIL-53- $L^2$  and the GCMC simulated ones are shown in Figure 9. They strongly deviate from the ones of CAU-10-H and Al-MIL-53.<sup>[8,31]</sup> For Al-CAU-10- $L^{0,2,4,6}$  a maximum water uptake of 200  $\text{mg g}^{-1}$  is found. The typical S-shape of

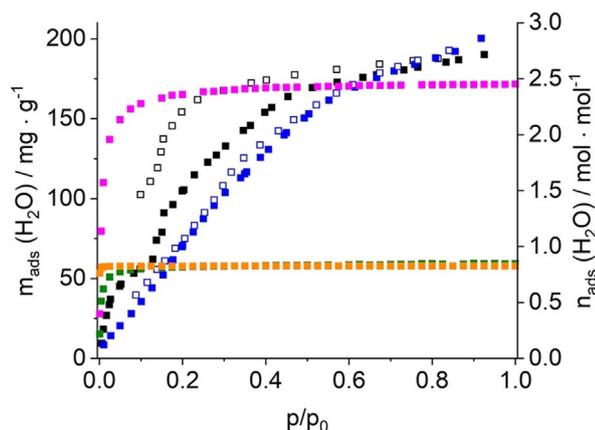

**Figure 8.** Nitrogen sorption isotherms of Al-CAU-10-L<sup>0,2,4,6</sup> (black circles) and Ga-MIL-53-L<sup>2</sup> (red circles) measured at 77 K. Filled symbols represent adsorption, empty symbols represent desorption.

the isotherm is not observed which is in line with the results of the structural studies since Al-CAU-10-L<sup>0,2,4,6</sup> exhibits no structural flexibility.

The structural changes in Ga-MIL-53-L<sup>2</sup> are reflected in the shape of the water sorption isotherm. At low relative pressures, up to  $p/p_0 = 0.17$ , one H<sub>2</sub>O molecule per formula unit is adsorbed which correlates well with the formation of Ga-MIL-53-L<sup>2</sup>\_lp2. The GCMC simulated water adsorption isotherms for Ga-MIL-53-L<sup>2</sup>\_lp2 and \_np forms show nearly identical uptake of 60 mg g<sup>-1</sup> at saturation, which matches the experimental uptake at the first plateau of the adsorption isotherm (Figure 9).

However, due to its more confined porosity, the np form saturates at slightly lower relative pressure than the Ga-MIL-53-L<sup>2</sup>\_lp2 structure. The steep adsorption profile for the Ga-MIL-53-L<sup>2</sup>\_lp2/\_np is associated with a high water adsorption en-

**Figure 9.** Experimental water sorption isotherms of Al-CAU-10-L<sup>0,2,4,6</sup> (blue squares) and Ga-MIL-53-L<sup>2</sup> (black squares) measured at 298 K, together with simulated sorption isotherms for Ga-MIL-53-L<sup>2</sup>\_lp1 (pink squares), Ga-MIL-53-L<sup>2</sup>\_lp2 (green squares) and Ga-MIL-53-L<sup>2</sup>\_np (orange squares). Filled symbols represent adsorption, empty symbols represent desorption. One has to keep in mind that structural changes upon water adsorption are not taken into account in the GCMC calculations.

thalpy of  $\approx 60$  kJ mol<sup>-1</sup> and 70 kJ mol<sup>-1</sup>, respectively, which also emphasizes the high hydrophilicity of this MOF. Further, the GCMC calculated water saturation uptake of 180 mg g<sup>-1</sup> of Ga-MIL-53-L<sup>2</sup>\_lp1 clearly manifests the experimentally observed water loading at higher relative pressure with a maximum uptake of 190 mg g<sup>-1</sup>. This whole set of simulations supports that there is a water-induced structural transition from Ga-MIL-53-L<sup>2</sup>\_lp2 to \_lp1 above  $p/p_0 = 0.1$ .

GCMC derived preferential arrangements of the adsorbed water molecules within the pores of Ga-MIL-53-L<sup>2</sup>\_np and \_lp1 are depicted in Figure S32 and Figure S33, respectively. In the case of the np form,  $\mu$ -OH sites are involved in intra-framework O( $\mu$ -OH)···O(OH) H-bonds as H-donors, and as H-acceptors for the neighbouring adsorbed water molecules. The latter also form H-bonds with -OH and -NO<sub>2</sub> sites of the linker molecules. In Ga-MIL-53-L<sup>2</sup>\_lp1, at  $p/p_0 \approx 0.01$  the  $\mu$ -OH sites only act as H-donors to water molecules (Figure S33). The adsorbed water molecules form H-bonds between each other and also interact with adjacent -OH and -NO<sub>2</sub> sites of the linker molecules. This leads at  $p/p_0 \approx 0.1$ , to an extended H-bonded 3D network (Figure S33).

## Conclusions

In conclusion, the in situ nitration of H<sub>2</sub>L<sup>0</sup> by Al(NO<sub>3</sub>)<sub>3</sub> and Ga(NO<sub>3</sub>)<sub>3</sub> before framework formation, leads to linker molecules with nitro groups in the 2-, 4- and 6-positions, detected by <sup>1</sup>HNMR spectroscopy. As proven by experiments using *m*-H<sub>2</sub>BDC-NO<sub>2</sub>, the nitro group's position at the aromatic ring strongly influences the formation of the final framework. A mixture of all observed linker molecules leads to a rigid Al-CAU-10, whereas the selective incorporation of the linker nitrated in position 2, gives rise to a flexible Ga-MIL-53 type compound as illustrated by the experimental and simulated water adsorption isotherms. This work highlights the very strong structure-directing role of differently substituted linker molecules in the crystallization of Al and Ga-MOFs, in this particular case leading to a new and uncommon MIL-53 type structure with a bent linker molecule.

## Experimental Section

**Materials and methods:** Gallium nitrate heptahydrate (Ga(NO<sub>3</sub>)<sub>3</sub>·7H<sub>2</sub>O, ABCR, 99.99% puratrem), aluminium nitrate nonahydrate (Al(NO<sub>3</sub>)<sub>3</sub>·9H<sub>2</sub>O, Grüssing, reinst), 5-hydroxybenzene-1,3-dicarboxylic acid (H<sub>2</sub>L<sup>0</sup>, Sigma-Aldrich, > 95%), 2-nitrobenzene-1,3-dicarboxylic acid (*m*-H<sub>2</sub>BDC-NO<sub>2</sub>, ABCR, > 95%) and glacial acetic acid (Grüssing, 99%) were commercially obtained and used without further purification.

Powder X-ray diffraction data (PXRD) were collected on a Stoe Stadi MP equipped with a MYTHEN 1 K detector (Cu<sub>K $\alpha$</sub>  radiation,  $\lambda = 1.5406$  Å). Three-dimensional electron diffraction data were collected on a JEOL JEM2100 TEM, equipped with a Timepix detector from Amsterdam Scientific Instruments. Infrared (IR) spectra were measured on a Bruker ALPHA-FT-IR A220/D-01 using an ATR-unit. <sup>1</sup>HNMR spectra were recorded with a Bruker AVANCE III HD Pulse Fourier Transform spectrometer equipped with a cryo-probehead Prodigy BBO400S1 BB-H&F-D-05-Z operating at a frequency of

400.13 MHz ( $^1\text{H}$ ).  $^1\text{H}$   $^{13}\text{C}$ HMBC NMR spectra were recorded with a Bruker AvanceNEO 500 operating at a frequency of 500.13 MHz ( $^1\text{H}$ ) and 125.76 MHz ( $^{13}\text{C}$ ). Referencing was performed using deuterium oxide/ sodium deuteroxide (1.25%). The CHNS-measurements were performed with a vario MICRO cube elemental analyser from Elementar. Thermogravimetric data was collected on a NETZSCH STA 409 CD analyser (airflow =  $7.5\text{ dm}^3\text{ h}^{-1}$ , heating rate =  $4\text{ K min}^{-1}$ ) and on a Linseis STA PT 1000 (airflow =  $6\text{ dm}^3\text{ h}^{-1}$ , heating rate =  $4\text{ K min}^{-1}$ ). Sorption measurements were carried out using a BEL Japan Inc. BELSORP-max with nitrogen gas and water vapour at 77 and 298 K, respectively. Depending on the compound, the samples were treated for 16 h at a temperature between 180 and  $240\text{ }^\circ\text{C}$  under reduced pressure ( $p < 10^{-2}\text{ mbar}$ ) prior to the measurement. The syntheses of the compounds were carried out in Pyrex® glass vials ( $V = 6\text{ mL}$ ) which were heated in aluminium blocks or in regular ventilation ovens using custom-made steel autoclaves with Teflon® inserts (total volume of  $2\text{ mL}$ ).<sup>[32]</sup> Temperature dependent PXRD data (TD PXRD) were collected with a Stoe capillary furnace in  $0.5\text{ mm}$  quartz capillaries. Temperature dependent DRIFT (TD DRIFT) measurements were conducted on a Bruker Vertex70 FTIR-spectrometer using a Praying Mantis™ diffuse reflection accessory and a Praying Mantis™ High Temp. Reaction Chamber by Harrick scientific products. More details to the experimental methods are given in the Supporting Information. In situ IR experiments were carried out employing the ATR-IR unit ReactIR 45 m by Mettler Toledo with an AgX-Fiber  $6.5\text{ mm}$  probe.

**Syntheses:** For the synthesis of Al-CAU-10- $\text{L}^{0,2,4,6}$   $56.4\text{ mg H}_2\text{L}^0$ ,  $500\text{ }\mu\text{L}$  deionized water,  $300\text{ }\mu\text{L}$  acetic acid and  $200\text{ }\mu\text{L}$  of an aqueous solution of aluminium nitrate nonahydrate ( $1\text{ mol L}^{-1}$ ) were mixed in a  $6\text{ mL}$  Pyrex® glass vial under stirring for 30 seconds at maximum rate (Table 2). The suspension was heated in an aluminium block for 1 h at  $120\text{ }^\circ\text{C}$  and after cooling to room temperature the yellow product was separated by centrifugation in a  $3\text{ mL}$  vial at  $9000\text{ rpm}$  for 3 min. Residues of  $\text{H}_2\text{L}^0$  were removed by washing two times with methanol (redispersion and centrifugation). The yellowish solid was dried at  $80\text{ }^\circ\text{C}$  for 1 h.  $[\text{Al}(\text{OH})(\text{C}_8\text{H}_{2.08}\text{O}_5(\text{NO}_2)_{0.92})\cdot\text{H}_2\text{O}] \cdot \text{H}_2\text{O}$  CHNS: C = 34.2% (34.0% calcd), H = 2.7% (1.8% calcd) and 4.1% (calcd 4.6%).

For the synthesis of Ga-MIL-53- $\text{L}^2$ \_lp1  $56.4\text{ mg H}_2\text{L}^0$ ,  $500\text{ }\mu\text{L}$  deionized water,  $300\text{ }\mu\text{L}$  acetic acid and  $200\text{ }\mu\text{L}$  of an aqueous solution of gallium nitrate heptahydrate ( $0.7\text{ mol L}^{-1}$ ) were mixed in a  $2\text{ mL}$  Teflon reactor, which was placed in a custom-made steel autoclave and heated at  $120\text{ }^\circ\text{C}$  for 24 h. After isolation by centrifugation at  $9000\text{ rpm}$  for 3 min, the samples were dried under atmospheric conditions. The second large pore form Ga-MIL-53- $\text{L}^2$ \_lp2 and the narrow pore form Ga-MIL-53- $\text{L}^2$ \_np were obtained by thermal treatment of Ga-MIL-53- $\text{L}^2$ \_lp1 at  $130\text{ }^\circ\text{C}$  and  $240\text{ }^\circ\text{C}$  in glass capillaries under reduced pressure ( $p < 10^{-2}\text{ mbar}$ ), respectively.  $[\text{Ga}(\text{OH})(\text{C}_8\text{H}_2\text{O}_7\text{N})\cdot 3\text{H}_2\text{O}] \cdot \text{H}_2\text{O}$  CHNS: C = 26.7% (26.3% calcd), H = 2.8% (2.5% calcd) and 3.3% (calcd 3.8%).

**Table 2.** Overview of reaction parameters for the synthesis of Al-CAU-10- $\text{L}^{0,2,4,6}$ , Ga-MIL-53- $\text{L}^2$ \_lp1, Ga-MIL-53- $\text{L}^2$ \_lp2, Ga-MIL-53- $\text{L}^2$ \_np as well as Ga-MIL-53- $m$ -BDC- $\text{NO}_2$ .

Compound	M:L	AA : $\text{H}_2\text{O}$	$T, t$ [ $^\circ\text{C}, \text{h}$ ]	Yield [%]
Al-CAU-10- $\text{L}^{0,2,4,6}$	1:1.5	1:2.4	120, 1	63.5
Ga-MIL-53- $\text{L}^2$ _lp1	1:2.1	1:2.4	120, 24	28.9
Ga-MIL-53- $\text{L}^2$ _p2			thermal activation	
Ga-MIL-53- $\text{L}^2$ _np			thermal activation	
Ga-MIL-53- $m$ -BDC- $\text{NO}_2$	1:1	–	120, 1	34.8

The linker 2-nitrobenzene-1,3-dicarboxylic acid ( $m$ - $\text{H}_2\text{BDC-NO}_2$ ) was employed in the synthesis of Ga-MIL-53- $m$ -BDC- $\text{NO}_2$ . The compound is obtained by mixing  $20.0\text{ mg } m$ - $\text{H}_2\text{BDC-NO}_2$ ,  $900\text{ }\mu\text{L}$  deionized water,  $50\text{ }\mu\text{L}$  NaOH ( $2\text{ mol L}^{-1}$ ) and  $50\text{ }\mu\text{L}$  of an aqueous solution of gallium nitrate heptahydrate ( $0.72\text{ mol L}^{-1}$ ) in a  $6\text{ mL}$  Pyrex® glass vial under stirring for 30 seconds at maximum rate. The suspension was heated in an aluminium block for 1 h at  $120\text{ }^\circ\text{C}$  and after cooling to room temperature the white product was separated by centrifugation in a  $3\text{ mL}$  vial at  $9000\text{ rpm}$  for 3 min. Remaining residues of  $m$ - $\text{H}_2\text{BDC-NO}_2$  were removed by washing two times with methanol (redispersion and centrifugation). The white solid was dried at  $80\text{ }^\circ\text{C}$  for 1 h. For characterization by PXRD the dry product was transferred into a capillary, which was sealed after activation of the product at  $220\text{ }^\circ\text{C}$  for 1 h under reduced pressure ( $p < 10^{-2}\text{ mbar}$ ).  $[\text{Ga}(\text{OH})(\text{C}_8\text{H}_3\text{NO}_6)\cdot\text{H}_2\text{O}] \cdot \text{H}_2\text{O}$  CHNS: C = 30.7% (30.6% calcd), H = 2.4% (1.9% calcd) and 4.3% (calcd 4.5%).

**Structure solution and refinement:** All compounds were obtained as microcrystalline powders. Therefore PXRD data had to be used for the structure determinations. Crystal data and the results of the Rietveld refinements of Al-CAU-10- $\text{L}^{0,2,4,6}$ , Ga-MIL-53- $\text{L}^2$ \_lp2, Ga-MIL-53- $\text{L}^2$ \_np, Ga-MIL-53- $m$ -BDC- $\text{NO}_2$  as well as the results of the Le Bail fit of Ga-MIL-53- $\text{L}^2$ \_lp1 are summarized in Table 1. The final Rietveld plots of Al-CAU-10- $\text{L}^{0,2,4,6}$  and Ga-MIL-53- $\text{L}^2$ \_np are shown in Figure 1, the other plots are given in Figure S34, S37 and S39. More details on the structure determination can also be found in the Supporting Information (Figure S34–S46 and Table S8–S13). For the structure elucidation of Al-CAU-10- $\text{L}^{0,2,4,6}$  the crystal data of CAU-10- $\text{CH}_3$ <sup>[8]</sup> was used to create a starting model, which was refined by the Rietveld method<sup>[33]</sup> using TOPAS Academic.<sup>[34]</sup> The structure of Ga-MIL-53- $\text{L}^2$ \_np was solved from 3D electron diffraction (3D ED) data of a sub-micron sized single crystal (Figure S36) and the structural model was subsequently refined against PXRD data. Details on the data-collection procedure can be found in the Supporting Information. The structural information of Ga-MIL-53- $\text{L}^2$ \_np was used to create an initial model for Ga-MIL-53- $\text{L}^2$ \_lp2 and Ga-MIL-53- $m$ -BDC- $\text{NO}_2$ , which were also refined using the Rietveld method. For Ga-MIL-53- $\text{L}^2$ \_lp1 only a structureless Le Bail fit<sup>[35]</sup> was carried out and the phase purity was confirmed (Figure S41). It is presumed water molecules occupying the pores of Ga-MIL-53- $\text{L}^2$ \_lp1 are arranged in a disordered fashion.

Deposition numbers 2057515, 2057516, 2057517, and 2057518 contain the supplementary crystallographic data for Al-CAU-10- $\text{L}^{0,2,4,6}$ , Ga-MIL-53- $\text{L}^2$ \_np, Ga-MIL-53- $m$ -BDC- $\text{NO}_2$  and Ga-MIL-53- $\text{L}^2$ \_lp2, respectively. These data are provided free of charge by the joint Cambridge Crystallographic Data Centre and Fachinformationszentrum Karlsruhe Access Structures service [www.ccdc.cam.ac.uk/structures](http://www.ccdc.cam.ac.uk/structures).

**Molecular simulations:** With the purpose of checking the favourable stability of Ga-MIL-53 and Ga-CAU-10 topologies in terms of ground state electronic energies, we have thoroughly optimized  $\text{L}^2$  and  $\text{L}^4$  variants of the theoretical Ga-CAU-10 models using the CP2K program.<sup>[36]</sup> The relevant DFT optimized geometries of Ga-MIL-53 systems are provided as supporting information. GCMC simulations were further performed to predict the water adsorption isotherms for Ga-MIL-53- $\text{L}^2$ \_lp2, Ga-MIL-53- $\text{L}^2$ \_lp1 and Ga-MIL-53- $\text{L}^2$ \_np crystal structures. All computational details are given in section 3 of the Supporting Information.

## Acknowledgements

Jannik Benecke, Jannick Jacobsen, Mirjam Poschmann, Lisa Mahnke, Dana Krause, Nicole Pienack, Helge Reinsch, Felix

Steinke and the spectroscopic section of the department of inorganic chemistry (University of Kiel) are thanked for their support with various measurements. The project was supported by the Deutsche Forschungsgemeinschaft (STO 643/10-1) and the state of Schleswig-Holstein, Germany. E.S.G. and A.K.I. acknowledge support from the Swedish Foundation for Strategic Research (SSF). Open access funding enabled and organized by Projekt DEAL.
