Received 16 March 2010; accepted 23 March 2010

Key indicators: single-crystal X-ray study; $T = 93\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.006\text{ \AA}$; H-atom completeness 99%; disorder in main residue; R factor = 0.064; wR factor = 0.196; data-to-parameter ratio = 12.6.

The title compound, $[\text{Na}(\text{C}_{23}\text{H}_{28}\text{N}_{17}\text{OS}_2)(\text{CH}_3\text{OH})(\text{C}_6\text{H}_5\text{OH})] \cdot 4\text{C}_6\text{H}_5\text{OH}$, is a five-coordinate Na^+ complex. The Na^+ cation is bound to three N atoms of the triazinide ligand, two from each pyrazole ring and one from the central deprotonated triazine ring system. O atoms from a methanol and a phenol molecule complete the five-coordinate NaN_3O_2 coordination environment. The asymmetric unit also includes three complete and two half phenol molecules, four of which are hydrogen bonded to the N atoms of the thiadiazole ring. Two of the phenol solvent molecules are disordered over two discrete inversion centres. The triazinide ligand is essentially planar (mean deviation from the least-squares plane = 0.0524 \AA), with the methyl groups of the *tert*-butyl substituents on the pyrazole rings located above and below the plane. The planarity of this system is further assisted by the formation of four intramolecular $\text{N}-\text{H} \cdots \text{N}$ hydrogen bonds between the $\text{N}-\text{H}$ bonds of both amino groups on the pyrazole rings and the N atoms of the triazine ring and also from each of the adjacent diazene ($-\text{N}=\text{N}-$) bonds. The highly polar molecules are stacked along the a axis through the central Na atom sandwiched by two kinds of alternating intermolecular hydrogen bonds: $\text{O}(\text{carbonyl}) \cdots \text{H}-\text{O}(\text{methanol})/\text{Na}/\text{O}-\text{H}(\text{phenol}) \cdots \text{O}(\text{carbonyl})$. These interactions form two polymer chains per molecule.

Comment

Azo pigments are widely used in imaging and painting industries because of their versatile colors, high tinctorial strength as well as their low price (Herbst & Hunger, 2004). Some novel azo pigments have recently been reported by Nagata *et al.* (2009) which include 2,6-bis[5-amino-3-*tert*-butyl-4-(3-methyl-1,2,4-thiadiazol-5-yl)diazenyl]-1*H*-pyrazol-1-yl]-1,3,5-triazin-4(1*H*)-one (*i.e.* Na-free compound of the title compound with one additional H atom at the N atom of the triazine one). In the course of our structural studies on this compound, however, we have isolated two kinds of single crystals from the reaction product: bis-azo and mono-azo compounds. To our surprise, the former is found to include a Na^I-atom as the central metal (*i.e.* the title compound); whereas the latter is a Na^I-free mono-azo compound. In the synthesis of azo pigments, it is quite common to use sodium nitrite for the preparation of diazonium salts. However, the inclusion of Na in the final product has not been reported to date. This paper deals with the structure of the Na^I-containing bis-azo compound, while the Na^I-free mono-azo compound will be reported elsewhere (Shibata & Mizuguchi, 2010).

The title compound, C₃₀H₃₈N₁₇NaO₃S₂·4(C₆H₆O), is a five-coordinate Na-bisazo complex, comprising as ligands two N atoms of each pyrazol ring and one N atom of the central triazine one as well as two O atoms of the solvent molecules: one methanol and one phenol. Fig. 1 shows the ORTEP plot of I. The asymmetric unit also includes three full phenol molecules (C30—C35/O3, C36—C41/O4, and C42—C47/O5) and two half molecules (C48—C50/O6 and C51—C53/O7). In four of these molecules, the O—H group of the molecule is hydrogen-bonded to the N atom of the 1,2,4-thiadiazol ring (N1, N2, N14, and N15) through O—H···N hydrogen bonds. On the other hand, the fifth phenol molecule (C48—C50/O6) remains free. There are four N—H···N intramolecular hydrogen bonds formed between the N—H of the amino group of the pyrazol ring and the N atom of the azo bond: N16—H16M···N3, N16—H16N···N9, N17—H17M···N13, and N17—H17N···N8. It is remarkable to note that the central Na atom bridges two monoazo moieties in a *cis* fashion to make the molecule entirely flat (mean deviation from the least-squares plane with a methyl group from the *t*-butyl substituent on the pyrazol ring above and below that plane: 0.0524 Å). Additionally, the four intramolecular N—H···N hydrogen bonds also contribute to the planarity of the system. The occurrence of the *cis* form is quite unusual, because the *trans* form of the Na-free structure as formed by free rotation around C7—N6 or C9—N10 is more stable according to molecular orbital calculations. However, the Na-coordination appears here to be the driving force to form the *cis* structure.

The incorporation of the Na^I cation to form a complex is due largely to the formation of strong Na—N bonds as shown by the distances Na1—N5 = 2.644 (3), Na1—N7 = 2.420 (3), and Na1—N11 = 2.642 (3) Å. The Na1—N5 and Na1—N11 distances are nearly equal, as indicated by the fact that the angles N5—Na1—N7 and N7—Na1—N11 are closely similar at 65.04 (8) and 65.51 (8)°, respectively. Furthermore, the O atoms of a phenol and methanol molecule are also coordinated to the Na atom, Na1—O2 = 2.437 (2) and Na1—O8 = 2.336 (3) Å, respectively generating a five-coordinate Na^I-bis-azo complex. Similar five-coordinate Na^I-complexes are found in other azo compounds (Mizuguchi *et al.*, 2007; Sato, Shibata *et al.*, 2008; Sato, Uta *et al.*, 2008). The azo bond in this molecule is also noteworthy. The bond lengths, N3—N4 and

supplementary materials

N12—N13 are 1.295 (4) and 1.308 (3) Å, respectively. These are longer than the standard N=N bond of about 1.24 Å, found in other bis-azo compounds (Mizuguchi *et al.*, 2007; Sato, Uta *et al.*, 2008).

Fig. 2 illustrates the molecular stack along the α axis. The methanol and phenol ligands to the Na atom are positioned above and below the bis-azo skeleton. The polar bis-azo molecules are arranged alternately in such a way as to effectively cancel their dipole moments to lower the lattice energy. In addition, two stacked columns are formed composed of the central Na^{I} atom sandwiched by alternating two kinds of intermolecular hydrogen bonds: O (carbonyl oxygen: $\text{O}1^{\text{ii}}$) \cdots O—H (methanol: $\text{O}8$)/ $\text{Na}1/\text{O}$ —H (phenol: $\text{O}2$) \cdots O (carbonyl oxygen: $\text{O}1^{\text{i}}$) (Fig. 2). This forms two one-dimensional polymer-chains per molecule and assures a high thermal-stability of the compound.

Experimental

The title compound was synthesized as described by Nagata *et al.* (2009). The structure reported here is of the Na^{I} complex product which made up approximately 80% of the product mixture according by emission spectrochemical analysis. A single crystal suitable for X-ray analysis was grown from a mixed solvent of methanol and phenol (1:1 in molar ratio) prepared at 80 °C. Needle shaped crystals were obtained in a closed system saturated with methanol vapor after standing for one week.

Refinement

The C atoms of the phenol molecule which acts as a ligand to the Na atom were disordered over two positions (C24—C29 and C24A—C29A) with occupancies of 0.786 (6)/0.214 (6), respectively. The entire molecule of another phenol was disordered over two sites (C42—C47/O5 and C42A—C47A/O5A) with occupancies of 0.750 (5) and 0.250 (5), respectively. The benzene rings of these disordered phenol molecules were refined anisotropically as rigid groups. The two half phenol-molecules were disordered about a center of symmetry (C48—C50/O6 and C51—C53/O7) with an occupancy of 0.5. Because of this disorder, there is a discrepancy between the H atom counts in the _chemical_formula_sum and the formula from the _atom_site data: one H atom is missing. The occupancies of all disorders described above extend to the associated H atoms. All H atoms were placed in geometrically idealized position and constrained to ride on their parent atoms, with C—H = 0.95, and 0.98 Å, and $U_{\text{iso}}(\text{H})$ = 1.2 and 1.5 $U_{\text{eq}}(\text{C})$, respectively, and with O—H = 0.84, and N—H = 0.88 Å and $U_{\text{iso}}(\text{H})$ = 1.2.

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

supplementary materials

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
