Structural elaboration of dicyanopyrazine: towards push–pull molecules with tailored photoredox activity†

Zuzana Hloušková,^a Milan Klikar,^a Oldřich Pytela,^a Numan Almonasy,^a Aleš Růžička,^b Veronika Jandová^a and Filip Bureš^{a*}

As an extension of the successful dicyanopyrazine photoredox catalysts, a series of X-shaped push–pull molecules with a systematically altered structure were designed and facily synthesized; their structure–property relationship was elucidated in detail *via* experimental as well as theoretical calculations. Dicyanopyrazines are proven to be powerful photoredox catalysts with a push–pull arrangement that allows facile property tuning by interchanging a particular part of the D–π–A system. Changing the mutual position of the cyano acceptors and the methoxy, methylthio and thienyl donors as well as modifying the linker allowed wide tuning of the fundamental properties of the catalysts. Contrary to the currently available organic photoredox catalysts, we provided a series of catalysts based on a pyrazine heterocyclic scaffold with easy synthesis and further modification, diverse photoredox characteristics and wide application potential across modern photoredox transformations. The photoredox catalytic activities of the target catalysts were examined in a benchmark cross-dehydrogenative coupling and novel and challenging annulation reactions.

Introduction

The idea of using visible light (VL) as a stimulant to promote organic transformations is more than a hundred years old, and G. Ciamician was the first researcher to utilize VL in photochemical reactions.¹ Nowadays, the transformation of solar energy into energy of a chemical bond is a burgeoning area of photochemistry.² This process, inspired by the chlorophyll mechanism of action, is realized by a photoredox catalyst/catalysis (PC) under laboratory conditions. An essential prerequisite of PCs is their ability to undergo single electron transfer (SET) either from or to the catalyst/substrate. In the last decade, it has been verified that photoredox catalysis is a very efficient tool in a number of chemical transformations. They also include new and unprecedented reactions, which provide novel compounds both for academia and industry. The portfolio of common VL-catalysed organic transformations includes but is not limited to oxidations,³ reductions,⁴ sp²–sp² (ref. 5)/sp²–sp³ (ref. 6)/sp³–sp³ (ref. 7) C–C as well as C–S (ref. 8), C–N

(ref. 9), C–O (ref. 10) and C–P (ref. 11) bond formation. VL photoredox catalysis has also been well utilized in cycloaddition reactions.¹² In the last two decades, the research on PC has mostly been focused on the application of transition metal complexes. The polypyridyl complexes of ruthenium and iridium represent the most prominent PCs with superior properties and wide applications.¹³ Dual catalysis is another significant extension of the original PC, which utilizes combined complexes of gold/iridium,¹⁴ gold/ruthenium¹⁵ and nickel/iridium.¹⁶ The main advantages of these complexes include their high photoredox activity, stability, facile synthesis and further modification. However, they are generally expensive, and the presence of toxic heavy metals is undesirable.

On the other hand, organic dyes represent a very promising group of rising photocatalysts. They include the well-known xanthene dyes such as fluorescein,¹⁷ Eosin Y,¹⁸ Eosin B,¹⁹ rose Bengal,²⁰ acridinium²¹ and pyrilium salts,²² which are readily available, cheap and possess good catalytic activity; nevertheless, the tuning of their properties is limited. Therefore, the attention of chemists has recently been drawn to the synthesis of organic catalysts with tunable properties.²³ The positive aspects of organic PCs include low price, accessibility, stability and solubility, but mostly their property tuning towards a given photoredox process.²⁴ Organic PCs should possess essential properties as follows: (i) absorption of light within the UV/Vis wavelength range, (ii) absorption maximum overlapping the emission band of the light source and (iii) capability to undergo SET or energy transfer. Good solubility in the reaction medium,

inactivity towards substrate/product of the catalysed reaction and low catalytic loadings are also desirable.²⁴

In 2012, push-pull molecules based on 4,5-disubstituted pyrazine-2,3-dicarbonitrile (dicyanopyrazine, DPZ) have been synthesized in our research group.²⁵ These X-shaped molecules proved superior CT-chromophores (charge-transfer, CT) with nonlinear optical properties. Further structural tuning resulted in DPZ derivative **1** bearing two 5-methoxythienyl donors, which showed an excellent performance as a photoredox catalyst. Subsequently, DPZ **1** was successfully applied in a benchmark cross-dehydrogenative coupling (CDC) reaction,²⁶ oxidation, oxidative hydroxylation, reductive dehalogenation,²⁴ chemodivergent radical cascade reactions between *N*-tetrahydroisoquinolines and *N*-itaconimides,²⁷ pH-controlled photooxygenation of indoles²⁸ and enantioselective oxidative C(sp³)-H olefinations.²⁹ Its catalytic activity in the aforementioned reactions was outstanding, and in many cases superior to that of other organometallic catalysts. Hence, our further synthetic attempts were focused on the structural modification of **1**, especially in terms of introducing an additional 2,5-thienylene ring.³⁰ In the present study, we present a thorough structural elaboration of the DPZ family of photoredox catalysts (Fig. 1). Considering that the original DPZ **1** is a D- π -A push-pull molecule,^{31,32} the structural variation may in principle involve the alternation of the acceptor (dicyanopyrazine), π -linker (2,5-thienylene) and the donor (methoxy group).

Fig. 1 summarizes the structural changes carried out within this work, which according to the particular part of the DPZ D- π -A system include:

(a) Alternation of the acceptor, especially in terms of mutual position of the CN groups: two series of disubstituted pyrazine-2,3/2,6-dicarbonitrile isomers.

(b) Utilization of OMe and SMe groups as electron donors and unsubstituted derivatives (R = H) as reference compounds.

(c) Introduction of an additional sulfidic (-S-) linker, which separates the electron donor from the pyrazine acceptor.

(d) Removal of the 2,5-thienylene π -linker and direct connection of electron donors to the pyrazine ring.

All the new DPZ derivatives **2–14** were spectrally characterized, and their fundamental properties were further investigated by X-ray analysis, electrochemistry, electronic absorption and emission spectra, which were supported by DFT calculations. DPZs **1–14** were subsequently tested as photoredox catalysts in benchmark CDC and annulation reactions and their thorough structure-catalytic activity relationships were elucidated.

Results and discussions

Synthesis

The synthesis of the original DPZ derivative **1** was published previously.²⁴ The synthetic strategy (Scheme 1) towards target molecules **2–14** utilized the commercially available 5,6-dichloropyrazine-2,3-dicarbonitrile **15**, and its isomer 3,5-dichloropyrazine-2,6-dicarbonitrile **16**, which was prepared in a five-step reaction sequence starting from malononitrile (Scheme 2). Its gradual nitrosation,³³ tosylation,³⁴ nucleophilic

Fig. 1 Structural tuning of the DPZ push-pull molecules.

substitution using another malononitrile,³⁵ acid-catalysed cyclization³⁵ and final Sandmeyer reaction³⁶ afforded **16** in 22% overall yield. More synthetic details are provided in the ESI.†

The chloro atoms in both derivatives **15** and **16** could be replaced in terms of nucleophilic substitution or Suzuki-Miyaura cross-coupling reaction (Scheme 1). Unfortunately, the same set of reactions carried out on the third possible isomer, 3,6-dibromopyrazine-2,5-dicarbonitrile,³⁷ failed. All attempts to further optimize/vary the reaction conditions were unsuccessful. Target molecules **1–3** and **9–10**, bearing a thiophene ring directly attached to the pyrazine core, were synthesized by Suzuki-Miyaura cross-coupling reactions between dichloropyrazine **15** or **16** and appropriate boronic acid derivative **17–19**. DPZ **10** proved to be unstable during storage. All PCs were isolated by column chromatography in yields in the range of 25–86%. Boronic acid pinacol esters **17** and **18** were synthesized as shown in the ESI.†

Compounds **4–8** and **11–14** were prepared from **15** or **16** and nucleophiles **20–24** in yields in the range of 24–72%. Derivatives **7**, **8**, and **13** were reported previously.^{38–40} Thiolates **20** and **21** were generated *in situ* from the corresponding thiophene

Scheme 1 General reaction scheme leading to the target push-pull pyrazines 1–14.

derivative and its gradual lithiation and reaction with sulphur, with more details presented in the Experimental section.

X-ray analysis

Suitable single crystals of compounds **7** and **12** were prepared by slow evaporation and hexane diffusion of their DCM solutions. X-ray analyses of parent compounds **1** and **2** were published previously.³⁹ Fig. 2 shows the ORTEP plots of all the aforementioned derivatives, and the ESI[†] presents more details and X-ray analysis of intermediate **27**. As can be seen from the dimethoxy derivative **7**, the parent DPZ adopts an almost planar arrangement with a torsion angle below 1.5° (see the side view). However, both thiophene rings in **1** and **2** showed considerable twist with a torsion angle between 15–35°. As a result, the dicyanopyrazine moiety in **1** and **2** is curved with inner torsion angles between 5–15°. In contrast to the DPZ 2,3-isomers (**1**, **2** and **7**), the 2,6-isomer **12** with a sulfidic linker adopts a completely different arrangement. Although the DPZ acceptor is planar, both 5-methoxythiophenes appended at positions 3 and 5 are perpendicularly localized below the DPZ ring. The

orientation of both rings is reverse and parallel with a mutual distance of about 4 Å. The D–A interaction, in particular the push-pull molecules, was estimated through the aromaticity Bird index of the pyrazine and thiophene rings.⁴¹ The pyrazine rings in **1**, **2**, **7** and **12** possess I_6 values of 81.8, 84.4, 71.2 and 90.8. Å, respectively, in comparison to the unsubstituted pyrazine ($I_6 = 88.8$), revealing a higher bond length alternation, and thus higher ICT in the 2,3-isomeric DPZs **1**, **2** and **7**.

The 2,6-isomer **12** possesses higher aromaticity than pyrazine, and therefore, the extent of the intramolecular charge transfer (ICT) is lower. This is because the additional sulfidic linker: (i) is generally a weaker electron donor than the methoxy group (such as in **7**),³¹ (ii) separates the 5-methoxythiophene moiety from the pyrazine acceptor and disallows their mutual D–A interaction and (iii) also delocalizes its lone electron pairs partially to the appended thiophene. The average Bird index of the thiophene rings in **1**, **2** and **12** are 61.6, 64.3 and 59.8, respectively. Taking $I_5 = 66$ as a reference value for the unsubstituted thiophene, the thiophene rings in **12** seem to be the most polarized, but are not directly conjugated to the DPZ

Scheme 2 Synthesis of 3,5-dichloropyrazine-2,6-dicarbonitrile **16**.

^a Measured in acetonitrile. ^b Excited state energy; calculated as the midpoint between the absorption and emission maxima (ref. 23). ^c $E_{\text{p(ox1)}}$ and $E_{\text{p(red1)}}$ are the peak potentials of the first oxidation and reduction, respectively; all potentials are given vs. SSCE. ^d $\Delta E = E_{\text{p(ox1)}} - E_{\text{p(red1)}}$ (electrochemical gap). ^e $E^{\text{ele}}(\text{HOMO/LUMO}) = E_{\text{p(ox1/red1)}} + 4.429$ (in AcCN vs. SCE) + 0.036 (difference between SCE (0.241 vs. SHE) and SSCE (0.205 vs. SHE)). ^f Excited-state redox potentials in acetonitrile calculated as follows: $E_{\text{ox}}^{\text{e}} = E_{\text{p(ox1)}} - E_{0,0}$ and $E_{\text{red}}^{\text{e}} = E_{\text{red}} + E_{0,0}$ (ref. 23). ^g Measured/calculated using emission maxima obtained in DCM.

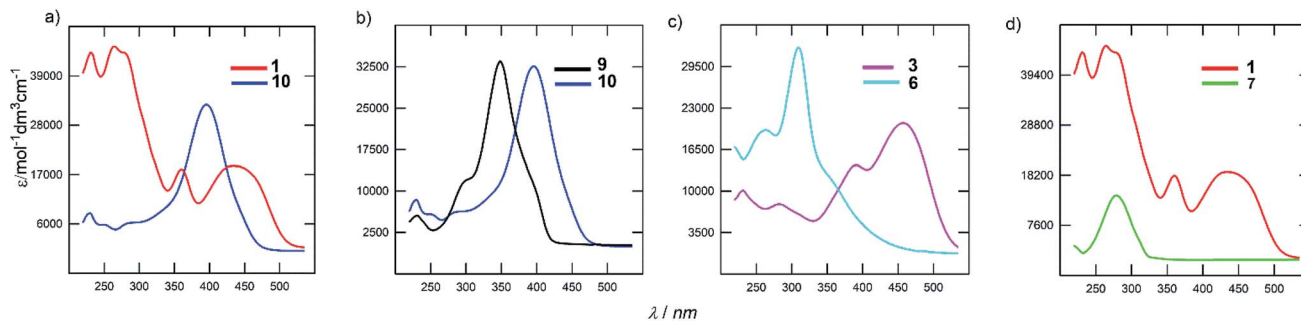

Fig. 3 UV/Vis absorption spectra of selected DPZ derivatives.

acceptor. The methoxy groups appended at the thiophene as in **1** also cause significant polarization compared to the unsubstituted derivative **2**.

Photophysical properties

The colour of the DPZ derivatives **1–14** ranges from yellow to red. Their fundamental photophysical properties were measured in acetonitrile (Table 1) and the less polar dichloromethane and 1,4-dioxane (Table S1 in the ESI[†]). However, only slight solvatochromism of the absorption spectra was observed with $\Delta\lambda_{\text{max}}^{\text{A}} = 0\text{--}21$ nm. The emission spectra of **1**, **2**, **9** and **10** with an enlarged π -system showed positive solvatochromism with $\Delta\lambda_{\text{max}}^{\text{F}} = 0\text{--}46$ nm, but no solvatochromism was observed for **7–8** and **13–4** with a truncated π -system.

The electronic absorption spectra of the representative derivatives are shown in Fig. 3. The longest-wavelength absorption maxima appear within a wide range of 278 to 443 nm and is clearly a function of the chromophore structure. Although the spectrum of the parent DPZ **1** contains two well-developed CT-bands, isomer **10** showed a single peak located between the two peaks of **1** (Fig. 3a). This observation obeys the Frenkel exciton model of multipodal push-pull chromophores⁴²

and distinguishes the quadrupolar and linear nature of **1** and **10** (similarly to the pair **2** and **9**), respectively. Thus, the mutual position of the donors and acceptors appended at the pyrazine core affects the shape and position of the bands significantly. This structural variation also dramatically affects the molar extinction coefficient, which dropped by two times.

Fig. 3b demonstrates the effect of the peripheral donor groups on the representative DPZ derivatives **9** and **10**, both with a single narrow absorption peak. Upon going from **9** to **10**, and thus two methoxy groups attached, the longest-wavelength absorption maximum shifts bathochromically by almost 50 nm. Further replacement of OMe with SMe groups, for instance in **13/14** or **7/8**, is accompanied by a similar red shift. The same trend was also observed in the well-developed series **2/1/3** (H/Ome/SMe). However, the increasing donating ability of the R-substituents in subseries **4–6** or **11–12** has the opposite effect, which reflects a non-conjugated arrangement due to the sulfidic bridge. Its impact can further be demonstrated by comparing representative chromophores **3** and **6**, both with SMe peripheral donors (Fig. 3c). The latter showed a substantially blue shifted spectrum by 136 nm. Truncation of the π -system has very similar effect, as shown for chromophores **1** and **7** in Fig. 3d.

^a Calculated using the DFT B3LYP/6-311++g(3df,2p) method.

The CT-band of **7** is positioned hypsochromically by 162 nm in comparison to DPZ **1**.

As can be seen from the emission data in Table 1, DPZ derivatives **1–14** are generally not or only weakly emissive, with fluorescence maxima $\lambda_{\text{max}}^{\text{F}}$ in the range of 363 to 571 nm. Only **7** and mainly **13** showed slight fluorescence with quantum yields exceeding 2%. All the derivatives bearing a sulfidic linker (**4–6** and **11–12**) proved to be not emissive.

The Stokes shifts are generally large, which implies high geometry reorganization upon excitation. The excited state energies $E_{0,0}$ were derived from the position of the longest-wavelength absorption/emission maximum. These values refer to the transition between the lowest vibrational states of the first excited and ground levels.

Electrochemistry

The first oxidation and reduction processes of chromophores **1–14** were studied by cyclic voltammetry (CV). The most important data is gathered in Table 1, and the ESI† presents the experimental set-up, conditions and measured CV diagrams. The first oxidations of **1–6** and **10–12** are all irreversible, and the first oxidations of the DPZs without a thiophene π -linker **7–9** and **13–14** are localized out of the potential window of the used solvent/electrolyte (MeCN/Bu₄NBF₄). On the other hand, the first reductions are irreversible, quasi- and reversible processes for DPZs **4–8/11–12**, **13–14** and **1–3/9–10**, respectively. The reversible reductions possess a cathodic/anodic peak separation of about 60 mV, which indicates one-electron processes. To make all the electrochemical data uniform, only the peak potentials $E_{\text{p(ox1)}}$ and $E_{\text{p(red1)}}$ are further considered. Inspection of the limiting currents revealed three times higher currents for the oxidations than for the reductions. This indicates that more electrons are being exchanged within the oxidation step. Although the first reduction takes place at the DPZ moiety, the first oxidation most likely involves the MeO/MeS-substituted thiophene moieties (see Fig. S20 in the ESI† for representative HOMO(−2/−1)/LUMO(+1/+2) localizations). The peak potential $E_{\text{p(ox1)}}$ and $E_{\text{p(red1)}}$ were found to be within the range of 1.25 to 1.82 V and −1.53 to −0.95 V, respectively. Since the half-wave potentials are not available for all the studied compounds, the $E_{\text{p(ox1)}}$ and $E_{\text{p(red1)}}$ values were recalculated as the HOMO/LUMO energies. The HOMO/LUMO levels and their differences (ΔE) are also visualized in the energy level diagram (Fig. S18 in the ESI†). When comparing the electrochemical behavior of the 2,3- and 2,6-isomers, *e.g.* **1** vs. **10**, the latter showed a deepened HOMO, unaltered LUMO and thus larger HOMO–LUMO gap. This electrochemical observation also corresponds to the aforementioned blue-shifted absorption spectrum of **10**. The attachment and variation of the electron donors (H→OMe/SMe) significantly alters the HOMO energy. For instance, the well-developed series of DPZs **2/1/3** (H/OMe/SMe) showed a gradually reduced electrochemical HOMO–LUMO gap of 2.87/2.46/2.33 eV, which also correspond to red-shifted absorption spectra (see above). In the 2,3-DPZ isomers (*e.g.* pairs **1/5**, **2/4** and **3/6**), the extension with an additional sulfidic linker lowered only the LUMO, whereas both the HOMO and LUMO levels

of the 2,6-isomers were affected, *e.g.* when going from **10** to **12**. Overall, the insertion of the sulfidic linker reduces the electrochemical HOMO–LUMO gap. Truncation of the π -system by removing the thiophene linker is less electrochemically obvious as oxidations of the chromophores **7–8** and **13–14** are out of the potential window. The redox potentials of the excited states E_{ox}^* and E_{red}^* were calculated by combining the electrochemical peak potentials and the excited state energies $E_{0,0}$ (Table 1), and these values are also visualized in Fig. S19 in the ESI.† Although the excited state oxidation potentials are almost unaltered, the principal changes are seen on the reduction potentials. Despite the limited data available, DPZs **1–14** seem to be strong oxidants with an E_{red}^* of up to 2.47 V.

DFT calculations

Quantum chemical calculations were run with the DFT software package Gaussian, versions 09 (ref. 43) and 16 (ref. 44). The total energies of all the possible conformers of DPZ derivatives **1–14** were calculated using the DFT B3LYP/6-311g(2d,p) method and, based on the lowest total energy, the most stable conformers were chosen. The DFT B3LYP/6-311++g(3df,2p) method involving symmetry constrains was applied to optimize their ground state geometries and to calculate the corresponding radical cations, radical anions, dications, dianions and triplets in acetonitrile. The same method was used to calculate the total energy, energy of the frontier orbitals and further quantum-chemical characteristics in acetonitrile (Tables 2 and S2 in the ESI†). The electronic absorption spectra (see the ESI†), longest-wavelength absorption maxima $\lambda_{\text{max}}^{\text{DFT}}$ (Table 2) and corresponding electron transitions between the molecular orbitals were calculated using the TD-DFT method with the B3LYP/6-311++g(3df,2p) basis set (n states = 10).

Fig. 4 shows the frontier molecular orbital levels of the ground state (black) and spin orbitals of the species formed upon one electron transfer (blue, green and yellow). The comparison of the DFT and electrochemically obtained (red) HOMO/LUMO levels shows good agreement. Fig. 4 can be considered fundamental for interpreting the photoredox catalytic properties of DPZ **1**. Compared to the non-ionized molecule, the radical cation possesses a lower highest occupied

Fig. 4 Energy level diagram of the frontier molecular orbitals and spin orbitals of DPZ **1**.

orbital (α HOMO) energy, which implies the more difficult removal of an additional electron from the positively charged species. On the contrary, the α HOMO level of the radical anion is higher, which facilitates the abstraction of the electron from the negatively charged species. Physical interpretation can be carried out based on the ionization energy/potential of the electron in the orbital, which is given by the negative value of the energy of the particular orbital (Koopman's theorem).⁴⁵ Hence, the ionization potential of the radical cation is higher and radical anion lower than that of the non-ionized molecule. In the triplet, the ground state HOMO is split into two spin orbitals, α and β , with higher and lower energy, respectively. The unpaired electron from the α HOMO can be transferred to another molecule to generate a radical cation. On the contrary, the partially occupied β HOMO may easily accept an electron from a molecule and form a radical anion. Both electron transfers from/to the triplet are energetically very close to the levels of the radical cation/anion (Fig. 4). The aforementioned mechanism is most likely responsible for the visible light-induced photoredox activity of **1** and potentially also all the other DPZ derivatives (see also Fig. S21–S33 in the ESI†).

The CT-band of compounds **1**, **2** and **12** is solely generated by the HOMO \rightarrow LUMO excitation. For the remaining molecules, close orbitals such as HOMO–2/–1 and LUMO+1/+2 are also involved, with the typical configuration interaction of two or exceptionally three (for **4** and **11**) electron transitions.

Multilinear regression implemented in the OPstat program (ref. 46) was applied to explore the dependence of the electrochemically obtained $E_{p(\text{ox}1)}$ values on a maximum of three explanatory variables from the set of the orbital energies given in Table S2 (see the ESI).† The first oxidation potentials correlates tightly with $E^{+\alpha}$ (α HOMO) and $E^{+\beta}$ (β HOMO) of the radical cation as well as with E^{2+} (HOMO) of the dication, excluding **4** and **11** as outliers (eqn (1)).

$$E_{p(\text{ox}1)} = -(1.219 \pm 0.144) - (0.481 \pm 0.034)E^{+\alpha}(\alpha\text{HOMO}) + (0.426 \pm 0.049)E^{+\beta}(\beta\text{HOMO}) - (0.297 \pm 0.029)E^{2+}(\text{HOMO}), \quad (1)$$

$$n = 7, s = 1.697 \cdot 10^{-2}, r = 0.996, F(3,3) = 118.0.$$

As can be seen, the first oxidation potential does not correlate with the E^G (HOMO) of the ground state, which implies that electron transfer from DPZ to the electrode is independent of the HOMO level. This further indicates that the common, widely applied and simplified correlations of the electrochemically and DFT-derived HOMO levels for push–pull molecules are incorrect. Eqn (1) also confirms the transfer of one/two electrons and formation of a radical cation/dication during the electrochemical oxidation of DPZs. The signs of the regression coefficients show that the first oxidation becomes difficult with more negative $E^{+\alpha}$ (α HOMO) and E^{2+} (HOMO) values and more positive $E^{+\beta}$ (β HOMO).

The first reduction peak potentials $E_{p(\text{red}1)}$ were examined in the same way as $E_{p(\text{ox}1)}$.

$$E_{p(\text{red}1)} = -(3.929 \pm 0.312) - (0.612 \pm 0.092)E^{-\alpha}(\alpha\text{HOMO}) - (0.270 \pm 0.032)E^{2-}(\text{HOMO}), \quad (2)$$

$$n = 13, s = 3.425 \cdot 10^{-2}, r = 0.972, F(2,10) = 84.14.$$

According to eqn (2), it was found that $E_{p(\text{red}1)}$ depends on the $E^{-\alpha}$ (α HOMO) of the radical anion and E^{2-} (HOMO) of the dianion. DPZ **7** with a limiting $E_{p(\text{red}1)}$ was excluded as an outlier. The correlations are again very tight and independent of E^G (LUMO). This implies that the electron transfer from the electrode to the molecule does not depend on the lowest unoccupied molecular orbital in the ground state, to which the electron is being transferred, but solely on the new orbitals generated during the electron transfer. Eqn (2) also reveals that both one- and two-electron processes are possible and the reduction is facilitated by the lowered energies $E^{-\alpha}$ (α HOMO) and E^{2-} (HOMO).

From the aforementioned analysis, we can conclude that the electrochemical potentials can be quantum-chemically quantified very well. Especially considering that radical cation and anions are open shell systems and DFT calculations were carried out just for the most stable conformer.

Visible light-induced photoredox activity

According to the first application of DPZ **1**,²⁴ the catalytic activity of all the synthesized PCs **1–14** was firstly examined in a benchmark cross-dehydrogenative coupling (CDC) reaction²⁶ between *N*-phenyltetrahydroisoquinoline and nitromethane, as shown in Table 3.

To compare the catalytic performance of all catalysts, the CDC reactions were carried out under standard conditions (1 mol% of the catalyst, Royal Blue LED source, 25 °C and 24 h reaction time). All reactions were repeated at least two times, and the average isolated yields ranged from 75% to 96%. Thus, all the PCs were capable, upon photoexcitation, to undergo SET and induce the one-electron oxidation of THIQ **29** to a radical cation. Although only limited excited state reduction potentials E_{red}^* are available (Table 1, Fig. S19 in the ESI†), the measured values are generally higher than the oxidation potential of the starting THIQ (0.79 V). As can be seen, the highest conversion and yields were achieved with original DPZ **1** and with new the DPZs **6**, **9** and **12**. On the other hand, DPZ **5** provided

Table 3 Benchmark photoredox CDC reaction catalysed by DPZ catalysts **1–14**

Acetone	1	2.2	Yes	83
Acetone	0.5	2.2	Yes	95

functionalized THIQ **30** in a diminished yield of 75%. In contrast to DPZ **1** with a CT-band ($\lambda_{\text{max}}^{\text{A}} = 440$ nm) almost perfectly centered to the emission band of the Royal Blue LED (~ 430 nm), the absorption maximum of **5** is significantly blue-shifted to 279 nm with a diminished overlap. The absorption spectra of **6**, **9** and **12** ($\lambda_{\text{max}}^{\text{A}} = 307$, 343 and 351 nm) showed better overlap with the emission peak of the light source. DPZ **5** also possesses one of the most positive $E^{\text{T}}(\beta\text{HOMO})$, which further hindered efficient SET from the substrate. Considering the structure of the most active catalysts, it seems that the presence of peripheral OMe/SMe groups (**1**, **12**, and **6**), thiophene moiety (**9**) or sulfidic linker (**6** or **12**) is the most crucial factor affecting their performance in the CDC reaction. This is consistent with the aforementioned structure–property relationships.

Secondly, the catalytic activity of DPZs **1–14** was further screened in a more challenging annulation reaction between *N,N*-dimethylaniline **31** and *N*-phenylmaleimide **32**. This reaction was first reported by Murata *et al.*;⁴⁷ however, its photo-redox version was recently reinvestigated.⁴⁸ Besides common PCs such as *N*-hydroxyphthalimide and $\text{Ru}(\text{bpy})_3\text{Cl}_2$, we were also curious whether it could be catalysed by DPZs.

The optimization of the reaction conditions using DPZ **1** is summarized in Table 4. The starting aniline **31** and maleimide **32** were reacted in a 2 : 1 molar ratio. The solvent screening revealed acetone was the best solvent, and irradiation and the presence of PCs are also essential for the reaction. Carrying out the annulation with the optimized catalyst loading of 0.5 mol% and the reaction time of 2.2 h (as monitored by GC/MS) afforded the desired product **33** in 95% isolated yield. Further extension of the reaction time led to the undesired oxidation of unreacted **31** to *N*-methyl-*N*-phenylformamide.

In contrast to the CDC reaction, the catalytic performance of DPZs **1–14** in the annulation reaction differed considerably. The best conversion and isolated yields of product **33** were achieved with 2,3-isomers **1** and **3** with OMe and SMe donors,

respectively. Both catalysts showed very similar and the most bathochromically shifted absorption maxima (440 and 443 nm, respectively, Table 1), which most likely ensure the efficient absorption of light and facilitate one-electron oxidation of the starting aniline **31**. The plausible mechanism further involves the formation of an α -aminoalkyl radical, its reaction with maleimide and final cyclization/rearomatization.^{48e,f} The calculated optical and electrochemical HOMO–LUMO gaps of the successful catalysts **1** and **3** are the lowest within the entire DPZ series (2.73/2.63 and 2.92/2.81 eV, respectively). Removal of the OMe or SMe peripheral groups, as in **2**, resulted in a hypsochromic shift of the CT-band, enlarged HOMO–LUMO gaps and, on the contrary, deepened $E^{\text{T}}(\beta\text{HOMO})$. However, the catalytic performance of **2** was worse than that of **1** and **3**. It should also be noted that the excited state reduction potentials, E_{red}^* , of **1** and **3** are very similar and closest to the oxidation potential of *N,N*-dimethylaniline (Fig. S19 in the ESI†). The 2,6-isomeric DPZ derivatives proved much less efficient than the 2,3-isomers. A noticeable yield of **33** was only achieved with DPZs **9** and **11**. When comparing the catalytic performance of the most active DPZs **1** and **3** with the formerly applied PCs (see above), they proved superior especially in terms of much shorter reaction time (generally 18–36 h) and low catalyst loading (generally 1–20 mol%) (Table 5).

The recent reports⁴⁸ focused mostly on the variation of the maleimide *N*-substituents (phenyl, substituted aryls, alkyls, *etc.*) and partially also on (4-)substituted *N,N*-dialkylaniline. Only Wu *et al.*^{48e} examined different acceptors such as maleic anhydride and acyclic olefins and found them unsuitable. Hence, we turned our attention towards expanding the original maleimide to the six-membered 1,2-dimethyl-1,2-dihydropyridazine-3,6-dione **34** (Table 6), which is easily accessible from maleic anhydride and dimethylhydrazine (see the ESI†). However, under the conditions optimized for the annulation of *N*-phenylmaleimide **32**, no cyclization product was observed. Although acetonitrile also proved to be unsuitable solvent, the reaction in 1,4-dioxane afforded an inseparable mixture

of the desired product **35** and the noncyclic intermediate. Upon further solvent optimization and testing various Lewis acids (ZnCl₂, SmOTf, and LiPF₆), we successfully isolated the target pyridazino[4,5-*c*]quinoline derivative **35** in 40% yield. Utilizing a dioxane : H₂O (1 : 2) mixture and 0.1 eq. of LiPF₆ allowed the reaction of α -aminoalkyl radical generated from **31** with **34** and subsequent cyclization to **35**. An increase in

^a Reaction times of 72/240 h.

the amount of Lewis acid, elevated temperature and increase in the amount of catalyst (0.5–10 mol%) did not significantly change the isolated yield (36–40%). The photoredox activity of DPZ **1** was further compared with common PCs such as Rose Bengal, Eosin Y, Ru(bpy)₃Cl₂ and acridinium perchlorate (Table 6). Although there was limited available data for the commercial catalyst, we can reasonably assume that the diminished catalytic activity of Ru(bpy)₃Cl₂ is due to the low oxidation capability Ru^{II+}. On the other hand, the excited state reduction potential of acridinium perchlorate ($E_{0,0} = 2.67$ eV)⁴⁹ is too far from the oxidation potential of the aniline **3**. Eosin Y possesses $E_{0,0} = 2.31$ eV,⁵⁰ which is close to that of DPZ, provides **35** in diminished 20% yield. However, Rose Bengal with similar redox properties was inactive in the formation of **35**. Table 7 summarizes the catalytic activity of all the DPZ catalysts under the optimized conditions and 72 h reaction time. Similarly to previous observations, catalysts **1** and **3** proved to be the most efficient and afforded **35** in the highest yields. Moreover, these two catalysts directed the reaction solely towards **35** with diminished side reactions, such as oxidation and dimerization of the starting aniline **31**. Using **1** and **3**, the reaction could be completed within 10 days with the isolated yields of 93% and 90%, respectively. Quinoline polycyclic systems represent structural motifs often found in medicinal chemistry, drugs, alkaloids and DNA-binders. For instance, Catto *et al.* demonstrated the cytotoxic activity of pyridazino[4,3-*c*]quinoline derivatives against HeLa and MCF-7 human cancer cell lines.⁵¹ Pyridazino-quinoline derivatives have also been proven to be useful in the treatment of neurological disorders.⁵² Hence, we believe that the developed photoredox strategy will open a new synthetic pathway towards pyridazino-quinoline derivatives.

Conclusion

A series of dicyanopyrazine-derived X-shaped push-pull molecules was designed and prepared. The target D- π -A molecules possess a systematically altered structure with varying positions of the CN groups and different donors and linkers. The X-ray analysis showed significant changes in the spatial arrangements of the target dicyanopyrazines depending on the substituents. The structural changes were also reflected in the optical and electrochemical properties of all the PCs. Their optical and electrochemical gaps could be tuned within the wide range of 1.64 eV and 0.67 V, respectively, and the excited state reduction/oxidation potentials were found to be up to 2.47/–1.18 V. The DFT calculations, especially the frontier molecular orbital and spin orbital diagrams, allowed interpretation of the photoredox fundamental properties of all the PCs. A close correlation between the electrochemically measured and DFT-calculated data with novel physico-chemical interpretation was provided. Finally, the photoredox activities of the target PCs were examined in a benchmark cross-dehydrogenative coupling and novel annulation reactions. We demonstrated the superior photoredox activity of the DPZ catalysts and first VL-induced formation of pyridazino[4,5-*c*]quinoline derivatives.

Experimental

All reagents and solvents were reagent grade and were purchased from Penta, Aldrich, and TCI and used as received. The starting 4,5-dichloropyrazine-3,6-dicarbonitrile **15**, thiophen-2-yl boronic acid **19**, 2-thiophenethiol **22**, and sodium thiomethoxide **24** were commercially available. All cross-coupling reactions were carried out in flame-dried flasks under an argon atmosphere. Thin layer chromatography (TLC) was conducted on aluminium sheets coated with silica gel 60 F254 with visualization by a UV lamp (254 or 360 nm). Column chromatography was carried out with silica gel 60 (particle size 0.040–0.063 mm, 230–400 mesh) and commercially available solvents. ^1H and ^{13}C NMR spectra were recorded on a Bruker AVANCE II/III 400/500 spectrometer (400/500 MHz or 100/125 MHz, respectively). Chemical shifts are reported in ppm relative to the signal of Me_4Si (0.00 ppm). The residual solvent signal was used as an internal reference (CDCl_3 7.25 and 77.23 ppm). Apparent resonance multiplicities are described as s (singlet), d (doublet), dd (doublet of doublet), and m (multiplet). ^1H NMR signals of thiophene are denoted as Th. The coupling constants, J , are reported in Hertz (Hz). High-resolution MALDI mass spectroscopy data were collected on an LTQ Orbitrap XL. Absorption spectra were measured on a UV/Vis PerkinElmer Lambda 35 spectrophotometer at room temperature. Fluorescence spectra were measured on a PTI Quantmaster 40 steady state spectrofluorimeter, and dilute solutions with absorption bands were used for these fluorescence measurements. The fluorescence kinetics were measured on Horiba Jobin Yvon Fluorolog TCSPC spectrofluorimeter with excitation using an IBH NanoLED 405 nm of about 250 ps FWHM pulse duration. The fluorescence lifetimes were obtained using the iterative reconvolution procedure.

General procedure for the Suzuki–Miyaura cross-coupling

In a Schlenk flask, 5,6-dichloropyrazine-2,3-dicarbonitrile **15** (199 mg, 1.0 mmol) or 3,5-dichloropyrazine-2,6-dicarbonitrile **16** (199 mg, 1.0 mmol) and a suitable amount of boronic acid or boronic acid pinacol ester (2.2 eq.) were dissolved in a mixture of THF/ H_2O (50 mL, 4 : 1). Argon was bubbled through the solution for 10 min, whereupon $\text{Pd}_2(\text{dba})_3$ (46 mg, 0.05 mmol, 5%), SPhos (20.5 mg, 0.05 mmol, 5%), and Cs_2CO_3 (684 mg, 2.1 mmol) were added and the resulting reaction mixture was stirred at 65 °C for the indicated time. The reaction mixture was diluted with water (40 mL) and extracted with CH_2Cl_2 (3 \times 40 mL). The combined organic extracts were dried over anhydrous Na_2SO_4 , the solvents were evaporated *in vacuo* and the crude product was purified by column chromatography.

General procedure for the synthesis of compounds 5, 6 and 12

In a Schlenk flask, 2-methoxythiophene (400 mg, 3.5 mmol) or 2-methylthiophene (458 mg, 3.5 mmol) was dissolved in dry THF (20 mL) at -78 °C. $n\text{BuLi}$ (1.62 mL, 2.5 M sol. in hexane, 4 mmol) was added dropwise and the mixture was stirred 1 hour at -78 °C. 1,2-Bis(dimethylamino)ethane (41 mg, 0.35 mmol) and sulphur (112 mg, 3.5 mmol) were added and stirring was

continued at -45 °C for 1 h. Thereafter, 5,6-dichloropyrazine-2,3-dicarbonitrile **15** (358 mg, 1.8 mmol) or 3,5-dichloropyrazine-2,6-dicarbonitrile **16** (358 mg, 1.8 mmol) was added and the resulting solution was stirred overnight. The reaction mixture was diluted with water (20 mL) and extracted with CH_2Cl_2 (3 \times 20 mL). The combined organic extracts were dried over anhydrous Na_2SO_4 , the solvents were evaporated *in vacuo* and the crude product was purified by flash chromatography.

General procedure for the synthesis of compounds 4 and 11

Thiophene-2-thiol **22** (100 mg, 0.5 mmol) and 5,6-dichloropyrazine-2,3-dicarbonitrile **15** (199 mg, 1 mmol) or 3,5-dichloropyrazine-2,6-dicarbonitrile **16** (199 mg, 1 mmol) were dissolved in acetone (10 mL) and pyridine (0.1 mL, 1.5 mmol) was added. The resulting mixture was stirred for the indicated time. The reaction mixture was diluted with water (10 mL) and extracted with CH_2Cl_2 (3 \times 10 mL). The combined organic extracts were dried over anhydrous Na_2SO_4 , the solvents were evaporated *in vacuo* and the crude product was purified by flash chromatography.

General procedure for the synthesis of compounds 7 and 13

A solution of triethylamine (0.15 mL, 1.1 mmol) in methanol (1 mL) was added dropwise to a solution of 5,6-dichloropyrazine-2,3-dicarbonitrile **15** (100 mg, 0.5 mmol) or 3,5-dichloropyrazine-2,6-dicarbonitrile **16** (100 mg, 0.5 mmol) in methanol **23** (2.5 mL). The resulting mixture was stirred for the indicated time. The reaction was diluted with water and the crude product was extracted with Et_2O (3 \times 5 mL). The combined organic extracts were dried over anhydrous Na_2SO_4 , the solvents were evaporated *in vacuo* and the crude product was purified by flash chromatography.

General procedure for the synthesis of compounds 8 and 14

A solution of 5,6-dichloropyrazine-2,3-dicarbonitrile **15** (100 mg, 0.5 mmol) or 3,5-dichloropyrazine-2,6-dicarbonitrile **16** (100 mg, 0.5 mmol) was dissolved in acetone (1.5 mL) at 0 °C, and sodium thiomethoxide **24** (0.35 g, 21% aq. sol.) was added dropwise. The resulting reaction mixture was stirred at 0 °C for 1 h. Then the solvent was evaporated *in vacuo* and the crude product was washed with water, followed by crystallization from ethanol.

5,6-Bis(5-methoxythiophen-2-yl)pyrazine-2,3-dicarbonitrile (1).²⁴ The title compound was prepared from **15** (199 mg, 1.0 mmol) and pinacol ester **17** (528 mg, 2.2 mmol) following the general method for the Suzuki–Miyaura reaction (reaction time = 6 h). Compound **1** was an orange solid (304 mg, 86%); mp = 178 °C. R_f = 0.20 (SiO_2 , CH_2Cl_2 : Hex = 2 : 1). Spectral data according to the literature.²⁴

5,6-Di(thiophen-2-yl)pyrazine-2,3-dicarbonitrile (2).²⁴ The title compound was prepared from **15** (199 mg, 1.0 mmol) and 2-thienylboronic acid **19** (281 mg, 2.2 mmol) following the general method for the Suzuki–Miyaura reaction (reaction time = 3 h). Compound **2** was a yellow solid (72 mg, 28%); mp = 178 °C. R_f =

0.20 (SiO₂, CH₂Cl₂ : Hex = 2 : 1). Spectral data according to the literature.²⁴

5,6-Bis(5-(methylthio)thiophen-2-yl)pyrazine-2,3-dicarbonitrile (3). The title compound was prepared from **15** (199 mg, 1.0 mmol) and 4,4,5,5-tetramethyl-2-(5-(methylthio)thiophen-2-yl)-1,3,2-dioxaborolane **18** (563 mg, 2.2 mmol) following the general method for the Suzuki–Miyaura reaction (reaction time = 1 h). Compound **3** was a red solid (97 mg, 25%); mp = 168–171 °C. *R_f* = 0.25 (SiO₂, CH₂Cl₂ : Hex = 1 : 1). ¹H-NMR (500 MHz, CDCl₃): δ(¹H) = 7.62 (d, *J* = 4 Hz, 2H, Th), 6.86 (d, *J* = 4 Hz, 2H, Th), 2.63 (s, 6H, OCH₃) ppm. ¹³C-NMR (125 MHz, CDCl₃): δ(¹³C) = 149.87, 146.31, 137.33, 131.94, 127.43, 113.32, 19.88 ppm. HR-FT-MALDI-MS (DHB): *m/z* calcd. for C₁₆H₁₀N₄S₄⁺ ([M⁺]), 385.97828; found: 385.97878.

5,6-Bis(thiophen-2-ylthio)pyrazine-2,3-dicarbonitrile (4). The title compound was prepared from **15** (199 mg, 1.0 mmol) and thiophene-2-thiol **22** (100 mg, 0.5 mmol) following the general method (reaction time = 5 h). Compound **4** was a yellow solid (215 mg, 60%); mp > 220 °C (decomp.). *R_f* = 0.40 (SiO₂, CH₂-Cl₂ : Hex = 1 : 1). ¹H-NMR (400 MHz, CDCl₃): δ(¹H) = 7.44 (dd, *J* = 1.2 and 5.6 Hz, 2H, Th), 7.35 (dd, *J* = 1.2 and 3.6 Hz, 2H, Th), 7.19 (dd, *J* = 3.6 and 9.2 Hz, 2H, Th) ppm. ¹³C-NMR (125 MHz, CDCl₃): δ(¹³C) = 159.01, 138.45, 134.50, 128.68, 120.31, 113.30 ppm. HR-FT-MALDI-MS (DHB): *m/z* calcd. for C₁₄H₇N₄S₄⁺ ([M + H⁺]), 358.95481; found: 358.95496.

5,6-Bis((5-methoxythiophen-2-yl)thio)pyrazine-2,3-dicarbonitrile (5). The title compound was prepared from **15** (358 mg, 1.8 mmol) and 2-methoxythiophene (400 mg, 3.5 mmol) following the general method (reaction time = 14 h). Compound **5** was a yellow solid (300 mg, 40%); mp = 209–212 °C. *R_f* = 0.15 (SiO₂, CH₂Cl₂ : Hex = 1 : 1). ¹H-NMR (500 MHz, CDCl₃): δ(¹H) = 7.02 (d, *J* = 4 Hz, 2H, Th), 6.26 (d, *J* = 4 Hz, 2H, Th), 3.96 (s, 6H, OCH₃) ppm. ¹³C-NMR (125 MHz, CDCl₃): δ(¹³C) = 173.00, 159.96, 138.31, 128.56, 116.65, 105.90, 105.05, 60.56 ppm. HR-FT-MALDI-MS (DHB): *m/z* calcd. for C₁₆H₁₀O₂N₄S₄⁺ ([M⁺]), 419.96811; found: 419.96794.

5,6-Bis((5-(methylthio)thiophen-2-yl)thio)pyrazine-2,3-dicarbonitrile (6). The title compound was prepared from **15** (358 mg, 1.8 mmol) and thiophene-2-thiol **22** (458 mg, 3.5 mmol) following the general method (reaction time = 14 h). Compound **6** was a yellow solid (267 mg, 33%); mp = 145–148 °C. *R_f* = 0.85 (SiO₂, CH₂Cl₂ : Hex = 2 : 1). ¹H-NMR (500 MHz, CDCl₃): δ(¹H) = 7.19 (d, *J* = 4 Hz, 2H, Th), 7.06 (d, *J* = 4 Hz, 2H, Th), 2.58 (s, 6H, SCH₃) ppm. ¹³C-NMR (125 MHz, CDCl₃): δ(¹³C) = 158.89, 148.12, 138.97, 129.82, 128.48, 119.75, 113.34, 21.04 ppm. HR-FT-MALDI-MS (DCTB): *m/z* calcd. for C₁₆H₁₀N₄S₆⁺ ([M⁺]), 449.92242; found: 449.92258.

5,6-Dimethoxypyrazine-2,3-dicarbonitrile (7). The title compound was prepared from **15** (100 mg, 0.5 mmol) and methanol **23** (2.5 mL) following the general method (reaction time = 4 h). Compound **6** was a pale yellow solid (80 mg, 85%); mp = 162–165 °C. *R_f* = 0.80 (SiO₂, Et₂O : Hex = 2 : 1). ¹H-NMR (400 MHz, CDCl₃): δ(¹H) = 4.12 (s, 6H, OCH₃) ppm. ¹³C-NMR (125 MHz, CDCl₃): δ(¹³C) = 152.12, 123.02, 113.30, 56.13 ppm. Spectral data according to the literature.³⁶

5,6-Bis(methylthio)pyrazine-2,3-dicarbonitrile (8). The title compound was prepared from 5,6-dichloropyrazine-2,3-dicarbonitrile **15** (100 mg, 0.5 mmol) and sodium

thiomethoxide **24** (0.35 g, 21% aq. sol.) following the general method (reaction time = 1 h). Compound **8** was a pale green solid (52 mg, 47%); mp = 157–160 °C. *R_f* = 0.9 (SiO₂, CH₂-Cl₂). ¹H-NMR (400 MHz, CDCl₃): δ(¹H) = 2.66 (s, 6H, SCH₃) ppm. ¹³C-NMR (125 MHz, CDCl₃): δ(¹³C) = 160.77, 126.50, 113.93, 14.10 ppm. HR-FT-MALDI-MS (none): *m/z* calcd. for C₈H₆N₄S₂⁺ ([M⁺]), 222.00284; found: 222.00287.

3,5-Di(thiophen-2-yl)pyrazine-2,6-dicarbonitrile (9). The title compound was prepared from **16** (199 mg, 1.0 mmol) and 2-thienylboronic acid **19** (281 mg, 2.2 mmol) following the general method for the Suzuki–Miyaura reaction (reaction time = 14 h). Compound **8** was a yellow solid (132 mg, 45%); mp = 237–238 °C. *R_f* = 0.63 (SiO₂, CH₂Cl₂ : Hex = 1 : 1). ¹H-NMR (400 MHz, CDCl₃): δ(¹H) = 8.48 (dd, *J* = 1 and 4 Hz, 2H, Th), 7.88 (dd, *J* = 0.4 and 4.8 Hz, 2H, Th), 7.29 (dd, *J* = 4 and 4.8 Hz, 2H, Th) ppm. ¹³C-NMR (125 MHz, CDCl₃): δ(¹³C) = 150.45, 138.10, 135.51, 132.50, 130.10, 120.36, 115.72 ppm. HR-FT-MALDI-MS (DHB): *m/z* calcd. for C₁₄H₇N₄S₂⁺ ([M + H⁺]), 295.01066; found: 295.01054.

3,5-Bis(5-methoxythiophen-2-yl)pyrazine-2,6-dicarbonitrile (10). The title compound was prepared from **16** (199 mg, 1.0 mmol) and pinacol ester **17** (528 mg, 2.2 mmol) following the general method for the Suzuki–Miyaura reaction (reaction time = 5 h). Compound **10** was an orange solid (106 mg, 30%) which gradually decomposed during storage; mp = 183–186 °C. *R_f* = 0.39 (SiO₂, CH₂Cl₂ : Hex = 1 : 1). ¹H-NMR (400 MHz, CDCl₃): δ(¹H) = 8.23 (d, *J* = 4.8 Hz, 2H, Th), 6.37 (d, *J* = 4.8 Hz, 2H, Th), 4.03 (s, 6H, OCH₃) ppm. ¹³C-NMR (125 MHz, CDCl₃): δ(¹³C) = 175.74, 150.01, 133.17, 124.29, 117.28, 116.36, 107.96, 60.80 ppm. HR-FT-MALDI-MS (DHB): *m/z* calcd. for C₁₆H₁₂N₄O₂S₂⁺ ([M + 2H⁺]), 356.03962; found: 356.04000.

3,5-Bis(thiophen-2-ylthio)pyrazine-2,6-dicarbonitrile (11). The title compound was prepared from thiophene-2-thiol **22** (100 mg, 0.5 mmol) and **16** (199 mg, 1 mmol) following the general method (reaction time = 14 h). Compound **11** was a yellow solid (86 mg, 24%); mp = 183–186 °C. *R_f* = 0.49 (SiO₂, CH₂Cl₂ : Hex = 1 : 1). ¹H-NMR (500 MHz, CDCl₃): δ(¹H) = 7.49 (dd, *J* = 1 and 5.5 Hz, 2H, Th), 7.06 (dd, *J* = 1 and 3.5 Hz, 2H, Th), 6.98 (dd, *J* = 4 and 5.5 Hz, 2H, Th) ppm. ¹³C-NMR (125 MHz, CDCl₃): δ(¹³C) = 164.17, 138.20, 134.54, 128.34, 121.89, 120.06, 113.11 ppm. HR-FT-MALDI-MS (DHB): *m/z* calcd. for C₁₄H₆N₄S₄⁺ ([M + H⁺]), 358.95481; found: 358.95486.

3,5-Bis((5-methoxythiophen-2-yl)thio)pyrazine-2,6-dicarbonitrile (12). The title compound was prepared from 2-methoxythiophene (400 mg, 3.5 mmol) and **16** (358 mg, 1.8 mmol) following the general method (reaction time = 24 h). Compound **12** was a yellow solid (308 mg, 41%); mp = 168–172 °C. *R_f* = 0.36 (SiO₂, CH₂Cl₂ : Hex = 1 : 1). ¹H-NMR (400 MHz, CDCl₃): δ(¹H) = 6.84 (d, *J* = 4 Hz, 2H, Th), 6.10 (d, *J* = 4 Hz, 2H, Th), 3.92 (s, 6H, OCH₃) ppm. ¹³C-NMR (125 MHz, CDCl₃): δ(¹³C) = 172.71, 165.39, 138.13, 121.63, 113.23, 105.78, 104.88, 60.35 ppm. HR-FT-MALDI-MS (DCTB): *m/z* calcd. for C₁₆H₈N₄O₂S₄⁺ ([M - H⁺]), 416.96028; found: 416.96046.

3,5-Dimethoxypyrazine-2,6-dicarbonitrile (13). The title compound was prepared from **16** (100 mg, 0.5 mmol) and methanol **23** (2.5 mL) following the general method (reaction time = 12 h). Compound **12** was a yellow solid (68 mg, 72%); mp = 142–146 °C. *R_f* = 0.75 (SiO₂, Et₂O : Hex = 2 : 1). ¹H-NMR (400

MHz, CDCl₃): $\delta(^1\text{H}) = 4.18$ (s, 6H, OCH₃) ppm. ¹³C-NMR (125 MHz, CDCl₃): $\delta(^{13}\text{C}) = 162.32, 112.78, 110.90, 56.03$ ppm. Spectral data according to the literature.⁴⁰

3,5-Bis(methylthio)pyrazine-2,6-dicarbonitrile (14). The title compound was prepared 5,6-dichloropyrazine-2,3-dicarbonitrile **16** (100 mg, 0.5 mmol) and sodium thiomethoxide **24** (0.35 g, 21% aq. sol.) following the general method (reaction time = 1 h). Compound **14** was a pale yellow solid (44 mg, 40%); mp = 219–220 °C. *R*_f = 0.86 (SiO₂, CH₂Cl₂). ¹H-NMR (500 MHz, CDCl₃): $\delta(^1\text{H}) = 2.70$ (s, 6H, SCH₃) ppm. ¹³C-NMR (125 MHz, CDCl₃): $\delta(^{13}\text{C}) = 164.42, 121.64, 113.51, 13.55$ ppm. HR-FT-MALDI-MS (none): *m/z* calcd. for C₈H₆N₄S₂⁺ ([M⁺]), 222.00284; found: 222.00302.

General method for the CDC reaction

In a 10 mL snap vial equipped with a magnetic stirring bar, THIQ **29** (31 mg, 0.15 mmol) was dissolved in nitromethane (1.5 mL) and then photocatalyst **1–14** (1.5 μmol) was added. The reaction mixture was stirred under irradiation with a Royal Blue LED at 25 °C from a distance of 5 cm. The temperature was maintained using a Peltier cooler. After 24 h, the solvent was removed *in vacuo* and the residue was purified by flash chromatography (SiO₂; petroleum ether (PE): ethyl acetate (EA) 10 : 1) to obtain pure product **30**.

General method for the annulation reaction

Method A. In a 5 mL snap vial equipped with a magnetic stirring bar, *N,N*-dimethylaniline **31** (63 μL, 0.5 mmol) and *N*-phenylmaleimide **32** (43 mg, 0.25 mmol) were dissolved in acetone (3 mL) and then photocatalyst **1–14** (0.5 mol%) was added. The reaction mixture was stirred for 2 h and 20 min at 25 °C (Peltier cooler) under irradiation by a Royal Blue LED from a distance of 5 cm. The solvent was removed *in vacuo* and the crude product was purified by column chromatography (Al₂O₃, PE : EA 3 : 1) to obtain pure product **33**.

Method B. In a 5 mL snap vial equipped with a magnetic stirring bar, *N,N*-dimethylaniline **31** (63 μL, 0.5 mmol) and 1,2-dimethyl-1,2-dihydropyridazine-3,6-dione **34** (35 mg, 0.25 mmol) were dissolved in a mixture of 1,4-dioxane : H₂O (1 mL : 2 mL), and thereafter photocatalyst **1–14** (0.5 mol%) and LiPF₆ (4 mg, 0.025 mmol) were added. The reaction mixture was stirred 72 h at 30 °C (Peltier cooler) under irradiation by a Royal Blue LED from a distance of 5 cm. The solvent was removed *in vacuo* and the crude product was purified by flash chromatography (SiO₂, EA) to obtain pure product **35**.

Conflicts of interest

There are no conflicts to declare.

Acknowledgements

Dr N. Sato is gratefully acknowledged for providing us generously with 3,6-dibromopyrazine-2,5-dicarbonitrile. The work has partially been supported from European Regional development Fund-Project “Organic redox couple based batteries for

energetics of traditional and renewable resources (ORGBAT)” No. CZ.02.1.01/0.0/0.0/16_025/0007445 and by the Technology Agency of the Czech Republic (TG02010058, GAMA02/002).
