Provenance

Uranium mineralization

#### ABSTRACT

From koppunuru study area totally 58 samples were collected in 7 different boreholes, minimum depth of 28 m and Maximum depth of 157.7 m. The borehole samples geochemical analysis (major and trace elements) was carried out at Atomic Minerals Directorate for Exploration & Research (AMD), Hyderabad, India. Major and trace element studies have been conducted on the Neoproterozoic Palnad sub-basin Andhra Pradesh, South India, to determine their Geochemistry, Uranium mineralization and provenance characteristics. Geochemically, this sedimentary basin has a different litho – unit like as gritty quartzite, conglomerate, and Shale. This study area mainly dominated by Uranium deposited and radioactive elements are predominately deposit. Strong positive correlation between Uranium and Lead ( $r = 0.887$ ) suggested radiogenic nature of this system.

## Specifications Table

Subject area	Geochemistry
More specific subject area	Geochemistry, sedimentology,
Type of data	Table, graph, figure
How data was acquired	The sample pellets were analyzed using a The Magix Pro PW 2440 (PANalytical) WDXRF (Wavelength Dispersive X-Ray Fluorescence Spectroscopy). International rock standard GSR-4 and GSR-5 were used as reference material during major and trace element analyses.
Data format	Analyzed
Experimental factors	Samples were crushed and powered to 230 mesh size in an agate mill. Major and trace elements were determined from pressed pellets, which were prepared by using collapsible aluminum cups. These cups were filled with boric acid and about 1 g of each powdered rock sample was put on top of the boric acid and these cups were pressed under a hydraulic press at 20 t pressure.
Experimental features	Major and minor element studies of Koppunuru sediment samples.
Data source location	Koppunuru, Guntur District, Andhra Pradesh, South India.
Data accessibility	Data available within the article provide a direct URL to data

## Value of the data

- Determine to the geochemical characteristics of Uranium bearing formations.
- Tectonic activity, weathering index of sediment and Provenance of Palnad sub basin.
- Characterization of unconformity uranium deposits in Koppunuru sediment.
- Relationship between major oxide and trace elements especially Uranium deposits.

(r &gt; 0.5 is significant at 95 % confidence level; n = 11)

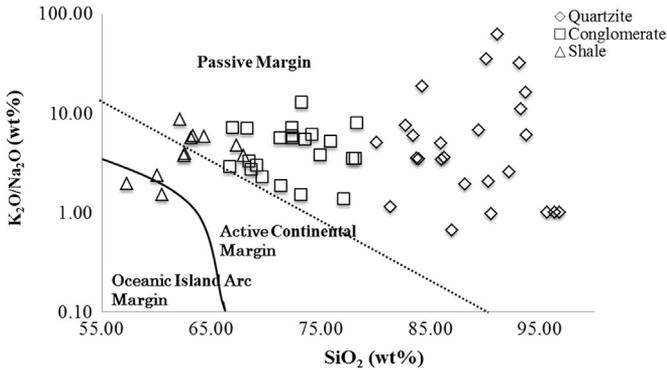

Fig. 2. Discriminant diagram [1] showing deposition of Palnad sediments in a passive margin tectonic setting.

## 1. Data

The sampling location was chosen from Koppunuru Neo Proterozoic palnad-sub basin, Guntur District, Andhra Pradesh (Fig. 1). Tables 1–3 is representing the Concentration of Major oxide (wt. %) and Trace element (ppm) data from Gritty Quartzite, Conglomerate and Shale of Palnad Sub-basin, Andhra Pradesh (A.P). Tables 4–6 is representing Pearson correlation coefficient for Gritty Quartzite, Conglomerate and Shale in Palnad sub-basin, A.P, South India. ( $r > 0.5$  is significant at 95% confidence level). Discriminant diagram [1] showing deposition of Palnad sediments in a passive margin tectonic setting (Fig. 2).

## 2. Experimental design, materials and methods

Sediment samples were crushed and powered to 230 mesh size in an agate mill. Major and trace elements were determined from pressed pellets, which were prepared by using collapsible aluminum cups. These cups were filled with boric acid and about 1 g of each powdered rock sample was put on top of the boric acid and these cups were pressed under a hydraulic press at 20 t pressure. The sample pellets were analyzed using a The Magix Pro PW 2440 (PANalytical) WDXRF (Wavelength Dispersive X-Ray Fluorescence Spectroscopy). International rock standard GSR-4 and GSR-5 were used as reference material during major and trace element analyses. The precision and accuracy of the data were well within the standards and an analytical precision ( $< 5\%$  of RSD) was observed for major oxides whereas % error in accuracy of analysis was 1%. The % of RSD for trace elements was within 1–5%, whereas accuracy (% error) was within 5–10%.

The Palnad sub - basin has shown immense potential of uranium mineralization in overall samples (10–9458 ppm. Average – 611 ppm). Uranium mineralization occurs as stringers, veins and along cavities and as grain boundary fillings. Pitchblende, coffinite and mixed phases of U, Ti, Si, Al, Ca, P and Pb constitute radioactive phases of ore body. Pitchblende and coffinite contain almost nil amounts of Thorium [2].  $\text{SiO}_2$  vs.  $\text{K}_2\text{O}/\text{Na}_2\text{O}$  discriminant diagram showing deposition of Palnad sediments are in passive margin tectonic setting, the shale only is showing Active Continental Margin and Oceanic Island Arc Margin (Fig. 2) [1].

## Acknowledgments

The authors are thankful to DAE-BRNS for financial support for the project (No. 2008/36/48-BRNS/1976 dated 14/11/2008) Atomic Minerals Directorate for Exploration and Research (AMD), Hyderabad, India (2008/36/48-BRNS/1976 dated 14/11/2008) for analytical support.
