

# Respiratory Syncytial Virus Outbreak in a Long-Term Care Facility Detected Using Reverse Transcriptase Polymerase Chain Reaction: An Argument for Real-Time Detection Methods

L. Brett Caram, MD,\* Jodi Chen, MD,<sup>†</sup> E. William Taggart, BS,<sup>‡§</sup> David R. Hillyard, MD,<sup>‡§</sup> Rosemary She, MD,<sup>‡§</sup> Christopher R. Polage, MD,<sup>‡§</sup> Jack Twersky, MD,<sup>||</sup> Kenneth Schmader, MD,<sup>||</sup> Cathy A. Petti, MD,<sup>‡§</sup> and Christopher W. Woods, MD, MPH\*

**OBJECTIVES:** To report an outbreak of respiratory syncytial virus (RSV) in a long-term care facility (LTCF) during ongoing routine respiratory illness surveillance.

**DESIGN:** Rapid antigen testing, viral culture, direct fluorescent antibody (DFA) testing, and reverse transcriptase polymerase chain reaction (RT-PCR) testing for up to 15 viruses in symptomatic residents and chart review.

**SETTING:** A 120-bed LTCF.

**MEASUREMENTS:** Comparison of rapid antigen testing, respiratory viral cultures, and DFA testing and RT-PCR in residents with symptoms of a respiratory tract infection.

**RESULTS:** Twenty-two of 52 residents developed symptoms of a respiratory tract infection between January 29, 2008, and February 26, 2008. RSV was detected using RT-PCR in seven (32%) of the 22 cases. None of the seven cases had positive RSV rapid antigen testing, and only two had positive culture or DFA results. This outbreak occurred during a time when state wide RSV rates were rapidly declining. One patient was admitted to the hospital during the infection and subsequently died.

**CONCLUSION:** RSV may cause outbreaks in LTCFs that traditional diagnostic methods do not detect. RT-PCR can provide a more timely and accurate diagnosis of outbreaks, which allows for early symptomatic treatment, rational use of antibiotics, and improved infection control. *J Am Geriatr Soc* 57:482–485, 2009.

**Key words:** respiratory syncytial virus; long-term care facilities; reverse transcriptase polymerase chain reaction (RT-PCR)

Respiratory syncytial virus (RSV), a well-known cause of lower respiratory tract infection in young children,<sup>1</sup> is now increasingly recognized as an important cause of respiratory infection in adults.<sup>2</sup> The clinical effect of RSV may approach that of nonpandemic influenza, a cause of significant morbidity and mortality in adults.<sup>3,4</sup> Based on national mortality and Centers for Disease Control and Prevention viral surveillance data over a 25-year period (1976–1999), the annual mortality associated with RSV has been estimated at approximately 10,000 deaths per year in adults aged 65 and older.<sup>5</sup> In addition to high-risk individuals with cardiopulmonary disease and immunocompromising conditions,<sup>2,6–10</sup> older adults are increasingly recognized as an at-risk population for RSV infection. RSV infections develop in 4% to 10% of high-risk adults and 3% to 7% of healthy elderly patients annually.<sup>4</sup> The effect in frail elderly people, especially those in long-term care facilities (LTCFs), can be substantial.<sup>9,11</sup> A review of various studies of RSV infection in LTCFs estimated that 5% to 10% of LTCF residents develop RSV infection annually, of whom 10% to 20% have lower respiratory tract disease.<sup>9</sup> RSV infections lead to an annual average of 15 hospitalizations and 17 deaths per 1,000 persons in LTCF.<sup>12</sup>

Although the effect of RSV infection in older adults is substantial, RSV infections are often underdiagnosed in this population for a number of reasons: low clinical suspicion, decreased viral shedding rates in older individuals, poor sensitivity of rapid antigen testing, and delayed results in traditional viral culture or paired serum antibody testing.<sup>7,9,13–16</sup> Until recently, diagnosis of RSV and other respiratory viruses has largely relied on culture and antigen detection using immunofluorescence assays. The sensitivity of these tests is limited, and the diagnosis is often retrospective.<sup>14</sup> Reverse transcriptase polymerase chain reaction (RT-PCR) has recently emerged as a rapid, highly sensitive, highly specific method of detection.<sup>15,16</sup> The objective of this report is to describe the use of RT-PCR in detecting outbreak of RSV in a LTCF.

**SUBJECTS, MATERIALS, AND METHODS**

In February 2007, ongoing routine surveillance for symptomatic and asymptomatic respiratory viral infections detected a respiratory illness outbreak in a 56-room, 120-bed LTCF. Prospective informed consent for surveillance and approval from the institutional review board had been obtained. A respiratory tract illness (RTI) clinical case was defined as three respiratory symptoms (new-onset or increase in chronic cough, new-onset or increase in sputum, dyspnea, chills, headache, myalgias, malaise, sore throat, or nasal congestion) or two respiratory symptoms and temperature of 38.0°C or greater. Investigators abstracted data from the medical record and performed a standardized interview to obtain epidemiological and clinical data from ill residents. Flocked nasopharyngeal swabs (Copan Diagnostics, Corona, CA) were collected from patients and transported on ice to ARUP Laboratories, Salt Lake City, Utah.

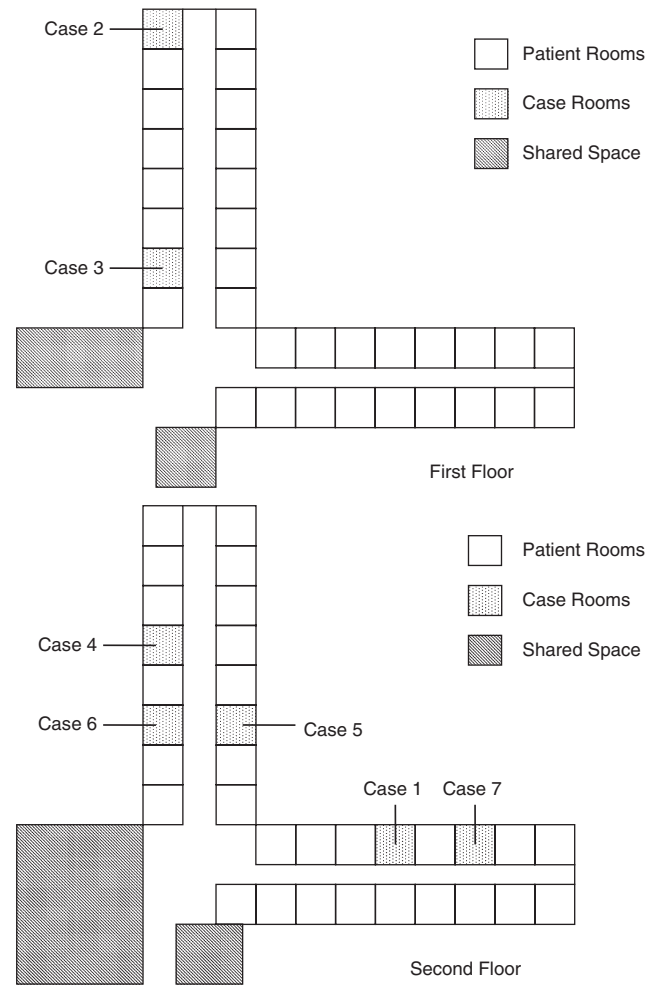

The nasopharyngeal specimens were cultured for viruses using the R-mix shell vial system (Diagnostic Hybrids Inc., Athens, OH). Direct fluorescent antibody (DFA) testing was performed on the original samples and the 24-hour R-mix shell vial culture cells. The D<sup>3</sup> Ultra DFA Respiratory Kit detected influenza A and B, RSV, parainfluenza 1-3, and adenovirus, and a separate kit was used to detect human metapneumovirus (Diagnostic Hybrids Inc.). All assays were performed according to the manufacturer's recommendations.<sup>17</sup>

Total nucleic acid was extracted from 140 µL of original specimen using the QIAmp Virus BioRobot 9604 Kit (Qiagen, Valencia, CA). Multiplex PCR was performed with the Luminex xTAG Respiratory Virus Panel (Luminex Corp., Austin, TX) assay for detection of influenza A (H1/H3); influenza B; RSV A and B; parainfluenza 1-4; coronaviruses 229E, OC43, NL63, and HKU1; human metapneumovirus; enterovirus or rhinovirus; and adenovirus.

**RESULTS**

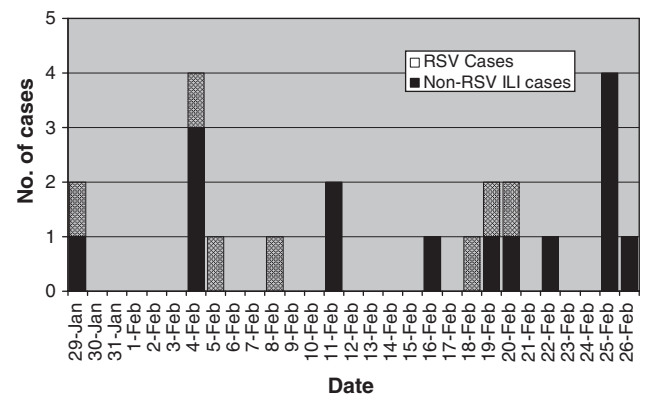

Of the 52 residents enrolled in the active surveillance program between January 29, 2008, and February 26, 2008, 22 (42%) developed symptoms of RTI. In the two-story LTCF, six cases (27%) were on the first floor, and 16 (73%) cases were on the second floor (Figure 1). All resident cases shared a common dining hall, smoking room, recreation room, and physical and occupational therapy room.

Using multiplex RT-PCR, RSV from NP swabs was detected in seven (32%) of the 22 cases of RTI. All RSV cases were group B. Only one sample was positive for another viral etiology—Influenza B. All seven RT-PCR positive cases had negative RSV rapid antigen tests, and only two had positive DFA results. The first case of RSV was detected on January 29, 2008, and six additional cases were identified during the subsequent 30-week period through February 2, 2008 (Figure 2). The surveillance program included sampling of asymptomatic patients during this period as well. None of the asymptomatic patients sampled (n = 22) were positive for RSV. Based on the Centers for Disease Control and Prevention RSV surveillance data, the biweekly rate of RSV detection using antigen tests in North Carolina during this time was rapidly declining, from 27% during the week of January 26 to 9% during the week of February 23.<sup>18</sup>

**Figure 1.** Distribution of respiratory syncytial virus case patients in the two-story long-term care facility, North Carolina, January 29 through February 26, 2008.

The clinical characteristics of the RSV-positive and RSV-negative patients with RTI are shown in Table 1. RSV-positive and -negative patients presented with a common clinical RTI syndrome characterized most often by cough

**Figure 2.** Epidemic curve of patients with respiratory tract illness (RTI) during respiratory syncytial virus (RSV) outbreaks, long-term care facility, North Carolina, January 29, 2008 through February 26, 2008. RSV infection occurred in 13% of residents during the outbreak period. Only one case of RTI was attributable to an alternate viral etiology.

**Table 1. Clinical Characteristics of Respiratory Syncytial Virus–Positive and –Negative Patients**

Characteristic	Positive (n = 7)	Negative (n = 15)
Age, mean ± SD	68.1 ± 16.8	72.0 ± 14.5
Female, n (%)	1 (14.3)	1 (6.7)
African American, n (%)	4 (57.1)	7 (46.7)
Charlson comorbidity score	6.57 ± 1.13	7.64 ± 2.82
Smoking (current or past), n (%)	7 (100)	12 (80.0)
Previous vaccination, n (%)		
Influenza vaccine	6 (85.7)	15 (100)
Pneumococcal vaccine	6 (85.7)	13 (86.7)
Death at 60 days, n (%)	1 (14.3)	0
Immunosuppression, current or past 30 days	0	2 (13.3)
Radiation therapy above diaphragm, current or previous 30 days	0	1 (6.7)
Bed or wheelchair bound	4 (57.1)	8 (53.3)
Symptoms, n (%)		
Wheezing	3 (42.9)	4 (26.7)
Rhinorrhea	4 (57.1)	6 (40.0)
Sore throat	2 (28.6)	3 (20.0)
Change in sputum production	5 (71.4)	7 (46.7)
New or increased cough	5 (71.4)	9 (60.0)
Myalgia	3 (42.9)	2 (13.3)
Hoarseness	2 (28.6)	2 (13.3)
Sneezing	1 (14.3)	5 (33.3)
Pleuritic chest pain	2 (28.6)	1 (6.7)
Shortness of breath	2 (28.6)	4 (26.7)
Subjective limitation of routine activities*	4 (57.1)	2 (13.3)

SD = standard deviation.

with sputum production, shortness of breath, wheezing, myalgia, restriction of activities, and nasal congestion. Of the RSV-positive patients, only one was febrile. Chest X-ray was performed in two (28%) of the seven RSV-positive cases, compared with eight (53%) of the 15 RSV-negative patients with acute RTI symptoms. The primary treatment team performed rapid influenza testing in none of the RSV-positive cases and in only two of the RSV-negative cases.

Most cases received symptomatic treatment with guaifenesin, acetaminophen, and inhaled albuterol. Two veterans received loratidine for presumed allergic rhinitis. The primary team prescribed broad-spectrum antibiotic coverage for pneumonia in two of the RSV-positive cases (moxifloxacin in one, vancomycin and piperacillin/tazobactam in another), but no evidence of bacterial infection was obtained from these patients using sputum culture, blood culture, or urine antigen testing. Two veterans were sent to the emergency department, one of whom was admitted to the general medicine service for a presumed chronic obstructive pulmonary disease exacerbation with possible pneumonia. This patient subsequently developed an acute myocardial infection, resulting in stage IV congestive heart failure. This patient was then placed on hospice care and died 1 month after symptom onset.

## DISCUSSION

This report describes an outbreak of RSV in a single LTCF diagnosed using RT-PCR during ongoing surveillance for respiratory viruses. Almost half (42%) of the LTCF residents developed RTI during this outbreak, which occurred toward the end of the RSV season. Thirty-two percent of those who developed RTI were RSV positive, resulting in a RSV infection rate of 13% of total residents. This attack rate is slightly higher than but comparable with the numbers quoted in the literature of 4% to 10% of high-risk adults during each RSV season.<sup>4</sup> Only one case of RTI was attributable to another viral etiology. Moreover, RSV infection was associated with the hospitalizations for pneumonia for two case patients and the death of one case patient, further highlighting the substantial effect of RSV on LTCF residents, most of whom have a number of comorbid diagnoses.

Although RSV has known outbreak potential, higher clinical suspicion and better diagnostic tools are needed. Rapid antigen tests are notoriously insensitive for diagnosis;<sup>19</sup> the rapid antigen tests in all of the RSV case patients were negative. The lack of pathognomonic clinical features also makes diagnosis of RSV based on clinical presentation alone difficult,<sup>20</sup> especially because RSV seasons often overlap with those of other respiratory viruses, such as influenza.<sup>21</sup> Improved molecular diagnostic technology allows for more-rapid and more-precise identification of the pathogen. RT-PCR provides diagnosis within 4 to 6 hours from easily obtained nasal swab samples. In an adult population that usually sheds lower viral titers, RT-PCR has been shown to be 73% sensitive and 99% specific, compared with the traditional criterion standard of viral culture, which was 39% sensitive and 100% specific.<sup>15</sup>

RSV is transmitted by close contact through large droplets and fomites. Standard infection-control measures, primarily contact isolation, limit nosocomial spread of RSV infection in elderly people and children.<sup>11</sup> In this outbreak, all case patients used shared areas with no restriction of access or contact isolation. Three case patients continued to attend the facility hemodialysis unit, three continued to undergo physical and occupational therapy in the shared activity room, and four continued to participate in recreational therapy in the recreation room. The ongoing surveillance is performed in real time with DFA and culture only. RT-PCR is not done daily, but as RT-PCR becomes more cost effective, use of this rapid and sensitive diagnostic test will become more widespread, leading to better infection control methods, such as hand washing, contact isolation, and the timely implementation of activity restriction, to limit real-time spread of the infection. In addition, education of staff in infection-control measures and screening staff for viral infections are crucial in further improving infection control.<sup>22</sup>

Prompt diagnosis and control of RSV infection can potentially lead to shorter outbreak periods, shorter length of hospital stays, appropriate and targeted antibiotic therapy, and overall lower cost.<sup>23</sup> In one study, LTCF residents were prescribed an average of 2.4 antibiotic courses per year, with more than 8% of infections ultimately attributable to influenza and RSV infection.<sup>12</sup> Antibiotics have consistently been shown to be prescribed in excess during

influenza and RSV seasons. The full effect of RSV in LTCF may lead to development and use of better vaccination and prophylactic therapy.<sup>19</sup>

It was not possible to collect specimens from the LTCF clinical staff, which limited the ability to understand their role in disease transmission. In addition, successful infection control using RT-PCR requires ongoing surveillance, etiological diagnosis, appropriate infection control infrastructure, and partnership with laboratories with appropriate diagnostic technology.

In summary, RT-PCR is an important tool in early diagnosis of respiratory infection, which not only allows for early treatment and rational use of antibiotics, but also improves infection control in LTCFs.
