The title compound, $[\text{Mn}_2(\text{C}_7\text{H}_4\text{NO}_4)_4(\text{C}_6\text{H}_7\text{N})_4]$ or $[\text{Mn}_2(\mu\text{-NBz})_2(\kappa^2\text{-NBz})_2(4\text{-Mepy})_4]$, where NBz is 4-nitrobenzoate and 4-Mepy is 4-methylpyridine, is a centrosymmetric dinuclear complex in which the Mn^{II} atoms are bridged by two NBz ligands with Mn···Mn = 4.1324 (4) Å. The Mn^{II} atom in this dimeric species is present in a distorted octahedral environment with the four coordinating O atoms forming the equatorial plane and the two pyridyl N atoms occupying the axial sites. An important structural feature of the dimeric complex is that each of the bridging carboxylate ligands binds to the metal ions in an asymmetric fashion involving bent and linear Mn—O—C units. The crystal packing is consolidated by C—H···O and C—H···π interactions.

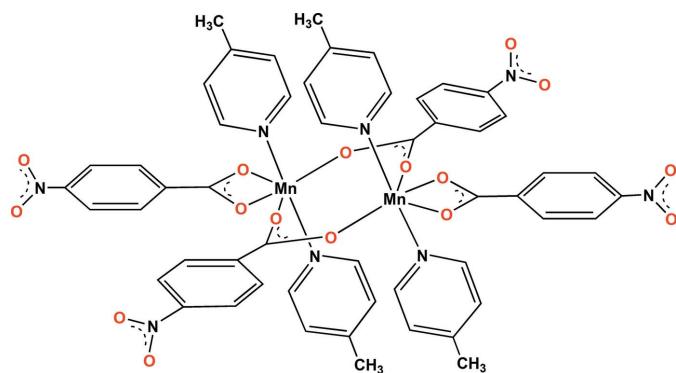

1. Chemical context

Polynuclear manganese complexes with carboxylate ligation have received great attention due to their potential applications in catalysis (Arafa *et al.*, 2014), magnetism (Miyanaga *et al.*, 2004) and their antitumor activity (Dey *et al.*, 2015) as well as in other areas. The occurrence of Mn in a number of oxidation states (II–IV) under normal conditions and also the ability of carboxylato ligands to display a variety of coordination modes are the main reasons why Mn–carboxylates have received a lot of attention in the recent past. It has been reported that an Mn-based binuclear complex of composition $[\text{Mn}_2(\text{bbppnol})(\mu\text{-O}_2\text{CCH}_3)_2]$ [bbppnol = N,N' -bis(2-hydroxybenzyl) N,N' -bis(2-methylpyridyl)-2-ol-1,3-propanediamine] with two bridging acetato ligands is active as a catalyst in the epoxidation of cyclohexene and cyclooctene (Castaman *et al.*, 2009). A series of dimeric complexes with the general formula $[\text{Mn}_2(\text{O}_2\text{CCH}_3)L]$ {where $L = 2,2'\text{-[2-hydroxy-5-(pivalamidomethyl)-1,3-phenylene]bis}(1H\text{-benzo}[d]\text{imidazole-4-carboxylic acid}), 2,2'\text{-[5-benzyl-2-hydroxy-1,3-phenylene]bis}(1H\text{-benzo}[d]\text{imidazole-4-carboxylic acid})$ etc.} have been explored as catalysts for the water-oxidation reaction with a view to generating O₂ and H₂ (Arafa *et al.*, 2014). Microwave-assisted alcohol oxidation with *tert*-butylhydroperoxide (TBHP) has been carried out (Sutradhar *et al.*, 2014) using a Schiff base-containing Mn dimer. Manganese complexes are also recognized for their magnetic behaviour since coordination compounds of this metal often display large ground-state spin (S) values and the polynuclear manganese cluster $[\text{Mn}_{12}\text{O}_{12}(\text{CH}_3\text{COO})_{16}(\text{H}_2\text{O})_4]\cdot 2\text{CH}_3\text{COOH}\cdot 4\text{H}_2\text{O}$ is considered to be the first single molecule magnet (SMM) (Uhrecký *et al.*, 2013; Sessoli *et al.*, 1993). Complexes of manganese are also considered to be important

OPEN ACCESS

in view of the occurrence of an Mn_4Ca unit in the active site of Photosystem II that catalyses the water-splitting reaction to evolve oxygen in nature (Nocera, 2012).

Keeping in mind earlier results published from our laboratory (Chakrabarty *et al.*, 2007) on the synthesis and catalytic properties of cobalt(III)-oxide pseudo-cubane units of the type $[Co_4O_4(\mu-O_2CR)_4L_4]$, where R is an alkyl or aryl group and L is a monodentate pyridyl ligand, and also due to their relevance as catalysts for the water-oxidation reaction (McCool *et al.*, 2011), we explored whether analogous manganese complexes could also be synthesized. These efforts have led to the synthesis of the title complex, among others. Herein we report the synthesis, crystal structure and some salient properties of the dimeric manganese(II) compound $[Mn_2(\mu\text{-NBz})_2(\kappa^2\text{-NBz})_2(4\text{-Mepy})_4]$, **I**, which belongs to a structure type constituted of only a limited number of complexes (*vide infra*).

2. Structural commentary

Fig. 1 shows the molecular structure of the dimeric complex. The two Mn atoms are related by an inversion centre and are bridged by the carboxylate anions of two NBz ligands in a *syn*-

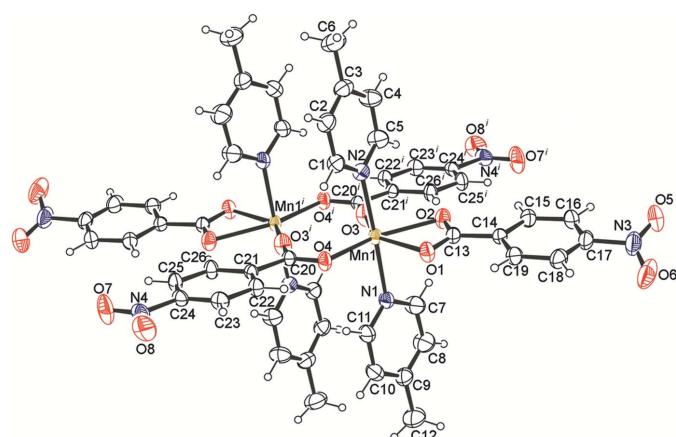

Figure 1

syn fashion. Each Mn^{II} atom is further coordinated by a carboxylato ligand in chelating mode. The four oxygen atoms – two from a pair of bridging NBz ligands and two from a chelating NBz ligand – are nearly coplanar with each of the central Mn atoms, forming an equatorial plane; the axial positions for both are occupied by two 4-methylpyridine ligands completing the distorted octahedral geometry around each Mn^{II} atom. The bridging Mn–O(carboxyl) bond lengths ($\sim 2.1 \text{ \AA}$) are found to be shorter than the Mn–O(carboxyl) distances ($\sim 2.3 \text{ \AA}$) in the chelating ligands (Table 1). For the chelating NBz anions, the longer Mn–O distances can be attributed to the steric crowding imposed by the neighbouring bridging bis-monodentate NBz anions.

The $Mn \cdots Mn$ distance of $4.1324 (4) \text{ \AA}$ in **I** precludes any direct bonding interaction between the Mn^{II} atoms and is comparable to the corresponding distances in the structurally related Co^{II} complexes $[(Co(dpe)(NO_2BDC)) \cdot 0.5(dpe)]_n \cdots nH_2O$ (4.181 \AA ; Luo *et al.* 2003), $[Co_2(4,4'\text{-bipy})_2(O_2CC_6H_5)_4]_n$ (4.060 \AA ; Zhang *et al.* 2007) and $Co_2(\mu\text{-}4\text{-nbz})_2(\kappa^2\text{-}4\text{-nbz})_2(4\text{-CNpy})_4$ (4.226 \AA ; Chakravorty & Das, 2016). However, it is considerably shorter than in its most closely related analogue $[Mn_2(\mu\text{-OBz})_2(\kappa^2\text{-OBz})_2(py)_4]$ in which the $Mn \cdots Mn$ separation is 4.531 \AA (Ran *et al.*, 2006).

The highly distorted nature of the MnO_4N_2 octahedron in the title species, which is probably due to the steric crowding of both the bridging and chelating NBz ligands surrounding the Mn^{II} atom, is manifested by the O–Mn–O and O–Mn–N angles. While the former are in the range $56.95 (4)\text{--}150.77 (4)^\circ$, the latter are in the range $88.02 (5)\text{--}94.59 (5)^\circ$.

In the title compound, the carboxyl $-\text{COO}$ and $-\text{NOO}$ planes of the chelating NBz anion deviate slightly from the phenyl ring plane, forming dihedral angles of $2.6 (3)$ and $23.6 (4)^\circ$, respectively. According to Kaduk (2000) and Kaduk & Golab (1999), completely planar phenyl carboxylates are associated with low conformational energy and any deviation from planarity leads to an increase in the energy of the system. However, this destabilization can be compensated for by efficient crystal packing in the solid state.

Table 2
Hydrogen-bond geometry (\AA , $^\circ$).

C_g is the centroid of the N2/C1–C5 ring.

$D\cdots H\cdots A$	$D\cdots H$	$H\cdots A$	$D\cdots A$	$D\cdots H\cdots A$
C1–H1 \cdots O4	0.93	2.61	3.172 (2)	119
C2–H2 \cdots O1 ⁱⁱ	0.93	2.65	3.278 (2)	125
C11–H10 \cdots O4	0.93	2.55	3.161 (2)	124
C22–H25 \cdots C_g ⁱⁱ	0.93	2.80	3.6844 (16)	160

Symmetry code: (ii) $-x + 1, -y, -z$.

3. Supramolecular features

The crystal structure of **I** features several intramolecular as well as intermolecular C–H \cdots O interactions wherein the O atoms from $-\text{NO}_2$ and $-\text{CO}_2$ groups of the NBz ligand act as hydrogen acceptors (Table 2 and Fig. 2). While the $D\cdots A$ separations for these weak contacts are in the range of 3.161 (2) to 3.369 (2) \AA , the $\angle \text{C–H}\cdots\text{O}$ angles are generally lower than 130° , except in one case where a hydrogen bond with a greater $D\cdots A$ separation of 3.369 (2) \AA forms has an angle of 172° . In addition, intermolecular C–H $\cdots\pi$ interactions involving the pyridyl ring π system of the 4-Mepy ligand link the complex molecules into chains along the a axis (Fig. 3). Although each of the above non-covalent contacts is individually weak, the presence of many of these supramolecular contacts clearly result in extra stability of the species in the solid state. Indeed, the involvement of the $-\text{NO}_2$ and $-\text{CH}_3$ groups at the 4-positions of the phenyl ring of the NBz ligand and the pyridyl ring of the 4-Mepy ligand may explain why the isolation of complexes analogous to **I** has not been possible for some combinations of carboxylato and pyridyl ligands.

4. Database survey

A survey of the Cambridge Structural Database (Groom *et al.* 2016) shows that only a few dinuclear Mn complexes with both bridging and chelating carboxylate linkages are known. We have tabulated some of the available data for complexes of the type $[\text{Mn}_2(\mu\text{-O}_2\text{CR})_2(\kappa^2\text{-O}_2\text{CR})_2\text{L}_4]$ in Table 3 in order to compare some of the important geometric parameters. For all complexes, the Mn–O bonds involving the chelating carboxylato ligands are longer than the corresponding Mn–O bonds in the bridging carboxylato ligands. Of particular note

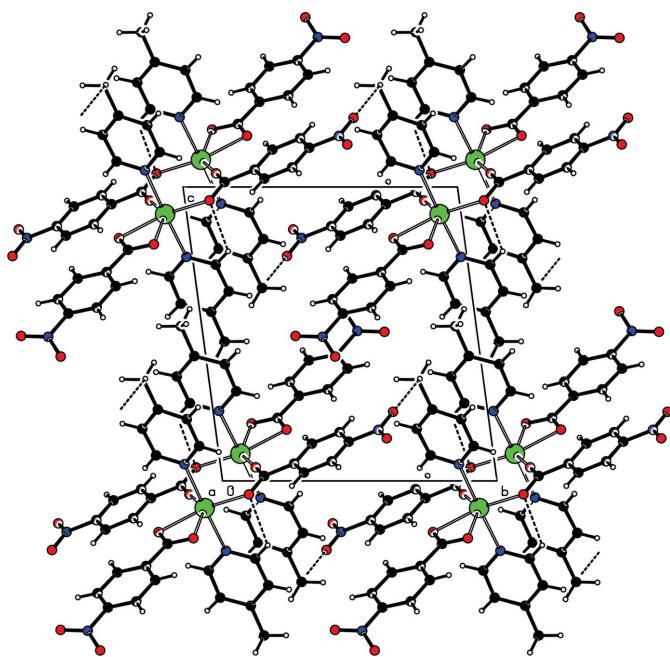

Figure 2
Packing diagram showing C–H \cdots O interactions (dashed lines) in the crystal structure of **I**.

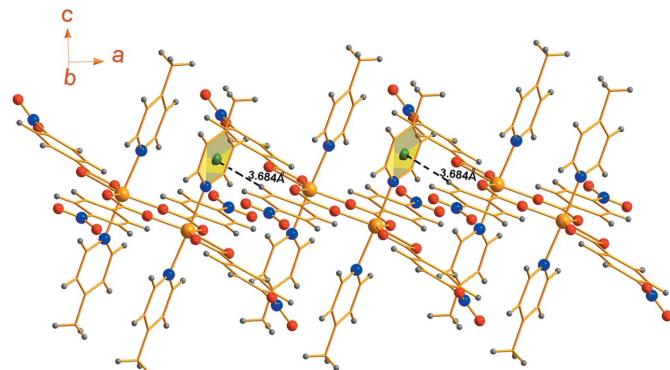

Figure 3
Intermolecular C–H $\cdots\pi$ interactions observed between phenyl-ring H atoms of NBz and phenyl ring π -systems of 4-Mepy in the crystal structure of **I**.

among the listed parameters is the near linearity of one of the the $\angle \text{Mn–O–C}$ angles [$178.20(1)^\circ$ and $116.68(8)^\circ$] observed in the crystal structure of **I**. For its most closely related known

species, [Mn₂(μ -OBz)₂(κ^2 -OBz)₂(py)₄] (Ran *et al.* 2006), the corresponding angles are 149.32 (1) and 133.39 (1)°, respectively. The more pronounced asymmetry of bonding in the bridging carboxylato groups in **I** may be ascribed to steric factors and also to differences in molecular packing effects resulting from the presence of substituents on the aromatic rings of both types of ligand.

5. Synthesis and crystallization

A mixture of MnSO₄·H₂O (0.845 g, 5 mmol), NaNBz (1.89 g, 10 mmol) and 4-Mepy (1 ml, 10 mmol) was stirred mechanically in water (20 ml) at room temperature for 4 h. The yellow precipitate that appeared was washed thoroughly with water and then with methanol before being dried in a vacuum desiccator over fused CaCl₂. Yield: 2.58 g (85% based on Mn). Light-yellow transparent crystals of **I** suitable for X-ray analysis were obtained in 2–3 days from a solution prepared by mixing 2 ml of a methanolic solution of NaNBz (1 mmol) with a solution (2 ml) of MnSO₄·H₂O (0.5 mmol) containing 4-Mepy (1 mmol) in methanol/water (1:1 v/v). Analysis calculated for C₄₈H₃₆N₈O₁₆Mn₂: C, 52.84%; H, 3.30%; N, 10.27%; found: C, 52.04%; H, 3.02%; N, 9.8%; μ_{eff} (295 K)/Mn = 5.36 BM.

The method developed by us to prepare **I** is simpler than the reported procedure for preparing the related species [Mn₂(μ -OBz)₂(κ^2 -OBz)₂(py)₄] (Ran *et al.* 2006) and the present

method can be easily extended to obtain other analogous manganese(II) complexes.

6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 4. Hydrogen atoms were positioned geometrically (aromatic C—H = 0.93 Å, methyl C—H = 0.96 Å) and were included in the refinement in the riding-model approximation, with $U_{\text{iso}}(\text{H})$ set at 1.2–1.5 $U_{\text{eq}}(\text{C})$.

6595 reflections with $I > 2\sigma(I)$

$R_{\text{int}} = 0.022$

$\theta_{\text{max}} = 30.0^\circ, \theta_{\text{min}} = 2.5^\circ$

$h = -12 \rightarrow 12$

$k = -15 \rightarrow 17$

$l = -18 \rightarrow 18$

Refinement

Refinement on F^2

Least-squares matrix: full

$R[F^2 > 2\sigma(F^2)] = 0.036$

$wR(F^2) = 0.110$

$S = 1.03$

7705 reflections

354 parameters

0 restraints

Hydrogen site location: inferred from
neighbouring sites

H-atom parameters constrained

$w = 1/[\sigma^2(F_o^2) + (0.0619P)^2 + 0.2308P]$
where $P = (F_o^2 + 2F_c^2)/3$

$(\Delta/\sigma)_{\text{max}} = 0.001$

$\Delta\rho_{\text{max}} = 0.33 \text{ e } \text{\AA}^{-3}$

$\Delta\rho_{\text{min}} = -0.25 \text{ e } \text{\AA}^{-3}$

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Symmetry code: (i) $-x+2, -y, -z$.

Hydrogen-bond geometry (\AA , $^\circ$)

Cg is the centroid of the N2/C1—C5 ring.
