Background: Gold nanoparticles with high biocompatibility and immunomodulatory properties have potential applications in the development of new diagnostic and therapeutic strategies for nanomedicine. Nanoparticles targeting macrophages can manipulate or control immunological diseases. This study assessed the activity of dendrimer-encapsulated gold nanodots (AuNDs) with three surface modifications [ie, out-facing groups with primary amine (AuNDs-NH₂), hydroxyl (AuNDs-OH), and quaternary ammonium ions (AuNDs-CH₃)] regulated macrophage function and antioxidant response through Nrf2-dependent pathway.

Methods: AuNDs were prepared and characterized. Intracellular distribution of AuNDs in human macrophages was observed through confocal microscopy. The activity of AuNDs was evaluated using macrophage functions and antioxidant response in the human macrophage cell line THP-1.

Results: AuNDs-NH₂ and AuNDs-CH₃, but not AuNDs-OH, drove the obvious Nrf2-antioxidant response element pathway in THP-1 cells. Of the three, AuNDs-NH₂ considerably increased mRNA levels and antioxidant activities of heme oxygenase 1 and NAD(P)H quinone dehydrogenase 1 in THP-1 cells. IL-6 mRNA and protein expression was mediated through Nrf2 activation in AuNDs-NH₂-treated macrophages. Furthermore, Nrf2 activation by AuNDs-NH₂ increased the phagocytic ability of THP-1 macrophages.

Conclusion: AuNDs-NH₂ had immunomodulatory activities in macrophages. The findings of the present work suggested that AuNDs have potential effects against chronic inflammatory diseases via the Nrf2 pathway.

Introduction

Engineering nanoparticles for application in the immune system is an exciting, emerging field in the development of nanotechnology.¹ Nanoparticles targeting immune cells (eg, macrophages) can help in manipulating or controlling immunological diseases, such as infectious diseases or tumors. Macrophages play many key roles in the host defense system. They not only phagocytose dead cells and pathogens but also shape the inflammatory response and modulate adaptive immunity. However, macrophages act as major effector cells in chronic inflammatory development. Redox signals affect the process of macrophage polarization and reprogramming.² A key master redox regulator is the nuclear factor erythroid 2-related factor 2 (Nrf2) signaling pathway, responsible for oxidative and xenobiotic stress.³ Moreover, Nrf2 is a vital target for anti-inflammation and antioxidant

cytoprotective pathways.^{4,5} Nrf2 activators exhibit protective effects in animal models of neurodegenerative diseases^{6–8} and chronic obstructive pulmonary disease.⁹ Accordingly, natural or synthetically derived Nrf2 modulators have been attracting attention as a promising therapeutic strategy for chronic inflammatory diseases.¹⁰

The extent of biocompatibility of a nanoparticle depends on its various surface properties. Owing to the inert and nontoxic core, gold nanoparticles usually exhibit relatively low toxicity and high biocompatibility compared with other metal-based nanoparticles, such as silver, zinc oxide, and iron oxide.^{11,12} Our previous study demonstrated that surface modification of gold nanodots (AuNDs) changed the lipopolysaccharide (LPS) assembly behavior to modulate immunological effects in human macrophages.¹³ Liu et al¹⁴ also demonstrated that surface modifications of AuNDs with amine out-facing group (AuNDs-NH₂) demonstrated reduced peroxidase-like activity while still retaining catalase-like activity. The methylation of AuNDs-NH₂ to form quaternary ammonium ions (AuNDs-CH₃) restored the intrinsic peroxidase-like activity.

In the present study, AuNDs with three types of out-facing groups—namely primary amine (AuNDs-NH₂), hydroxyl (AuNDs-OH), and quaternary ammonium ions (AuNDs-CH₃)—had different effects antioxidant response and macrophage functions via the Nrf2 activation pathway. Of the three, only AuNDs-NH₂ triggered transient reactive oxygen species (ROS) disturbance within 10 min and then decreased intracellular ROS in a time-dependent manner. AuNDs-NH₂ induced Nrf2 ser40 phosphorylation and subsequently triggered Nrf2 target gene transcriptional activation, and AuNDs-CH₃ activated Nrf2 through the noncanonical Nrf2-P62 pathway. However, AuNDs-OH did not trigger Nrf2- antioxidant response element (ARE) activation. AuNDs-NH₂ considerably increased *hemoxygenase 1 (HO-1)* and *NAD(P)H quinone dehydrogenase 1 (NQO1)* mRNA levels in THP-1 cells after 24 h of treatment. In addition, the antioxidant enzyme activities were elevated in AuNDs-NH₂-treated cells at 48 h, including NQO1, glutathione peroxidase (GPx), glutathione S-transferase (GST), and catalase. Only NQO1 and catalase enzyme activities were increased after AuNDs-CH₃ treatment. Moreover, mRNA and protein expression of IL-6 was mediated through Nrf2 activation in AuNDs-NH₂-treated macrophages. Furthermore, Nrf2 activation by AuNDs-NH₂ increased the phagocytic ability of THP-1 macrophages. Therefore, our findings provide rationale

strategies for the development of nanomaterials targeting the Nrf2 pathway against chronic diseases.

Materials and Methods

Materials

G4NH₂ and G4OH dendrimers, HAuCl₄, methyl iodide, LPS, and ML385 were purchased from Sigma-Aldrich (St. Louis, MO, USA). 2',7' dichlorodihydrofluorescein diacetate (DCFH-DA) was obtained from Thermo Fisher Scientific (Grand Island, NY, USA). The AuNDs were synthesized according to a previous study.¹⁵ In brief, G4NH₂ and HAuCl₄ were mixed, and the solution was incubated at 4 °C overnight and then irradiated with microwave at 120 °C for 30 min (CEM; Discover LabMate System). The precipitations and AuNDs were filtered through an MWCO membrane filter (3 KDa) from Millipore (PES membrane, MA, USA). The extra AuCl₄⁻ was removed using anionic exchange chromatography (Fractogel EMD TMAE Hicap; Rockland, Merck, MA, USA). The internal tertiary amine groups and the surface amine groups of dendrimer-encapsulated AuNDs were treated with methyl iodide in 1 mL of 1:1 (v/v) N,N'-dimethylformamide/H₂O at room temperature overnight to form AuNDs-CH₃. The reaction mixture was extracted, dried under a vacuum, and dissolved in water.¹⁴

Physicochemical Properties of AuNDs

Zeta potential was measured on the Zetasizer Nano system (Zetasizer Nano ZS; Malvern Instruments, Worcestershire, UK). All measurements were performed with three independent experiments at room temperature. The gold content of AuNDs and percentages of cell uptake were quantified through inductively coupled plasma mass spectrometry (ICP-MS). Polarities of AuNDs were measured using pyrene, a type polarity probe.^{16–18} The I₁:I₃ ratio is an index of the polarity of its environment; I₁ and I₃ are intensities at 372 and 383 nm, respectively. AuND sizes were determined on a dynamic light scattering instrument (Malvern Zetasizer, Nano ZS) with an argon laser wavelength ($\lambda = 633$ nm; detector angle = 173°; typical sample volume = 100 μ L). Endotoxin levels of AuNDs were measured using the kinetic turbidimetric assay. The spike recoveries of AuNDs-NH₂, AuNDs-CH₃, and AuNDs-OH were 86%, 85%, and 93%, respectively.

Intracellular Distribution of AuNDs

THP-1 cells were purchased from Bioresource Collection and Research Centre in Food Industry Research and

Development Institute, Taiwan. The cells were seeded in a 3.5-cm μ -dish (ibidi GmbH, Martinsried, Germany) and treated for 3 days with 100 nM PMA. After replacement with fresh serum-free medium for 1 day, the cells were treated with 1 mg/mL AuNDs for 6 and 24 h. MitoTracker (Invitrogen, Molecular Probe, OR, USA) and LysoTracker (Invitrogen) were used for intracellular biodistribution of AuNDs. MitoTracker is a cell-permanent probe that contains a mildly thiol-reactive chloromethyl moiety for labeling mitochondria. LysoTracker is a fluorescent acidotropic probe for labeling and tracking acidic organelles in live cells and can be used to investigate intracellular lysosomes. The red MitoTracker and LysoTracker were detected with confocal microscopy upon excitation using a 577-nm diode laser, and the emission was measured at 590 nm. The intracellular distributions of the AuNDs were detected with confocal microscopy on excitation using a 405-nm diode laser, and the emissions were measured at 420–460 nm. To examine whether AuNDs are excreted through exocytosis or destroyed in cells, PMA-activated THP-1 cells were treated with 1 mg/mL AuNDs for 24 h. Then, AuNDs were removed by replacement with a new culture medium for another 48 h. The cells were stained with LysoTracker (red) and then examined using confocal microscopy.

Measurement of Intracellular ROS

ROS generation was determined using DCFH-DA. PMA-activated THP-1 cells were plated with an appropriate number in 6-well plates or 96-well black microtiter plates and treated for 10 and 30 min with or without AuNDs or LPS, diluted directly into the culture media. Treatment with 1 μ g/mL LPS for 30 min was used as a positive control. An appropriate number of cells were incubated with 5 μ M DCFH-DA at 37 °C for 30 min and then immediately measured using a microplate reader or through flow cytometry with a 485-nm excitation wavelength and 520-nm emission wavelength.

Adenovirus-Based ARE Luciferase Reporter Assay

The use of adenovirus-based luciferase reporter assay has been established.^{19,20} In brief, the PMA-activated cells (1.5×10^4 cells/well) were seeded on 96-well white plates (cat. no. 136101; Nalge Nunc, Roskilde, Denmark). After infection with the recombinant adenovirus containing ARE constructs at a multiplicity of infection of 1 in serum-free

medium for 16 h, the infected THP-1 cells were treated with AuNDs for 24 h. Luciferase activity was determined in triplicate on the Luciferase Assay System (Promega, Madison, WI, USA) by using a programmed microplate luminometer²¹ (MicroLumatPlus LB96V, EG&G Berthold, Germany).

Quantitative Real-Time Reverse Transcription-Polymerase Chain Reaction Assays

THP-1 cells were seeded in 6-well plates and then treated for 3 days with 100 nM PMA. After replacement with fresh serum-free medium for 1 day, the cells were treated with 1 mg/mL AuNDs for 24 or 48 h. Next, RNA was extracted using an RNAzol RT kit (Life Technologies, Rockville, MD, USA). The purified RNAs were stored at -80 °C, and cDNA was synthesized with total RNA (3 μ g). Quantitative real-time reverse transcription-polymerase chain reaction (quantitative PCR) was used to measure *NQO1*, *HO-1*, *IL-1 β* , and *IL-6* expression, and the assays were performed using the Assay-on-Demand Gene Expression Assay Mix (Applied Biosystems, Foster City, CA, USA). The assay ID for *NQO1* was Hs00168547_m1, of *HO-1* was Hs00157965_m1, for *IL-1 β* was Hs01555410_m1, for *IL-6* was Hs00174131_m1, and for glyceraldehyde-3-phosphate dehydrogenase (*GAPDH*) was Mm99999915_g1. Quantitative PCR to measure *NQO1*, *HO-1*, *IL-1 β* , *IL-6*, and *GAPDH* expression were performed using TaqMan Universal PCR Master Mix (Applied Biosystems). The reaction mixtures were prepared by mixing aliquots of cDNA, 0.5 μ L of Assay-on-Demand Gene Expression Assay Mix, and 5 μ L of TaqMan Universal PCR Master Mix (Applied Biosystems) in a final volume of 10 μ L. The reaction mixtures were analyzed on an ABI PRISM 7900 Sequence Detector System (Applied Biosystems) with the following PCR program: 95 °C for 10 min, followed by 40 cycles of 60 °C for 1 min, and 95 °C for 15 s. Quantitative values were obtained from the threshold cycle (C_t) number. The relative mRNA levels of the target genes were derived using the eq $2^{-\Delta C_t}$, where $\Delta C_t = C_{t_{\text{target gene}}} - C_{t_{\text{GAPDH}}}$. Data were presented as the fold relative to the control value.²²

IL-1 β and IL-6 ELISA

THP-1 cells were seeded in 6-well plates and then treated for 3 days with 100 nM PMA. After replacement with fresh serum-free medium for 1 day, the cells were treated with 1 mg/mL AuNDs for 48 h. Human IL-1 β and IL-6

proteins were measured using ELISA (Affymetrix eBioscience), according to manufacturer instructions.

Antioxidant Enzyme Activity Assays

Antioxidant enzyme activities were determined in AuNDs-treated cell at 48 h. The measured enzymes included NAD(P)H dehydrogenase [quinone] 1 (NQO1), glutathione peroxidase (GPx), catalase, and glutathione-S-transferase (GST). The enzyme activities of NQO1, GPx, catalase, and GST were determined using enzyme activity assays (Abcam, Cambridge, MA, USA), according to the instruction manuals.

Phagocytosis Assay

The phagocytosis assay was performed with pHrodo *Escherichia coli* BioParticles conjugates (Thermo Fisher Scientific). THP-1 cells were activated by PMA for 3 days and cultured with sera-free medium 24 h after PMA removal. THP-1 cells were treated with AuNDs for 24 or 48 h and then harvested from the culture plates for the following assay. The cells were incubated with pHrodo *E. coli* (1 mg/mL) at 37 °C for 2 h. The pHrodo dye conjugates were nonfluorescent outside the cell but brightly red fluorescent in phagosomes. The percentage of phagocytosis was detected through flow cytometry with the wavelength of excitation at 560 nm and emission at 585 nm.

Nrf2 and P62 Phosphorylations Through Flow Cytometry

Nrf2 ser40 and P62 ser349 phosphorylations were determined through flow cytometry. THP-1 cells were activated using PMA for 3 days and cultured with sera-free medium for another 24 h after PMA removal. THP-1 cells were treated with AuNDs at various time points. The cells were fixed with a paraformaldehyde buffer followed through methanol permeabilization. Anti-Nrf2 (phospho S40) and anti-SQSTM1/p62 (phospho S349) antibodies were purchased from Abcam. Anti-rabbit IgG conjugated with Alexa Fluor 488 (Invitrogen) was used as the secondary antibody. The percentage of Nrf2 and P62 phosphorylation was detected through flow cytometry with excitation wavelength of 495 nm and emission wavelength of 519 nm.

Statistical Analysis

All statistical analyses were conducted on Prism 4.0 (GraphPad Software, San Diego, CA, USA). Significant

differences between treatment groups were determined through using an unpaired *t*-test. The results of experimentally treated groups and their corresponding controls were compared using one-way analysis of variance. Differences were considered statistically significant at **P* values of <0.05, ***P* <0.01, and ****P* <0.001.

Results

Physicochemical Properties and Intracellular Distribution of AuNDs in THP-1 Macrophages

Our previous study indicated that dendrimer-encapsulated AuNDs are highly biocompatible with macrophages.¹³ The preparations of AuNDs are described in the previous report,¹⁵ in which the detailed physicochemical properties are examined. In brief, the dimensions of AuNDs are uniformly smaller than the parent dendrimers (ie, G4NH₂ and G4OH). Both AuNDs-NH₂ and AuNDs-CH₃ diminish the intrinsic cytotoxicity of G4NH₂ through an irreversible backfolding of out-facing 1°-amines. Such a significant deactivation of the external 1°-amines can minimize the interaction between G4NH₂ and cell membranes during internalization. Because of the absence of 1°-amines within the G4OH structure, AuNDs-OH are also highly biocompatible.¹⁵ Our previous reports examined the morphology and photoluminescence of AuNDs.^{23–25} The photoluminescence of AuNDs peaks at approximately 460 nm in an aqueous solution.²⁶ The size of a single AuND is theoretically <1 nm, making it difficult to observe particle size using high-resolution transmission electron microscopy. Yeh et al²³ found that AuNDs form a layer-by-layer film on the transmission electron microscopy copper grid. The proximity distance range of the gold atoms was speculated to be nearly 0.2884 nm.²⁷ Other physicochemical properties, endotoxin levels, and uptake percentage of the three AuNDs are summarized in Table 1.

In summary, all three AuNDs exhibited positive zeta potential. The gold content of AuNDs-NH₂ and AuNDs-CH₃ was higher than that of AuNDs-OH. Polarity assays were performed using a well-known polarity probe (ie, pyrene)²⁸ to measure the hydrophobicity of AuNDs. The polarity change from the microenvironment was indicated by two vibrational peaks of pyrene appearing at approximately 370 nm (I₁) and 380 nm (I₃). Our results revealed that AuNDs-OH is more hydrophobic than AuNDs-NH₂ and AuNDs-CH₃. Because our cell model is a macrophage, we also quantified the endotoxin levels of

Table 1 Physicochemical Properties, Endotoxin Levels, and Uptake Percentage of AuNDs

	AuNDs-NH2	AuNDs-CH3	AuNDs-OH
Zeta potential (mV)	+2.8	+12.6	+2.4
Au ($\mu\text{g}/\mu\text{g}$)	0.078 \pm 0.005	0.074 \pm 0.003	0.002 \pm 0.000
Polarity (I_1/I_3)*	0.77	0.72	0.52
Size (nm)	<1	<1	<1
Endotoxin (EU/mL)#	<0.005	0.00825	0.01826
Cell uptake (%)	3.03 \pm 0.24	2.62 \pm 0.22	1.76 \pm 0.22

Notes: * I_1/I_3 ratio of pyrene fluorescence is an index of polarity of its environment. The ratios of the fluorescence intensity of I_1/I_3 considerably decay to far lower than 1, indicating that the microenvironment is more hydrophobic; #Endotoxin levels of AuNDs were measured using a kinetic turbidimetric assay. The spike recoveries of AuNDs-NH2, AuNDs-CH3, and AuNDs-OH were 86%, 85%, and 93%, respectively.

the three AuNDs to ensure that our experiments were free of LPS contaminants. The endotoxin levels were <0.005 (EU/mL) in AuNDs-NH2, 0.00825 (EU/mL) in AuNDs-CH3, and 0.01826 (EU/mL) in AuNDs-OH. The endotoxin levels of all three AuNDs were lower than the clinically acceptable concentration (0.25 EU/mL). Furthermore, the percentages of cellular uptake after AuND treatments were determined through ICP-MS. After 24 h of treatment, the cellular uptake percentage of AuNDs-OH was the lowest among the three AuNDs.

Next, we investigated the intracellular distributions in THP-1 macrophages after 24 h of treatment. All three AuNDs accumulated in the intracellular lysosome (Figure 1A) after entering macrophages and did not obviously affect or accumulate in the mitochondria (Figure 1B). No AuNDs influenced mitochondrial ATP production after 24 h of treatment (data not shown). We assessed whether AuNDs are retained in the cells or excreted through exocytosis. THP-1 cells were treated with AuNDs for 24 h, and then AuNDs were removed by replacement with a new culture medium for another 48 h. The results revealed that all AuNDs were retained in lysosomes after 72 h of treatment (Figure 1C).

AuNDs-NH2 Reduce Intracellular ROS Levels in Macrophages

The cellular redox system is involved in various physiological homeostatic mechanisms, such as cell differentiation, activation, death, and survival.^{29,30} Major endogenous ROS generation occurs in various organelles, such as the mitochondrial electron transport chain, endoplasmic reticulum system, and NADPH oxidase complex.³⁰ Excessive ROS production triggers oxidative stress, which may result in lipid peroxidation, DNA damage, and protein dysfunction, leading to various disorders.³¹ Several studies have reported that nanoparticles can increase intracellular ROS

levels and induce oxidative stress.³² We determined the intercellular ROS levels after AuNDs' entry into macrophages. Our results revealed that ROS levels decreased in cells treated by AuNDs-NH2, but not AuNDs-CH3 or AuNDs-OH, after 24 h of treatment (Figure 2A) and in a time-dependent manner (Figure 2B). Furthermore, we examined the change in ROS levels in THP-1 cells within 30 min of treatment with AuNDs-NH2 and found that intracellular ROS levels transiently increased at 10 min but returned to those of the control group at 30 min (Figure 2C). LPS treatment was a positive control for ROS production within 30 min in macrophages. These results indicate that AuNDs-NH2 cause short-term ROS disturbance and then significantly reduce the intracellular ROS content. Therefore, we speculate that AuNDs-NH2 may regulate antioxidant mechanisms in macrophages.

Nrf2 Activation and Phosphorylation Occur in AuNDs-NH2-Treated Cells

Nrf2 is a master regulator of antioxidant responses. Nrf2 localizes within the cytoplasm and interacts with Kelch-like ECH-associating protein 1 (Keap1), which subsequently is ubiquitinated and degraded in the proteasome under normal conditions. In the canonical Keap1/Nrf2 pathway, oxidative stress or electrophile compounds modify Keap1 cysteine residues, leading to Keap1 conformation changes. Next, Nrf2 translocates to the nucleus and binds to the ARE or electrophile responsive element (EpRE), leading to target gene expression.^{3,30} In the noncanonical Nrf2-ARE activation pathway, a regulator of autophagy/xenophagy, p62/SQSTM1, facilitates Keap1 degradation and subsequently stabilizes and translocates Nrf2 into the nucleus.²⁸ Nrf2 expression can be upregulated through Keap1-independent mechanisms, which include other transcriptional (eg, AHR-ARNT and NF- κ B),^{33,34} posttranscriptional (microRNAs),^{35–38} and posttranslational (eg, phosphorylation and acetylation) modifications.^{39,40} We

Figure 1 Intracellular distribution and Exocytosis or destruction of AuNDs in THP-1. The PMA-activated THP-1 cells were treated with 1 mg/mL AuNDs (blue), followed by staining with LysoTracker ((A), red) and MitoTracker ((B), red); (C) After 24 h treatment, AuNDs were removed through replacement with a new culture medium for another 48 h. The cells were stained with LysoTracker (red) and examined using confocal microscopy (magnification 1200 \times).

used the ARE reporter system to evaluate whether AuNDs activate the Nrf2 pathway in THP-1 cells and found that both AuNDs-NH₂ and AuNDs-CH₃ can activate Nrf2 (Figure 3A). Because none of the three types of AuNDs caused oxidative stress in cells and AuNDs-NH₂ only transiently triggered ROS disturbance at 10 min, we speculated that AuNDs may activate

Nrf2 through Keap1-independent mechanisms by activating intracellular kinases or other noncanonical pathways, such as the autophagic pathway-associated protein P62. Our results revealed that AuNDs-NH₂ caused Nrf2 Ser40 phosphorylation, and Nrf2 translocated to the nucleus (Figure 3B and C) through the canonical pathway.

Figure 2 ROS levels after AuNDs treatment in THP-1 cells. THP-1 cells were activated using PMA for 3 days, and cells were cultured with sera-free medium for 24 h after PMA removal. The intracellular ROS were determined at (A) 24 h; (B) 1, 3, 5, and 24 h through flow cytometry; and (C) 10 and 30 minutes using a fluorescent microplate reader. ** $P < 0.01$ and *** $P < 0.001$ compared with the cell control group.

Ser349 phosphorylation of P62 binds to Keap1, separating Nrf2 from Keap1, and Nrf2 can then enter the nucleus to activate downstream genes through noncanonical pathways. Blockage of autophagosome maturation and accumulation of P62 result in prolonged Nrf2 activation in a P62-concentration-dependent manner.⁴¹ We found that AuNDs-CH₃ induced P62 Ser349 phosphorylation (Figure 3D), suggesting that AuNDs-CH₃ activate Nrf2 through the P62–Keap1–Nrf2 non-canonical pathway. P62 is an autophagy adaptor protein, which mediates the formation of protein aggregates intended for autophagy turnover. This means that P62 facilitates selective degradation of protein cargo through activating autophagy.⁴¹ The direct interaction between P62 and Keap1 allows Keap1 sequestration into the autophagosomes, leading to impairment of Nrf2 ubiquitylation and activation of the

Nrf2 signaling pathway.⁴¹ Our result indicated that AuNDs-NH₂ and AuNDs-CH₃ may activate Nrf2 through different pathways. However, the role of Nrf2 activation by AuNDs-CH₃ through the P62-dependent pathway needs further study. Moreover, we found that AuNDs-NH₂ and AuNDs-CH₃ can induce mRNA levels of *HO-1* and *NQO1* in THP-1 cells, but the increase in the levels of HO-1 and NQO1 in AuNDs-NH₂-treated cells was significantly greater than that in AuNDs-CH₃-treated cells (Figure 3E and F).

AuNDs-NH₂ Activate Antioxidant Enzyme Activities

We further examined the activities of several Nrf2-mediated antioxidant enzymes in AuNDs-treated cells. Our results revealed that the activities of NQO1, GPx,

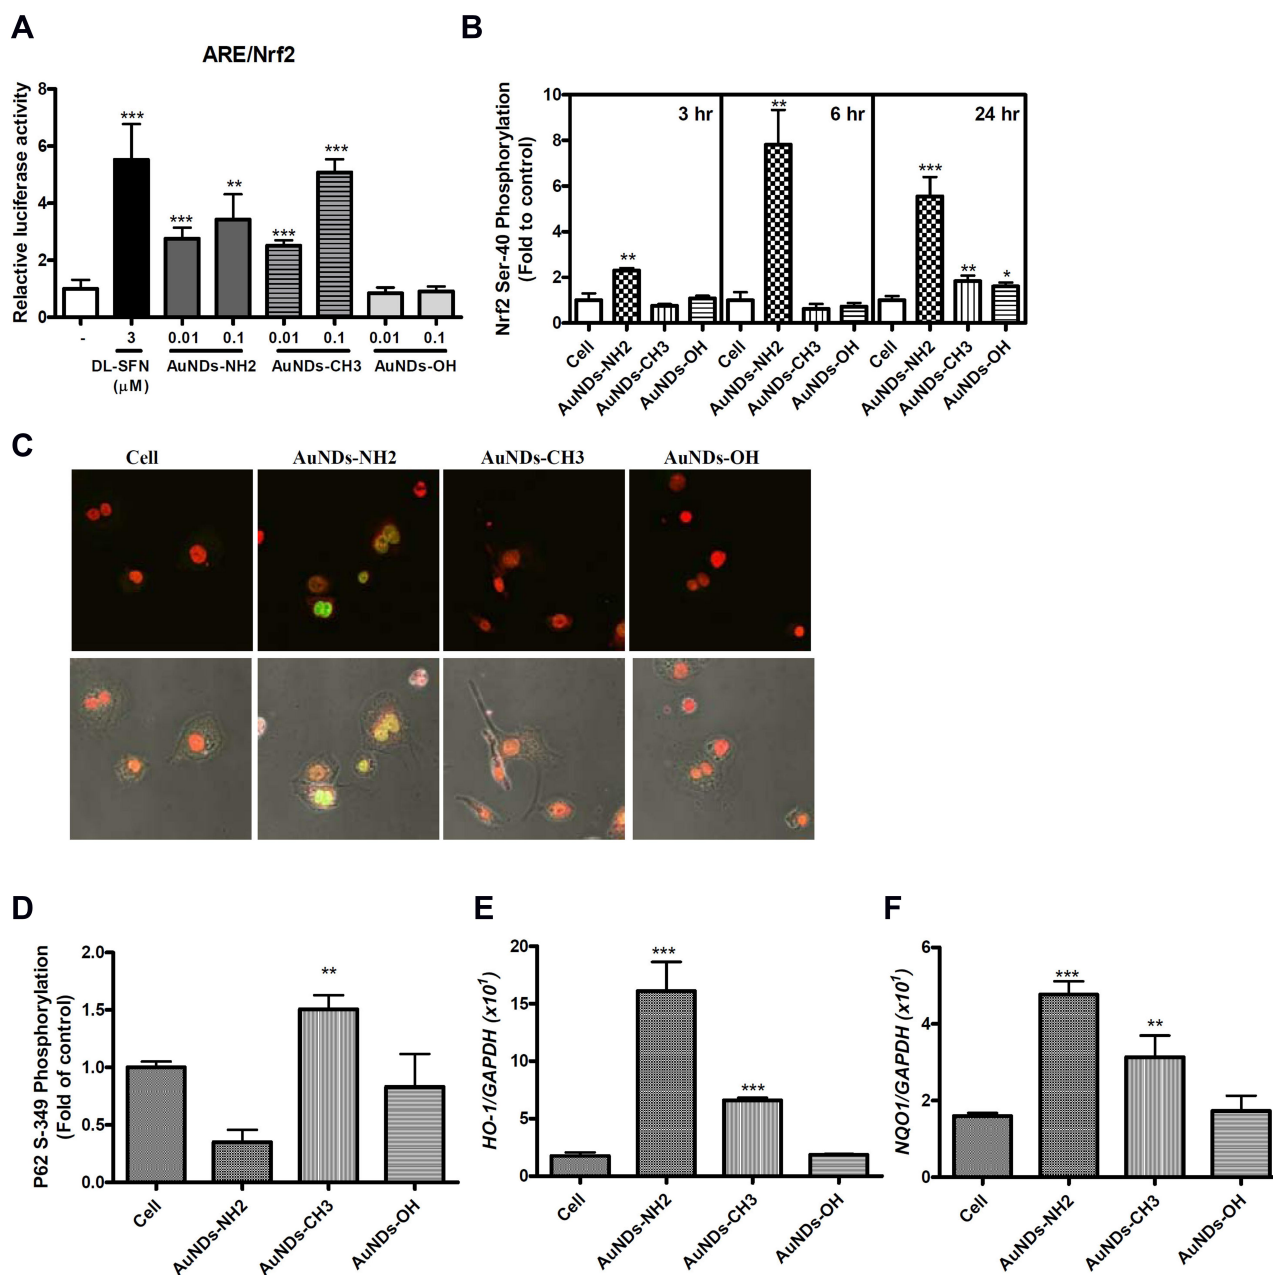

Figure 3 Nrf2 activation and phosphorylation of AuNDs-treated THP-1 cells. THP-1 cells were activated using PMA for 3 days, and cells were cultured with sera-free medium 24 h after PMA removal. (A) Nrf2 activation was determined after 24 h treatment using the ARE-driven reporter system in THP-1 cells. DL-Sulforaphane (DL-SFN), an Nrf2 activator, was used as the positive control. (B) Flow cytometry measurement of nuclear Nrf2 phosphorylation was conducted at 3, 6, and 24 h of AuNDs treatment. (C) Nrf2 phosphorylation of AuNDs-NH2-treated cells was examined using confocal microscopy. (D) Flow cytometry measurement of p62 phosphorylation was conducted at 24 h after AuNDs treatment. (E and F) The *HO-1* and *NQO1* mRNA levels determined after 24 h treatment using quantitative PCR. * $P < 0.05$, ** $P < 0.01$, and *** $P < 0.001$ compared with the cell control group.

catalase, and GST increased after 48 h of AuNDs-NH2 treatment (Figure 4). Similarly, AuNDs-CH3 increased activities of NQO1 and catalase (Figure 4A and D). Next, we used a Nrf2 inhibitor, ML385, to investigate whether the Nrf2 activations can be restored in AuNDs-NH2-treated cells. ML385 is mainly bound with the Neh1 domain of Nrf2, which interferes with the binding of Nrf2 and thus affects the combination of Nrf2 and the

ARE element.⁴² Our results revealed that mRNA levels of *HO-1* and *NQO1* were reduced through pretreatment with the ML385 inhibitor (Figure 5B and C). tBHQ was a positive control for Nrf2 activation (Figure 5A). However, ML385 did not inhibit *HO-1* mRNA expression in AuNDs-CH3-treated cells (Figure 5B). This indicates that AuNDs-CH3 may also affect other pathways involved in the regulation of HO-1. In addition to Nrf2,

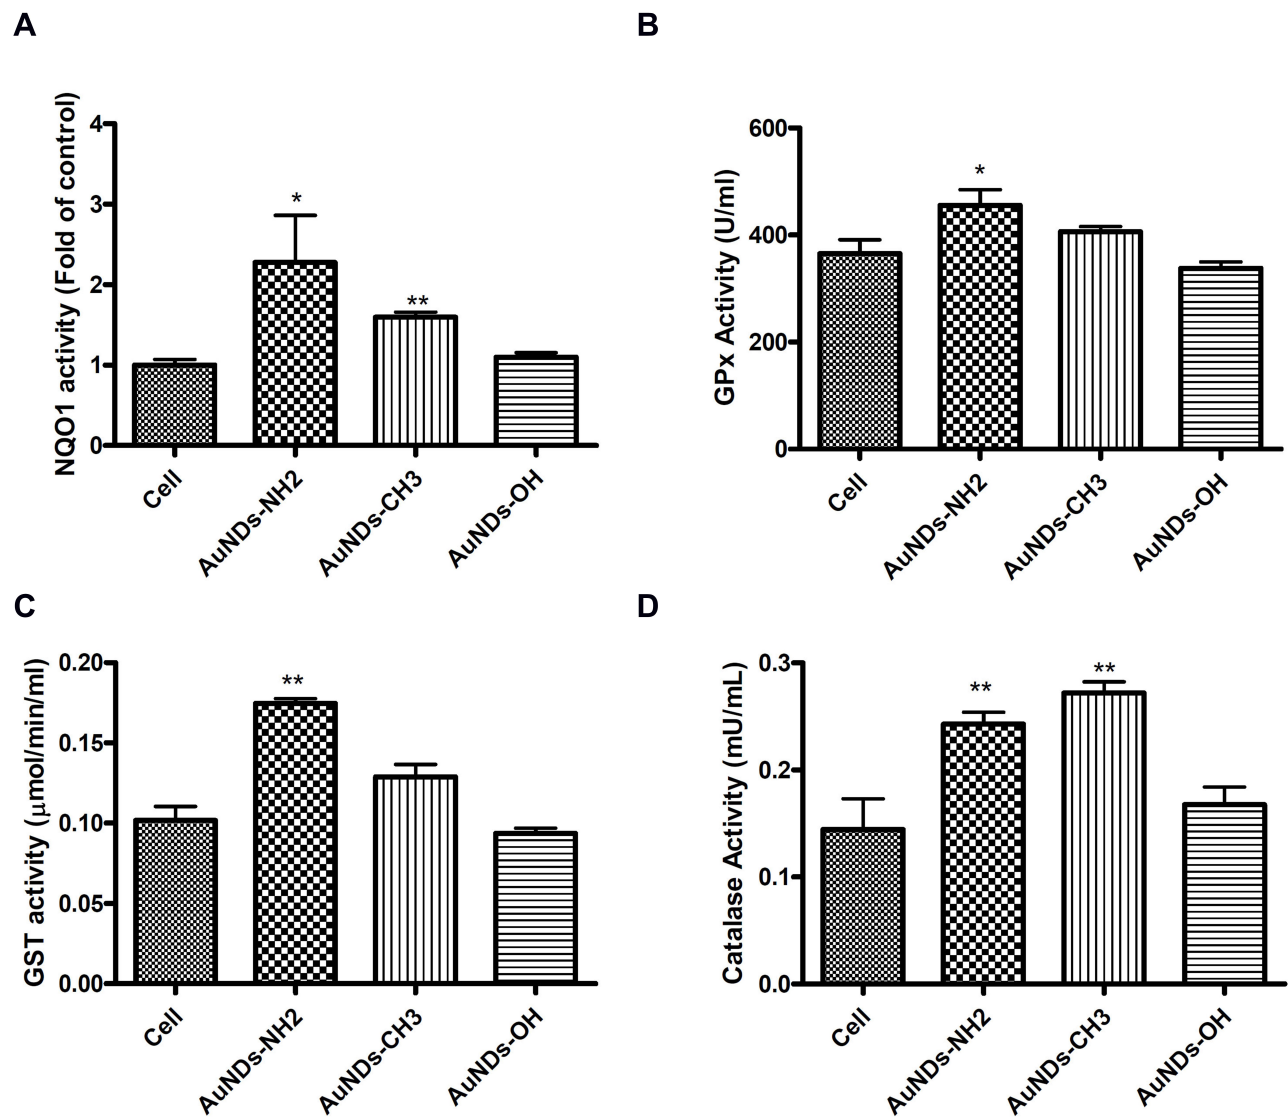

Figure 4 Antioxidant enzymes in AuNDs-treated cells. THP-1 cells were activated using PMA for 3 days, and cells were cultured with sera-free medium 24 h after PMA removal. (A) NQO1, (B) GPx, (C) GST, and (D) catalase enzyme activities were measured after 48 h in AuNDs-treated THP-1 cells. * $P < 0.05$ and ** $P < 0.01$ compared with the cell control group.

several transcription factors such as activator protein-1, nuclear factor- κ B, and some upstream kinases have been identified as regulators of *HO-1* gene induction.⁴³

Nrf2 Modulated Expression of Proinflammatory Cytokines in AuNDs-Treated Macrophages

Many studies have suggested that Nrf2 is essential for the control of inflammation.^{4,5,44,45} Kobayashi et al⁵ reported that Nrf2 binds to the upstream regions of the *IL6* and *IL1b* genes leading to interferes with LPS-induced transcriptional upregulation of proinflammatory cytokines. Therefore, we investigated the expression levels of these proinflammatory

genes in AuNDs-treated cells. We found that AuNDs-NH2 upregulated *IL-1 β* and *IL-6* mRNA and protein expression (Figure 6). The Nrf2 inhibitor ML385 significantly reduced the AuNDs-NH2-induced increase in *IL-6* expression in macrophages (Figure 6B and D). However, ML385 pretreatment did not affect *IL-1 β* expression in AuNDs-NH2-treated cells (Figure 6A and C). ML385 blocked Nrf2 transcriptional activity by binding to the DNA-binding domain of Nrf2. AuNDs-NH2 increased the expression of *IL-1 β* from 50 to 150 pg/mL and of *IL-6* from 10 to 25 pg/mL. Nrf2 is required for the assembly of NLRP3 inflammasome activators, including the apoptosis-associated speck-like protein containing a caspase recruitment domain (ASC) adaptor, which may promote *IL-1 β* production.^{46,47} Our data indicated that

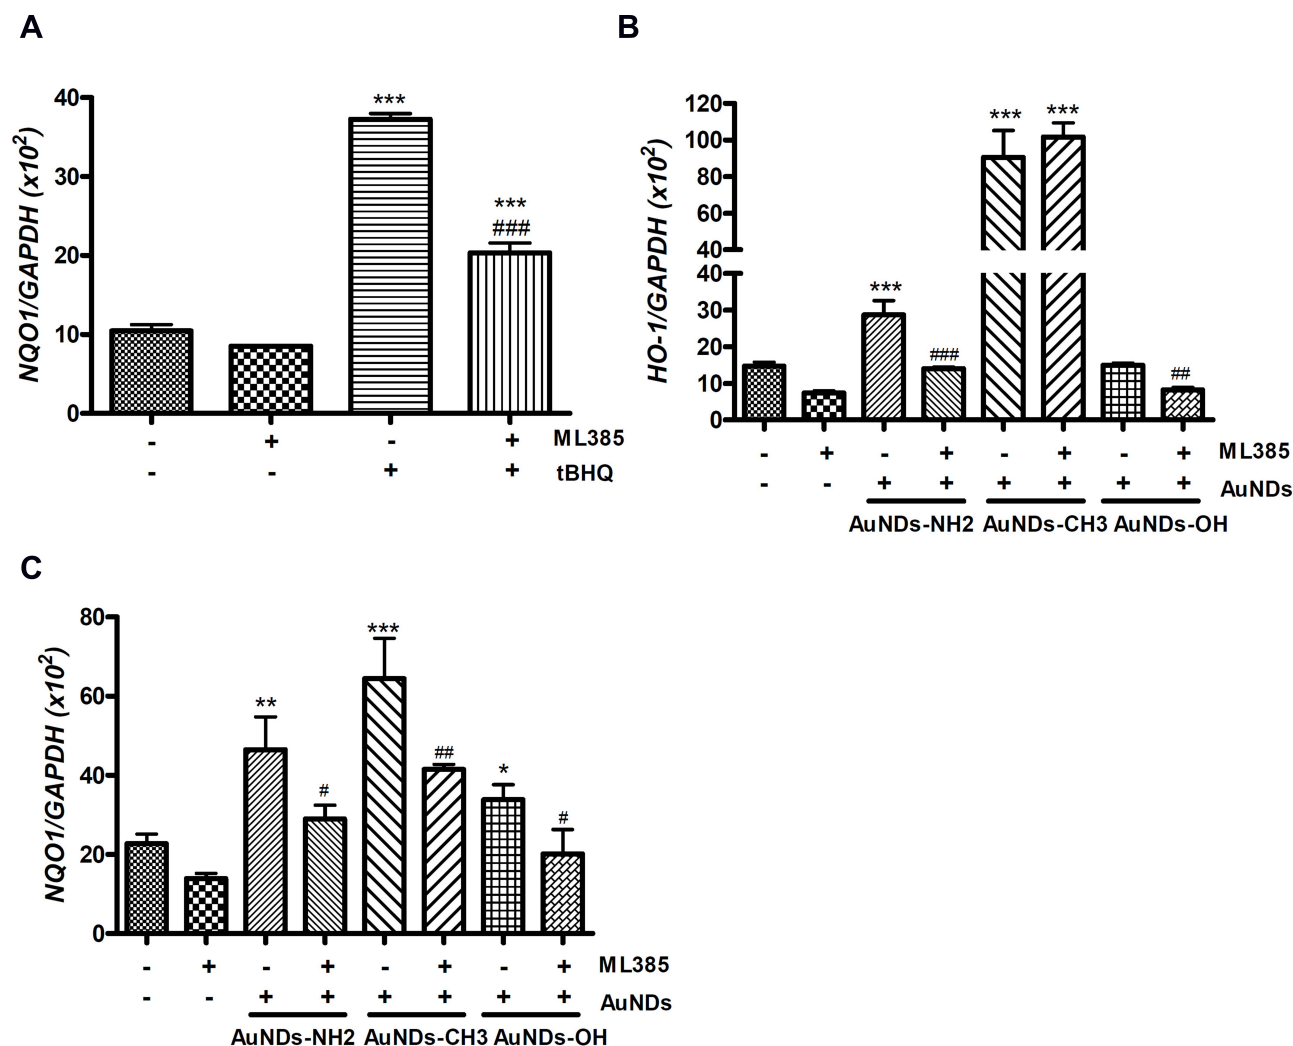

Figure 5 The mRNA levels of *HO-1* and *NQO1* in AuNDs-treated cells with ML385 pretreatment. THP-1 cells were activated using PMA for 3 days, and cells were cultured with sera-free medium for 24 h after PMA removal. (A) tBHQ was a positive control for activation of Nrf2 and the inhibitory effect of ML385 pretreatment. The mRNA levels of (B) *HO-1* and (C) *NQO1* were determined after AuNDs treatment at 48 h using quantitative PCR. * $p < 0.05$, ** $p < 0.01$, and *** $p < 0.001$ compared with the cell control group. # $p < 0.05$, ## $p < 0.01$, and ### $p < 0.001$ compared with the AuNDs-treated group without ML385 pretreatment.

AuNDs-NH2-induced increased IL-1 β productions may be irrelevant to the transcriptional control of Nrf2. It was reported that the ARE element sequence is found in the promoter region of IL-6, so Nrf2 can regulate IL-6 expression.⁴⁸ Our result indicated that AuNDs-NH2 directly regulates IL-6 expression via a Nrf2-dependent pathway.

AuNDs-NH2 Increase Phagocytic Ability in Macrophages

In addition to the regulation of antioxidant and inflammatory responses, Nrf2 was found to regulate the phagocytic capacity of immune cells.⁴⁹ Our result indicated that AuNDs-NH2 increased the phagocytic ability of human macrophages after 24 and 48 h of treatment. AuNDs-CH3 and AuNDs-OH also slightly affected phagocytosis at 24

h, but their effect was lower even than that of the control group at 48 h after treatment (Figure 7). ML385 reduced the effect of AuNDs-NH2 on phagocytosis, suggesting that Nrf2 participates in macrophage phagocytosis.

Discussion

Our results (Figure 8) revealed that AuNDs mainly accumulate in lysosomes. Nanoparticle-induced oxidative stress responses are torchbearers for further pathophysiological effects, including genotoxicity, inflammation, and fibrosis, through activation of associated cell signaling pathways.⁵⁰ None of the three AuNDs induced significant oxidative stress in macrophages. Only AuNDs-NH2 transiently increased ROS levels at 10 min after treatment and then decreased intracellular ROS levels in a time-

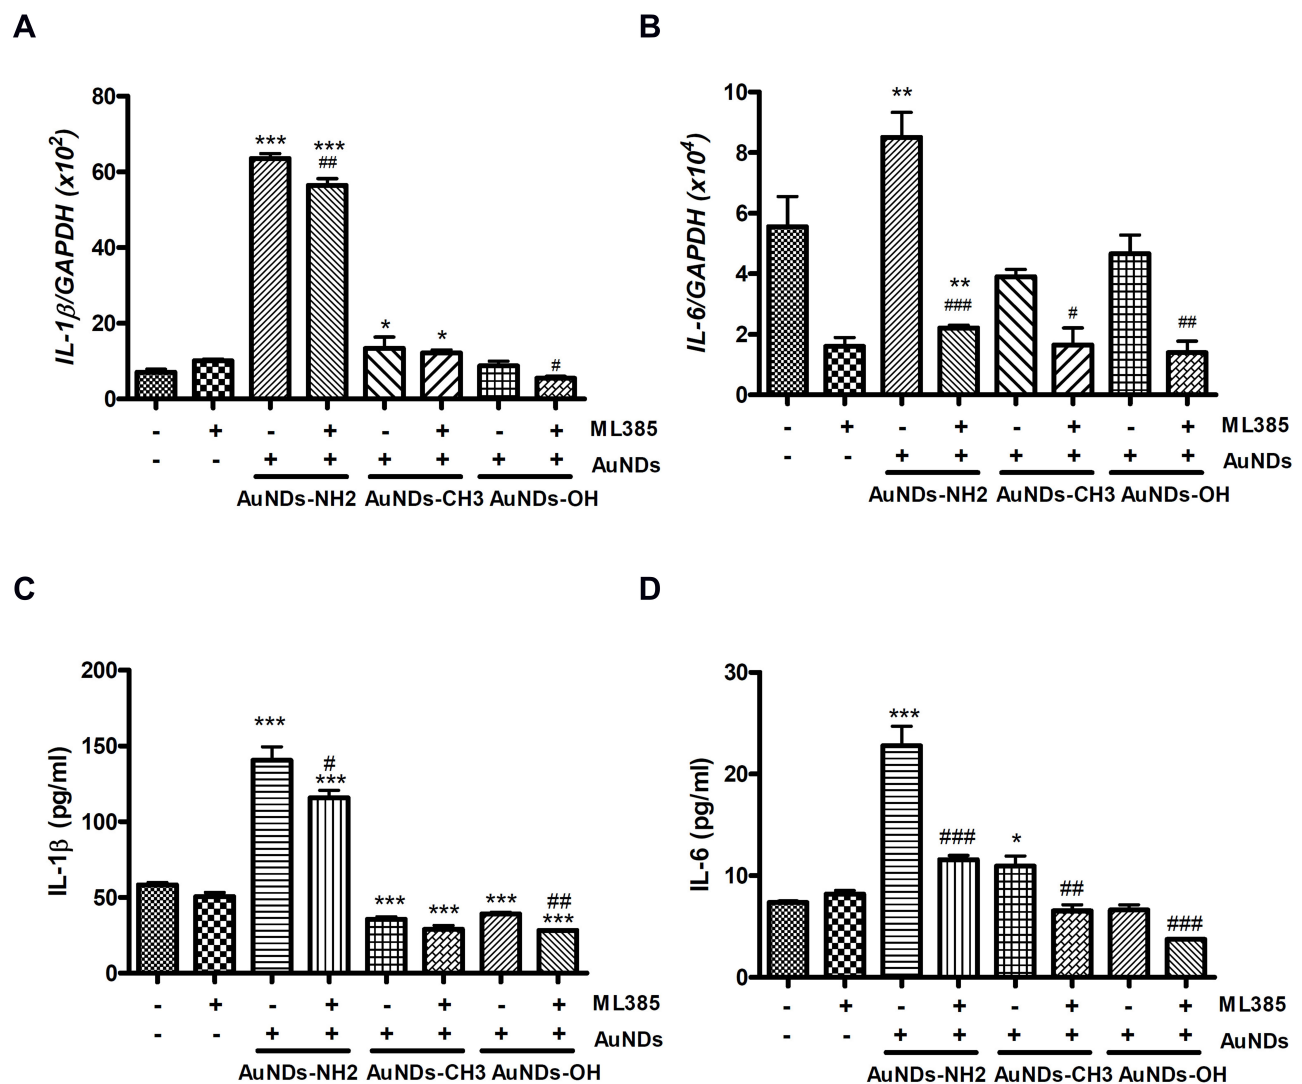

Figure 6 Nrf2 target cytokines were determined in AuNDs-treated cells. *IL-1β* and *IL-6* mRNA (**A** and **B**) and cytokine proteins (**C** and **D**) levels of AuNDs in THP-1 cells. THP-1 cells were activated through PMA for 3 days, and cells were cultured with sera-free medium 24 h after PMA removal. Cytokine mRNA and protein levels determined after 48 h treatment through quantitative PCR and ELISA. * $P < 0.05$, ** $P < 0.01$, and *** $P < 0.001$ compared with the cell control group. # $P < 0.05$, ## $P < 0.01$, and ### $P < 0.001$ compared with the AuNDs-treated group without ML385 pretreatment.

dependent manner. We speculated that this transient ROS perturbation may activate intracellular kinases to promote phosphorylation of Nrf2 Ser40, followed by the activation of Nrf2 downstream genes and the increase in antioxidant and phagocytic abilities.

Nrf2 plays a vital role in regulating cellular antioxidant and other cytoprotective responses, including purine, pentose, and lipid metabolisms, inflammation, and proteostasis,⁵¹ as well as cytoprotective mechanisms against various environmental stresses.⁵² Nrf2 is sequestered in the cytosol by Keap1 and constantly degraded by the ubiquitin–proteasome system under normal physiological conditions.⁵³ Oxidative stress and chronic inflammation may be as primary etiologic factors in many chronic diseases.⁵⁴ Nrf2 modulators

have been attracting attention as a promising therapeutic strategy for chronic diseases dominated by oxidative stress and inflammation, such as neurodegenerative,⁵⁵ cardiovascular, and metabolic diseases.^{10,51,56} Activation of endogenous antioxidant gene expression, modulated via the Nrf2 pathway, has a better neuroprotective effect than that afforded by conventional antioxidant therapy.^{57–59} In experimental models of asthma and chronic obstructive pulmonary disease (COPD), Nrf2 targeting also suppresses airway inflammation and oxidative stress.^{60,61}

In macrophage, Nrf2 acts as the upstream regulator of inflammatory cytokine production in a ROS-independent manner.⁵ Moreover, Nrf2 directly regulates the expression of several other macrophage-specific genes that are

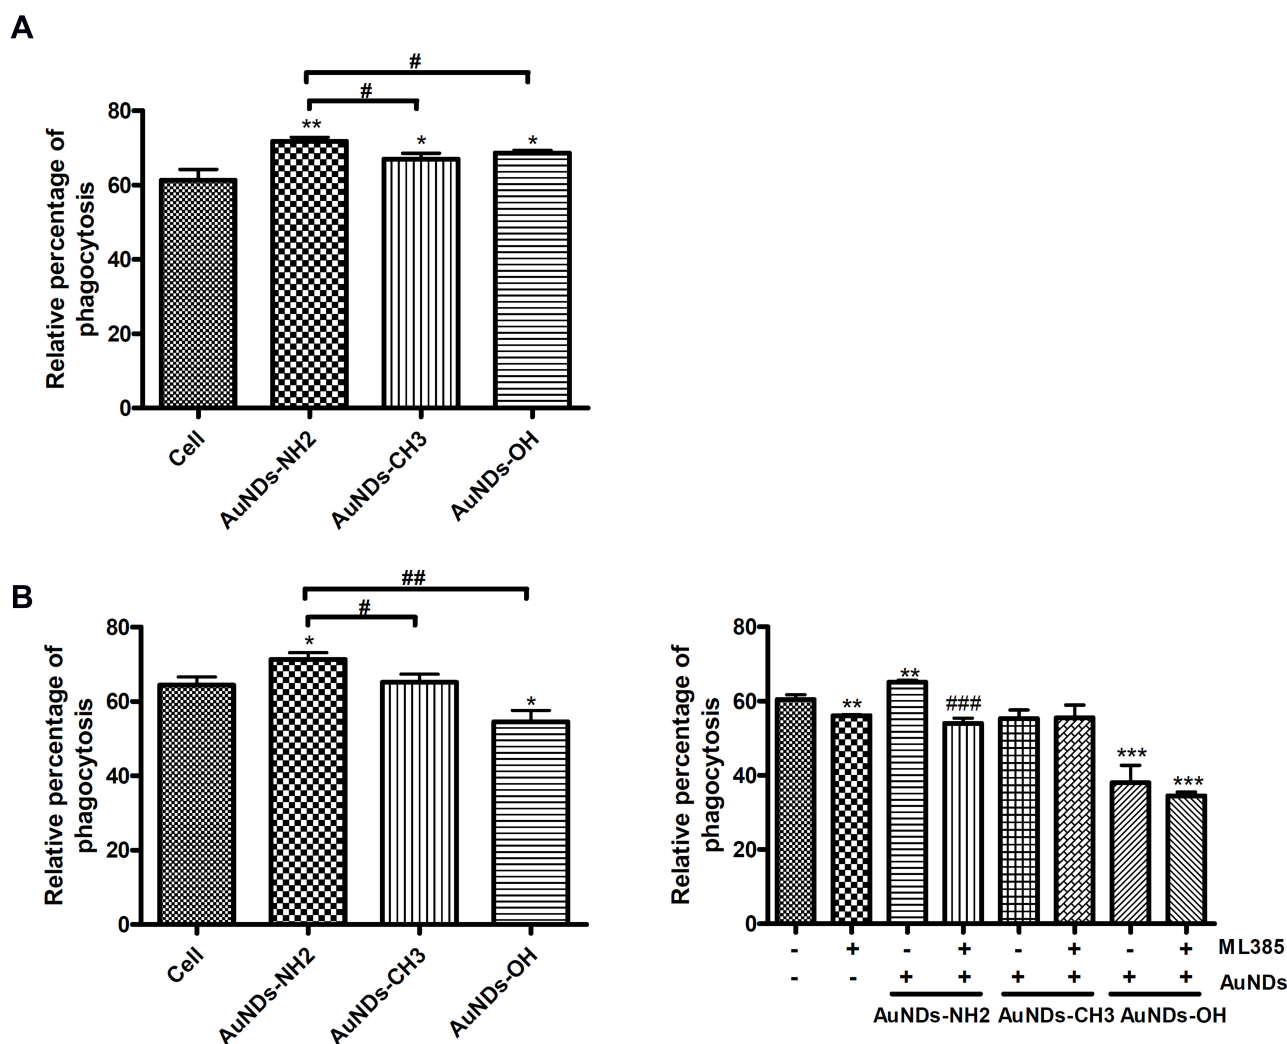

Figure 7 AuNDs-NH2 increased macrophage phagocytosis in an Nrf2-mediated manner. THP-1 cells were activated using PMA for 3 days, and cells were cultured with sera-free medium 24 h after PMA removal. Phagocytosis levels were determined after AuNDs treatment for (A) 24 and (B) 48 h with or without ML385 pretreatment. * $P < 0.05$, ** $P < 0.01$, and *** $P < 0.001$ compared with the cell control group. # $P < 0.05$, ## $P < 0.01$, and ### $P < 0.001$ compared with the AuNDs-treated group without ML385 pretreatment.

associated with phagocytosis and scavenger receptor for oxidized low-density lipoprotein.^{49,62} Our results indicated that AuNDs-NH2 upregulated IL-1 β and IL-6 mRNA and protein expression. Because the ARE element sequence is found in the promoter region of IL-6, Nrf2 may regulate IL-6 expression.⁵¹ ML385, an inhibitor of Nrf2 transcriptional activity, significantly reduced AuNDs-NH2-mediated Nrf2 activation and expression of *NQO1*, *HO-1*, and *IL-6* mRNA, as well as the phagocytic ability in macrophages. AuNDs-NH2-induced increased IL-1 β production may not occur through Nrf2 transcriptional regulation. However, further research is needed to determine whether AuNDs-NH2 activate Nrf2 to prevent LPS-induced proinflammatory cytokines. In addition, only AuNDs-NH2 increase phagocytic ability in macrophages via a Nrf2-mediated

pathway. Targeting Nrf2 signaling improves infection clearance by enhancing phagocytosis activity, which might be a therapeutic target. Harvey et al demonstrated that sulforaphane, which targets Nrf2 signaling, improves bacterial clearance by alveolar macrophages in patients with COPD and in a mouse model.⁴⁹ Furthermore, in a mouse model of papain-induced rhinosinusitis, disruption of the epithelial-specific Nrf2 pathway increased the severity of eosinophilic sinonasal inflammation.⁶³ In myeloid cell-specific Keap1-deficient mice model, activation of Nrf2 signaling in macrophages and neutrophils improves host survival by increasing antibacterial and anti-inflammatory defenses during sepsis.⁶⁴ Therefore, Nrf2 activators have pivotal immunomodulating effects on leukocytes to control bacterial infection and protect against sepsis.

Figure 8 Pictorial description of how the AuNDs mediated Nrf2, antioxidant enzyme activities, and phagocytosis abilities in macrophages.

The pharmacologic activators of Nrf2 can be classified as electrophiles, protein–protein interaction inhibitors, and multitarget drugs.⁵⁶ The most common Nrf2 activators are electrophilic molecules that covalently oxidated or alkylated cysteine residues present in the thiol-rich Keap1 protein.^{65–67} Protein–protein interaction inhibitors activate Nrf2 by interrupting the docking of Nrf2 to the Kelch propeller of Keap1, which exhibits better selectivity than electrophilic compounds.⁶⁸ Moreover, Nrf2 can be upregulated through Keap1-independent posttranslational modifications (eg, phosphorylation and acetylation). Several kinases have been linked to ARE activation, including extracellular signal-regulated kinase (ERK1/2),^{69,70} p38 mitogen-activated protein (MAP) kinase,⁷¹ glycogen synthase kinase 3 (GSK-3),⁴⁰ phosphatidylinositol 3-kinase and its downstream target Akt/protein kinase B (PKB), and protein kinase C (PKC).⁷² Future studies should clarify which mechanisms regulate Nrf2 activation in AuNDs-NH₂-treated cells. AuNDs-CH₃ did not affect intracellular ROS levels, but it may phosphorylate P62 Ser349 to activate the noncanonical P62–Keap1–Nrf2 pathway. The deficiency in autophagy upregulated P62, thereby inhibiting the Keap1–Cul3–E3 ubiquitin ligase complex and stabilizing Nrf2.⁷³ AuNDs-CH₃ affected Nrf2 activation and downstream genes but did not have

the obvious phagocytosis ability of AuNDs-NH₂. Additional experiments are warranted to determine whether AuNDs-CH₃ blocks autophagosome maturation and P62 accumulation, resulting in prolonged Nrf2 activation in a P62-concentration-dependent manner in macrophage. AuNDs-OH also did not affect intracellular ROS levels or activate the Nrf2 pathway, probably due to its surface modifications or insufficient amount entered the cells. Our result indicated that nanozymes not only exhibited intrinsic enzyme-like activity but also triggered intracellular signaling pathways in macrophages through modifications of superficial atoms of nanomaterials. However, future studies should investigate how out-facing groups of primary amine and quaternary ammonium ions in AuNDs phosphorylate different intracellular regulators (such as Nrf2 and P62), leading to different consequences including the expression of cytokine and phagocytic ability in macrophages.

Conclusions

Nrf2 can be a therapeutic target for chronic diseases, such as inflammation and cardiovascular diseases. Preclinical studies have reported that Nrf2 activation has potent anti-inflammatory effects in myeloid leukocytes and macrophages. To the best of our knowledge, this is the first

study demonstrating that Nrf2 and its downstream targets are induced in macrophages by AuNDs-NH₂ treatment without triggering excess oxidative stress. This finding may provide a rationale strategy for nanomaterials targeting the Nrf2 pathway against certain chronic inflammatory diseases.

International Journal of Nanomedicine

Dovepress

Publish your work in this journal

The International Journal of Nanomedicine is an international, peer-reviewed journal focusing on the application of nanotechnology in diagnostics, therapeutics, and drug delivery systems throughout the biomedical field. This journal is indexed on PubMed Central, MedLine, CAS, SciSearch®, Current Contents®/Clinical Medicine,

Journal Citation Reports/Science Edition, EMBase, Scopus and the Elsevier Bibliographic databases. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/international-journal-of-nanomedicine-journal>
