**Purpose:** Programmed death-ligand 1 (PD-L1) has been widely used as a prognostic biomarker and an immunotherapeutic target in numerous cancers, but information on the clinical significance of its expression in endometrial serous carcinoma (ESC) is largely lacking. Here, we evaluate the predictive value of PD-L1 expression in ESC.

**Materials and Methods:** A total of 79 cases of ESC accessioned between January 2003 and September 2015 were selected for further analysis. PD-L1 expression was evaluated in whole tissue sections of these cases by using the tumor proportion score (TPS, cut-off 1%) and combined positive score (CPS, cut-off 1) scoring methods.

**Results:** Overall, there was a heterogeneous expression of PD-L1, focal or patchy, in ESCs. PD-L1 positivity was observed in 43.0% of ESCs by TPS and 73.4% of ESCs by CPS. Kaplan–Meier survival analysis showed that patients with PD-L1-positive tumors suffered significantly worse OS and PFS, when compared with PD-L1 negative tumors (log-rank  $p = 0.037$  and  $p = 0.003$ , respectively). In contrast, PD-L1 positivity by CPS within the ESC cases showed no statistical significance for OS and PFS (log-rank  $p = 0.720$  and  $p = 0.928$ , respectively). Multivariate Cox analysis showed that PD-L1 positivity by TPS was significantly associated with PFS (HR = 1.921,  $p = 0.039$ ) but not OS (HR = 1.229,  $p = 0.631$ ).

**Conclusion:** PD-L1 expression is frequently found in ESC, suggesting a potential role of the PD-1/PD-L1 pathway as a potential therapeutic target for these tumors. PD-L1 expression by TPS also serves as a negative prognostic marker in ESC and implies an unfavorable outcome.

## Background

Endometrial carcinoma is the 6th leading cause of cancer-related death among women worldwide.<sup>1</sup> It can broadly be divided into two types: endometrioid carcinoma (type 1) and non-endometrioid carcinoma (type 2). Unlike type 1 carcinomas, type 2 carcinomas are highly aggressive and typically carry a poor prognosis.<sup>2</sup> Endometrial serous carcinoma (ESC) is a type 2 endometrial cancer with a high mortality and recurrence rate.<sup>3</sup> According to the Classification of Female Genital Tumors by World Health Organization (WHO 2020),<sup>4</sup> ESCs are subclassified into pure and mixed groups. At present, patients with ESC are treated with radical hysterectomy and pelvic lymphadenectomy, omentectomy with or without adjuvant chemoradiation therapies.<sup>5</sup> Regardless of therapy, the outcome of ESC patients tends to be poorer than patients with endometrioid carcinomas.<sup>6</sup> Notably, it has been proposed in recent years that similar genetic landscape cancers even without the same tissue or origin can be classified together.<sup>7,8</sup> According to this

classification, ESC and serous ovarian carcinoma can be considered as one category for similar cancer genetic drivers and progression mechanisms,<sup>9</sup> such as TP53 mutation.<sup>2</sup> Therefore, the treatment strategies of ovarian serous carcinoma carry significant potential value for ESC. Among different therapeutic strategies, novel immunotherapy such as Pembrolizumab gave the active response to advanced recurrent patients of ovarian serous carcinoma.<sup>10</sup> As such, novel immunotherapeutic strategies need to be developed and established for patients with ESC.<sup>6</sup>

Programmed cell death receptor 1 (PD-1) and its ligand (PD-L1) are playing a progressively important role in our understanding of tumor immunology and in cancer treatment. Binding of PD-L1 to its receptor PD-1 leads to an inactivation of T cells in a variety of cancers; thus, anti-PD-1/PD-L1 antibodies deregulate the adverse impact of tumor-infiltrating T cells, which in turn may reverse the tumor immune resistance.<sup>11,12</sup> Several studies have investigated PD-L1 expression and its prognostic values in endometrial cancer, but most of such studies focused on endometrioid carcinomas without considering ESC as a separate or independent group.<sup>13–19</sup> Of note, clinical trials with anti-PD-1 antibody (Pembrolizumab) have been performed in advanced recurrent endometrial cancer. Unfortunately, these trials did not separate ESCs from other histologic types of endometrial cancer.<sup>20</sup>

The relatively poorer outcome for patients with ESC using traditional treatment methods portends great importance in finding effective targeted immune. The main aim of our study is to investigate PD-L1 expression in and its prognostic value in ESC.

## Materials and Methods

### Patients

Female patients with a final histologic diagnosis of ESC between January 2003 and September 2015 in our Hospital were selected for further analysis. Hematoxylin and eosin (H&E) and immunohistochemistry (IHC) stained slides were reviewed by at least 2 gynecologic pathologists. All tumors were classified according to the WHO (2020) Classification of Female Genital Tumors.<sup>4</sup> Patients were clinically staged by using the FIGO (2018) system. Excluded cases included patients who had undergone their operations outside of our hospital or those with uterine tumor metastasis from other sources. Ultimately, 79 patients were included in the final cohort. Archived paraffin tissue blocks were obtained for all included

cases. All related clinical and pathologic data including age, body mass index (BMI), serum CA125 level, stage, ascites or peritoneal wash status, myometrial invasion, lymph node metastasis, lymphovascular space invasion (LVSI), residual disease status, treatment, and clinical prognosis were retrieved from the database of clinical information system. Overall survival (OS) was defined as the time (months) between the date of surgery/diagnosis and the date of the death. Progression-free survival (PFS) was defined as the time (months) between the date of initial treatment and the date of progression to new tumor event. The normal upper limitation of serum CA125 was defined as 35U/mL. Optimal cytoreductive surgery of cancer staged III–IV was defined as  $\leq 1$  cm maximal diameter of the largest residual tumor nodule at initial treatment.<sup>3</sup> Both the result of p16 and p53 were recorded. The study was approved by the Institutional Research Ethics Board at Zhejiang University School of Medicine Women's Hospital, China.

### Immunohistochemistry (IHC)

In brief, 4  $\mu$ m thick formalin-fixed, paraffin-embedded whole tissue sections were dried fixed on positively charged slides for 1 hour at 56 to 60°C. With antigen repaired, the slides were placed in the Autostainer Link 48 platform (Dako), where they were incubated with the monoclonal mouse anti-human PD-L1 antibody, clone 22C3 pharmDx (Dako, Santa Clara, CA), then the anti-mouse linker antibody and finally a substrate-chromogen solution (DAB). The incubation time and rinsing of slides between reagents was monitored. The reagent times were set in the Dako Link software. Slides were subsequently counterstained for 5 minutes with hematoxylin. Mounting was performed using non-aqueous, permanent mounting media. Positive and negative control tissue for the quality assurance of IHC was monitored.

### Analysis of PD-L1 Expression

Two pathologists independently reviewed and evaluated all the IHC-stained PD-L1 slides. Assessment of PD-L1 expression involved calculating the tumor proportion score (TPS) and combined positive score (CPS) as described previously.<sup>21,22</sup> Intra-tumoral and peri-tumoral immune cells, mainly lymphocytes and macrophages were counted. Of note, these cells were within one 20  $\times$  field of the tumor nest or edge. PD-L1 positivity was defined by using a cut-off score  $\geq 1\%$  for TPS and  $\geq 1$  for CPS. Of note, only the ESC areas were assessed in the cases of mixed ESC.

## Statistical Analysis

For the description of clinicopathological parameters, continuous variables are expressed as the mean  $\pm$  standard deviation (normally distributed) or median and 0–100th range (abnormally distributed), and categorical values are reported as frequencies. Chi-square or Fisher's exact test was used for cross-tables. Cox regression was used for multivariate analysis, with enter and forward selection. Kaplan–Meier survival analysis and Log rank test were used to assess the relationship between survival outcomes (OS and PFS) and PD-L1 expression. A significance level of 0.05 was used. IBM SPSS 20 (Armonk, NY) and GraphPad Prism 8 (San Diego, CA) were used for survival analysis.

## Results

### Clinicopathological Characteristics of Patients

Tissue samples of this study included 79 total hysterectomies and staging specimens. Among them, 45 cases were pure ESC and 34 were ESC mixed with endometrioid carcinoma. All pure ESCs and ESC areas in mixed ESCs

were p16 block positive and demonstrated p53 mutant expression. Patient age ranged from 49 to 84 with the mean of  $63 \pm 6.8$  years. Among the cases, 37 (46.8%) of 79 were aged older than 63 years, 31 (39.2%) had overweight (BMI  $\geq 25\text{kg/m}^2$ ), 19 (24.1%) had abnormal serum levels of CA125 ( $>35$  U/mL).

Regarding clinical staging information, 38 (48.1%) of the 79 cases had stage I disease, while 41 (51.9%) had stage II or above. As for the other prognosis-related parameters, 29 (35.4%) of 79 had deep myometrial invasion, 19 (24.1%) showed evidence of LVSI, 7 (8.9%) had more than 1cm residual disease, and 10 (12.7%) had positive malignant cells in ascites/peritoneal washes. Among all 79 cases, lymph node dissections were obtained in 70 cases, of which 16/70 (22.9%) had lymph nodal metastasis. The information on this baseline data is summarized in Table 1.

### Correlation of PD-L1 Expression with Clinicopathological Features in ESCs

As mentioned, we examined the PD-L1 expression both in tumor cells and in tumor-infiltrating immune cells, including lymphocytes and macrophages. Overall, there was

**Table 1** PD-L1 Expression in Relation to Clinicopathological Parameters

Variable	Category	TPS (n)		p-value	CPS (n)		p-value

	Positive	3	7		2	8	

**Note:** <sup>†</sup>p < 0.05, Chi-square or Fisher's exact test was used.

**Abbreviations:** PD-L1, Programmed death-ligand 1; TPS, tumor proportion score; CPS, combined positive score; MI, Myometrial invasion; LNM, Lymph node metastasis; LVSI, Lymphovascular space invasion; RD, residual disease.

**Figure 1** PD-L1 expression in endometrial serous carcinoma. (A–C) Representative area of endometrial serous carcinoma at medium power (H&E, 200x); (D) Corresponding negative PD-L1 expression; (E) Corresponding PD-L1 expression in tumor cells; (F) Corresponding PD-L1 expression in immune cells.

a heterogeneous expression of PD-L1, focal or patchy, in ESCs (Figure 1). Using TPS, PD-L1 expression was seen in 43.0% ( $n = 34$ ) of the 79 ESC cases studied. Using CPS, PD-L1 expression was seen in 73.4% ( $n = 58$ ) of 79 ESC cases.

The association of PD-L1 positivity by TPS and clinicopathological variables in ESC cases was analyzed. A statistical correlation was found between PD-L1 positivity by TPS and clinicopathological parameters, including age  $\leq 63$  years ( $p = 0.025$ ), stage II–IV ( $p = 0.015$ ), myometrial invasion  $\geq 50\%$  ( $p = 0.001$ ), and presence of LVSI ( $p = 0.002$ ). However, there was no significant difference between PD-L1 positivity by CPS and clinicopathological parameters (Table 1).

## Prognostic Significance of PD-L1 Expression and Clinicopathological Features in ESCs

Univariate analysis showed that PD-L1 positivity by TPS (HR: 2.132;  $p = 0.043$ ), elevated serum CA125 (HR: 2.458;  $p = 0.019$ ), advanced stage (HR: 5.276;  $p < 0.001$ ), myometrial invasion  $\geq 50\%$  (HR: 2.925;  $p = 0.004$ ), LVSI (HR: 2.319;  $p = 0.032$ ), and positive ascites (HR: 2.661;  $p = 0.034$ ) were related to poor OS in patients with ESC. Variables with  $p < 0.05$  in the univariate analysis were used in the multivariable model by using an enter and forward stepwise selection. Only advanced stage (HR: 4.491;  $p = 0.001$ ) and myometrial invasion  $\geq 50\%$  (HR:

**Table 2** Univariate and Multivariate Analysis of the Clinicopathologic Parameters and OS

TPS of PD-L1 (Negative vs Positive)	2.132	0.043 <sup>†</sup>	1.229	0.531–2.843	0.631
CPS of PD-L1 (Negative vs Positive)	1.167	0.722	-	-	-

**Note:** <sup>†</sup> $p < 0.05$ , Cox regression was used for multivariate analysis, with enter and forward selection.

**Abbreviations:** BMI, body mass index; MI, myometrial invasion; LNM, lymph node metastasis; LVSI, lymphovascular space invasion; RD, residual disease; TPS, tumor proportion score; CPS, combined positive score; HR, hazard ratio; CI, confidence interval.

2.192;  $p = 0.039$ ) were found to be the prognostic factors of poor OS in the final multivariate Cox model (Table 2).

The univariate analysis showed that poor PFS was linked with PD-L1 positivity by TPS (HR: 2.380;  $p = 0.005$ ), elevated serum CA125 (HR: 2.312;  $p = 0.009$ ), advanced stage (HR: 3.139;  $p < 0.001$ ), myometrial invasion  $\geq 50\%$  (HR: 2.046;  $p = 0.019$ ), lymph node metastasis (HR: 2.134,  $p = 0.032$ ), LVSI (HR: 2.149;  $p = 0.019$ ), residual disease  $> 1$ cm (HR: 2.888;  $p = 0.017$ ), and positive ascites (HR: 3.361;  $p = 0.002$ ). Meanwhile, parameters adjusted by the univariate model were enrolled for analyzing in multivariate Cox model, and the results showed that PD-L1 positivity by TPS (HR: 1.921;  $p = 0.039$ ) and advanced stage (HR: 2.724;  $p = 0.003$ ) were independent prognostic factors of poor PFS (Table 3).

## PD-L1 Expression Inversely Correlates with PFS and OS in ESCs

Available complete follow-up information was included in a survival analysis for 79 patients with ESC. The median follow-up time was 66 months (range from 6 to 168). Kaplan–Meier survival analysis showed that patients with PD-L1-positive tumors suffered significantly worse OS, when compared with PD-L1 negative tumors (log-rank  $p = 0.037$ ) (Figure 2A). Similarly, patients with PD-L1 positive tumors suffered significantly worse PFS than did those with PD-L1-negative tumors ( $p = 0.003$ ; Log rank test) (Figure 2C). In contrast, PD-L1 positivity by CPS

within the ESC cases showed no statistical significance for OS and PFS (Figure 2B and D).

## Discussion

Immunotherapy has been applied in clinical pathology at a robust rate due to promising effects in numerous solid tumors, including gynecologic tumors.<sup>23–25</sup> However, the role of PD-L1 expression has not been clear in ESCs, largely due to limited available survival-based evidence. In this study, we analyzed PD-L1 expression in ESC tumors and correlated its expression with clinicopathologic parameters and survival outcomes to enhance our understanding of the role of the PD-1/PD-L1 pathway as a potential therapeutic target for this kind of tumor.

In our cohort, the prevalence of PD-L1 positivity in ESCs was 43.0% by TPS (cut-off 1%) and 73.4% by CPS (cut-off 1). In addition, PD-L1 positivity by TPS was linked to a poorer outcome in ESC patients, and it was an independent prognostic factor. However, PD-L1 positivity by CPS within the ESC cases showed no statistical significance for OS and PFS. Currently, studies on the association between PD-L1 positivity and survival from ESC are lacking. We could not correlate our ESC-specific data to other studies, as none of the other groups separately analyzed this tumor type. Notably, Gulec et al demonstrated that PD-L1 positivity (cut off  $> 5\%$  tumor cells) was an independent poor predictor of non-endometrioid endometrial cancers. PD-L1 expression in tumor cells was

**Table 3** Univariate and Multivariate Analysis of the Clinicopathologic Parameters and PFS

Variable	Univariate		Multivariate (Enter/[Forward] Selection)

associated with shorter OS, but PD-L1 expression in immune cells was not related with OS.<sup>14</sup>

In addition, we found that elevated serum CA125, advanced stage, deep myometrial invasion, lymph node

metastasis, LVSI, residual disease >1cm and positive ascites were independent prognostic factors in ESC patients. Comparable findings have been reported elsewhere. Olawaiye et al reported that elevated serum

**Figure 2** Kaplan-Meier curves of overall survival (OS) and progression-free survival (PFS) in patients with endometrial serous carcinoma (ESC). (A) OS in PD-L1-negative group (green) and PD-L1-positive group (blue) using tumor proportion score (TPS) (cut off 1%). (B) OS in PD-L1-negative group (green) and PD-L1-positive group (blue) using combined positive score (CPS) (cut off 1). (C) PFS in PD-L1-negative group (green) and PD-L1-positive group (blue) using TPS (cut off 1%). (D) PFS in patients in PD-L1-negative group (green) and PD-L1-positive group (blue) using CPS (cut off 1).

CA125 levels correlated with advanced stage of ESC.<sup>26</sup> Some studies have observed that deep myometrial invasion was linked with worse outcome in ESC patients.<sup>27–29</sup> The incidence of lymph node metastasis is more common in ESC than in endometrioid carcinoma,<sup>30–33</sup> and lymphadenectomy was associated with improved OS in ESC patients.<sup>34</sup> Studies have demonstrated that LVSI was an independent prognostic factor for ESC patients.<sup>35,36</sup> Garg et al showed that the risk of death was 4.3 times higher among stage IA ESC patients with positive peritoneal cytology compared to the negative cytology group.<sup>37</sup> Our findings are similar to previously published observations that optimal cytoreduction correlates with improved outcomes for patients with ESC.<sup>38–40</sup> Of note, we found that PD-L1 positivity in tumor cells was significantly correlated with advanced stage, deep myometrial invasion and LVSI.

Our study has several strengths relative to the previous studies. To our knowledge, our study is the first of this kind to focus on a large cohort of ESCs, especially considering the relative rarity of this kind of tumor. We utilized whole tissue sections to reduce sampling bias because of the frequent PD-L1 intra-tumor heterogeneity. Moreover, the genomic data from The Cancer Genome Atlas (TCGA) defined endometrial cancer types into four molecular subgroups: polymerase epsilon (POLE) ultra-mutated, microsatellite instability, copy-number low, and copy-number high.<sup>41</sup> Most of the copy-number-high tumors had TP53 mutations and diagnosed as high-grade serous cancers. Currently, analysis of TP53 mutations or p53 expression by IHC has been suggested as a reliable marker for these tumors.<sup>42</sup> Of note, all ESC cases studied here were p53 mutant type by IHC analysis. Thus, our data may potentially provide clinically useful information benefiting those copy-number-high tumors with PD-L1 expression.

Our study also has limitations, notably that 34 mixed ESC cases were included and the lack of external validation in this ESC cohort. Such lack of external validation reflects the novelty of this study. Potential biases were also present, which were caused by other residual confounding factors, such as not adjusting ESC cases by TCGA classification, diabetes status, etc. Therefore, ESC areas should be confirmed by analysis of TP53 mutations in addition to p53 expression by IHC in the future. Intra-tumoral lymphocytes and macrophages usually have membranous staining, which may be misinterpreted as tumor cells. Future studies with a larger cohort and new testing such

as multiplex IHC will be needed to further validate our findings.

## Conclusion

In summary, PD-L1 is commonly expressed in tumor cells as well as in immune cells within the ESC cases we studied. Such observation suggests that immune therapy by targeting the PD-1/PD-L1 pathway may represent an alternative therapeutic choice for ESC. This may be particularly useful for those cases showing PD-L1 expression in ESC tumor cells because patients with such tumors have a worse outcome than those patients with negative PD-L1 expression.

## Abbreviations

ESC, endometrial serous carcinoma; PD-L1, programmed death-ligand 1; IHC, immunohistochemistry; BMI, body mass index; MI, myometrial invasion; LNM, lymph node metastasis; LVSI, lymphovascular space invasion; RD, residual disease; TPS, tumor proportion score; CPS, combined positive score; OS, overall survival; PFS, progression-free survival; HR, hazard ratio; CI, confidence interval.

## Data Sharing Statement

The datasets generated or analyzed during the current study available from the corresponding author on reasonable request.

## Ethics Approval and Consent to Participate

The study was approved by the Institutional Research Ethics Board at Zhejiang University School of Medicine Women's Hospital, China (No: IRB-20200281-R). All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and/or national research committee and with the Helsinki declaration. Each enrolled patient permitted and signed up informed consent to use their samples and records for scientific research.

## Acknowledgments

We are grateful to Junjie Zhu (Department of Epidemiology, School of Public Health, Fudan University, Shanghai, China/Department of Epidemiology and Health Statistics, School of Public Health, Dali University, Dali, China) for statistical technical assistance.

## Cancer Management and Research

Dovepress

### Publish your work in this journal

Cancer Management and Research is an international, peer-reviewed open access journal focusing on cancer research and the optimal use of preventative and integrated treatment interventions to achieve improved outcomes, enhanced survival and quality of life for the cancer patient.

The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/cancer-management-and-research-journal>
