# Digestive symptoms of COVID-19 and expression of ACE2 in digestive tract organs

Jiabin Xu<sup>1,2,3</sup>, Mei Chu<sup>4</sup>, Fan Zhong<sup>4,5</sup>, Xinghua Tan<sup>4</sup>, Guofang Tang<sup>4</sup>, Jianbo Mai<sup>4</sup>, Niangmei Lai<sup>4</sup>, Chenyu Guan<sup>1,2,3</sup>, Yujie Liang<sup>1,2,3</sup> and Guiqing Liao<sup>1,2,3</sup>

## Abstract

SARS-CoV-2 has resulted in numerous cases of Coronavirus Disease 2019 (COVID-19) worldwide. In addition to fever and respiratory symptoms, digestive symptoms also are observed in some patients with COVID-19. Angiotensin-converting enzyme 2 (ACE2) was reported to be the receptor for SARS-CoV-2. The aim of this study was to comprehensively investigate the digestive symptoms that occur in COVID-19 patients, and the potential pathogenic route of the SARS-CoV-2 infection in digestive tract organs (from the oral cavity to the gastrointestinal tract). We investigated the digestive symptoms of 48 patients with COVID-19 and explored ACE2 expression in digestive tract and lung cancers, based on a series of bulk and single-cell RNA sequencing data obtained from public databases. We found that 25% (12/48) of the patients with COVID-19 suffered from digestive symptoms, among which pharyngalgia (7/48) was the most common manifestation, followed by diarrhea (3/48), anorexia (3/48), and nausea (1/48). The bulk tissue RNA sequencing analysis indicated that digestive tract organs had higher ACE2 expression levels compared to the lung, and the expression of ACE2 in the lung increased with age. Single-cell RNA-Seq results showed that the ACE2-positive-cell ratio in digestive tract organs was significantly higher compared to the lung. ACE2 expression was higher in tumor cells compared to normal control (NC) tissues. While in gastric tissues, ACE2 expression gradually increased from chronic gastritis to metaplasia, to early cancer. Our data might provide a theoretical basis for screening the SARS-CoV-2 susceptible population and for the clinical classification of treatment of patients with COVID-19.

## Introduction

The global pandemic, Coronavirus Disease 2019 (COVID-19), caused by Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) infection<sup>1</sup>, has been raging throughout the world. By June 25, 2020, COVID-19 has been found in 215 countries, with a total of >9.2 million confirmed cases worldwide, including over 479,000 deaths<sup>2</sup>.

It has been established that SARS-CoV-2 invades host cells by binding to the transmembrane receptor Angiotensin-converting enzyme 2 (ACE2)<sup>3</sup>, which also is the receptor for SARS-CoV and HCoV-NL63<sup>4,5</sup>. ACE2 plays a crucial role in the cellular entry for SARS-CoV-2, which means that ACE2-positive cells may act as target cells and are susceptible to infection<sup>6</sup>. Thus, the expression of ACE2 might affect the invasion path and pathogenicity of the virus.

The common symptoms of COVID-19 include fever, fatigue, cough, myalgia, and dyspnea<sup>7–9</sup>. Also, some patients may suffer from digestive system symptoms, such as pharyngalgia, diarrhea, nausea, vomiting, and abdominal pain<sup>10</sup>, suggesting that the digestive tract organs also may be targeted by the virus. Studies have reported that ACE2 was expressed in lung, esophagus epithelial cells, ileum<sup>11</sup>, colon<sup>12</sup>, kidney, bladder<sup>13</sup>, and oral mucosa<sup>14</sup>. However,

information is lacking concerning the comparative analysis of ACE2 expression in the entire digestive tract from the oral cavity through the gastrointestinal tract. The oropharynx and gastrointestinal tract are physiologically interlinked and share similar microbial environments<sup>15</sup>. They also share similarities with respect to the micro-environment associated with epithelial carcinogenesis. Reports show that oral bacteria play a role in the genesis of digestive tract tumors<sup>16–18</sup>. More than 1% of COVID-19 cases co-exist with malignant tumors<sup>10</sup>. It is unclear whether there are differences in ACE2 expression between tumor and normal cells.

In this study, we assessed the clinical characteristics and investigated the digestive symptoms of 48 patients with COVID-19 in Guangzhou Eighth People’s Hospital.

**Table 2 ACE2 expression in aerodigestive cancers.**

Cancer	Sample type	Sample size No.	Mean expression log <sub>2</sub> (FPKM + 1)	Standard deviation
Lung	NC	108	7.174	0.8162

Note: data was downloaded from The Cancer Genome Atlas (TCGA). ACE2 angiotensin-converting enzyme 2; NC normal control, ACE2 angiotensin-converting enzyme 2; NC normal control.

We explored ACE2 expression in digestive tract cancers and lung cancers, based on a series of bulk tissue RNA sequencing data from two independent databases, and single-cell transcriptome data from three single-cell databases. The results showed that nearly a quarter of COVID-19 patients had gastrointestinal symptoms, that ACE2 expression was higher in the digestive tract than the lung, and the ratio of ACE2-positive cells in tumor tissues was higher than that in paracancerous normal tissue.

**Materials and methods**

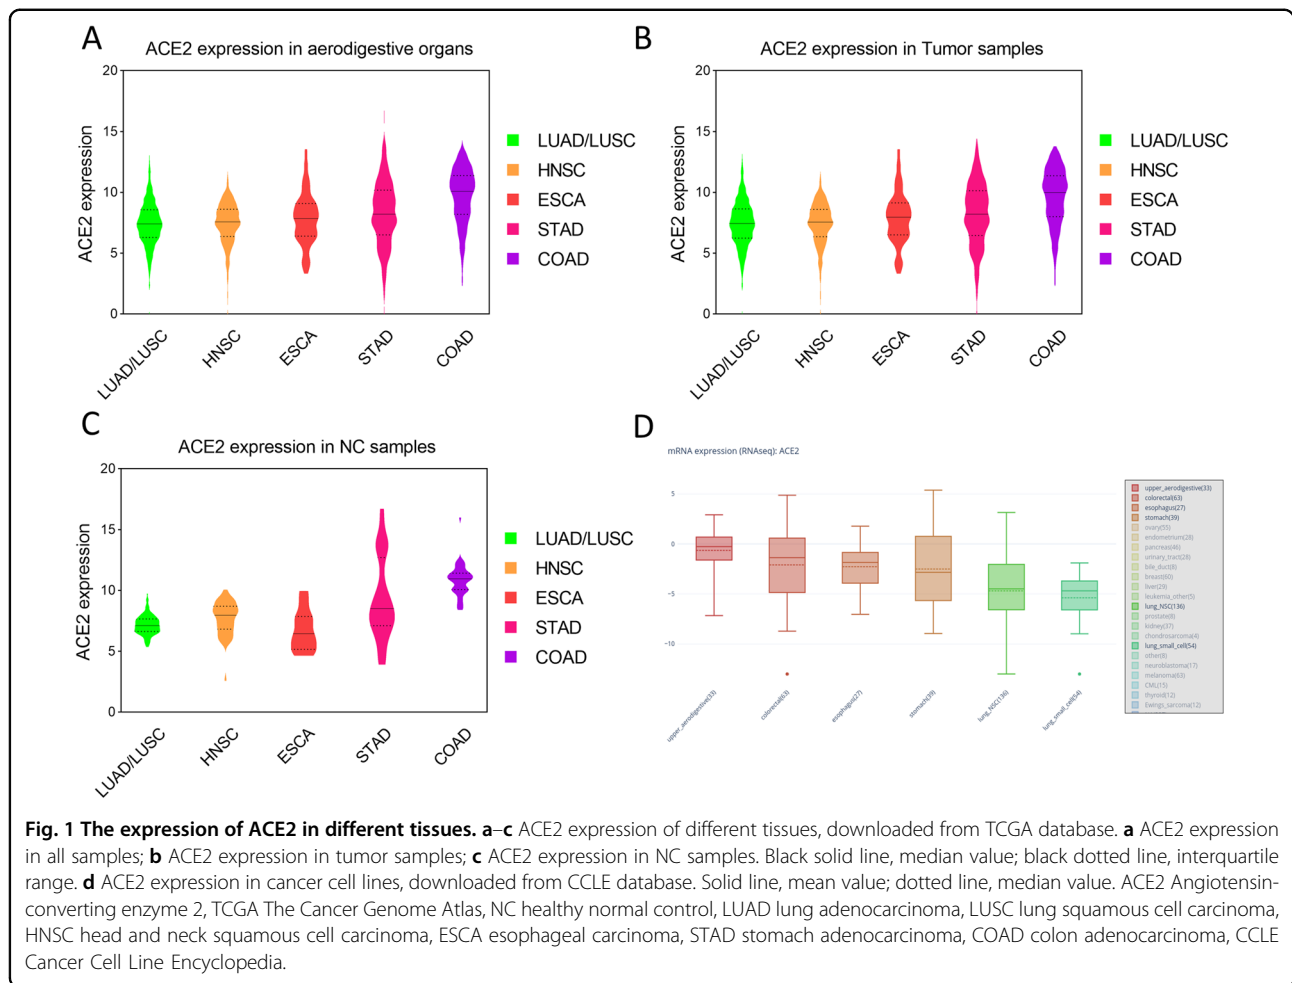

**Patients’ involvement and data collection**

Forty-eight hospitalized patients (admitted from January 26 to March 20, 2020) in Guangzhou Eighth People’s Hospital (the hospital exclusively designated for COVID-19 patients in Guangzhou), who were clinically diagnosed with “viral pneumonia” based on their clinical symptoms (fever or respiratory symptoms) with typical changes in chest radiology, were preliminarily included in this study. Patients without or with negative test results were excluded from this study.

Demographic information, clinical characteristics (including medical history, comorbidities, signs, and symptoms) were obtained from the electronic medical record system of Guangzhou Eighth People’s Hospital and analyzed by three independent researchers. All patients included in our study provided consent for the nasopharyngeal swabs and clinical information collection. This study was approved by the institutional ethics board of Guangzhou Eighth People’s Hospital (No. 202006139) and complied with the Declaration of Helsinki concerning medical research using human subjects.

**Nucleic acid detection of SARS-CoV-2**

Nasopharyngeal swabs were collected and placed into a sterile tube containing RNA preservation solution.

The swabs were sent for SARS-CoV-2 RNA extraction and detection within 1 h by a real-time reverse transcriptional polymerase chain reaction (RT-PCR) system by following the commercial test kit instructions (Da'an Gene cooperation, Cat DA0930) as previously described<sup>19</sup>. Briefly, two PCR primer and probe sets targeting ORF1a/b and nCoV-N genes were separately added into the same reaction tube. Positive and negative controls were involved for detection.

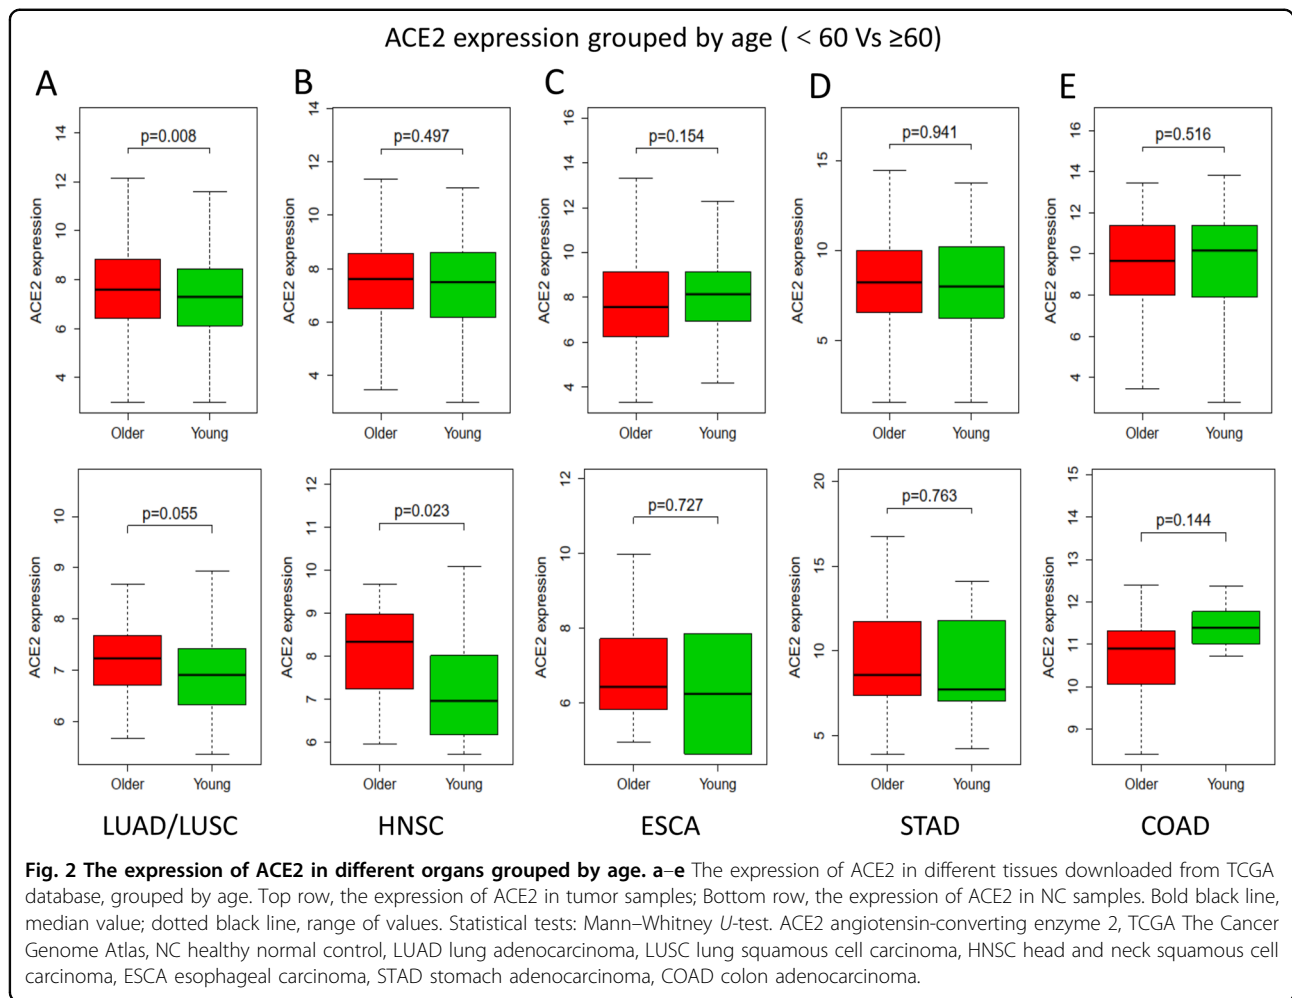

**Bulk tissue RNA sequencing (RNA-Seq) data analysis**

The RNA-seq data (level 3) and clinical information for samples were downloaded from The Cancer Genome Atlas (TCGA) (<https://portal.gdc.cancer.gov/repository>) using the GDC Data Transfer Tool. The datasets used for ACE2 analysis included head and neck squamous cell carcinoma (HNSC), esophageal carcinoma (ESCA), stomach adenocarcinoma (STAD), colon adenocarcinoma (COAD), lung adenocarcinoma (LUAD), and lung squamous cell carcinoma (LUSC). Gene expression was

presented as log<sub>2</sub> (Fragments Per Kilobase per Million mapped reads (FPKM) + 1). The effects of age and sex on ACE2 expression were explored. We also downloaded the boxplot for ACE2 expression in human cancer cell lines from the Cancer Cell Line Encyclopedia (CCLE) (<https://portals.broadinstitute.org/ccle>) database for verification.

**Single-cell RNA sequencing (scRNA-Seq) data analysis**

The lung cancer dataset, EXP0068, downloaded from the Cancer Single-cell State Atlas (<http://biocc.hrbmu.edu.cn/CancerSEA/home.jsp>), and the lung tissue dataset, SRA878024, downloaded from the PanglaoDB (<https://panglaoDB.se/index.html>), were merged for further analysis. The esophageal squamous cell carcinoma (ESCC) dataset GSE81812, oral cancer dataset GSE103322, gastric cancer dataset GSE134520, and colorectal cancer dataset GSE81861 were obtained from the Gene Expression Omnibus (GEO) (<https://www.ncbi.nlm.nih.gov/geo/>). For GSE103322, cells from lymph nodes were removed. The R package Seurat version 3.1.1<sup>20</sup> was used for single-

cell data analysis. Gene-by-barcode count matrices were normalized, log-transformed, and scaled, followed by dimension reduction using principal components analysis (PCA). Uniform manifold approximation and projection (UMAP) was used to carry out dimensionality reduction and clustering.

All analyses were performed in R (R version 3.6.1) and GraphPad 8, and the level of significance was set at  $p \leq 0.05$ .

## Results

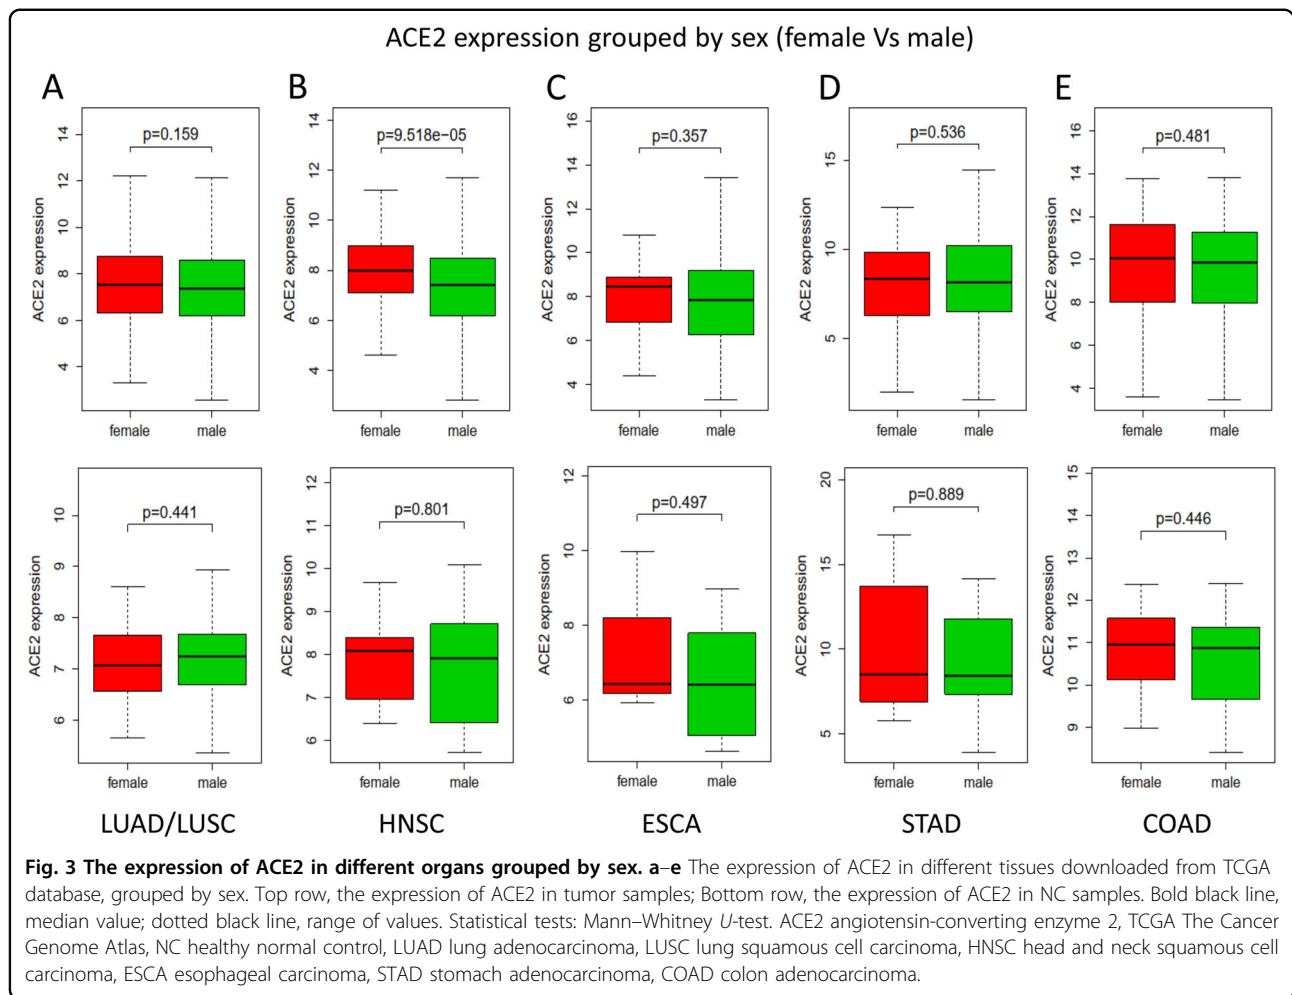

### Demographics and clinical characteristics

A total of 48 patients diagnosed as COVID-19 were included in the study. Twenty-five patients were male, and 23 were female. The median patient age was 41 years and ranged from 18 to 90 years. The majority (75%) of the patients included in the study were under 60 years of age. 27% (13/48) of the patients had at least one underlying comorbidity, the most common of which was hypertension (9/48). Three patients suffered from diabetes, chronic obstructive pulmonary disease (COPD), or chronic renal diseases, respectively. Two patients presented with

cardiovascular and cerebrovascular disease. One patient had chronic liver disease, malignancy, or digestive system disease, respectively. The most common symptoms were fever or cough (29/48), followed by digestive symptoms (12/48), fatigue (6/48), or dyspnea (2/48). Among patients who presented with digestive system symptoms, pharyngalgia (7/48) was the most common manifestation, followed by diarrhea (3/48), anorexia (3/48), and nausea (1/48) (Table 1).

### Bulk tissue RNA-Seq data analysis

A total of 2556 tumor samples and 236 normal control (NC) samples were downloaded from the TCGA database. Table 2 shows the expression of ACE2 ( $\log_2(\text{FPKM} + 1)$ ) in the different samples. Figure 1a–c, respectively, show ACE2 expression in all tumor and NC samples from the different tissues. The results showed that digestive tract organs had higher ACE2 expression compared to the lung. In digestive tract cancers, ACE2 expression gradually increased from the oral cavity to the esophagus, stomach, and the colon,

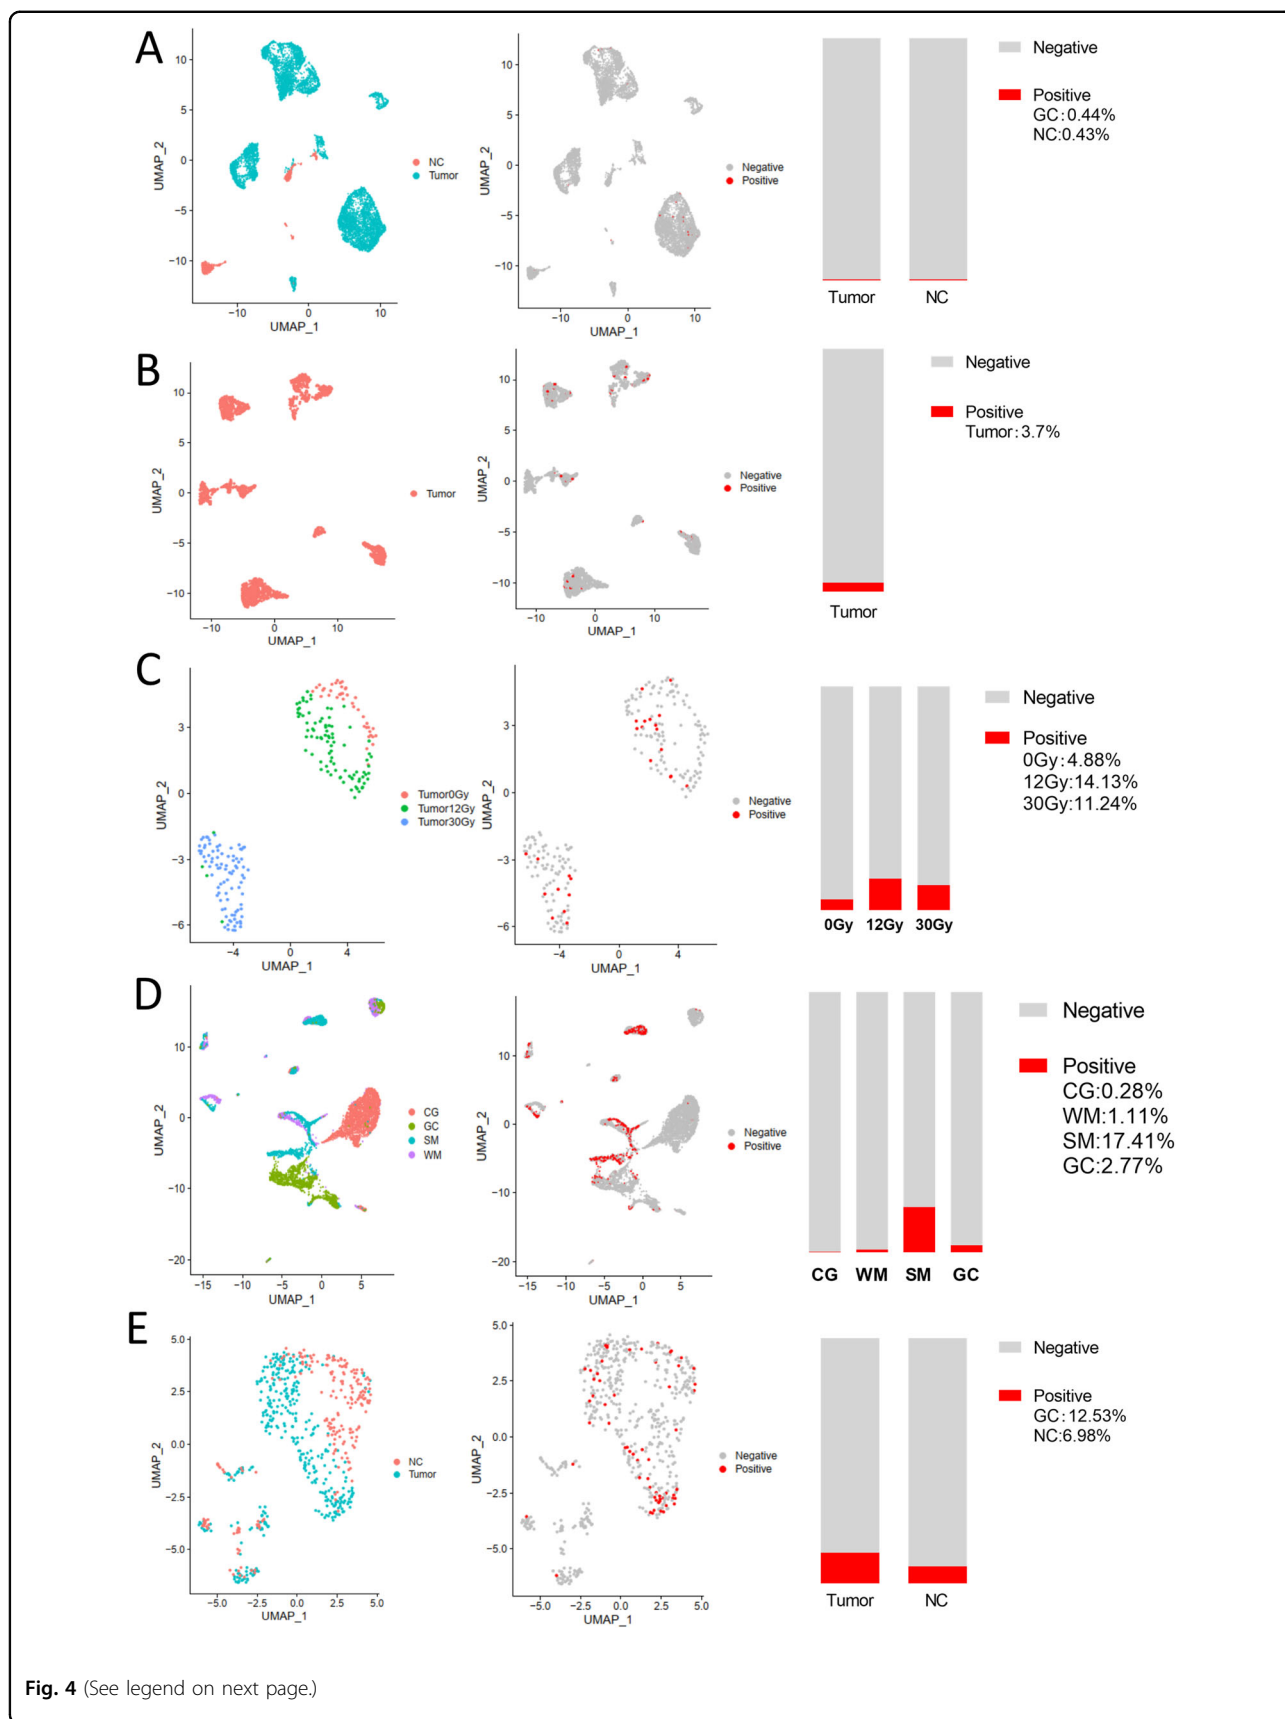

following the path of the digestive tract (Fig.1a–c). The results were validated using the cancer cell line data from the CCLE dataset (Fig. 1d).

To analyze the effect of age or sex on ACE2 expression, the patients were divided into a young group (<60) and an older group (≥60) based on age (Fig. 2), and the patients also were separated into females and males (Fig. 3), based on the clinical data in the TCGA database. The results revealed that for lung cancer, based on either tumor samples or NC samples (Fig. 2a), ACE2 expression in the older group was higher compared to the young group. Also, for oral cancer, the expression of ACE2 was significantly increased in the older group for the NC samples (Fig. 2b), as well as in the female group for the tumor samples (Fig. 3b).

#### ScRNA-Seq data analysis

Six different scRNA-Seq datasets were included in this study. SRA878024 and EXP0068 were lung normal tissue or lung cancer scRNA-Seq data, respectively. GSE103322 was oral cancer scRNA-Seq data. GSE81812 was scRNA-Seq data for the ESCC cell line, KYSE-180, treated with

different doses of radiotherapy. GSE134520 included scRNA-Seq data from chronic gastritis (CG), wild intestinal metaplasia (WM), severe intestinal metaplasia (SM), and gastric cancer (GC). GSE81861 included scRNA-Seq data from colon cancer and adjacent normal tissues. The results showed that ACE2-positive cells accounted for the lowest proportion in lung samples, with 0.43% (3/705) in the NC group and 0.44% (33/7447) in the tumor group (Fig. 4a). The ACE2-positive rate in oral cancer cells was 3.7% (75/2027) (Fig. 4b), while the ACE2-positive ratio in KYSE-180 treated with different doses of radiotherapy was, 4.88% (2/41) for 0 Gy, 14.13% (13/92) for 12 Gy, and 11.24% (10/89) for 30 Gy (Fig. 4c). The ratios of ACE2-positive cells in the CG, WM, SM, and GC groups were 0.28% (83/29678), 1.11% (59/5325), 17.41% (3017/14310), and 2.77% (114/4110), respectively (Fig. 4d). The ACE2-positive-cell ratio was 6.98% (15/215) in normal colonic mucosal cells, and 12.53% (47/375) in colon cancer (Fig. 4e). The ACE2-positive rate in the esophageal and oral mucosa was reported to be nearly 1.2%<sup>11</sup> and 0.52%<sup>14</sup>, respectively. We found that the ACE2-positive-cell ratio

NC healthy normal control, ESCC esophageal squamous cell carcinoma, CG chronic gastritis, WM wild intestinal metaplasia, SM severe intestinal metaplasia, GC gastric cancer, UMAP Uniform Manifold Approximation and Projection, ACE2 angiotensin-converting enzyme 2.

**Fig. 5 ACE2 expression increases along with the path of digestive tract.** ACE2-positive cell proportion in aerodigestive cancers. \*ACE2-positive cell proportion in oral mucosa reported by Xu et al.<sup>14</sup>; \*\*ACE2-positive cell proportion in esophageal epithelium reported by Zou et al.<sup>11</sup>. ACE2 angiotensin-converting enzyme 2, NC healthy normal control, CG chronic gastritis, WM wild intestinal metaplasia, SM severe intestinal metaplasia, GC gastric cancer.

in digestive tract organs was significantly higher than in the lung. The ACE2 expression also was higher in tumor cells compared to NC tissues. The ACE2 expression in gastric tissues gradually increased from chronic gastritis to metaplasia, then cancer (Fig. 5).

## Discussion

This study investigated the gastrointestinal symptoms of 48 patients with COVID-19 who were admitted to the Guangzhou Eighth People's Hospital. We explored ACE2 expression in digestive tract cancers and lung cancers, based on both bulk tissue RNA-Seq data and scRNA-Seq data.

The median age of the 48 patients was 41 years, which was similar to data reported by Xu et al. (41 years)<sup>21</sup>, but was younger than the ages found in many other reports<sup>8,9,22,23</sup>. Consistent with other recent reports, hypertension and diabetes were the most common underlying comorbidities, and fever and cough were the most common symptoms of COVID-19 infection<sup>9,23</sup>. In this study, 25% of the COVID-19 patients exhibited digestive symptoms, which was lower than the percentage reported by Xu et al.<sup>21</sup> and Zhang et al.<sup>22</sup>. The reason for this difference may be that the patients in this

study were younger and presented with fewer underlying digestive system diseases. The most common digestive symptom was pharyngalgia, which was consistent with other studies<sup>22,24</sup>.

We observed that the expression of ACE2 in the lung increased with age but was independent of sex, which was consistent with the report by Chen et al.<sup>25</sup>. This may partly explain why older patients with COVID-19 are more likely to develop pneumonia.

This study found that ACE2 was highly expressed in digestive tract tumors or paracancerous tissues, compared to the lung for both the bulk tissue analysis and the single-cell analysis. Elevated ACE2 expression in the digestive tract suggested that the digestive tract organs also should be considered to be vulnerable targets for SARS-CoV-2 infection. It was reported that SARS-CoV-2 might cause a cytokine storm and multi-organ failure in severe pneumonia patients<sup>26</sup>. Similarly, SARS-CoV-2 might interact with ACE2 in digestive organs, causing further damage to the mucous membrane barrier, and increase inflammatory cytokine production. Oral-related symptoms are rarely reported with COVID-19 infections, but this does not indicate that an oral infection route for SARS-CoV-2 should be excluded. The oral cavity and gastrointestinal organs share similarities in the microbiome, inflammation, and tumorigenesis. Thus, we expect that the oral and gastrointestinal organs should exhibit common interactions in the route of SARS-CoV-2 infection. Furthermore, recent studies have reported a high positive rate of SARS-CoV-2 detection in saliva<sup>27,28</sup>, indicating that oral infection could be an early symptom of COVID-19.

Interestingly, we found that the ACE2-positive rate in tumor cells was significantly higher compared to the NC group. Moreover, ACE2 expression in gastric tissues gradually increased from chronic gastritis to intestinal metaplasia, to early gastric cancer. Similar findings were reported for the colon<sup>29</sup>. These results suggested that cancer patients might have a higher risk of SARS-CoV-2 infection. From another perspective, we suspected that increased expression levels of ACE2 affected the occurrence of digestive tract tumors. ACE2 hydrolyzes Ang II to Ang-(1-7), which negatively regulates the active Renin-Angiotensin System (RAS). Reports show that Ang-(1-7) plays an inhibitory role in the genesis and development of

tumors<sup>30,31</sup>. However, SARS-CoV-2 could cause an inflammatory cytokine storm. When the disease develops into a long-term chronic state, a potential risk might develop for malignant changes to occur in the mucosa under the effect of various cytokines. Therefore, we suggest that when following patients with COVID-19, the risk of tumorigenesis should be considered.

In summary, the ACE2-positive cells in digestive tract tissues might provide possible routes for SARS-CoV-2 infection. ACE2 expression in lung tissue increased with age, which might explain, at least partially, why older patients with COVID-19 are more likely to develop pneumonia. ACE2 expression was correlated to histological grading, suggesting that cancer patients might be more susceptible to SARS-CoV-2. Future research should focus on whether the expression of ACE2 in digestive tract organs could affect the replication of SARS-CoV-2 and whether SARS-CoV-2 infection could affect the genesis or development of tumors.
