Abstract: An efficient method for the synthesis of pharmaceutically prospective pyrrole–aminopyrimidine ensembles (in up to 91% yield) by the cyclocondensation of easily available acylethynylpyrroles with guanidine nitrate has been developed. The reaction proceeds under heating (110–115 °C, 4 h) in the KOH/DMSO system. In the case of 2-benzoylethynylpyrrole, the unexpected addition of the formed pyrrole–aminopyrimidine as N- (NH moiety of the pyrrole ring) and C- (CH of aminopyrimidine) nucleophiles to the triple bond is observed.

1. Introduction

One of the main trends in modern organic chemistry is the synthesis of heterocyclic ensembles, each of the fragments of which has promising biological activity. These ensembles include, in particular, pyrrole–pyrimidines, which combine two of the most fundamental life-supporting molecular systems in their molecule and represent privileged objects for drug design.

The pyrrole core is a key structural motif in a plethora of natural products such as chlorophyll, hemoglobin, bile pigments, vitamin B₁₂, and others [1]. Pyrrole and its derivatives are also important components of a number of pharmaceuticals and new compounds with a variety of pharmacological activity [2,3]. Basing on pyrroles, anti-tumor agent sunitinib, the anti-hyperlipidemic atorvastatin [2,3], neotropic aloracetam [2], antipsychotic elopiprazole [2], and nonsteroidal anti-inflammatory agent tolmetin [2] were created.

The pyrimidine ring is a main structural moiety of nucleic acids, vitamins, coenzymes, and uric acid [4], as well as the frequent scaffold in medicines [4,5]. According to the literature data, the presence of the amino group in pyrimidine enhances its pharmacological properties [5]. The aminopyrimidine ring is a fragment of nucleotide bases in DNA and RNA, which are important components of living cells [4]. Substituted 2-aminopyrimidines exhibit cardiotonic [6], antitrypanosomal and antiplasmoidal [7], antimicrobial [8–11] and antiplatelet aggregation activity [12]. They are also ligands of histamine H₄ and H₃ receptors [13,14], inhibitors of IRAK4 (interleukin-1 receptor-associated kinase 4) [15], the vascular endothelial growth factor inhibitor [16], serine/threonine protein kinase inhibitors, candidates for treating drug-resistant tuberculosis [17]. There are numerous 2-aminopyrimidine-tailored pharmaceuticals [18,19] including antiviral (Lamivudine [18], Etravirine and Rilpivirine [19]), anti-cancer (Imatinib [18,19], Erlotinib, Lapatinib [18], Nilotinib, Dabrafenib, Ceritinib, Osimertinib, and Pazopanib [19]), anxiolytic (Buspirone) [19], hypolipidemic (Rosuvastatin) [18], etc.

2-Aminopyrimidines with pyrrole substituents represent molecular systems, which could be particularly promising for medicinal chemistry, due to the presence of two

pharmacologically active units in their structure. This assumption is supported by the fact that among pyrrole–aminopyrimidines there are inhibitors of JAK2 (Janus kinase 2) [20,21], Cdc7 kinase (Cell division cycle 7-related protein kinase) [22,23], and Polo-like kinase 1 [24], as well as representatives with prominent antifungal activity against *Aspergillus niger* [25].

The fact that pyrrole–aminopyrimidines have a great potential for cancer treatment [20–24] generates interest in the targeted synthesis of these derivatives.

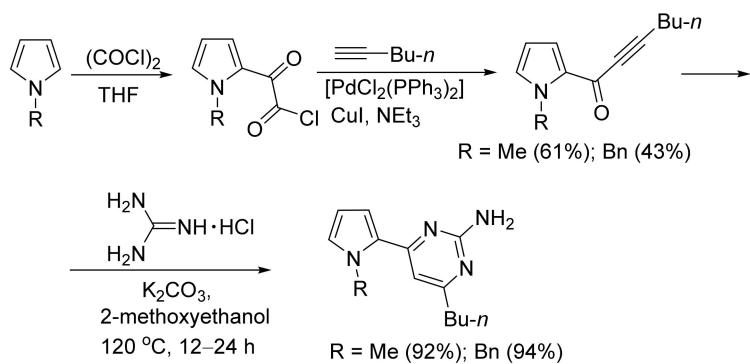

Few known syntheses of pyrrole–aminopyrimidine ensembles are based on three approaches. The first is to build up the pyrrole moiety on aminopyrimidines starting from 1-(2-aminopyrimidin-4-yl)-2-bromoethanones [20,23,26].

The second approach involves construction of the aminopyrimidine ring via the addition of guanidine to pyrroles with ethylenic substituents. Among the latter are 3-dimethylamino-2-(pyrrole-2-carbonyl)acrylonitrile [27], benzylidene acetyl pyrrole [28], pyrrolylenaminone [20], pyrrolyl vinamidinium salts [29].

The third approach to the synthesis of pyrrole–aminopyrimidine ensembles is the coupling of halopyrimidines with pyrroles under Buchwald–Hartwig conditions [21] or their boronate derivative under Suzuki reaction conditions and $\text{PdCl}_2(\text{dppt})$ catalysis [21]. (Pyrrol-2-yl)-2-aminopyrimidine was also obtained from *N*-Boc-pyrrole, which was deprotonated upon treatment with LiTMP (Lithium tetramethylpiperide) and, after subsequent transmetalation (using $\text{ZnCl}_2 \cdot \text{TMEDA}$) and coupling with 2,4-dichloropyrimidine, was transformed into *N*-Boc-2-(2-chloro-4-pyrimidyl)pyrrole [30]. The chloro group of the latter was substituted with allylamine, and after subsequent cleavage of the allyl group under classical conditions afforded the target product.

The most common approach to the synthesis of aminopyrimidines, i.e., cyclocondensation of alkynones with guanidine [31–38], was not always applied to the preparation of pyrrole–aminopyrimidines.

To our knowledge, there is only one work concerning the synthesis of pyrrole–aminopyrimidines from guanidine and pyrrol-2-ylhexynones [39], obtained by glyoxylation of *N*-methyl- and *N*-benzylpyrroles with oxalyl chloride and subsequent Pd/Cu-catalyzed decarbonylative alkynylation of the pyrrolylglyoxylyl chlorides with hexyne (Scheme 1).

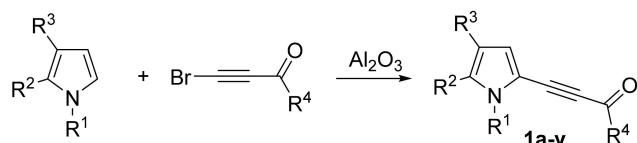

Scheme 1. Synthesis of pyrrole–aminopyrimidines from pyrrol-2-ylhexynones and guanidine. Previous work [39].

This is likely due to the fact that, until recently, alkynones with pyrrole substituents were difficult to obtain. Such compounds have become readily available owing to the discovery of the cross-coupling reaction of pyrroles with acylhaloacetylenes in the medium of solid oxides and metal salts [40–42], and was widely used by us in the synthesis of diverse pyrrole heterocyclic ensembles and fused heterocyclic systems [42].

2. Results and Discussion

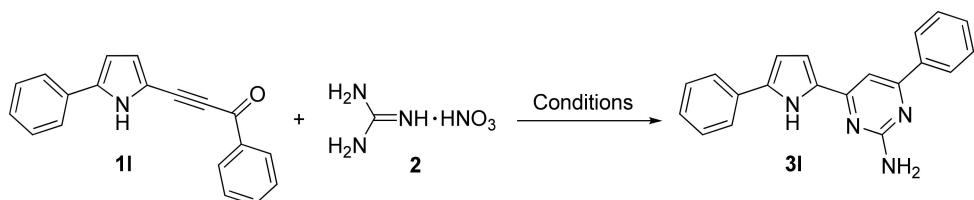

In the present paper, we have developed an effective method for the assembly of pyrrole–aminopyrimidines via the reaction of 2-acylethynylpyrroles **1a–v**, obtained according to Scheme 2, with guanidine nitrate.

Scheme 2. Synthesis of 2-acylethynylpyrroles.

To commence the investigation, 2-benzoylethynyl-5-phenylpyrrole (**1l**, 1.0 equiv) was refluxed with guanidine nitrate (**2**, 1.0 equiv) in the presence of Na_2CO_3 (2.0 equiv) in MeCN for 4 h (Scheme 3). These conditions are known [36] to be effective for the synthesis of 2-aminopyrimidines from alkynes and guanidine. However, in our case, the yield of the target pyrrole–aminopyrimidine **3l** did not exceed 11%.

Scheme 3. The reaction of 2-benzoylethynyl-5-phenylpyrrole (**1l**) with guanidine nitrate.

Therefore, in order to find optimal reaction conditions for the construction of pyrrole–aminopyrimidine ensembles, we screened combinations of bases, solvents, reagent ratio, temperature, and reaction time using the same pyrrole **1l** and guanidine nitrate as reference reagents (Scheme 3, Table 1). The reaction was carried out open to air and controlled by the $^1\text{H-NMR}$ spectroscopy.

The results showed that the yield of the pyrrole–aminopyrimidine **3l** depended on the nature of the base, solvent and other reaction conditions. As seen from Table 1, among the bases tested, only KOH, Cs_2CO_3 and K_3PO_4 demonstrated a good activity (entries 11, 12, 16 and 18–22). However, in the case of the latter two bases, a significant excess of both the base and guanidine should be used to achieve a preparatively acceptable yield of aminopyrimidine **3l**. As the solvents, MeCN, *t*-BuOH, THF (tetrahydrofuran) and DMSO (dimethyl sulfoxide) were checked and it was established that yields of aminopyrimidine **3l** reached a maximum, when the reaction was carried out in DMSO in the presence of KOH (entry 22). Using this catalytic system, the effect of the ratio of reagents and reaction conditions on the yield of the target product was examined. Finally, the desired aminopyrimidine **3l** was obtained in 89% isolated yield, when 2-benzoylethynyl-5-phenylpyrrole (**1l**), guanidine and KOH in a ratio of 1:1:1.5 were reacted in DMSO at 110–115 °C for 4 h (entry 22).

Having established near to optimal reaction conditions, we have further investigated the substrate scope of this reaction (Figure 1). The experiments revealed that the reaction of 2-acylethynylpyrroles **1a–v** with guanidine nitrate in these conditions proceeded efficiently and selectively thus offering a short-cut to pyrrole–aminopyrimidine ensembles **3a–v** in good to high yields.

As follows from Figure 1, the reaction tolerates different (aliphatic, cycloaliphatic, aromatic and vinyl) substituents in the pyrrole ring, i.e., the synthesis has quite general character.

The moderate yield of aminopyrimidine **3a** is due to the formation of side products: 3-[2-(2-amino-6-phenylpyrimidin-4-yl)-1*H*-pyrrol-1-yl]-1-phenyl-3-(1*H*-pyrrol-2-yl)prop-2-en-1-one (**4a**, 13%) and 3-[2-amino-4-phenyl-6-(1*H*-pyrrol-2-yl)pyrimidin-5-yl]-1-phenyl-3-(1*H*-pyrrol-2-yl)prop-2-en-1-one (**5a**, 8%) (Scheme 4). Using the reagents ratio of **1a**:2:KOH = 1:2:2.5 allowed to increase the yield of the aminopyrimidine **3a** to 40%, the content of adduct **4a** in this case in the reaction mixture did not exceed 6% and adduct **5** was not detected at all.

The formation of pyrrole–aminopyrimidine **3**, probably, proceeds as nucleophilic addition of guanidine to the triple bond of 2-acylethynylpyrrole **1**, intramolecular cyclization of adduct **A** with participation of the carbonyl group and elimination of water from the intermediate 3,4-dihydropyrimidin-4-ol **B** (Scheme 5).

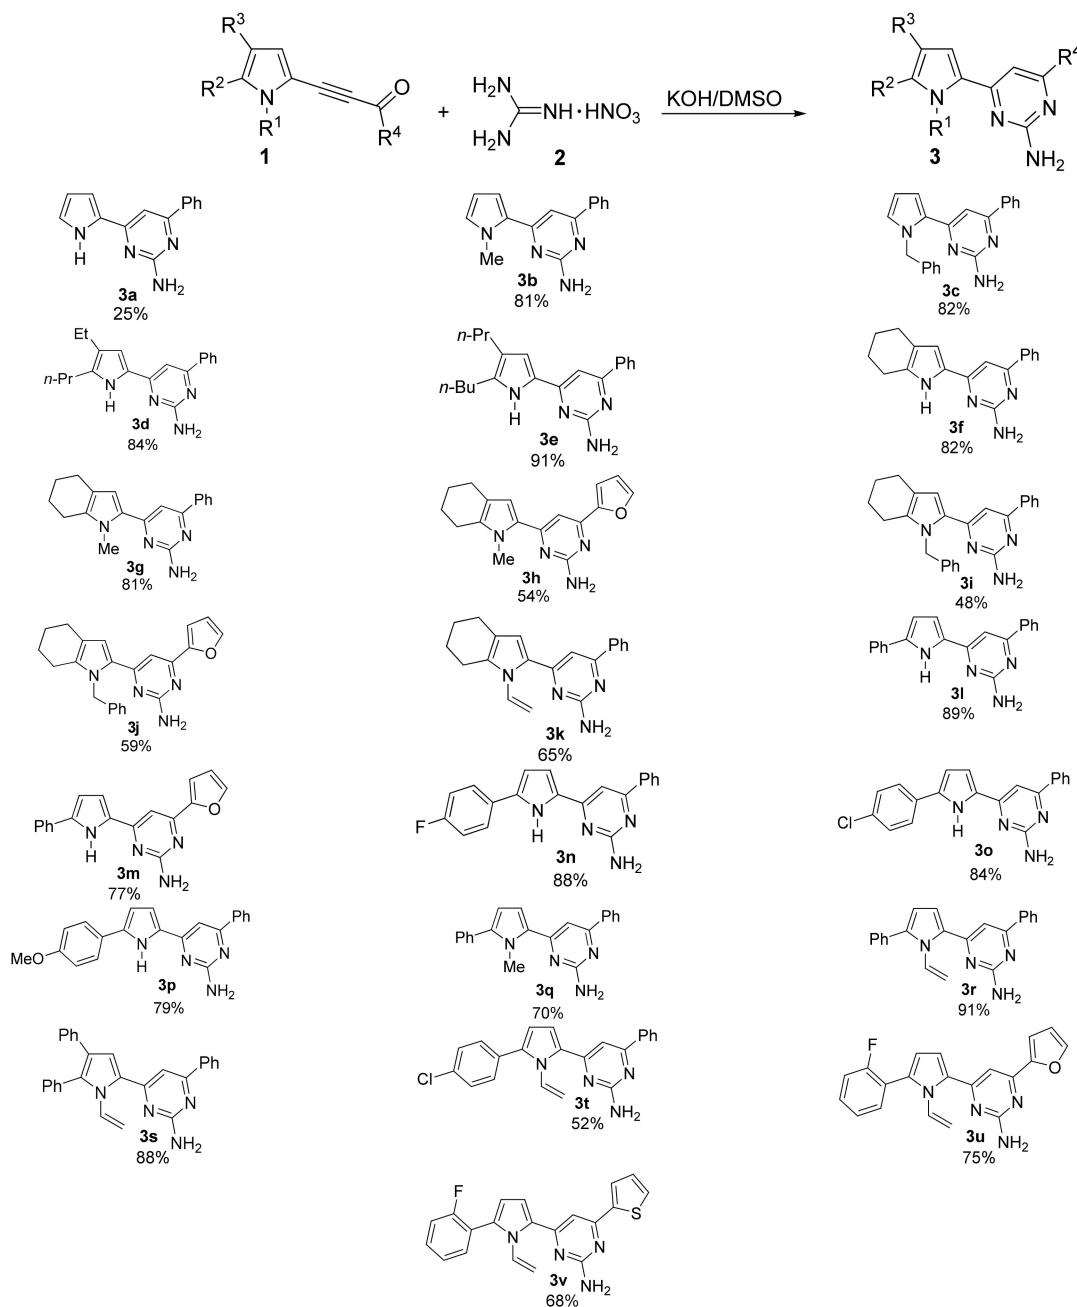

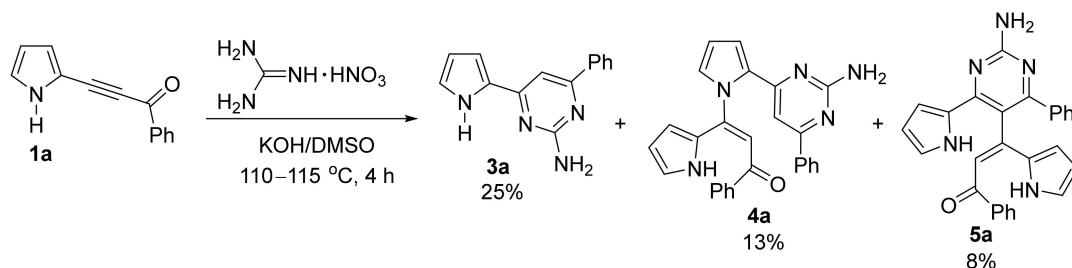

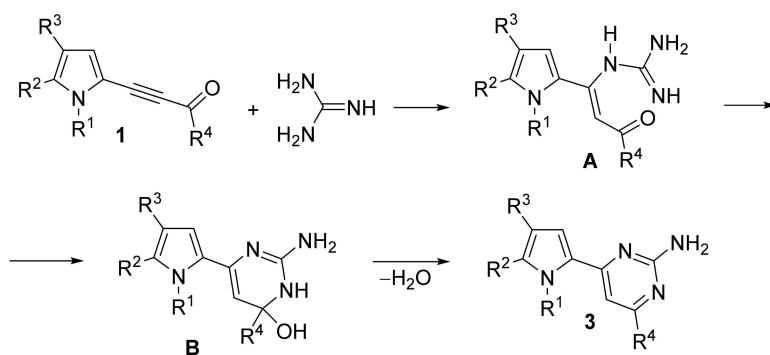

Figure 1. Synthesis of pyrrole-aminopyrimidine ensembles **3a–v** from 2-acylethynylpyrroles **1a–v** and guanidine nitrate. Reagents and conditions: (i) guanidine nitrate (0.40 mmol), KOH·0.5H₂O (0.60 mmol), DMSO (8 mL), 110–115 °C, 0.5 h; (ii) 2-acylethynylpyrrole (0.40 mmol), 110–115 °C, 4 h.

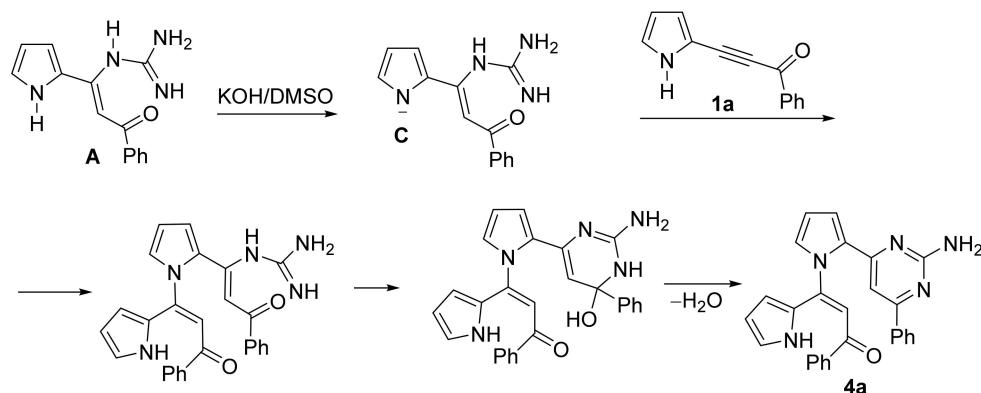

Scheme 4. The reaction of 2-benzoylethynylpyrrole **1a** with guanidine nitrate.

Scheme 5. Proposed route of pyrrole–aminopyrimidine ensembles **3** formation.

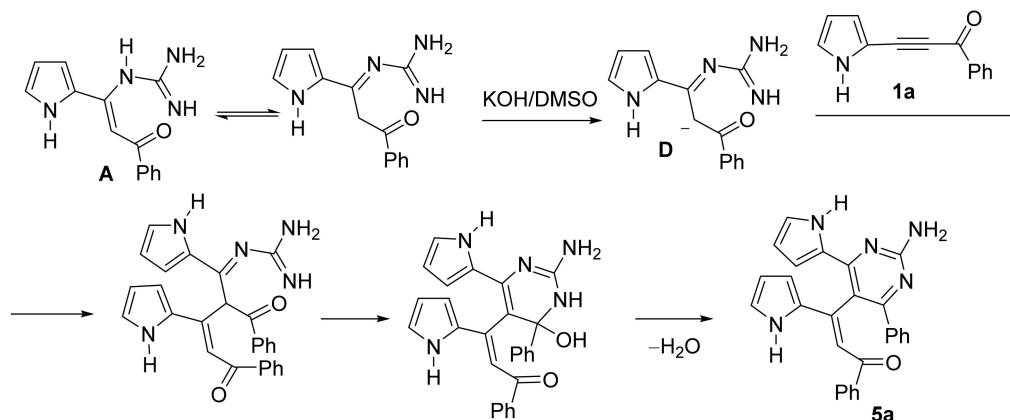

The formation of compound **4** likely involves the nucleophilic addition of N-anion **C** of adduct **A**, existing in the reaction mixture due to the deprotonating ability of the super-base KOH/DMSO system, to the starting 2-acylethynylpyrrole **1a** (Scheme 6).

Scheme 6. Proposed route of adduct **4a** formation.

Adduct **5**, is, probably, a result of the attack of carbocentered anion **D** of the aminopyrimidine ring to the triple bond of pyrrole **1a** (Scheme 7).

A control experiment showed that adducts **4** and **5** did not result from the direct addition of aminopyrimidine **3a** to the triple bond of the starting 2-acylethynylpyrrole **1a**.

Scheme 7. Proposed route of adduct **5a** formation.

3.1. General Procedures

^1H , ^{13}C , ^{15}N and ^{19}F NMR spectra (Nuclear magnetic resonance spectra) were recorded in CDCl_3 and DMSO-d_6 using a Bruker Avance 400 NMR spectrometer (Germany, 400.13, 100.6, 40.5 and 376.5 MHz, respectively). The assignment of signals in the ^1H NMR spectra was made using COSY and NOESY experiments. Resonance signals of carbon atoms were assigned based on ^1H - ^{13}C HSQC and ^1H - ^{13}C HMBC experiments. The values of the δ ^{15}N were measured through the 2D ^1H - ^{15}N HMBC experiment. The chemical shifts (δ) are given in ppm and referenced to residual solvent: 7.27 ppm (CDCl_3) and 2.50 ppm (DMSO-d_6) for ^1H , 77.1 ppm (CDCl_3) and 39.5 ppm (DMSO-d_6) for ^{13}C and ^{15}N -MeNO₂ (0.0 ppm), respectively. The ^{19}F chemical shifts were referenced to CFCl_3 . Coupling constants in hertz (Hz) were measured from one-dimensional spectra and multiplicities were abbreviated as following: br (broad), s (singlet), d (doublet), dd (doublet of doublets), m (multiplet). The chemical shifts were recorded in ppm, coupling constants (J) in Hz. ^1H , ^{13}C - and ^{19}F -NMR spectra of all new synthesized molecules available in Supplementary Materials.

Infrared (IR) spectra were obtained on a Varian 3100 IF-IR spectrometer (Germany; 400–4000 cm^{-1} , KBr pellets or films). The (C, H, N) microanalyses were performed on a Flash EA 1112 CHNS-O/MAS (CHN Analyzer, Thermo Fisher Scientific, Monza, Italy) instrument. The chlorine and sulfur content was determined by using the titrimetric method. Fluorine content was determined on a SPECOL 11 (Carl Zeiss, Jena, Germany) spectrophotometer. Melting points (uncorrected) were determined with melting point SMP50 (Stone, Staffordshire, UK).

3.2. Synthetic Procedures

2-Acylethynylpyrroles **1a,f-l,n-r** were obtained from pyrroles and 2-acylbromoacetylenes accordingly to methodology [40–42]. Physico-chemical characteristics 2-acylethynylpyrroles **1a,f-l,n-r** were given in [40,43–47]. 2-Acylethynylpyrroles **1b,c-e,m,s-v** were obtained accordingly to the following procedure:

The corresponding pyrrole (1 mmol) and acyl(bromo)acetylene (1 mmol) were carefully ground in a porcelain mortar with alumina [10-fold amount by weight of combined mass of pyrrole and acyl(bromo)acetylene] at 20–25 °C for 5 min. The reaction mixture was left for 2 h. Then the mixture was subjected to column chromatography (alumina, eluent-n-hexane/diethyl ether, gradient 1:0–1:1); this afforded pure 2-acylethynylpyrroles **1b,c-e,m,s-v**.

General Procedure for the pyrrole–aminopyrimidine ensembles 3a–v synthesis: A mixture of guanidine nitrate (49 mg, 0.40 mmol) and KOH·0.5H₂O (39 mg, 0.60 mmol) was stirred in DMSO (8 mL) at 110–115 °C for 30 min. Then the 2-acylethynylpyrrole 1 (0.40 mmol) was added, and the mixture was stirred for 4 h. After cooling to 20–25 °C, the reaction mixture was diluted with saturated solution of NaCl (40 mL). The precipitate was filtered off, washed with water (3 × 20 mL) and dried. The obtained pyrrole–aminopyrimidines were purified by column chromatography (SiO_2 , eluent-*n*-hexane/diethyl ether, gradient 1:0–0:1).

4. Conclusions

In summary, we developed an effective access to novel families of pyrrole–pyrimidine ensembles, decorated with alkyl, cycloalkyl, aryl and vinyl groups, attractive objects for drug design, by using acylethynylpyrroles as the synthetic platform. This method has several synthetic advantages, such as the one-pot procedure, the use of readily available starting materials and good to high yields of the target ensembles and therefore can activate the interest of both synthetic and pharmaceutical communities.
