

Blastomycosis Mortality Rates, United States, 1990–2010

Diana Khuu, Shira Shafir, Benjamin Bristow, and Frank Sorvillo

Medscape **ACTIVITY** EDUCATION

Medscape, LLC is pleased to provide online continuing medical education (CME) for this journal article, allowing clinicians the opportunity to earn CME credit.

This activity has been planned and implemented in accordance with the Essential Areas and policies of the Accreditation Council for Continuing Medical Education through the joint providership of Medscape, LLC and Emerging Infectious Diseases. Medscape, LLC is accredited by the ACCME to provide continuing medical education for physicians.

Medscape, LLC designates this Journal-based CME activity for a maximum of 1.0 **AMA PRA Category 1 Credit(s)**[™]. Physicians should claim only the credit commensurate with the extent of their participation in the activity.

All other clinicians completing this activity will be issued a certificate of participation. To participate in this journal CME activity: (1) review the learning objectives and author disclosures; (2) study the education content; (3) take the post-test with a 75% minimum passing score and complete the evaluation at <http://www.medscape.org/journal/eid>; (4) view/print certificate.

Release date: October 16, 2014; Expiration date: October 16, 2015

Learning Objectives

Upon completion of this activity, participants will be able to:

1. Describe clinical features of blastomycosis, based on an epidemiologic study
2. Identify risk factors for blastomycosis-related mortality
3. Distinguish geographic differences in blastomycosis-related mortality.

CME Editor

Jean Michaels Jones, Technical Writer/Editor, *Emerging Infectious Diseases*. Disclosure: Jean Michaels Jones has disclosed no relevant financial relationships.

CME Author

Laurie Barclay, MD, freelance writer and reviewer, Medscape, LLC. Disclosure: Laurie Barclay, MD, has disclosed no relevant financial relationships.

Authors

Disclosures: **Diana Khuu, MPH; Shira Shafir, PhD, MPH; Benjamin Bristow, MD, MPH, DTM&H; and Frank Sorvillo, PhD**, have disclosed no relevant financial relationships.

Blastomycosis is a potentially fatal fungal infection endemic to parts of North America. We used national multiple-cause-of-death data and census population estimates for 1990–2010 to calculate age-adjusted mortality rates and rate ratios (RRs). We modeled trends over time using Poisson regression. Death occurred more often among older

persons (RR 2.11, 95% confidence limit [CL] 1.76, 2.53 for those 75–84 years of age vs. 55–64 years), men (RR 2.43, 95% CL 2.19, 2.70), Native Americans (RR 4.13, 95% CL 3.86, 4.42 vs. whites), and blacks (RR 1.86, 95% CL 1.73, 2.01 vs. whites), in notably younger persons of Asian origin (mean = 41.6 years vs. 64.2 years for whites); and in the South (RR 18.15, 95% CL 11.63, 28.34 vs. West) and Midwest (RR 23.10, 95% CL 14.78, 36.12 vs. West). In regions where blastomycosis is endemic, we recommend that the diagnosis be considered in patients with pulmonary disease and that it be a reportable disease.

Blastomycosis is a systemic infection caused by the thermally dimorphic fungus *Blastomyces dermatitidis* that can result in severe disease and death among humans and animals. *B. dermatitidis* is endemic to the states bordering the Mississippi and Ohio Rivers, the Great Lakes, and southern Canada; it is found in moist, acidic, enriched soil near wooded areas and in decaying vegetation or other organic material (1). Conidia, the spores, become airborne after disruption of areas contaminated with *B. dermatitidis*. Infection occurs primarily through inhalation of the *B. dermatitidis* spores into the lungs, where they undergo transition to the invasive yeast phase. The infection can progress in the lung, where the infection may be limited, or it can disseminate and result in extrapulmonary disease, affecting other organ systems (2).

The incubation period for blastomycosis is 3–15 weeks. About 30%–50% of infections are asymptomatic. Pulmonary symptoms are the most common clinical manifestations; however, extrapulmonary disease can frequently manifest as cutaneous and skeletal disease and, less frequently, as genitourinary or central nervous system disease. Liver, spleen, pericardium, thyroid, gastrointestinal tract, or adrenal glands may also be involved (3). Misdiagnoses and delayed diagnoses are common because the signs and symptoms resemble those of other diseases, such as bacterial pneumonia, influenza, tuberculosis, other fungal infections, and some malignancies (4). Accurate diagnosis relies on a high index of suspicion with confirmation by using histologic examination, culture, antigen detection assays, or PCR tests (5).

Antifungal agents, such as itraconazole for mild or moderate disease and amphotericin B for severe disease, can provide effective therapy, especially when administered early (1,2). With appropriate treatment, blastomycosis can be successfully treated without relapse; however, case-fatality rates of 4%–22% have been observed (4,6–9). Although spontaneous recovery can occur (10,11), case-patients often require monitoring of clinical progress and administration of drugs on an inpatient basis. Previous studies estimated average hospitalization costs for adults to be \$20,000; that is likely less than the current true cost (12). Some reviews of outbreaks indicate a higher distribution of infection among persons of older age, male sex (2,13), black, Asian, and Native American racial/ethnic groups (3,13), and those who have outdoor occupations (13,14). Both immunocompetent and immunocompromised hosts may experience disease and death (2,6,15–19), although *B. dermatitidis* disproportionately affects immunocompromised patients, who tend to have more rapid and extensive pulmonary involvement, extrapulmonary infection, complications, and higher mortality rates (25%–54%) (2,6,16–19).

Past studies have expanded the knowledge about blastomycosis through focusing on cases documented in

specific immunocompromised persons and statewide occurrences or in areas in which the disease is endemic (4,6–9,16–18); however, such studies may be limited for making definitive conclusions by their scope and small sample size. Much remains unknown about the public health burden of blastomycosis-related deaths in the United States. Reports suggest an increase in the number of blastomycosis cases in recent years (13,20). Clearer identification of risk factors from national data may raise awareness of blastomycosis in the United States and support adding it to the list of reportable diseases in regions where the pathogen is endemic to improve surveillance and control. In this study, we assessed the public health burden of blastomycosis-related deaths by examining US mortality-associated data and evaluating demographic, temporal, and geographic associations as potential risk factors.

Methods

Data Source

We used publicly available multiple-cause-of-death (MCO) data from the National Center for Health Statistics to examine blastomycosis-related deaths in the United States during 1990–2010. These data are derived from US death certificates and include information on the causes of death coded by the International Classification of Diseases, 9th and 10th Revisions (ICD-9, ICD-10), demographic variables of age, sex, and race/ethnicity, date of death, and geographic region of residence.

Case Definition

We defined a case-patient as deceased US resident listed in the MCO dataset during 1990–2010 whose death certificate listed blastomycosis as the underlying or contributing cause of death. The ICD-9 code 116.0 (years 1990–1998) and ICD-10 codes B40.0–B40.9 (years 1999–2010) were used to identify blastomycosis-related deaths.

Analysis

To ensure more stable estimates, we aggregated data for the study period. We calculated mortality rates and rate ratios (RRs) with 95% confidence limits (CLs) by age, sex, race/ethnicity, geographic region, and year of death using a maximum likelihood analysis presuming the response variable had a Poisson distribution (21), and with bridged-race population estimates data and designated geographic boundaries from the US census. We computed age-adjusted mortality rates using adjustment weights from the year 2000 US standard population data. We assessed temporal trends in age-adjusted mortality rates using a Poisson regression model of deaths per person-years in the population, designating year and age group dummy variables as independent variables, and the population as the offset.

We calculated the percentage change by year based on the estimated slope parameter and examined the Poisson regression models for overdispersion. We performed all analyses using SAS for Windows version 9.4 (SAS Institute Inc., Cary, NC, USA).

Results

We identified 1,216 blastomycosis-related deaths among 49,574,649 deaths in the United States during 1990–2010. Among those 1,216 deaths, blastomycosis was reported as the underlying cause of death for 741 (60.9%), and as a contributing cause of death for 475 (39.1%). The overall age-adjusted mortality rate for the period was 0.21 (95% CL 0.20, 0.22) per 1 million person-years. Using Poisson regression, we identified a 2.21% (95% CL –3.11, s1.29) decline in blastomycosis-related mortality rates during the period (Figure).

Age

The mean age at death from blastomycosis was 60.8 years. Using 75 as the average age at death (22,23), we calculated that 19,097 years of potential life were lost. The mortality rates associated with blastomycosis increased with increasing age, peaking in the 75- to 84-year age group (Table 1). The mean age at death from blastomycosis was significantly lower among Hispanics ($p < 0.01$), Native Americans ($p < 0.01$), blacks ($p < 0.01$), and Asians ($p < 0.01$) than among whites based on the t test for difference in means.

Sex

Death related to blastomycosis was significantly more likely in men than in women ($p > 0.05$). The average age at death was significantly lower for men than for women ($p = 0.02$) (Table 1). The annual mortality rate over the period obtained from using Poisson regression declined for both men and women (Table 2).

Race/Ethnicity

Native Americans and blacks were significantly more likely to die from blastomycosis-related complications than

whites; overall, Asians and Hispanics were significantly less likely to die of blastomycosis than other groups (Table 1). The annual mortality rate over the period declined among blacks and whites (Table 2).

Geographic Region

Most (96.7%) of the blastomycosis-related deaths occurred in the southern and midwestern regions, and a small proportion of deaths occurred in the northeastern and western regions. The midwestern region had the highest mortality rate, followed by the southern, northeastern, and western regions (Table 1). Percentage changes in mortality rates per year over the period, calculated by using Poisson regression, showed an increase in mortality rates in the midwestern region, and a decline in the southern region (Table 2).

Table 3 shows the results of a subanalysis of the demographic characteristics of populations in the southern and midwestern regions. In the southern region, the mean age at death from blastomycosis was significantly lower among Native Americans ($p = 0.03$), blacks ($p < 0.01$), and Hispanics ($p = 0.02$) than among whites based on a t test for difference in means. In the midwestern region, the mean age at death from blastomycosis was significantly lower among Native Americans ($p = 0.02$), Asians ($p < 0.01$), blacks ($p < 0.01$), and Hispanics ($p < 0.01$) than among whites. Furthermore, the mean age at death from blastomycosis in the midwestern region was significantly lower among Asians than among Native Americans ($p < 0.01$), blacks ($p < 0.01$), and Hispanics ($p = 0.04$).

Discussion

Our findings indicate that blastomycosis is a noteworthy cause of preventable death in the United States. These findings confirm the demographic risk factors of blastomycosis indicated in previous case reports and extend these to mortality rates. Blastomycosis death occurred more often among older persons than among younger persons (24), and more often among men than women (2,24). The age association found likely represents waning age-related immune function and higher prevalence of

Figure. Number of blastomycosis-related deaths and age-adjusted mortality rates per 1 million person-years, by year, United States, 1990–2010.

SYNOPSIS

Table 1. Blastomycosis-related deaths by sex, race/ethnicity, age group, and geographic region with corresponding age-adjusted mortality rates, United States, 1990–2010*

Characteristic	No. (%) deaths	Mean age at death, y	Age-adjusted mortality rate/1 million person-years (95% CL)†	Age-adjusted mortality rate ratio (95% CL)

‡Age-specific rates.

immunocompromising conditions. The observed sex differences in blastomycosis mortality may be attributable to differences in occupational or recreational exposures that increase risk for infection (14). For example, those who work outdoors involving construction, excavation, or forestry, or participate in outdoor recreational activities such as hunting (7,11), may more likely be exposed than those who principally work indoors.

The disproportionate burden of blastomycosis deaths sustained by persons of Native American or black race is also consistent with previous reports (3,24). Increased exposure and prevalence of infection, reduced access to health care, and genetic differences may play a role in the observed race-specific disparities in blastomycosis mortality rates (25). A finding of the current study is that even though persons of Asian descent are at lower risk for dying from blastomycosis than whites, those who died from blastomycosis did so at a much younger age (22.6 years younger). This disparity is even greater in the midwestern region, where Asians died at an age 27.2 years younger than did whites.

Consistent with the recognized geographic distribution of *B. dermatitidis* (1–2), we found that death related to blastomycosis occurred more often among persons who

resided in the midwestern or southern regions than among those in the western and northeastern regions. During the study period, the southern region showed decreases in mortality rates, and the midwestern region, which had the highest mortality rate, showed an increase in rate.

The use of population-based data and large numbers can provide insight, though some limitations associated with using MCODE data should be considered. First, potential underdiagnosis and underreporting of death related to blastomycosis may lead to underestimates of mortality rates and the true public health burden of blastomycosis in the United States. Low physician awareness of blastomycosis may be a contributor. Second, it was not possible to verify accuracy of recorded data or access supplemental data. For example, there may be reporting errors regarding correct race/ethnicity identification on death certificates and in population census reports. Third, we could not adjust for other possible confounders (i.e., smoking, socioeconomic factors, activity, lifestyle, occupation) because these data are not recorded on death certificates. These limitations must be considered along with our findings.

This study sheds light on the scope of the incidence of blastomycosis in the United States, though the true

incidence may be greater than that reported here. Although *B. dermatitidis* infection may be difficult to prevent because of its widespread distribution in areas where blastomycosis is endemic, deaths resulting from blastomycosis can be prevented with early recognition and treatment of patients with symptomatic infection. The continued incidence of blastomycosis in the United States, as indicated by the observed modest decrease in the mortality rates over the 21-year study period, calls for improvement in provider and community awareness, which may lead to including blastomycosis as a diagnostic consideration in patients with pulmonary disease refractory to treatment. Our findings, recent reports of disproportionately high infection rates among Asians (26), and the lack of decline in the mortality rates in the midwestern region support further investigation. We also encourage improvements in blastomycosis surveillance that involve examining trends

in incident cases, hospitalization (including length of stay), timely diagnosis, and treatment to further elucidate the burden of blastomycosis in the United States.

Acknowledgments

We thank Matthew Redelings for his contributions to the analysis of data in this study.

etymologia

Blastomycosis [blas' to-mi-ko' sis]

From the Greek *blastós* (“germ, sprout”) and *mykēs* (“fungus, mushroom”), this invasive fungal infection was first reported in 1894 by T. C. Gilchrist. Gilchrist initially believed the disease was caused by a protozoan, but in collaboration with W. R. Stokes, he subsequently isolated the organism,

which he named *Blastomyces dermatitidis*. The infection became known as Chicago disease because most early cases were identified in the Chicago area, but it was subsequently shown to be endemic to much of eastern North America. Sporadic cases have also been reported in Africa, the Middle East, and India.
