Abstract: Efficient delivery of nucleic acids into target cells is crucial for nucleic acid-based therapies. Various nucleic acid delivery systems have been developed, each with its own advantages and limitations. We previously developed a nanoparticle-based delivery system for small chemical drugs using pH-responsive PEG₈-PDPA₁₀₀-PEG₈ polymer micelles as carriers. In this study, we extend the application of these pH-responsive micelle-like nanoparticles (MNPs) to deliver oligonucleotides. We demonstrate that the MNPs efficiently encapsulate and deliver oligonucleotides of different lengths (20–100 nt) into cells. The cargo oligonucleotides are rapidly released at pH 5.0. We prepared MNPs carrying a Texas red-fluorescently labeled anti-human epidermal growth factor receptor 2 (HER2) aptamer (HApt). Compared to free HApt, the HApt-MNPs resulted in significantly better cellular uptake, reduced cell viability, and increased apoptosis in SKBR3 breast cancer cells, which overexpress HER2. Moreover, HApt-MNPs were significantly less cytotoxic to MCF7 breast cancer cells, which express low levels of HER2. After cellular uptake, HApt-MNPs mainly accumulated in lysosomes; inhibition of lysosomal activity using bafilomycin A1 and LysoTracker Red staining confirmed that lysosomal activity and low pH were required for HApt-MNP accumulation and release. Furthermore, HER2 protein expression declined significantly following treatment with HApt-MNPs in SKBR3 cells, indicating that HApt-induced translocation of HER2 to lysosomes exerted a potent cytotoxic effect by altering signaling downstream of HER2. In conclusion, this pH-responsive and lysosome-targeting nanoparticle system can efficiently deliver oligonucleotides to specific target cells and has significant potential for nucleic acid-based cancer therapies.

Keywords: pH-responsive micelle-like nanoparticles, nucleic acid delivery, HER2-targeted therapy

Introduction

In recent decades, nucleic acid-based therapeutic agents have been developed and used in the clinic to treat multiple diseases, including cancer,^{1–4} diabetes,^{4–6} cardiovascular diseases,^{7,8} and infectious diseases.^{9–11} However, the large size, high anionic charge density, and hydrophilic properties of DNA and RNA molecules significantly limit their cellular uptake.^{12–15} Hence, a plethora of nucleic acid carriers have been developed in an attempt to overcome these barriers.

In general, nucleic acid delivery systems can be classified into two major groups: viral and nonviral.^{16–19} Viral vectors, such as retrovirus or adenovirus-based systems, have high transduction efficiencies. However, their application is limited by high production costs and biosafety and immunogenicity concerns.^{18,20,21} Nonviral systems, such as lipid- or polymer-based approaches, have gained much attention due to their low cytotoxicity,

weak or lack of immunogenicity, and ease of production.^{22–26} Among the nonviral delivery systems, polymeric nanoparticles are an attractive option for gene therapy due to their unique properties including self-assembly behavior, ability to condense and protect nucleic acids, cell association, efficient cell transfection, and low cytotoxicity.^{23,25–28} Recently, the addition of stimuli-sensitive functions has enabled polymeric nanoparticles to specifically respond to pathological or externally applied “triggers” (eg, temperature, pH, enzymatic catalysis, and light or magnetic fields) and further extended their potential applications.^{29–32} For example, pH-responsive polymeric nanoparticles capable of protecting nucleic acids in the blood circulation and actively releasing their cargo in the tumor microenvironment and/or inside the target tumor cells have received overwhelming interest in the context of cancer therapy.

We previously developed a novel pH-responsive delivery system for small chemical anticancer drugs from amphiphilic triblock copolymers composed of poly[2-(diisopropylamino)ethyl methacrylate] (PDPA) and methoxy-poly(ethyleneglycol) segments (PEG₈-PDPA-PEG₈; n=30, 50, or 100).^{29,33} The PEG shell of the micelle-like nanoparticles (MNPs) prolongs the circulation of MNPs in the blood by reducing nonspecific associations with plasma proteins and tissues.^{34,35} The PDPA core serves as a pH sensor, which is hydrophobic at physiological pH (pH > 7.4) and becomes hydrophilic at acidic conditions due to protonation of di-isopropylamin.^{36,37} Thus, the pH-responsive MNPs are stable at pH 7.4 but swell and disaggregate at a pH < 6.0. MNPs composed of PEG₈-PDPA₁₀₀-PEG₈ have been proven to possess a range of desirable properties, such as low cytotoxicity, superior efficiency to deliver small chemical drugs, and considerable lysosomal accumulation after cellular uptake.²⁹

Human epidermal growth factor receptor 2 (HER2), a member of the epidermal growth factor-related protein (ErbB) family of receptor tyrosine kinases, is overexpressed on the plasma membranes of tumor cells in a variety of cancers compared to normal cells. Overexpression of HER2 is associated with the development and progression of a multitude of malignancies and is a major therapeutic target in several cancers.³⁸ Downregulation of HER-2 expression attenuates HER2 signaling and promotes cell cycle arrest and apoptosis by altering a number of downstream signaling pathways.^{39,42,43} Recently, a 42 nucleotide (nt) trimeric anti-HER2 aptamer (HApt) derived from degradation of HER2 in lysosomes was reported to kill HER2-overexpressing N87 gastric cancer cells and SKBR3 breast cancer cells.^{40,41}

The anti-HApt exerts a cytotoxic effect by inducing cross-linking of HER2 on the cell surface, which results in the translocation of HER2 from the plasma membrane to cytoplasmic vesicles (mainly in lysosomes), where HER2 is thought to be degraded by proteases.⁴¹

In this study, we extended the application of our PEG₈-PDPA₁₀₀-PEG₈ MNPs to the delivery of oligonucleotides. The MNPs could efficiently package oligonucleotides of varied lengths (20–100 nt) and release them in a pH-dependent manner. We prepared MNPs encapsulating fluorescently labeled HApt and demonstrated that, compared to the free HApt, HApt encapsulated within MNPs was more efficiently taken-up and exerted more potent cytotoxic effects in SKBR3 breast cancer cells, which overexpress HER2.

Materials and methods

Synthesis of oligonucleotides

HApt (42 nt) is a trimeric concatenation of the 14 nt HApt (5′-GCAGCGGTGTGGGG-3′). HER2-negative control aptamer (NCApt) is a trimeric concatenation of a negative control oligonucleotide (5′-AGATTGCACTTACTATCT-3′).^{40,41} High performance liquid chromatography-purified HApt, NCApt, and other oligonucleotides (between 20 and 100 nt) (Table 1) were commercially synthesized (Sangon Biotech Co., Ltd., Shanghai, People’s Republic of China). The dye Texas red was conjugated to the 5′-end of each oligonucleotide to enable fluorescent detection.

Synthesis of PEG₈-PDPA₁₀₀-PEG₈ triblock copolymers

PEG₈-PDPA₁₀₀-PEG₈ triblock copolymers were synthesized according to the method described previously.²⁹ The pH sensitivity of PEG₈-PDPA₁₀₀-PEG₈ was assessed using dynamic light scattering (DLS; Zetasizer Nano ZS; Malvern Instruments, Malvern, UK) and UV-vis spectroscopy (UV-2450; Shimadzu, Kyoto, Japan).

Preparation of polymeric PEG₈-PDPA₁₀₀-PEG₈ MNPs

MNPs without oligonucleotides (unloaded MNPs) were prepared using a solvent evaporation method, as described previously.²⁹ Briefly, 3 mg of copolymer was dissolved in 1 mL of tetrahydrofuran (THF). Phosphate-buffered saline (PBS, 1 mM, pH 7.4) was added dropwise under high-speed stirring, and polymeric micelles were obtained after complete evaporation of THF. The final concentration of copolymer was adjusted to 0.3 mg/mL. Oligonucleotide-loaded MNPs (oligo-MNPs) were prepared by adding oligonucleotides

Abbreviations: HApt, human epidermal growth factor receptor 2 aptamer; NCapt, negative control aptamer; nt, nucleotide.

dissolved in PBS in a dropwise manner to polymeric PEG₈-PDPA₁₀₀-PEG₈ THF solution under high-speed stirring. The final concentration of oligonucleotides was adjusted to 500 nmol/L. The oligo-MNPs were transferred into dialysis tubing (molecular weight cutoff, 50,000 g/mol) and dialyzed against PBS to remove free oligonucleotides. The size and morphology of the MNPs were examined by DLS and transmission electron microscopy (TEM; JEM-1400; JEOL, Tokyo, Japan).

Circular dichroism analysis

Free and MNP-encapsulated HApt (1 μM) in PBS were analyzed using a Chirascan spectrometer (Chirascan; Applied Photophysics Ltd, Surrey, UK). Circular dichroism (CD) spectra were obtained from 300 to 200 nm using a 2 mm quartz cuvette at 25°C. The background CD spectrum of unloaded MNPs was obtained and subtracted from the CD spectrum of the HApt-MNPs.

Rates of pH-dependent release of HApt from micelles

The release profile of HApt from HApt-MNPs was studied at various pH values using a fluorescence spectrophotometer (F-4500; Hitachi, Tokyo, Japan) at 610 nm. Briefly, 2 mL of Texas red-labeled HApt-loaded micelles was sealed in a dialysis tube (molecular weight cutoff, 50,000 g/mol), placed in a beaker containing 50 mL of PBS (10 mmol/L, pH = 5.0, 6.5, or 7.4) at 37°C, and the concentration of fluorescent HApt in the PBS solution was measured after different time points.

Accumulative HApt release rate (%) was calculated using $A1/A2 \times 100$, where $A1$ is the absorption intensity of Texas red-labeled HApt at different time points and $A2$ is the intensity of the total amount of Texas red-labeled HApt (including free and encapsulated HApt).

Quantification of MNP uptake by HeLa cells

Human cervical carcinoma HeLa cells were plated in 24-well plates (10⁶ cells/well) and incubated for 24 h at 37°C in a 5% CO₂ atmosphere. MNPs containing Texas red-labeled oligonucleotides (500 nM) were added to each well and incubated for 8 h, and then, cells were washed twice with ice cold PBS to remove excess MNPs, harvested, and resuspended in PBS. Flow cytometry was performed on a fluorescence activated cell sorting (FACS) Calibur flow cytometer (BD Biosciences, San Jose, CA, USA), and data were analyzed using FlowJo 7.6.1. Uptake of fluorescent oligonucleotides by HeLa cells

was also observed using fluorescence microscopy (AMG EVOS, Mill Creek, WA, USA).

Cell viability assays

Human breast cancer cell lines MCF7 and SKBR3 and human cervical carcinoma cell line HeLa were obtained from American Type Culture Collection (Manassas, VA, USA). SKBR3 cells were maintained in McCoy's 5A medium (Thermo Fisher Scientific, Waltham, MA, USA), and HeLa cells and MCF7 cells were maintained in Dulbecco's Modified Eagle's Medium (DMEM; Thermo Fisher Scientific); both media were supplemented with 100 U/mL penicillin G/streptomycin sulfate and 15% (v/v) fetal bovine serum (FBS) (Thermo Fisher Scientific), and cells were cultured at 37°C in a 5% CO₂ atmosphere.

Cells were seeded into collagen-coated 96-well plates (10⁴ cells/well), incubated for 24 h, and then incubated with different concentrations of unloaded MNPs for 8 h, followed fresh complete media for 16 h. Cell viability was measured using the Cell Counting Kit-8 (CCK-8; Dojindo, Kumamoto, Japan).

To assess aptamer-mediated killing of breast cancer cells, SKBR3 or MCF7 cells were incubated in 24-well plates with free HApt or HApt-MNPs at an aptamer concentration of 100, 125, or 150 nmol/L containing McCoy's 5A or DMEM without FBS for 8 h. Next, cells were cultured in fresh complete media for 16 h and then stained with 2 μM calcein acetoxymethyl ester and 4 μM propidium iodide (PI) (Beyotime Biotechnology Co., Ltd., Nantong, People's Republic of China) for 30 min. Cells were observed under a fluorescence microscope; live cells were stained green, and dead cells were stained red.

Apoptosis assays

An Annexin V-PI apoptosis detection kit (Signalway Antibody Co., Ltd., College Park, MD, USA) was used to assess apoptosis. SKBR3 cells cultured in 12-well plates were treated with free HApt, MNP-encapsulated HApt, or NCApt (125 nmol/L HApt or NCApt) for 8 h and then incubated in fresh complete media for 16 h. Cell apoptosis was analyzed using the FACSCalibur flow cytometry.

Confocal imaging of HApt-MNPs in SKBR3 cells

SKBR3 cells were incubated with Texas red-labeled HApt-MNPs for 8 h (HApt concentration of 125 nM), followed by fresh complete media for 16 h. Cells were washed three times with PBS, fixed in 3.7% paraformaldehyde in PBS for 15 min at room temperature, washed, permeabilized with 0.5% Triton X-100 in PBS, washed, and then incubated in 1% bovine serum albumin in PBST for 30 min at room temperature. Nuclei

were counterstained with 4,6-diamidino-2-phenylindole (Sigma-Aldrich Co., St Louis, MO, USA) or Hoechst 33342 (Sigma-Aldrich Co.) for 10 min at room temperature. HApt fluorescence was examined by confocal microscopy (TCS SP8; Leica Microsystems, Wetzlar, Germany). Texas red fluorescence intensity was measured by calculating the corrected total cell fluorescence (CTCF) using ImageJ.^{44,45}

$$\text{CTCF} = \text{Integrated density} - (\text{area of selected cell} \times \text{mean fluorescence of background readings})$$

HER2 immunoblotting

SKBR3 or MCF7 cells were cultured in six-well plates (10⁶ cells/well) in complete media for 24 h. Free HApt or HApt-MNPs were added (HApt concentration of 125 nM) and incubated for 24 h, and then, cells were collected, transferred to microcentrifuge tubes, and lysed in RIPA buffer (Pierce, Appleton, WI, USA) for 30 min on ice; protein concentrations were estimated using the bicinchoninic acid (BCA) assay (Bio-Rad Laboratories Inc., Hercules, CA, USA). An equal volume of sample buffer (125 mM Tris, pH 6.8, 4% sodium dodecyl sulfate (SDS), 10% glycerol, 0.006% bromophenol blue, and 1.8% β-mercaptoethanol) was added to each sample and boiled for 35 min. Samples (15 μg total protein) were loaded onto protein precast gels (Bio-Rad Laboratories Inc.) and electrophoresed at 120 V for 90 min, and proteins were transferred to polyvinylidene fluoride (PVDF) membranes at 300 mA for 115 min in transfer buffer. The membrane was immediately placed into blocking buffer (5% nonfat dry milk, 10 mM Tris, pH 7.5, 100 mM NaCl, 0.1% Tween 20) for 1 h at room temperature and then incubated with primary anti-HER2 (rabbit; 1:10,000) or anti-β actin (rabbit; 1:5,000) antibodies (Abcam, Cambridge, UK) overnight at 4°C. The membrane was washed twice in washing buffer (10 mM Tris, pH 7.5, 100 mM NaCl, 0.1% Tween 20) and then incubated with alkaline phosphatase-conjugated antirabbit IgG secondary antibody (1:3,000; Abcam) diluted in 5% nonfat dry milk solution at room temperature. The membrane was washed three times, and protein signals were developed using enhanced chemifluorescence substrate (EMD Millipore, Billerica, MA, USA) and visualized using a Tanon 5500 (Tanon Science & Technology Co., Ltd., Shanghai, People's Republic of China). The relative amounts of each protein were determined by quantification of the band density values using ImageJ.

Statistical analysis

The Student's *t*-test was used to compare data; *P*-values < 0.05 were considered statistically significant.

Results

Physicochemical properties and encapsulation efficiency of oligo-MNPs

The physicochemical properties of the oligo-MNPs are summarized in Table 2. The diameter of the oligo-MNPs decreased as the length of encapsulated oligonucleotide increased. Encapsulation efficiency increased as oligonucleotide length increased from 20 to 80 nt. The polydispersity index values obtained using DLS revealed the size uniformity of the oligo-MNPs. At pH 7.4, the oligo-MNPs were negatively charged and their zeta potentials exhibited small fluctuations between -32.1 and -40.1 mV, suggesting that the oligo-MNPs are electrically stabilized by forming colloidal dispersions at pH 7.4 in PBS. In acidic solution (pH <6.0), the PEG₈-PDPA₁₀₀-PEG₈ copolymers were positively charged due to protonation of the tertiary amine groups on the PDPA residues. However, the zeta potentials became negative when the pH was changed from acidic to alkaline (starting at pH ~ 6.5) due to deprotonation of the PDPA residues.²⁹ Since both the empty MNPs and oligo-MNPs were prepared in PBS at pH 7.4, they were expected to display a negative surface charge and the MNPs exhibited a more negative charge after oligonucleotide encapsulation. We were unable to determine exactly how the MNPs encapsulate oligonucleotides, though the hydrophobic interactions between nucleic acids and PDPA may play a major role.

MNP-encapsulated HApt is structurally similar to free HApt

The diameter and charge of HApt-MNPs in pH 7.4 PBS were 156.8 ± 9 nm and -35.9 mV, compared to 184.8 ± 16 nm and -10.6 mV for unloaded MNPs (Table 2). TEM showed

that the HApt-MNPs had a regular round shape and were uniformly dispersed (Figure 1A).

We used CD spectroscopy to investigate the structural integrity of HApt in HApt-MNPs; structural integrity is thought to be required for HApt to bind to HER2 expressed on the cell membrane.⁴¹ CD spectra of free HApt and HApt-MNPs (both at $1 \mu\text{M}$ HApt) were obtained from 300 to 200 nm. The CD spectrum of empty MNPs was subtracted from the CD spectrum of HApt-MNPs. Both free HApt and MNP-encapsulated HApt exhibited positive peaks at 265 and 210 nm and a negative peak at 245 nm (Figure 1B). The similarity of the CD spectra for free HApt and HApt-MNPs suggests that the conformation of HApt was preserved after encapsulation. Furthermore, the peak values were much larger for HApt-MNPs than free HApt. Since the same concentrations of HApt were analyzed for free HApt and HApt-MNPs, the larger peak values for HApt-MNPs may be caused by condensation of HApt within the MNPs.⁴⁶⁻⁴⁸ The CD spectra of the free and MNP-encapsulated NCApt were similar (Figure S1).

The rate of oligo-MNPs uptake is influenced by the length of oligonucleotide encapsulated

To assess the cellular uptake of oligo-MNPs, we incubated HeLa cells with Texas red-labeled oligo-MNPs (0.15 mg/mL MNPs, equivalent to 125 nM oligonucleotide). After the encapsulation reaction, the oligo-MNPs were purified to remove free oligonucleotides. Cellular uptake of the fluorescently labeled oligonucleotides was determined by flow cytometry. Oligonucleotides of the same length with different sequences exhibited comparable cellular uptake rates

Table 2 Properties of MNPs containing oligonucleotides of different lengths

Sample	Micelle concentration (mg/mL)	Diameter (nm)	PDI (± 0.012)	Zeta (± 1.7 mV)	Encapsulation efficiency ($\pm 6\%$)
Unloaded MNP	0.3	184.8 ± 16	0.08	-10.6	–
Free-20	–	0.7088	0.759	-24.1	–
MNP-20	0.3	168 ± 10	0.120	-32.1	38.11%
Free-42 (HApt)	–	0.7001	0.665	-20.3	–
MNP-42 (HApt)	0.3	156.8 ± 9	0.113	-35.9	51.88%
Free-54 (NCApt)	–	0.7168	0.751	-21.9	–
MNP-54 (NCApt)	0.3	154.9 ± 13	0.141	-32.7	73.09%
Free-80	–	0.6962	0.618	-18.5	–
MNP-80	0.3	135.3 ± 15	0.118	-32.3	73.16%
Free-100	–	0.8903	0.423	-26.2	–
MNP-100	0.3	137.9 ± 13	0.113	-40.1	51.85%

(Table 1), suggesting that oligonucleotide sequence does not have a major impact on the cellular uptake of oligo-MNPs. However, as shown in Table 1, the uptake rate declined as the oligonucleotide length increased >80 nt, suggesting that longer oligonucleotides (>80 nt) negatively affect the uptake of oligo-MNPs. The fluorescent signals were mainly localized inside the cells (Figure S2). We suspect that larger portions of longer oligonucleotides will be exposed to the outside of the micelles, which may prevent oligonucleotide condensation and limit cellular uptake.

HApt is rapidly released from HApt-MNPs at pH values under pH 5.0

The cumulative levels of Texas red-labeled oligonucleotide were measured in vitro under different pH conditions at 37°C to examine pH-responsive release of oligonucleotides from oligo-MNPs. Under mildly alkaline conditions (pH 7.4), HApt was released slowly from HApt-MNPs, which reached $9.7\% \pm 5.0\%$ after 47 h. Under weakly acidic conditions (pH 6.5), the release rate increased to $27\% \pm 4.0\%$ after 47 h. However, at pH 5.0, HApt was rapidly released from as early as 12 h incubation and the level of fluorescence was nearly 60% after 26 h (Figure 2). These results confirm that HApt is released from HApt-MNPs in a pH-responsive manner. HApt was not fully released at pH 5.0, consistent with our previous study.²⁹ The hydrophobic PDPA core may become gradually protonated and became swollen but not collapse under acid conditions, trapping some HApt with the core. At the same time, small amounts of HApt release may also partly explain the absorption of HApt on the dialysis tubing.

HApt-MNPs are more efficiently taken up by SKBR3 cells than free HApt

We used SKBR3 breast cancer cells as a cellular model of *HER2* overexpression and MCF7 cells as a model of normal/low *HER2* expression.⁴⁹ *HER2* mRNA and protein levels were examined using quantitative real-time polymerase chain reaction and Western blotting, respectively. *HER2* mRNA expression was 11.3-fold higher in SKBR3 cells than in MCF7 cells (Figure S3A). Accordingly, *HER2* protein was abundantly expressed in SKBR3 cells but barely detectable in MCF7 cells (Figure S3B).

Figure 2 Release of HApt from HApt-MNPs under neutral (pH 7.4) and acidic (pH 6.5 and 5.0) conditions at 37°C.

Notes: The MNP concentration was 0.15 mg/mL, equivalent to 125 nM HApt. The pH-dependent release rates of HApt from the micelles were quantified using fluorescence spectrophotometer. Data are mean \pm SD (n=3).

Abbreviations: HApt, human epidermal growth factor receptor 2 aptamer; MNPs, micelle-like nanoparticles.

SKBR3 cells were incubated with the same aptamer concentration (125 nM) of free HApt or HApt-MNPs. Confocal fluorescence microscopy showed the Texas red signals were much stronger in SKBR3 cells incubated with HApt-MNPs than free HApt at 8 h (Figure 3). Moreover, after 16 h incubation, fluorescent signals were observed in distinct clusters in SKBR3 cells incubated with HApt-MNPs compared to the weaker, diffuse signals in cells incubated with free HApt. This clustering pattern suggests that the HApt-MNPs were taken up into vesicular compartments after binding to HER2 on the cell membrane.^{38,41}

The intensity of the cellular fluorescent signals was 1.72-fold higher in SKBR3 cells incubated with HApt-MNPs (CTCF =1,497,627.0) than cells incubated with control NCapt-MNPs (CTCF =871,819.2) at the same aptamer concentration (125 nM), suggesting that cellular uptake of the HApt-MNPs partially depends on HER2-mediated endocytosis. As nanoparticles up to several hundred nanometers can enter cells via endocytosis in membrane-bound vesicles, a certain amount of HApt-MNPs and NCapt-MNPs must also have been taken up by SKBR3 cells via HER2-independent endocytosis (Figure 3).

The importance of the HApt-HER2 interaction on the uptake of HApt-MNPs was also supported by flow cytometry

analysis of SKBR3 and MCF7 cells. After incubation with HApt-MNPs, a lower percentage of MCF7 cells, which express low levels of HER2, was fluorescent (29.1%) compared to HER2-overexpressing SKBR3 cells (56.8%; Figure S4).

Moreover, we performed competitive assays of HApt-MNP uptake and cell viability. After 24 h preincubation of SKBR3 cells with free HApt (0.5 or 1.0 μ M), the media were refreshed and the cells were incubated with HApt-MNPs (containing 100 nM HApt) for 24 h. Pretreatment with free HApt significantly decreased the efficiency of HApt-MNP uptake (Figure S5A) as well as the mortality of the cell compared to cells treated with only HApt-MNPs (Figure S5B). Preincubation with the control NCapt had no apparent effect on HApt-MNP uptake or cell viability (Figure S5A and B). These results indicate that the uptake of HApt-MNPs and the resulting cell death are, at least to some extent, dependent on the HApt-HER2 interaction.

Unloaded MNPs exhibit low cytotoxicity toward breast cancer cell lines

To evaluate the cytotoxicity of the unloaded MNPs toward breast cancer cells, HER2-overexpressing SKBR3 cells and HER2-underexpressing MCF7 cells were incubated with

Figure 3 Confocal fluorescence microscopy images of SKBR3 cells incubated with Texas red-labeled free or MNP-encapsulated HApt or NCapt. **Notes:** SKBR3 cells were incubated with free or MNP-encapsulated HApt or NCapt (125 nmol/L HApt or NCapt) for 8 h and then incubated in fresh complete media for 16 h. Confocal fluorescence microscopy images from three independent experiments (n=3) are shown. Fluorescently labeled aptamers are shown in red; nuclei are stained with 4, 6-diamidino-2-phenylindole (blue). All scale bars are 50 μ m. CTCF was measured using ImageJ in 10 fields of view for each condition. ****P**<0.01 is considered statistically significant. **Abbreviations:** CTCF, corrected total cell fluorescence; HApt, human epidermal growth factor receptor 2 aptamer; MNPs, micelle-like nanoparticles; NCapt, negative control aptamer.

different concentrations (10–200 $\mu\text{g/mL}$) of unloaded MNPs for 8 h, followed by fresh complete media for 16 h. The CCK-8 assay showed that both cell lines remained highly viable. The percentages of viable SKBR3 and MCF7 cells were ~ 75 and $>85\%$, respectively, even when incubated with the highest concentration of unloaded MNPs (200 $\mu\text{g/mL}$; Figure 4A and B).

HApT-MNPs exert a potent cytotoxic effect in HER2-overexpressing SKBR3 cells

Next, we evaluated the cytotoxicity of HApT-MNPs in SKBR3 and MCF7 cells. In the CCK-8 assay, no significant cytotoxicity was observed in either SKBR3 or MCF7 cells treated with MNPs carrying the control NCapt (Figure 5A and B) or unloaded MNPs (Figure 4A and B). In contrast, when the aptamer concentration was ≥ 125 nM, at least 60% of HER2-overexpressing SKBR3 cells were killed by HApT-MNPs, whereas only 10% of MCF7 cells were killed (Figure 5A and B). This suggested that the cytotoxicity of HApT-MNPs depends on the expression of HER2 in the target cells and was confirmed by live-dead cell staining of SKBR3 cells treated with free HApT or HApT-MNPs (Figure 5C) and apoptosis assays of SKBR3 cells incubated with free or MNP-encapsulated HApT or NCapt (Figure 5D). The LD_{50} of HApT-MNPs in SKBR3 cells was 115 nM, while the LD_{50} of free HApT was >5 μM (Figure S6). These data indicate that the interaction between HER2 and HApT enables HApT-MNPs to exert a specific cytotoxic effect in HER2-overexpressing cells.

HApT-MNPs accumulate in lysosomes and induce degradation of HER2

To demonstrate the HApT-MNPs primarily accumulate in lysosomes after cellular uptake, a lysosome tracker (LysoTracker Green) was used to stain SKBR3 cells. The cells were cultured with Texas red-labeled HApT-MNPs or free HApT for 8 h at the same HApT concentration (125 nM), followed by fresh complete media for 16 h, and then stained. The cellular Texas red signals were much stronger for HApT-MNPs (Figure 6A, top panel) than free HApT (Figure 6A, bottom panel). HApT-MNPs appeared to be distributed in a clustered pattern within SKBR3 cells, suggesting that the nanoparticles were located in the vesicular compartments after uptake. Merging the Texas red and LysoTracker signals indicated that the nanoparticles were colocalized to lysosomes. Furthermore, stronger lysosomal signals were observed in cells incubated with HApT-MNPs, suggesting more lysosomes accumulated after cellular uptake of HApT-MNPs. These results demonstrate that HApT-MNPs were more efficiently delivered to lysosomes than free HApT.

HER2 protein expression was quantified by Western blotting in cells treated for 24 h with HApT-MNPs or free HApT (Figure 6B). HER2 protein expression significantly decreased in cells treated with HApT-MNPs ($24,454.43 \pm 1,632.02$) compared to cells treated with free HApT ($79,276.08 \pm 2,162.13$), suggesting HApT-MNPs efficiently direct HER2 to lysosomes for degradation in HER2-overexpressing SKBR3 cells.

To determine whether the increased HER2 degradation and cytotoxic effects observed in SKBR3 cells treated with HApT-MNPs can be attributed to altered lysosomal activity,

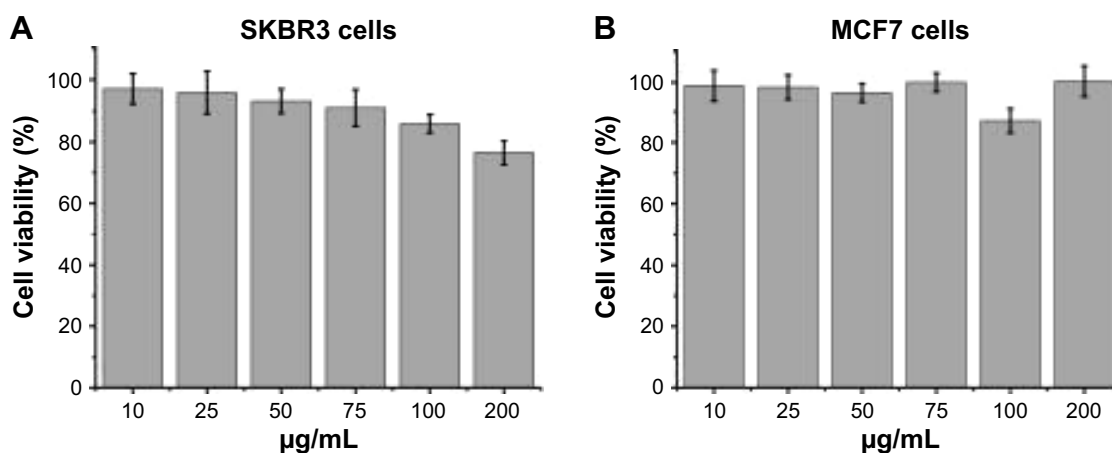

Figure 4 Cell viability of SKBR3 (A) and MCF7 (B) cells after incubation with different concentrations of unloaded MNPs.

Notes: Cells were incubated with different concentrations of unloaded MNPs (10–200 $\mu\text{g/mL}$) for 8 h, followed by fresh complete media for 16 h. Cell viability was measured using the CCK-8. Data are mean \pm SD ($n=5$). Both cell lines remained highly viable after incubation with unloaded MNPs.

Abbreviations: CCK-8, Cell Counting Kit-8; MNPs, micelle-like nanoparticles.

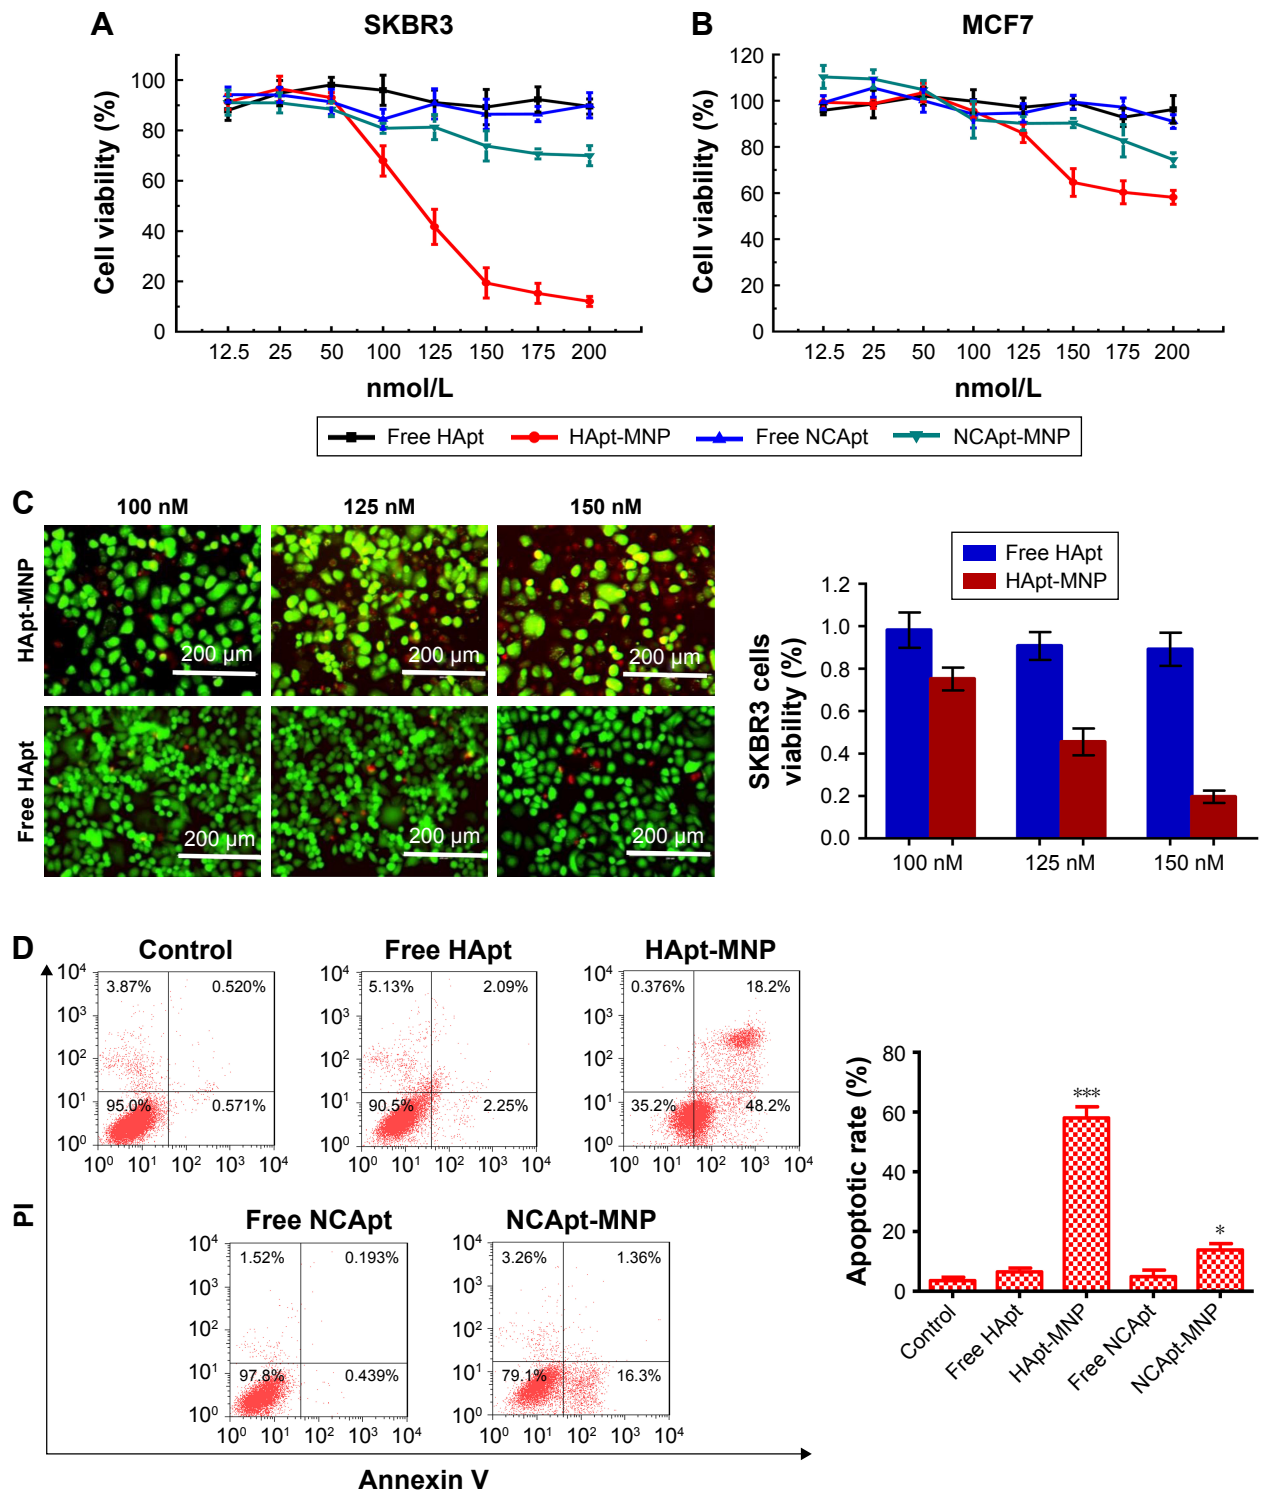

Figure 5 Cell viability of SKBR3 and MCF7 cells treated with different concentrations of free HApt, free NCApt, MNP-encapsulated HApt, or MNP-encapsulated NCApt. **Notes:** Cells were incubated with different concentrations of free HApt, free NCApt, MNP-encapsulated HApt, or MNP-encapsulated NCApt (HApt or NCApt concentration ranged from 12.5 to 200 nmol/L) for 8 h, followed by fresh complete media for 16 h. SKBR3 (A) and MCF7 (B) cell viability was measured using the CCK-8 assay. Data are mean ± SD (n=5). (C) Fluorescence imaging of SKBR3 cells incubated with different concentrations of free HApt or HApt-MNPs. Green (calcein-AM) and red (PI) staining indicate live and dead cells, respectively. All scale bars are 200 μm. Cell viability was determined by counting the numbers of live (green) and dead (red) cells in five fields of view per condition. Data are mean ± SD of three independent experiments. (D) Flow cytometric analysis of apoptosis in SKBR3 cells treated with free HApt, free NCApt, MNP-encapsulated HApt, or MNP-encapsulated NCApt. HApt-MNP led to a significantly higher apoptotic rate than the same concentrations of free HApt, free NCApt, or NCApt MNP. Data are mean ± SD of three separate determinations. *P<0.05 relative to untreated cells; ***P<0.001 compared to untreated cells. **Abbreviations:** calcein-AM, calcein acetoxy-methylester; CCK-8, Cell Counting Kit-8; HApt, human epidermal growth factor receptor 2 aptamer; MNPs, micelle-like nanoparticles; NCApt, negative control aptamer; PI, propidium iodide.

Figure 6 Lysosomal function is required for the cytotoxic effect of HApt-MNPs.

Notes: (A and B) SKBR3 cells were treated with HApt-MNPs or free HApt for 8 h at the same HApt concentration (125 nM), followed by fresh complete media for 16 h, then stained with lysosome tracker (green fluorescence) and Hoechst 33342 (blue fluorescence). (A) Confocal fluorescence microscopy images. Cellular signals were much stronger for HApt-MNPs (red, top panel) than free-HApt (red, bottom panel). Scale bars =10 μ m. (B) Western blot of HER2 protein expression. β -Actin was used as a protein loading control. Mean (\pm SD) HER2 band intensity was 24,454.43 (\pm 1,632.02) for HApt-MNPs and 79,276.08 (\pm 2,162.13) for free HApt (n=3). (C and D) SKBR-3 cells were treated with HApt-MNPs (125 nM) and bafilomycin A1 (Baf) for 24 h. (C) Cell viability was assessed using the CCK-8 assay. Values are mean (\pm SD) of five independent experiments. (D) Western blot of HER2 protein expression. β -Actin was used as a protein loading control. Mean (\pm SD) HER2 band intensity was 22,714.28 (\pm 1,326.53) for cells treated with HApt-MNPs and bafilomycin A1 and 16,424.66 (\pm 924.12) for cells treated with HApt-MNPs without bafilomycin A1 (n=3).

Abbreviations: CCK-8, Cell Counting Kit-8; HApt, human epidermal growth factor receptor 2 aptamer; MNPs, micelle-like nanoparticles.

we examined whether cell viability and HER2 protein expression were affected when lysosomal function was compromised using bafilomycin A1, a macrolide antibiotic that passively permeates into lysosomes and increases lysosomal pH, which disrupts lysosomal activity.^{50,51} Figure 6C indicates that pretreatment with bafilomycin A1 followed by co-incubation with HApt-MNPs increased cell viability (by ~25%) and upregulated HER2 (by ~38%) compared to cells treated with the same concentration of HApt-MNPs without bafilomycin A1 to block lysosomal function (Figure 6D). The increase in pH inside cells treated with bafilomycin A1 was confirmed by LysoTracker Red staining (Figure S7). Together, these results confirm that HApt-MNPs were released inside lysosomes at low pH.

Discussion

HER2, a member of the epidermal growth factor-related protein (ErbB) family, is commonly overexpressed on the plasma membrane in a variety of tumors, including gastric and breast cancers, mainly due to amplification of the *erbB2* gene.

Overexpression of HER2 on the cell surface promotes tumor progression and metastasis. Monoclonal antibodies targeting HER2 (eg, Herceptin/Trastuzumab) are clinically used to treat HER2-overexpressing metastatic gastric and breast cancers. Stimulation of the immune system (eg, ADCC) is critical for the cytotoxic of monoclonal antibodies. However, the resulting immune reactions also lead to several side effects.⁵²

The trimeric version of the HApt used in this study was initially developed by Mahlke et al,⁴¹ who demonstrated that HApt promoted translocation of HER2 from the cell surface to the cytoplasm in HER2-overexpressing N87 gastric cancer cells, which was associated with lysosome-dependent clearance of HER2 protein. Lee et al⁴⁰ reported that HApt exerted a cytotoxic effect in HER2-overexpressing SKBR3 breast cancer cells. HApt has been shown to induce cross-linking of HER2 on the cell surface, resulting in the translocation of HER2 to cytoplasmic vesicles for lysosomal degradation. Furthermore, HApt-mediated HER2 degradation triggered G0/G1 phase cell cycle arrest and cell death in

SKBR3 cells.^{40,41} Therefore, HApt does not exert a cytotoxic effect by directly stimulating the immune system.

Based on these previous reports, we hypothesized that our previously reported pH-responsive nanocarrier²⁹ would be ideally suited to deliver HApt to HER2-overexpressing cells. The MNPs are pH-responsive nanocarriers that encapsulate nucleic acids, which could facilitate cross-linking and thus internalization of HER2, and disassemble under acidic conditions, which may increase targeted degradation of HER2 in lysosomes. In this study, we confirmed that compared to free HApt, HApt-carrying nanoparticles (HApt-MNPs) increased HApt uptake and lysosomal transport in HER2-overexpressing SKBR3 cells (Figures 3 and 6A). Endogenous HER2 protein expression decreased significantly in cells treated with HApt-MNPs compared to cells treated with free HApt (Figure 6B). When lysosome activity was blocked, cell viability and HER2 protein expression increased in cells treated with HApt-MNPs compared to cells treated with the same concentration of HApt-MNPs alone (Figure 6C and D). Cell viability and apoptosis assays showed that HApt-MNPs exerted a more potent cytotoxic effect in SKBR3 cells than free HApt (Figure 5A, C, and D). Collectively, these data demonstrate that HApt-MNPs exert a specific cytotoxic effect in HER2-overexpressing SKBR3 cells.

Several factors may contribute to the more potent cytotoxic effects of HApt-MNPs than free HApt. First, the MNP nanoparticles increased the delivery of HApt into HER2-overexpressing cells compared to free HApt. Second, the pH-responsive release property of HApt-MNPs ensured that the encapsulated HApt cargo was released in endosomes/lysosomes. Third, the MNPs increase the local concentration of HApt: aggregation of HApt on MNPs would increase the ability of HApt to cross-link to HER2 on the cell surface.

The ability of MNPs to remain stable at normal physiological pH is beneficial, as it prolongs their retention time in the blood circulation and thereby greatly reduces the adverse effects of the drug cargo in normal tissues.^{37,39} Moreover, pH-sensitive release of HApt from MNPs in the endosomal or lysosomal compartments (pH 4.0–6.5) would result in rapid intracellular release of HApt in the target cells.^{53,54} Our lysosome activity inhibition experiments confirmed that the release of HApt inside the cell was dependent on low lysosomal pH. Furthermore, HApt must maintain the correct structure during loading and unloading within MNPs to retain its cytotoxic activity. We used CD spectroscopy to show that the conformation of HApt is likely to be preserved

after encapsulation within MNPs. Together these properties indicate that MNPs are a promising candidate for effective delivery of HApt to HER2-overexpressing cancer cells. Further studies are needed to evaluate the cytotoxic effect of HApt-MNPs in vivo.

These findings also indicate that MNPs could be used for the delivery of a range of oligonucleotides. Oligonucleotides ranging in length from 20 to 100 nt were efficiently encapsulated, with optimal encapsulation at 50 to 80 nt. The size of the MNPs declined as the length of encapsulated oligonucleotide increased. This indicates large single-stranded nucleic acids coil back on themselves due to complementary base pairing (hairpin structure) to form highly compacted supercoiled molecules.^{55,56} Further studies are necessary to determine whether supercoiling of long oligonucleotides suppresses the cellular uptake of oligo-MNPs.

Conclusion

Our pH-responsive and lysosome-targeting nanoparticle system can efficiently deliver a therapeutic oligonucleotide in vitro. The HApt-MNPs were translocated to lysosomes, where HApt was rapidly released at low pH. Therefore, MNPs may have the potential to improve the delivery and efficacy of nucleic acid-based cancer therapies.

Supplementary materials

Figure S1 Circular dichroism spectra of free and MNP-encapsulated HER2-NCApt.

Notes: The concentration of NCApt is 1 μ M. Both free and MNP-encapsulated NCApt exhibited positive peaks at 190 and 280 nm and negative peaks at 210 and 250 nm. The stronger peak signals associated with MNP-encapsulated NCApt suggest that NCApt was successfully encapsulated and condensed, while remaining conformationally unchanged.

Abbreviations: MNP, micelle-like nanoparticles; NCApt, negative control aptamer.

Figure S2 Representative fluorescent microscopy images of the uptake of Texas red-labeled oligonucleotide-MNPs by HeLa cells.

Notes: Texas red signals were mainly localized inside the cells. All scale bars are 100 μ m.

Abbreviations: HApt, human epidermal growth factor receptor 2 aptamer; MNPs, micelle-like nanoparticles; NCApt, negative control aptamer; nt, nucleotide.

Figure S3 HER2 mRNA and protein expressions in SKBR3 and MCF7 breast cancer cell lines.

Notes: (A) HER2 mRNA expression was quantified by quantitative reverse transcription polymerase chain reaction. Total RNA was extracted using TRIzol reagent (Thermo Fisher Scientific, Waltham, MA, USA), reverse transcribed using PrimeScript RT reagent Kit (TaKaRa, Dalian, People's Republic of China) according to the manufacturer's instructions, and amplified using SYBRPremix Ex Taq (TaKaRa). PCRs were performed in triplicate with the following conditions: 95°C/30 s, 40 cycles of 95°C/5 s, 60°C/15 s, and 72°C/10 s on a Stratagene MXP3000 cyclor (Stratagene, La Jolla, CA, USA) and repeated at least three times. Relative mRNA levels were calculated using the $-\Delta\Delta C_t$ method using β -actin as a control and expressed as $2^{-\Delta\Delta C_t}$. The primer pairs were as follows: β -actin-f/ β -actin-r: CTGGGACGACATGGAGAAA/AAGGAAGCTGGAAGAGTGC; HER2-f/HER2-r: GCAGCTTCATGTCTGTGCC/ACAGAGACTCAGACCCTGGC. Mean \pm SD values for three independent experiments are presented. Significant differences were determined using the Student's *t*-test, *** $P < 0.001$. (B) HER2 protein expression was analyzed by Western blotting. β -Actin was used as a protein loading control.

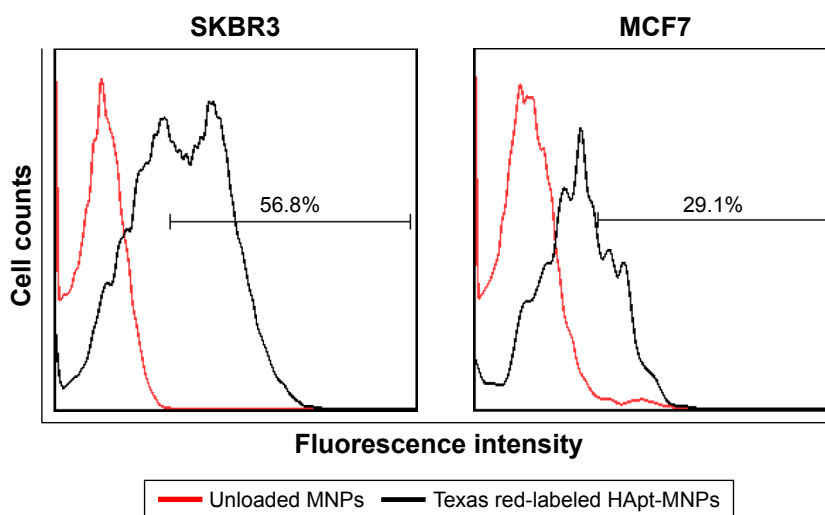

Figure S4 FACS analysis of the uptake of Texas red-labeled HApt-MNPs by SKBR3 and MCF7 cells.

Notes: Cells were incubated with HApt-MNPs (HApt concentration of 125 nM) for 8 h, followed fresh complete media for 16 h. The cellular uptake of HApt-MNPs was assessed by FACS. The percentage of fluorescent cells was much lower for MCF7 cells (which express no/low levels of HER2 as the HER2 gene is not amplified) compared to HER2-overexpressing SKBR3 cells (56.8%).

Abbreviations: FACS, fluorescence activated cell sorting; HApt, human epidermal growth factor receptor 2 aptamer; MNPs, micelle-like nanoparticles.

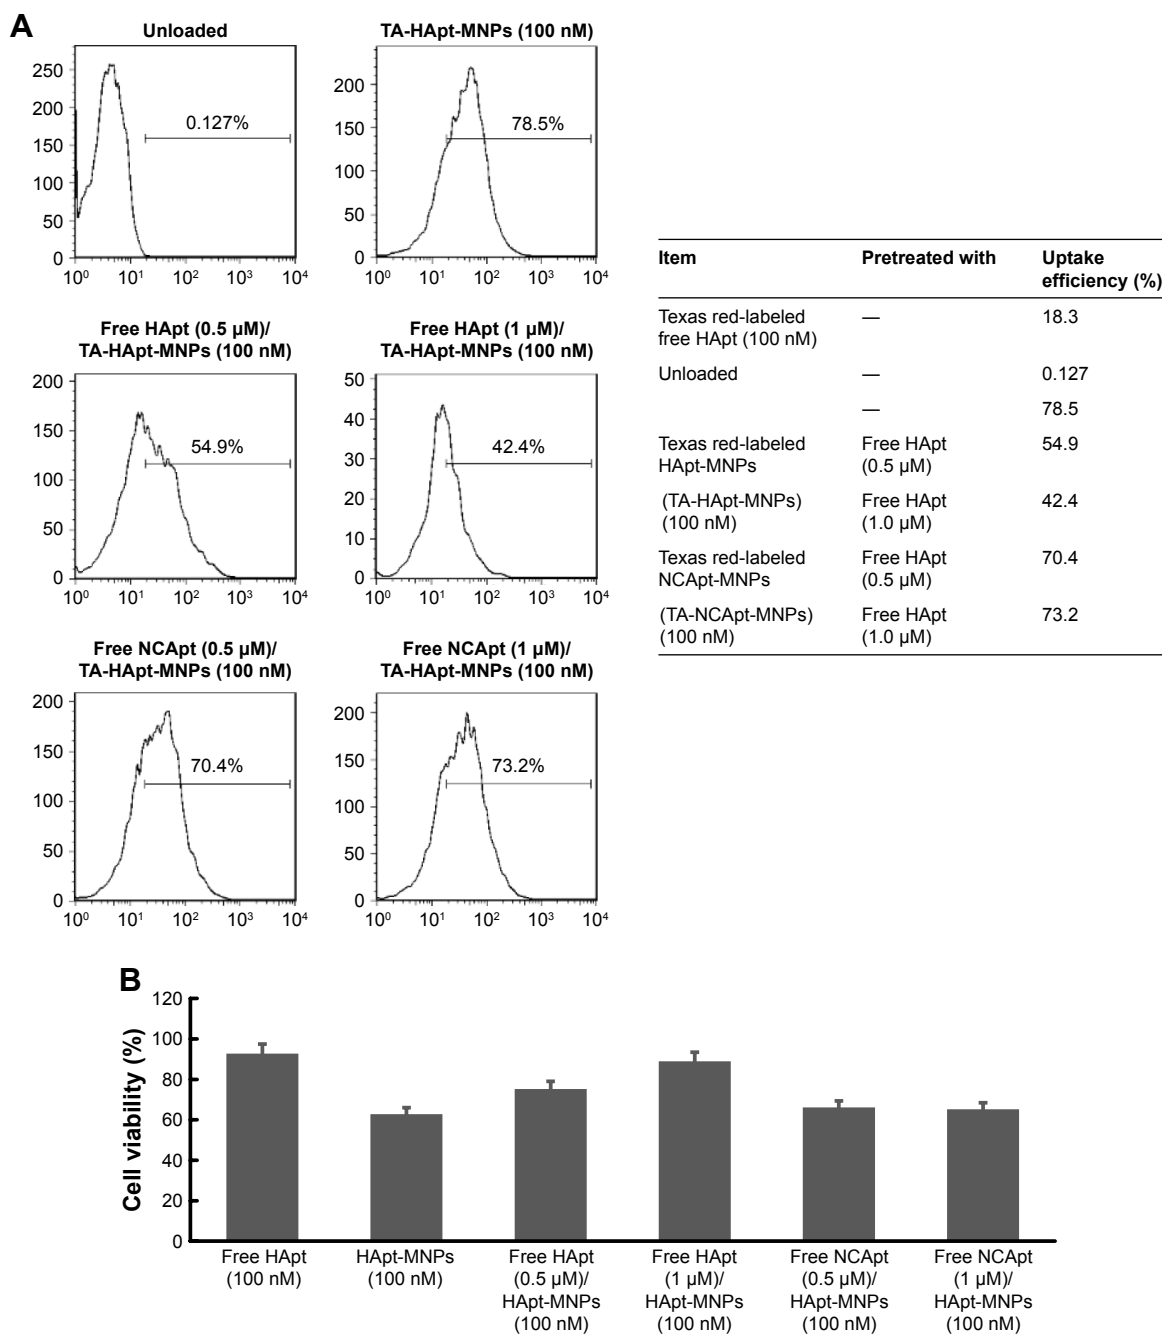

Figure S5 Competition binding, uptake and cell viability assays.

Notes: After a 24 h preincubation with free HApt (0.5 or 1.0 μ M), the media were refreshed and SKBR3 cells were incubated with HApt-MNPs (100 nM HApt) for 24 h. Uptake was assessed by determining percentage of fluorescent cells using flow cytometry. **(A)** Pretreatment with 1.0 μ M free HApt decreased the efficiency of HApt-MNP uptake (Texas red-labeled, TA-HApt-MNPs) by 36.1% (from 78.5 to 42.4%) compared to cells treated with only HApt-MNPs. **(B)** Pretreatment with 1.0 μ M free HApt increased the number of viable cells (10.6%) compared to cells treated with only HApt-MNPs (40.2%). Mean \pm SD values for three independent experiments are presented. Preincubation with the control NCApt had no significant effects on HApt-MNP uptake or cell viability.

Abbreviations: HApt, human epidermal growth factor receptor 2 aptamer; MNPs, micelle-like nanoparticles; NCApt, negative control aptamer; TA, Texas red.

Figure S6 Viability of SKBR3 cells after treatment with different concentrations of free HApt or NCApt.

Notes: Cells were incubated with 0.2–5 µM of free HApt or free NCApt for 8 h, followed fresh complete media for 16 h. Then, cell viability was assessed using the CCK-8 assay. Mean \pm SD values for three independent experiments are presented. Approximately 55.1% of SKBR3 cells treated with 5 µM free HApt were nonviable, compared to only 13.9% of cells treated with 5 µM free NCApt.

Abbreviations: CCK-8, Cell Counting Kit-8; HApt, human epidermal growth factor receptor 2 aptamer; NCApt, negative control aptamer.

Figure S7 LysoTracker Red staining of bafilomycin A1-treated cells.

Notes: SKBR3 cells cultured in a 24-well plate were incubated with McCoy's 5A media containing 50 nM bafilomycin A1 (Baf) (TOCRIS, Bristol, UK) dissolved in DMSO for 1 h at 37°C, followed by 50 nM LysoTracker Red (YEASEN Biotech Co., Ltd., Shanghai, People's Republic of China) for 30 min, washed three times with PBS, and then examined by fluorescence microscopy (AMG EVOS, Mill Creek, WA, USA). For control experiments, 1% DMSO was added to the medium. In the control group, the intensity of red-fluorescence was rather strong but faded sharply after the addition of bafilomycin A1, indicating an increase in lysosomal pH. Scale bars are 200 µm.

Abbreviations: DMSO, dimethyl sulfoxide; PBS, phosphate-buffered saline.
