

age 39 (range 34 to 54) and a median of 10 years of post-graduation experience. **Figure 1** summarizes appropriateness of respondents' answers regarding antibiotic initiation and antibiotic choice. The most common inappropriate choice was a fluoroquinolone. Vignettes were edited iteratively based on participant feedback on each case's realistic characteristics, missing necessary clinical data, formatting changes, and clarity (**Figure 2**).

Figure 1. Appropriateness of antibiotic initiation and antibiotic choice per clinical vignette.

Figure 2. Example of vignette editing process based on Think Aloud interview responses

Original Case 4

An 83 year-old man with non-insulin dependent diabetes mellitus, hypertension, and benign prostatic hypertrophy with a chronic indwelling urinary catheter has been living in your facility for the last 3 months. **This morning, staff noted he seemed confused and did not eat his breakfast but was able to take his morning pills.** The patient has no known antibiotic allergies and has not taken antibiotics in the prior 3 months.

His temperature is 100.4°F. His blood pressure is 135/90 with heart rate of 89, normal respiratory rate and oxygen saturation of 96% on room air. His physical exam is notable for normal cardiac and respiratory exam. He grimaces with applied suprapubic pressure and does not appear to have costovertebral angle tenderness. The chronic indwelling urinary catheter is in place with cloudy urine in bag. His Foley catheter is replaced and urinalysis from a fresh urine sample shows **white blood cell clumps, 3+ leukocyte esterase, 3+ nitrites, and many red blood cells.** His most recent creatinine clearance is 65 mL/min.

Missing Data

Missing information about baseline mental status added

Final Case 4

An 83 year-old man with non-insulin dependent diabetes mellitus, hypertension, and benign prostatic hypertrophy with a chronic indwelling urinary catheter has been living in your facility for the last 3 months. This morning, **staff noted he was newly confused** and did not eat his breakfast but was able to take his morning pills. **He has not had any sick contacts and there are no known COVID-19 cases in the facility.** The patient has no known antibiotic allergies and has not taken antibiotics in the prior 3 months.

His temperature is 100.4°F. His blood pressure is 135/90 with heart rate of 89, normal respiratory rate and oxygen saturation of 96% on room air. His physical exam is notable for normal cardiac and respiratory exam. He grimaces with applied suprapubic pressure and does not appear to have costovertebral angle tenderness. The chronic indwelling urinary catheter is in place with cloudy urine in the bag. His Foley catheter is replaced and urinalysis from a fresh urine sample shows white blood cell clumps, 3+ leukocyte esterase, 3+ nitrites, and many red blood cells. **SARS-CoV-2 PCR testing is negative.** His most recent creatinine clearance is 65 mL/min.

Realistic

Given frequency of COVID-19 infection and few localizing symptoms, COVID-19 testing added

Formatting

Prose formatting of test results preferred, as it simulates telephone conversation

Conclusion. This mixed-methods approach effectively captured prescribers' feedback about length, response method, and case characteristics for our clinical vignettes. Responses assessed differences in prescribers' decision to initiate antibiotic treatment and antibiotic choice. The refined vignettes will be used in a national survey.

94. Implementation of Antibiotic Prescribing Scorecards in the Ambulatory Care Setting

Sara Revolinski, PharmD, BCPS¹; J. Njeri Wainaina, MD, FACP, FHM¹; Maxx Enzmann, PharmD, BCPS²; Deanna Olexia, RPh²; Christopher Sobczak, MD, FACP, FAAP³; ¹Medical College of Wisconsin, Milwaukee, WI; ²Froedtert Hospital, Milwaukee, Wisconsin; ³Froedtert & the Medical College of Wisconsin, Milwaukee, Wisconsin

Session: P-06. Antimicrobial Stewardship: Non-Inpatient Settings

Background. Up to 56% of antibiotics prescribed in the ambulatory setting in the United States are inappropriately prescribed, with 30% of those determined to be unnecessary. In order to increase transparency and education about antibiotic prescribing in our ambulatory clinics at our institution, we implemented quarterly scorecards demonstrating antibiotic prescribing trends for primary care prescribers.

Methods. This pre-post interventional study analyzed the impact of prescriber scorecards on antibiotic prescribing, with the intervention consisting of real-time education and presentation of baseline data via scorecards. Prescribers were educated on

the scorecard project via live meetings in Nov-Dec 2020. In Dec 2020, prescribers were sent individual emails describing their baseline antibiotic prescription rate (defined as number of prescriptions per 100 patient encounters), de-identified comparison data for other prescribers within their individual clinic, and average rate of the top 10% of prescribers with the lowest prescription rates. Baseline data was from prescriptions dated Jan-Mar 2020. The email also explained the project and shared that quarterly scorecards would be distributed in 2021. Baseline data was compared to prescription data from Jan-Mar 2021. Knowing the COVID-19 pandemic resulted in significantly fewer encounters for respiratory infections, data was also analyzed with respiratory diagnoses removed from the dataset.

Results. In the pre-intervention period, 11,769 antibiotics were prescribed during 92,239 encounters for a prescription rate of 12.8 (95%CI: 12.5-13.0). Of 96,449 encounters in the post-intervention period, 7,326 antibiotics were prescribed for a rate of 7.6 (95%CI: 7.4-7.8; p<0.0001). When respiratory diagnoses were removed, prescription rates were 6.1 (95%CI: 5.9-6.2) in the pre-group, compared to 6.3 (95%CI: 6.1-6.5; p=0.0546). When analyzed by prescriber, significant decreases were seen in prescriptions by physicians (5.8 vs 5.4, p=0.0035) while increases were seen in prescriptions by advanced practice prescribers.

Conclusion. Antibiotic scorecards sent to prescribers may result in reduced antibiotic prescribing, but further research is needed to elucidate the impact of the scorecards in light of the COVID-19 pandemic.

95. Reduced Antibiotic Duration Defaults in Outpatient Automated Dispensing Cabinets Change Antibiotic Prescribing Habits in a Tertiary VA Healthcare System

Nicholas J. Newman, PharmD¹; Usha Stiefel, MD²; Robert C. Wenzell, PharmD¹; Daniel Papell, R.Ph. / B.S. in Pharmacy³; Jeffrey Cooney, Pharm.D., BCPS³; Sharanie Sims, PharmD⁴; Amy H. Shumaker, PharmD, BCPS¹; Ukwen Akpoji, PharmD, BCPS¹; ¹VA Northeast Ohio Healthcare System, Beachwood, Ohio; ²Cleveland VA Medical Center, Cleveland, OH; ³Northeast Ohio Veterans Affairs Healthcare System, Cleveland, Ohio; ⁴Louis Stokes Cleveland VA Medical Center, Cleveland, OH

Session: P-06. Antimicrobial Stewardship: Non-Inpatient Settings

Background. Ten percent of adult, outpatient visits result in an antibiotic prescription (Rx). At the start of our intervention, our VA healthcare system consisted of 13 community-based outpatient clinics (CBOCs), 9 of which did not have an on-site pharmacy but utilized automated dispensing cabinets (ADCs) for prepackaged outpatient Rx. ADC antibiotic orders are generated from electronic medical record (EMR) order sets. The stewardship team shortened the durations of 5 antibiotics in the ADC order sets to make them consistent with current literature and guidelines. We assessed the impact of these changes on antibiotic prescribing habits.

Methods. We compared outpatient antibiotic Rx data between 10/1/2018-9/30/2019 (pre-intervention) and 10/1/19-9/30/20 (post-intervention) from 8 CBOCs with ADCs (1 closed during the pandemic). Amoxicillin-clavulanate 875/125mg (AMC), cephalexin 500mg (CPH), levofloxacin 500mg and 750mg (LEV 500 and LEV 750), and sulfamethoxazole-trimethoprim 800/160mg (SXT) prescription durations were all reduced by 3 days. Process metrics included days supplied/1000 prescriptions (DS/1000 Rx), median DS, and ADC utilization rates. We used Mann-Whitney U and correlation statistical analyses to assess differences and associations.

Results. The DS/1000 Rx of antibiotics with a default duration change decreased in the post-intervention phase for CBOCs with ADCs (AMC, -25.4%; CPH, -21.1%; LEV 500, -18.9%; LEV 750, -28.0%; SXT, -27.4%). The median DS for these antibiotics all reduced by 3 days in concordance with new ADC prescriptions defaults (AMC, 10 vs 7 days, P<0.001; CPH, 10 vs 7 days, P<0.001; LEV 500, 8 vs 5 days, P<0.001; LEV 750, 8 vs 5 days, P<0.001; SXT 10 vs 7 days, P<0.001). Due to COVID-19, 7/8 ADC CBOCs closed for in-person visits from 3/20/20-5/4/20. ADC utilization was inversely proportional to DS/1000 Rx for most antibiotics (R: -0.51 to -0.77) except SXT.

Table 1. Antibiotic days' supply per 1000 prescriptions (excluding days' supply ≥ 30 days)

Drug	Days' supply per 1000 prescriptions		Percentage change
	Pre-intervention	Post-intervention	
Amoxicillin 500mg	8992	8846	-1.6%
Amoxicillin/clavulanate 875/125mg	9940	7413	-25.4%
Cephalexin 500mg	9907	7815	-21.1%
Ciprofloxacin 500mg	8189	7907	-3.4%
Doxycycline 100mg	10138	9837	-3.0%
Levofloxacin 500mg	7974	6467	-18.9%
Levofloxacin 750mg	7809	5621	-28.0%
Sulfamethoxazole/trimethoprim 800/160mg	9894	7182	-27.4%

Antibiotic days' supply per 1000 prescriptions (excluding days' supply ≥ 30 days)

Table 2. Median days' supply for antibiotics available in ADCs, pre- versus post-intervention

Drug	ADC Default Duration		Median Days' Supply		P-value
	Pre-intervention	Post-intervention	Pre-intervention	Post-intervention	
Amoxicillin 500mg	10	10	10	10	0.116
Amoxicillin/clavulanate 875/125mg	10	7	10	7	<0.001
Cephalexin 500mg	10	7	10	7	<0.001
Ciprofloxacin 500mg	7	7	7	7	0.276
Doxycycline 100mg	10	10	10	10	<0.001*
Levofloxacin 500mg	8	5	8	5	<0.001
Levofloxacin 750mg	8	5	8	5	<0.001
Sulfamethoxazole/trimethoprim 800/160mg	10	7	10	7	<0.001

*There was a shift towards shorter durations of doxycycline therapy in the post-intervention phase
