Qigong is a gentle exercise that promotes health and well-being. This study evaluated the acute physiological and psychological effects of one session of qigong exercise in older practitioners. A total of 45 participants (mean age, 65.14 years) were recruited. Meridian electrical conductance, State-Trait Anxiety Inventory (STAI), heart rate variability (HRV), and Short Form 36 (SF-36) were evaluated and compared before and after one session of qigong exercise. The results revealed that the electrical conductance of all meridians, except spleen and bladder meridians, increased significantly ($p < 0.05$). Compared with baseline values, upper to lower body ratio and sympathetic/vagal index were significantly improved and closer to 1 ($p = 0.011$ and $p = 0.007$, resp.). STAI-S and STAI-T scores decreased significantly ($p < 0.001$ and $p = 0.001$, resp.). The RR interval of HRV decreased significantly ($p = 0.035$), a significant positive correlation was observed between kidney meridian electrical conductance and SF-36 physical scores ($r = 0.74$, $p = 0.018$), and a positive correlation was observed between pericardium meridian electrical conductance and SF-36 mental scores ($r = 0.50$, $p = 0.06$). In conclusion, one session of qigong exercise increased meridian electrical conductance, reduced anxiety, and improved body and autonomic nervous system balance. These findings provide scientific evidence for acute physiological and psychological effects of qigong exercise in older practitioners.

1. Introduction

Qigong, an ancient Chinese healing practice that was originally a martial art, has been developed and used to improve physical fitness and strength in China for 7000 years [1–4]. The word “qigong” involves two theories: “qi,” the vital energy of the body and “gong,” the training or cultivation of qi [5]. Concentration, relaxation, meditation, breathing regulation, and body posture and movements are the basic components of qigong [1, 2]. In contrast to conventional exercise, qigong aims to achieve a harmonious flow of qi in the body and cultivate a spirit of systematic training exercise to improve physical fitness and overall well-being through the coordination of rhythmic movements, regulated breathing,

and meditation [6]. There are essentially two types of qigong: internal and external. Internal qigong or qigong exercise is self-directed and involves the use of movements, meditation, and controlled breathing patterns, whereas external qigong is typically performed by experienced practitioners who use their hands to direct qi onto patients for healing or treatment [1, 7–9]. Typically, qigong can be classified into dynamic and static qigong. Dynamic qigong involves the coordination of movements and meditation, whereas static qigong focuses on mental concentration and body relaxation without physical movements [1, 2].

Meridians are associated with the underdifferentiated, interconnected cellular networks that regulate growth and physiology. The meridian theory explains the distribution

and nonspecific activation of organizing centers, acupuncture points, and the high electrical conductance of the meridians [10–13]. In the human body, meridian theory deals with physical regulation and pathological changes [14, 15]. The condition of the meridian system can be measured by its electrical characteristics which have been studied since the 1950s. Acupuncture points have been widely accepted as areas of low electrical impedance and high conductance [16–20]. Skin conductance response is typically measured by applying a small direct current signal through two electrodes placed on the skin [13, 21]. Nakatani identified 12 channels of high electrical conductance on the left and right sides of the body (24 in total) and developed the Ryodoraku theory according to the philosophy of traditional Chinese medicine (TCM) [16]. Skin electrical conductance varies with the activity of a subject's autonomic nervous system and has been used to investigate mood changes and the mechanisms of the autonomic nervous system [22, 23]. The properties of meridians reflect the conditions of certain organs when their mutual relations and changes with microelectrical current are analyzed and compared [24]. The electrical information mapping transforms associated with various medical syndromes, signs, symptoms, and diseases were reported in a previous study [13].

The meridian electrical conductance investigates the meridian energy. Meridian energy analysis devices can reflex the conditions of certain organs through analysis of the symmetrical Yuan points. Changes with microelectrical currents represent the physiological phenomena of the relevant meridian [24, 25]. The electrical conductivity has been reported to monitor the effects of qigong workshop in the previous study [5]. Heart rate variability (HRV) is used as a sensitive index of autonomic nerve activity. The analysis of HRV provides quantitative information on autonomic control mechanisms [26]. It has been reported that five minutes of Tai Chi Qigong was found to improve HRV in nasopharyngeal cancer patients [27]. The State-Trait Anxiety Inventory (STAI) is a psychological inventory based on a 4-point Likert scale. It consists of forty questions on a self-report basis. These questionnaires are a highly reliable measure of stress and anxiety [28]. Qigong exercise significantly relieved anxiety and reduced stress among healthy people were reported in the previous study [29]. The SF-36 health survey is a self-report survey commonly used as a generic health questionnaire for adults which covers eight health domains, namely, physical functioning, physical role functioning, bodily pain, general health perceptions, vitality, social role functioning, emotional role functioning, and mental health [30]. SF-36 scores have been used to evaluate the effects of qigong exercise in breast cancer survivors [31]. The conceptual framework of this study was shown in Figure 1 guiding this study.

Long-term practice of qigong exercise may help in maintaining satisfactory health and preventing and treating illness. Qigong exercise has been reported to influence depression, stress, anxiety symptoms, chronic pain, immunity, infection, and quality of life [9, 32–36]. However, evidence-based research on the acute physiological and psychological effects of qigong exercise in older practitioners is yet to be reported. This study therefore evaluated the acute physiological and

psychological effects of one session of qigong exercise in older practitioners.

2. Methods and Measures

2.1. Study Design. This research involved a prospective, pre- and postcomparison study. After obtaining informed consent from the participants, meridian electrical conductance measurements, questionnaires, and baseline heart rate variability (HRV) measurements were obtained before and after one session of qigong exercise.

Chinese Bioenergy Qigong is a popular and well known exercise in Taiwan and Hong Kong. It is easy to learn with low cost. There is no limitation in time or place to practice. Hundred thousand people practice Chinese Bioenergy Qigong in Taiwan. It not only active body adjustment but also harmonizes mind adjustment. It is easy for general population to practice every day. Chinese Bioenergy Qigong is a 1-hour session of qigong exercise conducted and popularized by Dr. Li Cheng Chung, which includes warm-up movements, breathing regulation, gentle movements, body stretching, meditation, and relaxation. Thus Chinese Bioenergy Qigong was chosen to be the intervention program in this study. Additional details can be obtained from the following webpages:

<https://www.youtube.com/watch?v=M8b6WkAILB8>;

<https://info.ck17.org/index.php/chi-kung-demonstration/the-17-motions-of-the-health-sport> [37, 38].

Acute is referring to a condition of rapid onset and is of generally brief duration. In this study, the physiological and psychological conditions before and after qigong exercise were evaluated within 30 minutes, so the physiological and psychological effects of Qigong exercise were conceptually defined as acute effects.

2.2. Participants. One of the authors in this study, TT Wei, is the senior coach of Chinese Bioenergy Qigong. He announced the information about the study and searched for participants. Optimal qigong practicing environment to conduct the study was taken into consideration. It takes about two months to learn to practice Chinese Bioenergy Qigong. The low frequency of practicing may forget how to practice correctly.

As far back as 1875, in Britain, the Friendly Societies Act enacted the definition of old age as “any age after 50” [39]. The age of 50 years was defined as the working definition of “older” or “old” in World Health Organization (WHO) minimum data set (MDS) project meeting on aging in 2001 in order to take into account the real situation of older persons in developing countries [40]. Furthermore, participants aged 50 to 70 years were regarded as elders in the previous study [41].

From September 23, 2016, to November 5, 2016, elders aged 50 to 90 years from two communities (Tou-Liou and Tan-Mu) in Taiwan without severe medical conditions and practicing Chinese Bioenergy Qigong 5 days a week for at least 3 months were eligible to be recruited in this study

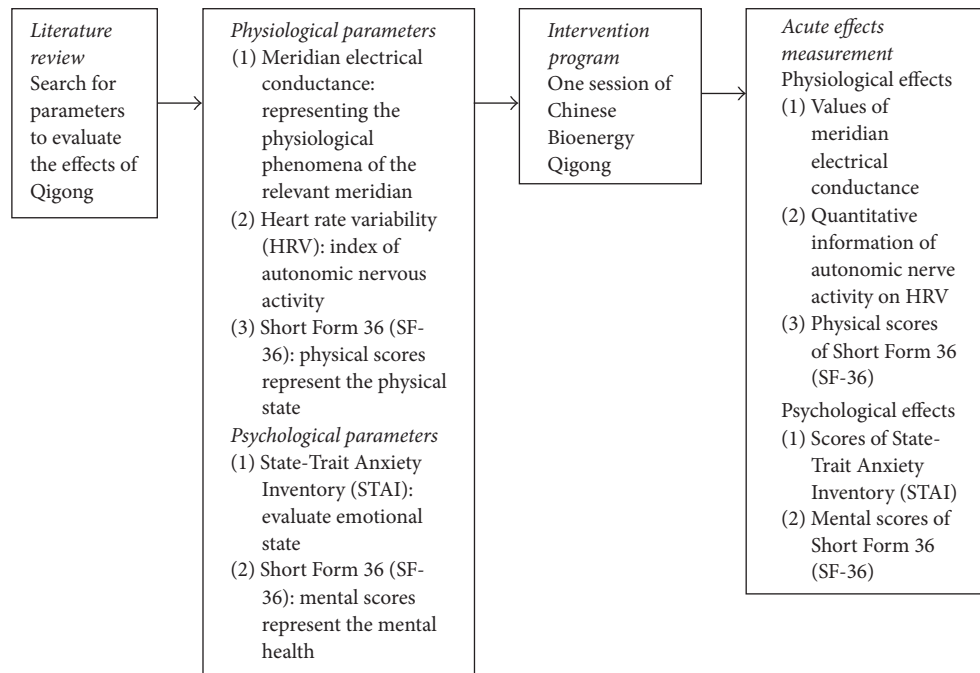

FIGURE 1: Conceptual framework.

in order to make sure the participants can practice qigong correctly and smoothly. Subjects who were unable to read and sign the consent form, had been diagnosed with a major illness (such as acute myocardial infarction, stroke, late-stage cancer, paralysis, and major organ transplantation), were pregnant, or had been diagnosed with a mental disorder (such as anxiety and depression) were excluded.

The study was approved by the Institutional Review Board of Shown Chwan Memorial Hospital, Taiwan (number 1040408). Informed consent was provided by all participants.

2.3. Measurements. In order to avoid interoperator variability, the machines were operated by the same skilled operator in this study [42]. The skin electrical conductance was operated by CY Lin, and heart rate variability was operated by CC Wang for all participants. The meridian electrical conductance and heart rate variability data were measured before and after qigong exercise within 30 minutes.

2.3.1. Meridian Electrical Conductance. The participants were rested on a chair for 10 minutes before measurements were recorded. All measurements were obtained on a sunny morning in fall to maintain temperature and moisture consistency. It has been reported that the degree of skin moisture would influence Meridian Energy Analysis Device (MEAD) measurement [25]. To avoid sweat after qigong influence MEAD measurement, all participants were required to dry the body with a dry towel especially wrists and ankle. The electrical conductance of 24 acupuncture points in the wrists and ankles of the 12 left and 12 right meridians was measured using a device (MEAD, 6th generation, Medpex Enterprises, Taiwan). The meridians were as follows: lung

(L, H1), pericardium (P, H2), heart (H, H3), small intestine (SI, H4), triple energizer (TE, H5), large intestine (LI, H6), spleen (SP, F1), liver (LIV, F2), kidney (K, F3), urinary bladder (B, F4), gallbladder (G, F5), and stomach (S, F6). The conductivity at the acupuncture point is directly proportional to the amperage of the DC current that flows through the skin when 12 V with an output current of 0–200 uA is applied to the points individually. Higher values indicate higher conductance between the reference electrode, which is 35 mm in diameter and clipped on the left palm, and the acupuncture point, which is measured using a 10 mm diameter cotton with saturated saline solution. The average electrical conductance of 24 meridians in each subject was calculated. The index of sympathetic/vagal balance was defined as the highest average limb electroconductivity value on the dorsal or ventral side, which was divided by the lowest value during MEAD analysis. The yin meridians were lung, pericardium, heart, liver, spleen, and kidney, while yang meridians were small intestine, triple energizer, large intestine, urinary bladder, gallbladder, and stomach. The upper meridians indicate those on hands and the lower meridians indicate those on feet. There are 12 meridians each on the left and right sides of the body. The upper to lower body ratio is calculated as the sum of the upper meridians divided by the sum of the lower meridians. The yin to yang ratio is defined as the sum of the yin meridians divided by the sum of the yang meridians. The left to right ratio means the sum of the left meridians divided by the sum of the right meridians [16, 20, 21].

2.3.2. Heart Rate Variability. Five-minute electrocardiography data were recorded immediately after the MEAD measurements. Polar heart-rate monitors (Polar Vantage

NV, Polar Electro Oy, Finland) were used to continuously collect heart rate data in the form of RR intervals from all participants before and after one session of qigong exercise. After data collection, HRV parameters were calculated using Kubios HRV (version 2.1; Biosignal Analysis and Medical Imaging Group, University of Eastern Finland, Finland) [27]. The participants' spectral HRV data were expressed in terms of RR intervals, lower frequency (LF), high frequency (HF), normalized LF, and normalized HF.

2.3.3. Questionnaire. Two instruments were adopted in this study. The first was the Short Form 36 (SF-36) health survey and the second was the State-Trait Anxiety Inventory (STAI). Both were self-report questionnaires.

Short Form 36 Health Survey. The SF-36 health survey is a self-report survey commonly used as a generic health questionnaire for adults. It covers eight health domains, namely, physical functioning, physical role functioning, bodily pain, general health perceptions, vitality, social role functioning, emotional role functioning, and mental health [30, 43]. The questionnaire includes 36 main questions, which contain several subset questions. These questions are related to the various domains deliberately nested into the instrument to ensure that participants carefully read and assess each question before responding.

State-Trait Anxiety Inventory. The STAI contains two subsets, which collect subjective data from participants on their state and trait anxiety in the form of two questionnaires of 20 questions each. These questionnaires are a highly reliable measure of stress and anxiety. State anxiety (STAI-S) is designed to assess individuals' reaction to stress and their emotional state at a particular time, whereas trait anxiety (STAI-T) is related to individuals' personality traits and their stress perceptions. The questions require the participants to rank their current and general feelings toward certain statements among four options of increasing frequency ranging from "almost never" to "almost always." Higher STAI scores suggest higher anxiety levels [28, 44, 45].

2.4. Statistical Analysis. The demographic data were expressed as means and standard deviations. The continuous data before and after one session of qigong exercise were compared using the paired *t*-test. The correlations between the variables were evaluated using the Pearson correlation test. STATA 11 was used for statistical analysis; $p < 0.05$ was considered statistically significant.

3. Results

3.1. Comparisons of Electrical Conductance of Meridians before and after Qigong Practice. A total of 45 participants (13 men and 32 women; mean age, 65.14 ± 9.38 years) were recruited in this study. All participants were Asian who live in Taiwan. More than half of the participants were married (75.56%). The mean value of education years was 10.62 ± 4.46 years. The mean values of heart rate before and after

qigong exercise were 73.24 ± 11.77 and 73.20 ± 11.03 bpm ($p > 0.05$). The electrical conductance of all meridians, except the spleen and bladder meridians ($p > 0.05$), increased significantly ($p < 0.05$) after one session of qigong exercise. The mean values of the electrical conductance of 12 meridians were significantly higher than the baseline values (Table 1). Compared with the baseline values, the upper to lower body ratio and sympathetic/vagal index were significantly improved and close to 1 ($p = 0.011$ and $p = 0.007$, resp.). However, no significant differences were observed in the yin to yang or left to right body balance ($p = 0.57$ and $p = 0.26$, resp.; Table 2).

3.2. Comparisons of STAI and SF-36 before and after Qigong Exercise. The STAI-S and STAI-T scores and the RR intervals of HRV decreased significantly ($p < 0.001$, $p = 0.001$, and $p = 0.035$, resp.). However, HF, LF, normalized HF, and normalized LF did not differ significantly ($p = 0.39$, $p = 0.84$, $p = 0.28$, and $p = 0.43$, resp.; Table 3). A significant positive correlation was observed between kidney meridian electrical conductance and SF-36 physical scores ($r = 0.74$, $p = 0.018$; Figure 2(a)). Furthermore, nonsignificant positive correlations were observed between kidney meridian electrical conductance and SF-36 total scores ($r = 0.30$, $p = 0.06$; Figure 2(b)). A positive relationship was observed between pericardium meridian electrical conductance and SF-36 mental scores ($r = 0.50$, $p = 0.06$) (Figure 3(a)). By contrast, a negative correlation was observed between pericardium meridian electrical conductance and STAI-S scores ($r = -0.57$, $p = 0.092$; Figure 3(b)).

4. Discussion

Qigong is a comprehensive mind-body practice and a low-cost exercise that has been practiced in China for 7000 years. Qigong can be performed anywhere at any time. Studies investigating the sustained benefits of regular qigong practice have revealed that it prevents bone loss, reduces oxidative stress, and increases antioxidant enzymes in middle-aged women and improves quality of life and sleep quality in elderly people [32, 46–48]. Moreover, qigong has been reported to effectively improve balance and strength and promote physical flexibility in healthy adults [49, 50]. TCM describes the meridian system as an essential pathway system and conduit for qi [51]. The core theory of the meridian system plays a crucial role in various therapies, including acupuncture, acupressure, moxibustion, tai chi, and qigong. Major acupuncture points are located on the skin along the 12 main meridian pathways. It is believed that qi is guided and transferred through a connection from the somatic meridian to the internal organs as an integrated system [52–54].

The application of Meridian Energy Analysis Device (MEAD) is of high clinical interest not only in the objective assessment of traditional Chinese medicine but also in predicting the meridian flow of the corresponding organ. However, some technical factors can influence skin electrical impedance, including the size of electrode, the amount of pressure it place on the skin, the accuracy of the acupoint

location, environment, and degree of skin moisture [25, 55, 56]. In order to control of the quality of study, the MEAD machine performed automatic digital calibration systems every time before taking measurement to help the operator to exactly control the confounding factors. To avoid interoperator variability, the MEAD machine was operated by the same skilled operator, CY Lin, for all participants. The environment and degree of skin moisture tried to be in the same condition as possible as we can. The MEAD usually indicates constant values in the human body in the absence of external stimulation, visceral abnormalities, of diseases. It has been reported by Nakatani that the reproducibility is 93.2% to support the use of MEAD [24, 25].

The acute physiological and psychological effects of qigong exercise on individual meridians are yet to be reported. After one session of qigong exercise, the electrical conductance of all meridians, except the spleen and bladder meridians, increased significantly in the current study. Our findings are consistent with previous studies, which have revealed that qigong exercise promotes qi and blood circulation to increase physical energy and health [57, 58]. According to TCM, the spleen is responsible for the transformation and transportation of different substances that are the foundation of after-birth existence. Spleen functions are essential in maintaining the digestive power of the body and transforming food into qi and blood [59]. The spleen in

TCM is similar to the gastrointestinal system in conventional medicine. Age-related selective decline in gut functions, such as changes in taste, esophageal sphincter motility, gastric emptying, and neurons of gut transit-related mesenteric plexus, may result in malnutrition [60]. Furthermore, aging has been associated with defects in structural and functional mucosal defense, diminished ability to generate protective immunity, and increased incidence of inflammation and oxidative stress; therefore, gastrointestinal disorders occur more frequently in elderly population [60, 61]. In this study, two possible reasons why the spleen meridian electrical conductance did not change significantly are functional deficiencies in the spleen and the long-term effects of age-related gastrointestinal tract states in older adults. In TCM,

the bladder meridian is the longest and largest detox pathway. It is often associated with disease symptoms caused by external harmful effects, including cold, wind, fire, dampness, dryness, and summer heat. Because the bladder meridian is considered the most exterior meridian, it is the first to be invaded during external attacks [62]; this means that rapidly modulating its electrical conductance during qigong exercise may be difficult.

We observed a significant positive correlation between kidney meridian electrical conductance and SF-36 physical scores in this study. In TCM, the kidney is considered the foundation for good health and vitality. The kidney is the powerhouse of the body which stores essence (jing) and is the support system for all aspects of organic life. The

FIGURE 3: Correlations between pericardium meridian electrical conductance and SF-36 mental scores (a) and STAI-S scores (b) after one session of qigong exercise.

stored essence comprises congenital and acquired essence and supply reserve energy to any organ. Kidney essence is the material basis for numerous functional activities and is responsible for human growth and development and human vitality [63]. The kidney also absorbs qi [64]. Based on the present findings, we hypothesized that many potential advantages of qigong exercise, such as the enhancement of physical fitness and strength, can be attributed to elevated kidney meridian electrical conductance.

Qigong can affect psychological state, influence the neuroendocrine system, and exert effects on immune cells [9, 65]. This mind-body training has been reported to improve immune functions by stimulating the homeostasis of the sympathetic and parasympathetic nerve systems through hypothalamic action [66–68]. Several studies have investigated the effects of qigong exercise on sleep, distress, anxiety, and depression [29, 69, 70]. In this study, participants were more comfortable, relaxed, and vigorous after one session of qigong exercise. The present findings showed a negative correlation between pericardium meridian electrical conductance and STAI-S scores and a positive correlation between pericardium meridian electrical conductance and SF-36 mental scores. The higher the SF-36 mental scores indicates the healthier the mental status, while the higher the STAI-S scores means the higher the anxiety status. Thus a positive correlation between pericardium meridian electrical conductance and SF-36 mental scores is consistent with a negative correlation between pericardium electrical conductance and STAI-S scores, although nonsignificant. In TCM, the pericardium is the heart's protective sack which is known as a fire-energy organ which protects the heart. Not only does pericardium provide the heart with physical protection, its energy also protects the heart from damage and disruption by excessive emotional energies generated by

the other organs including anger from the liver, fear from the kidneys, and grief from the lungs. The pericardium meridian is associated with heart and blood functions. Emotionally, pericardium energy is related to the loving feelings. Because the heart is the seat of spiritual or mental activities, the pericardium meridian is associated with mania and mental illness [71]. Based on the results of the present study, we hypothesized that decreased anxiety and improved mental status due to qigong exercise can be attributed to increased pericardium meridian electrical conductance.

Balanced meridians indicate that an individual is healthy [51, 72]. In our study, one session of qigong exercise improved energy balance between the upper and lower halves of the body. Moreover, the sympathetic/vagal index was significantly improved and closer to 1, indicating an improvement in the autonomic nervous system balance. However, a similar finding was not observed for HRV. Wu et al. reported that skin electrical conductance is a useful tool for detecting subtle noncardiovascular physical responses that may be more sensitive than HRV in analyzing autonomic responses [16]. The present findings are consistent with the results of their study.

The present study had some limitations. First, this is a one-group, pre- and postcomparison study. This study lacked control group of sham intervention to evaluate the placebo effect in this study. Second, the participants were older practitioners; therefore, future studies are suggested to elucidate the effects of qigong exercise across different age groups. Third, blood pressure data were not evaluated and thus the influence of blood pressure on the results was unknown. Fourth, substantial time has to be invested for learning and practicing these mind-body techniques. Fifth, to generalize these findings, further studies using larger sample sizes and/or different kinds of qigong are required. The present

findings might be generalized only to older populations who are more health conscious with practicing specific type of qigong exercise, such as Chinese Bioenergy Qigong.

5. Conclusions

One session of qigong exercise increased meridian electrical conductance, reduced anxiety, and improved balance in both the autonomic nervous system and the body overall. In conclusion, these findings provide scientific evidence for the acute physiological and psychological effects of qigong exercise in older practitioners. According to the results of this study, Chinese Bioenergy Qigong may be considered as one of the complementary therapies accompanied with conventional medicine to treat the patients with autonomic dysfunction or anxiety. More researches in the future are encouraged to investigate into the possible effects of Chinese Bioenergy Qigong on improving various pathological functions in different population.

 SF-36: Short Form 36
 LF: Lower frequency
 HF: High frequency
 STAI-S: State anxiety
 STAI-T: Trait anxiety.

Ethical Approval

The study was approved by the Clinical Research Ethics Committee of Show Chwan Memorial Hospital, Taiwan (no. 1040408).

Consent

Informed consent was provided by all participants.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

Chun-Yi Lin undertook the literature searches and the data analyses and was mainly responsible for drafts and revisions of the manuscript. Tze-Taur Wei, Chen-Chen Wang, Wan-Chen Chen, and Yu-Min Wang participated in the literature searches and contributed to data collection of the study. Song-Yen Tsai contributed to revisions and the final draft of the manuscript. All authors read and approved the final manuscript.

Acknowledgments

This study was supported by the Show Chwan Memorial Hospital, Changhua, Taiwan (RA15014).
