

Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.

Letter to the Editors-in-Chief

The effect of race on composite thrombotic events in patients with COVID-19

 Stroke

ABSTRACT

COVID-19 associated coagulopathy and mortality related to thrombotic complications have been suggested as biological mediators in racial disparities related to COVID-19. We studied the adjusted prevalence of acute ischemic stroke, pulmonary embolism, myocardial infarction, and deep venous thrombosis stratified by race in hospitalized patients in one New York City borough during the local COVID-19 surge. The multi-racial cohort included 4299 patients hospitalized with COVID-19, 9% of whom were white, 40% black, 41% Hispanic and 10% Asian or other. We found a 6.1% prevalence of composite thrombotic events. There were no significant race-specific differences in thrombotic events when adjusting for basic demographics, socioeconomic factors, medical comorbidities or biomarkers using a stepwise regression model. We therefore found no evidence that the racial disparities related to COVID-19, and specifically thrombotic complications, are caused by biological differences in race.

1. Introduction

Explosive community spread and a disparate effect on the most vulnerable members of society by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) has exposed long-standing racial/ethnic health inequities in the United States [1]. African Americans (AA) and Hispanics have been disproportionately affected by the virus, with higher rates of infection, hospitalization and death [2,3]. COVID-19 associated coagulopathy and mortality related to thrombotic complications have been suggested as plausible biological mediators in racial disparities related to COVID-19 [4–6]. Better understanding of the social versus biological mediators of race/ethnic disparities in COVID-19 can help guide future prevention and treatment strategies. We report the adjusted incidence of acute ischemic stroke (AIS), pulmonary embolism (PE), myocardial infarction (MI), and deep vein thrombosis (DVT) stratified by race in hospitalized patients in one New York City (NYC) borough during the local COVID-19 surge.

2. Methods

2.1. Study population and clinical features

We performed a retrospective analysis of patients admitted to three Montefiore Health System hospitals in the Bronx, New York, between March 1, 2020 and May 7th, 2020 with COVID-19. Emergency room visits not requiring admission were excluded. Baseline characteristics, medical comorbidities, medications and interventions, final disposition, and laboratory markers including SARS-CoV-2 real-time reverse transcriptase–polymerase chain reaction (RT-PCR) results (nasopharyngeal swab using FDA-approved assays), were systematically extracted from

the electronic medical record using automated data extraction tools [7]. Median income and population density (population divided by land mass) were obtained by zip code using publicly available US Census Bureau data for years 2014–2018 and 2010 respectively ([census.gov](https://www.census.gov)). We created *concentrated poverty index* (population density divided by mean income) to assess the unique interplay between housing density and poverty, a measure thought to be related to viral spread. Socioeconomic status (SES) was defined using a composite of median income, wealth (rental income and housing value), and education (percent graduated high school, percent with college education, percent in professional occupation), assessed by address and measured as a deviation from the population in New York State, based on census block [7].

Thrombotic events including AIS, MI (type 1 or 2), PE, and DVT were screened using the International Classification of Diseases, Tenth Revision codes at any location and confirmed by manual chart review. All cases of AIS, PE and DVT required clinical suspicion and confirmatory imaging to be included. Cases without confirmatory imaging were excluded. For quality assurance, we performed a separate detailed review of a subsample of 10 cases of DVT and PE each, and found 8 proximal and 2 distal cases of DVT; and anatomical heterogeneity in PE with 2 saddle, 6 segmental and 2 subsegmental. All cases of AIS were adjudicated by a vascular neurologist. Anticoagulants included heparin drip, enoxaparin at therapeutic doses, and direct oral anticoagulants at any dose. This included apixaban 2.5 mg and 5 mg twice daily, which were recommended in our hospital system starting at the height of the local pandemic as thromboprophylaxis in patients with a d-dimer of ≤ 3 $\mu\text{g/ml}$ or >3 $\mu\text{g/ml}$ respectively. COVID-19 medications include azithromycin and hydroxychloroquine. Race/ethnicity was self-reported and defined as non-Hispanic white (NHW), African American (AA), Hispanic, Asian or other. Those with missing race/ethnicity were

excluded.

2.2. Statistics

The primary outcomes were AIS, PE, DVT and MI. Continuous values were represented using mean ± standard deviation (SD), or median and interquartile range (IQR). Categorical variables were described using frequencies and proportions. Comparisons were performed using Student’s *t*-test, the nonparametric Mann–Whitney test or χ^2 tests as appropriate. No imputation was made for missing data. Candidate predictors with $P < 0.05$ in the univariate analysis were included in the stepwise multiple regression model as follows: Model 1 (unadjusted), Model 2 (adjusted for age and sex), Model 3 (adjusted for Model 2 + socio-economic status (SES)), Model 4 (adjusted for Model 3 + comorbidities), Model 5 (adjusted for Model 4 + biomarkers) and Model 6 (adjusted for Model 5 + medications/treatments). P -value < 0.05 was considered statistically significant for all analyses. Data were analyzed using IBM SPSS version 24. This study was approved by the Albert Einstein College of Medicine/Montefiore Medical Center Institutional Review Board.

3. Results

A total of 4299 patients, 391 NHW (9%), 1716 AA (40%), 1752 Hispanic (41%), 123 Asian (3%) and 317 other (7%), were hospitalized during the study period. Notably NHW patients were significantly older, had higher median income and SES, and were significantly more likely to live in communities with lower population density compared to all other racial groups. There were no major differences in treatment with steroids and anticoagulants. There were significant differences in treatment with azithromycin and/or hydroxychloroquine, mechanical ventilation and a number of comorbidities and clinical variables (Table 1). There were 262 (6.1%, 95% CI 5.4–6.8%) total cases of thrombotic events, including 53 AIS (20%), 62 PE (24%), 91 DVT (35%) and 56 cases of MI (21%). There were no significant differences in composite thrombotic events by race in univariate or multivariate analysis (Model 3: demographics and SES; Model 5: adds comorbidities, biomarkers; Model 6: adds medications; see Fig. 1). In the fully adjusted model, composite thrombotic events were associated with diabetes (OR 2.25 [1.2–4.21], $P = 0.011$) and a D-dimer level $>3 \mu\text{g/ml}$ (OR 3.09

[1.76–5.4] $P < 0.001$) (Supplemental material).

4. Discussion

Race/ethnic minorities have been hospitalized and are dying from COVID-19 at higher rates compared to NHWs, highlighting long standing health inequities rooted in structural racism and oppression of AA, Native American and Latinx populations on the local and national level [2,8,9]. To better understand possible mediators of the disparate effect of COVID-19-related mortality on race/ethnic minorities, we studied the prevalence of thrombotic events in patients treated in the Bronx, NY – a highly diverse borough with the highest incidence of COVID-19 in NYC [3]. While AAs and Hispanics were younger, more likely to be in the lowest quartile of SES and generally healthier, there were no differences in unadjusted rates of arterial and venous thrombosis. Adjusting for basic demographics, SES, comorbidities and clinical markers of disease severity did not yield any differences in composite thrombotic events when stratifying by race. Contrary to reports suggesting race-based biological differences in COVID-19 associated coagulopathy, we found no evidence of increased risk of arterial or venous thromboses in this large multi-racial cohort. Instead, we found significant differences in baseline demographic and socioeconomic characteristics between races, suggesting that community level factors drive differences in previously reported COVID-19-related racial disparities [10]. While only representative of local factors, these findings can inform future prevention and treatment strategies. This is one of the largest studies reporting specific outcomes related to race/ethnic and Covid-19 and is further strengthened by the large proportion of race/ethnic minorities, but was conducted solely in NYC, limiting generalizability. There are other important limitations having to do with the race/ethnic subgroups. While we did not see significant differences between race/ethnic subgroups, our cohort included only a small proportion of Asian patients making our findings related to this group limited and in need of further study. Another limitation is the likely undercount of thrombotic events in critically ill patients, given the limited ability to perform confirmatory studies. There is no reason to believe that this would lead to a differential misclassification. While prevalence of thrombotic events has varied across studies, we only included confirmed cases of AIS, PE, and DVT, likely yielding a conservative estimate.

In conclusion, we found no race-specific differences between the AA,

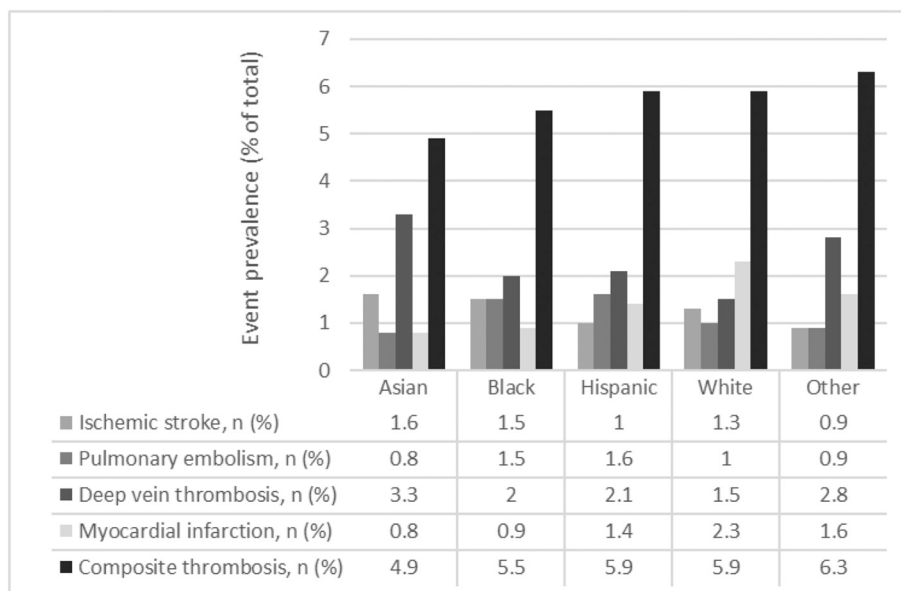

Fig. 1. Thrombotic event prevalence stratified by race. P values: ischemic stroke 0.792, pulmonary embolism 0.784, deep vein thrombosis 0.724, myocardial infarction 0.264, composite events 0.967.

Missing data: Median household income (n = 4), poverty index (n = 250), socio-economic status quartile (n = 821), BMI (n = 770), smoking status (n = 1886), oxygen saturation (n = 182), temperature (n = 160), troponin (n = 866), ESR (n = 3707), C-reactive protein (n = 1253), d-dimer (n = 1419), interleukin-6 (n = 2864), hemoglobin (n = 370), platelets (n = 370), white-blood cell count (n = 370), fibrinogen (n = 2351), ferritin (n = 1737), AST (n = 555), ALT (n = 493), INR (n = 761), PTT (n = 1136), creatinine (n = 378), procalcitonin (n = 2025), sodium (n = 386) and LDH (n = 1032).

Native American and Latinx populations on thrombotic complications in patients hospitalized with COVID-19. It is therefore unlikely that local racial disparities in COVID-19 are related to biological differences in thrombotic risk. Rather, more studies should focus on the effects of community-level healthcare inequities on race-specific outcomes in COVID-19.
