Rheumatic Heart Disease Is a Neglected Disease Relative to Its Burden Worldwide: Findings From Global Burden of Disease 2019

Seyyed-Hadi Ghamari, MD, MPH*; Mohsen Abbasi-Kangevari, MD, MPH*; Sahar Saeedi Moghaddam, MSc; Arya Aminorroaya, MD; Negar Rezaei, MD, PhD; Parnian Shobeiri, MD, MPH; Zahra Esfahani, MSc; Mohammad-Reza Malekpour, MD; Nazila Rezaei, MD; Ali Ghanbari, MSc; Mohammad Keykhaei, MD, MPH; Mohammadreza Naderian, MD; Bagher Larijani, MD; Mohamad Taghi Majnoon, MD; Farshad Farzadfar, MD, MPH, MHS, DSc; Ali H. Mokdad, PhD

BACKGROUND: Rheumatic heart disease (RHD) takes a heavy toll in low- and middle-income countries. We aimed to present worldwide estimates for the burden of the RHD during 1990 to 2019 using the GBD (Global Burden of Disease) study.

METHODS AND RESULTS: Sociodemographic index (SDI) and age-period-cohort analysis were used to assess inequity. The age-standardized death, disability-adjusted life years, incidence, and prevalence rates of RHD were 3.9 (95% uncertainty interval, 3.3–4.3), 132.9 (95% uncertainty interval, 115.0–150.3), 37.4 (28.6–46.7), and 513.7 (405.0–636.3) per 100 000 in 2019, respectively. The age-standardized incidence and prevalence rates increased by 14.4% and 13.8%, respectively. However, disability-adjusted life years and death rates decreased by 53.1% and 56.9%, respectively. South Asia superregion had the highest age-standardized disability-adjusted life years and deaths. Sub-Saharan Africa had the highest age-standardized incidence and prevalence rates. There was a steep decline in RHD burden among higher-SDI countries. However, only age-standardized deaths and disability-adjusted life years rates decreased in lower-SDI countries. The age-standardized years of life lost and years lived with disability rates for RHD significantly declined as countries' SDI increased. The coefficients of birth cohort effect on the incidence of RHD showed an increasing trend from 1960 to 1964 to 2015 to 2019; however, the birth cohort effect on deaths attributable to RHD showed unfailingly decreasing trends from 1910 to 1914 to 2015 to 2019.

CONCLUSIONS: There was a divergence in the burden of RHD among countries based on SDI levels, which calls for including RHD in global assistance and funding. Indeed, many countries are still dealing with an unfinished infectious disease agenda, and there is an urgency to act now to prevent an increase in future RHD burden.

Key Words: disability-adjusted life years ■ global burden of disease ■ heart ■ rheumatic fever ■ rheumatic heart disease

Rheumatic heart disease (RHD), a known complication following acute rheumatic fever,[1] remains to be the most acquired heart disease among people aged <25 years.[2] RHD is usually associated with overcrowding, poor housing conditions, and improper health literacy.[3] High sociodemographic index (SDI) countries have managed to reduce RHD incidence via significant elimination of acute rheumatic fever occurrence[4] and its recurrence.[5] Nevertheless, RHD still affects older adults, immigrants, marginalized, and underprivileged populations in high-SDI countries. The achievements in lowering RHD incidence are known to be attributable to improvements in socioeconomic status,[4] better performance of health care systems,

CLINICAL PERSPECTIVE

What Is New?

- The incidence and prevalence rates of rheumatic heart disease (RHD) increased globally, whereas death rates showed declining trend during the study period; RHD continues to take a heavy toll on far too many people in lower-income countries.
- Quantifying the burden of RHD with epidemiologic measures in this study, we provided a clearer picture of the inequity patterns in the RHD status by age, sex, country, and socioeconomic status, which have mainly been underestimated by the health authorities.
- There are fundamental disparities among countries and territories with disparate socioeconomic status on RHD, making it among the most neglected diseases relative to burden worldwide.

What Are the Clinical Implications?

- Until there is an effective vaccine for RHD, a multilevel approach is suggested, which includes primordial prevention via improving the socioeconomic status of populations at risk, primary prevention via treating patients with strep throat using benzathine–penicillin-G, secondary prevention via antibiotic prophylaxis among patients with previous rheumatic fever or RHD, and tertiary prevention via medical/surgical treatment of RHD complications.
- In settings with limited resources, the physicians' task for an antibiotic prescription could be shifted to community health workers, who could play a key role in delivering preventive medications via practical clinical algorithms, diagnostic tools, availability of appropriate antibiotics, and supportive supervision.

Nonstandard Abbreviations and Acronyms

ASDR	age-standardized death rate
ASIR	age-standardized incidence rate
ASPR	age-standardized prevalence rate
GBD	Global Burden of Disease
RHD	rheumatic heart disease
SDI	sociodemographic index
WHO	World Health Organization
YLDs	years lived with disability
YLLs	years of life lost

implementation of control programs,[6] and the widespread use of penicillin G benzathine to treat streptococcal pharyngitis.[7] Despite improvements in high-SDI countries, low and low-middle SDI countries have been less successful in lowering the burden of RHD.[8]

The World Health Organization (WHO) proposed prevention and treatment guidelines for RHD >6 decades ago.[9] Previous calls for advocacy, action, and investment to reduce the RHD burden have been neglected.[3] Moreover, there was a sharp decrease in focus on RHD after apparent RHD elimination in high-SDI countries,[10] and even the Global Rheumatic Heart Disease Control Program, coordinated by WHO since 1984, ended in the early 2000s.[11] Nevertheless, novel regional and international initiatives against RHD have emerged. The World Heart Federation has set a 2025 RHD reduction target, some low- and middle-SDI countries implemented national programs for RHD prevention and control,[12,13] and the World Health Assembly endorsed a global resolution on RHD in 2018.[14]

Prioritizing investment and providing proper action plans require accurate global, regional, and national burden estimates. The objective of this study was to present worldwide estimates of RHD prevalence, incidence, death, years of life lost (YLLs), years lived with disability (YLDs), and disability-adjusted life years (DALYs) from 1990 to 2019 by age groups and SDI quintiles using GBD (Global Burden of Disease) 2019.[15]

METHODS

The data that support the findings of this study are available from the corresponding author on reasonable request.

Data Source

The data of GBD were used in the study, which includes high-quality estimations on vital epidemiological measures, including prevalence, incidence, death, YLLs, YLDs, and DALYs for 286 causes of death, 369 diseases and injuries, and 87 risk factors in 204 countries and territories. GBD classified countries and territories into 7 superregions and 21 regions. The 7 superregions are high income; Latin America and Caribbean; Sub-Saharan Africa; North Africa and Middle East; Southeast Asia, East Asia, and Oceania; South Asia; and Central Europe, Eastern Europe, and Central Asia.[16] RHD data were extracted from GBD 2019: GBD code: B.2.1; *International Classification of Diseases, Tenth Revision* (*ICD-10*), codes I01 to I01.9, I02.0, and I05 to I09.9 were used for mapping mortality and new cases.[17] Sources used in the study are presented in Table S1.

Fatal Estimates

The vital registration system and surveillance data were transformed and modeled to provide the cause-specific death estimates. Furthermore, data were mapped to

the GBD list of disease causes. To enhance the comparability of death data sources, reclassification and redistribution of codes that are nonspecific or unspecific were performed. In addition, a regression analysis using Bayesian geospatial regression software (Cause of Death ensemble model) was considered to model deaths from RHD. Eight selected covariates for Cause of Death ensemble models of RHD were defined, including RHD summary exposure value scalar (+1 direction), improved water (–1 direction), malnutrition (+1 direction), sanitation (–1 direction), health care access and quality index (–1 direction), lag-distributed income per capita (–1 direction), SDI (–1 direction), and education via years per capita (–1 direction). Finally, the single cause death estimates were adjusted by applying CoDCorrect algorithm. YLLs were calculated using normative global life expectancy and the number of deaths by age.

Nonfatal Estimates

To provide estimates on the incidence and prevalence of RHD, data were collected using the existing scientific reports on cohorts, registries, population surveys, health system administrative data, and inpatient/outpatient claims data. RHD was defined by clinical diagnosis, and estimates of RHD included cases identified by clinical history and physical examination, including auscultation or standard echocardiographic criteria. Consistent disease estimates were produced by using epidemiologic state-transition disease modeling software, DisMod-MR, and Bayesian meta-regression software, MR-BRT. Two covariates were selected, including RHD summary exposure value scalar and lag-distributed income per capita. The survival of RHD was modeled using death/incidence ratios across various geographical locations and age groups. The 10-year prevalence was then calculated for each incidence cohort. YLDs were calculated by multiplying each sequela's prevalence by its disability weight (0.049; 95% CI, 0.031–0.072) and by adding the procedure-related morbidity associated with RHD treatment. RHD DALYs were calculated by summing YLDs and YLLs.

Decomposition Investigation

The contribution of population growth, aging, and variations in age-specific incidence rates to the witnessed new cases changes was investigated. In the first step, the age structure and age-specific incidence rate of RHD in 1990 were applied to the population size of 2019. In the second step, the age structure and age-specific incidence rate of RHD in 2019 were applied to the population size of 1990. The difference between the new cases, as calculated in the first and second steps, was considered the contribution of age structure changes from 1990 to 2019. The difference between the new cases in the first step and the actual new cases in 1990 was attributed to the population growth. The differences between the value of the second step and the actual new cases in 2019 were attributed to the changes in age-specific incidence rates.[18]

Inequity Pattern

Countries were categorized using SDI to investigate the burden of RHD based on development status.[19] SDI of countries was basically calculated using 3 factors: (1) average income per person, (2) educational attainment, and (3) total fertility rate. SDI scores were categorized into 5 quintiles, including high SDI, high-middle SDI, middle SDI, low-middle SDI, and low SDI.

Age-period-cohort analysis with the intrinsic estimator method was performed to decompose the effects of 3 collinear factors named age, period, and cohort. Data were stratified in 22 birth cohorts starting from 1910 to 1914, 6 5-year calendar periods starting from 1990, and 17 5-year age groups starting from age <5 years to age ≥80 years.[20]

Statistical Analysis

Age standardization was conducted using the direct method, applying a global age structure from the year 2019. Age-standardized rates of RHD for countries were calculated using the GBD world population standard and reported per 100 000 individuals. The 95% uncertainty intervals (95% UIs) were reported for each metric using 2.5% and 97.5% quintiles across 1000 draws. The comparison for the differences in values of each metric from 1990 to 2019 was computed to calculate the total and percentage of change. All essential data analysis, tables, and illustrations were performed using R statistical package v3.4.3 (http://www.r-project.org, RRID: SCR_001905). The "apc-ie" command in STATA software was used for age-period-cohort effect analysis.

RESULTS

Global and Superregional Burden of RHD

On global scale, RHD caused 305 651 (95% UI, 259 220–340 486) deaths in 2019: 173 933 (140 652–208 089) among women and 131 717 (113 445–159 904) among men. Between 1990 and 2019, there was a 15.6% (–30.5% to –2.1%) decrease in the number of deaths attributable to RHD: 17.2% (–34.2% to 3.1%) decrease among women and 13.4% (–30.9% to 8.0%) among men (Table 1). The age-standardized death rate (ASDR) of RHD at the global level decreased

Table 1. Global Burden of RHD in 1990 and 2019

	Age-standardized, rate per 100 000	22.1 (13.3 to 33.7)	24.5 (14.9 to 37.2)	19.7 (11.8 to 30.0)	25.2 (15.2 to 38.7)	28 (17 to 42.9)	22.4 (13.4 to 34.6)	13.9 (11.1 to 16.0)	14.4 (11.1 to 16.9)	13.7 (11.2 to 15.9)

DALYs indicates disability-adjusted life year; RHD, rhematic heart disease; YLDs, years lived with disability; and YLLs, years of life lost.

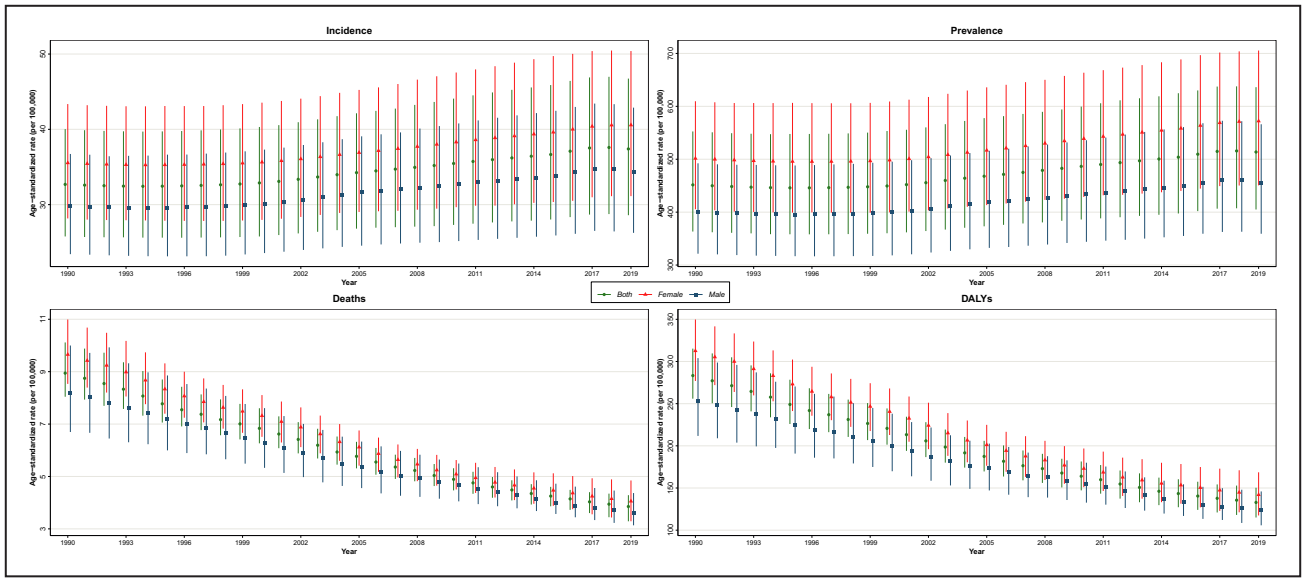

Figure 1. Age-standardized epidemiological measures (incidence, prevalence, deaths, and disability-adjusted life years [DALYs] of rheumatic heart disease at global scale across years from 1990 to 2019 by sex).

from 8.9 (8.0–10.1) per 100 000 population in 1990 to 3.9 (3.3–4.3) per 100 000 population in 2019. Although the trend of ASDRs of RHD from 1990 to 2019 was decreasing among both men and women, the rates were slightly higher among women than men (Figure 1 and Table 1). Considering the GBD superregions, the ASDRs of RHD were unfailingly highest among countries in South Asia superregion with 11.2 (8.6–13.4) in 100 000 population in 2019, and lowest among countries in Latin America and Caribbean, with 1.1 (1.0–1.2) in 100 000 population in 2019 (Table 2).

RHD led to nearly 10.7 million (9.2–12.1) DALYs in 2019 globally, which showed a decrease from just over 13.2 million (11.9–14.6) in 1990. Compatible with total trend in all-age DALYs, the age-standardized DALYs showed 54.6% (−62.2% to −45.3%) and 51.3% (−59.8% to −41.8%) decrease among women and men, respectively (Figure 1). Considering the age-standardized rates in 2019, RHD contributed to 132.9 (115.0–150.3) DALYs in 100 000 population, which was almost half of the age-standardized rate in 1990 (Table 1). During the past 30 years, the age-standardized DALY rate of RHD was consistently lowest among the high-income superregion, with 24.6 (22.3–27.0) in 100 000 population in 2019, and highest among South Asia superregion, with 348.5 (272.4–412.2) in 100 000 population in 2019 (Table 2). Consistent with the ASDRs, the age-standardized DALY rate decreased during the past 30 years; however, the rates were higher among women (Figure 1). Although the declining trend in age-standardized DALYs of RHD was consistent with trends in YLLs, with 58.8% (−65.6% to −52.5%) decrease since 1990, the age-standardized YLD rate increased by 13.9% (11.1%–16.0%) in the study period. In addition, YLDs contributed to 7.8% and 19.0% of rates in DALYs in 1990 and 2019, respectively. However, the contribution of YLLs decreased from 91.2% in 1990 to 81.4% in 2019 (Table 1).

Nearly 2.8 (2.2–3.5) million new cases and 40.5 (32.1–50.1) million prevalent cases of RHD were identified in 2019, worldwide, showing a 1.5- and 1.7-fold increase since 1990, respectively (Figure 1). The increase in the absolute values of new cases since 1990 was mainly attributable to population growth (44.6%), and 17.9% of the current trend was attributable to an increase in incidence rate of RHD (Table S2).

The global age-standardized incidence rate (ASIR) and age-standardized prevalence rate (ASPR) of RHD were 37.4 (28.6–46.7) and 513.7 (405.0–636.3) per 100 000 population in 2019, respectively. The corresponding rates in 1990 were 32.7 (25.8–40.0) and 451.6 (363.3–552.5) in 100 000 population for ASIR and ASPR, respectively. The ASIRs and ASPRs among women increased by 14.1% (10.6%–17.1%) and 14.1% (10.9%–16.7%) from 1990 to 2019, respectively (Table 1 and Figure 1). Among men, the corresponding rate increased by 15.1% (12.1%–17.7%) and 13.7% (11.2%–15.8%) from 1990 to 2019. Considering the GBD superregions, Sub-Saharan Africa and the high-income superregion showed the highest and lowest ASIRs and ASPRs for all the years from 1990 to 2019 (Tables 1 and 2).

Regional and National Burden of RHD

At the regional level, Oceania had the highest ASDRs attributable to RHD in 2019 among women (15.5

Table 2. Age-Standardized Rates (95% Uncertainty Intervals) Attributable to RHD in 1990 and 2019

GBD superregion	Measure	Age-standardized rate (per 100 000)						% Change (1990 to 2019)		
		1990			2019

DALY indicates disability-adjusted life year; GBD, Global Burden of Disease; RHD, rheumatic heart disease; YLDs, years lived with disability; and YLLs, years of life lost.

[9.5– 23.4] in 100 000 population), men (16.7 [7.8–31.1] per 100 000 population), and both sexes combined (16.1 [10.1–24.6] in 100 000 population). Concurrently, Oceania had the highest age-standardized DALY rate for women, men, and both sexes combined, with the rates of 639.8 (403.5–976.8), 615.5 (321.9–1065.4), and 627.4 (404.1–918.1) per 100 000 population, respectively. South, Central, and East Asia were the regions with the next highest ASDRs attributable to RHD for both women and men in 2019, with rates of 11.2 (8.6–13.4), 4.2 (3.6–4.7), and 4.0 (3.3–4.6) per 100 000 population, respectively.

South Asia, Central Sub-Saharan Africa, and Central Asia ranked the next highest age-standardized DALY rate in 2019. Central Sub-Saharan Africa had the fifth-highest ASDRs (4.0 [2.4–6.0] per 100 000 population in 2019) attributable to RHD; however, it was consistently the top region in terms of ASIRs (81.7 [60.6–104.2] per 100 000 population in 2019) and ASPRs (1195.6 [918.2–1511.3] per 100 000 population in 2019) in all years from 1990 to 2019.

The lowest ASDRs attributable to RHD were among the countries in Central Latin America region, with the rate of 0.7 (0.6–0.8) per 100 000 population in 2019. High-income Asia Pacific had the second lowest ASDRs (0.8 [0.6–0.9] per 100 000 population), whereas the lowest ASIR (2.5 [2.1–2.8] per 100 000 population), ASPR (34.2 [29.6–39.0] per 100 000 population), and age-standardized DALY (13.2 [11.5–14.5] per 100 000 population) were in this region in 2019.

From 1990 to 2019, the trends of ASDR and age-standardized DALY rate attributable to RHD were decreasing for all regions, with the highest decrease for Central Europe, followed by East Asia. The lowest decrease in ASDRs and DALYs during the study period was for Oceania, with 21.5% (–38.2% to –1.4%) and 17.6% (–35.4% to –4.6%) decrease, respectively.

The trends in ASIRs and ASPRs attributable to RHD varied markedly among various regions from 1990 to 2019. The ASIRs and ASPRs of 13 of 21 regions increased from 1990 to 2019, with the most increase in Oceania, with 8.1% (3.6%–12.7%) increase in ASIR and 8.1% (3.3%–13.0%) increase in ASPR. The most decrease in ASIRs and ASPRs was among countries of Central Europe and Eastern Europe, with 47.0% (–49.6% to –44.3%) and 37.1% (–40.4% to –33.8%) decrease in rates, respectively (Figure 2). Considering the trends in the absolute numbers of new cases of RHD, the overall changes of absolute numbers in all regions were increasing, except for Central Europe, East Asia, and Eastern Europe regions, which showed 39.8%, 26.5%, and 38.0% decrease in the number of new cases from 1990 to 2019. Table S2 presents the contribution of population growth, aging, and variations in age-specific incidence rates of RHD in the witnessed trends.

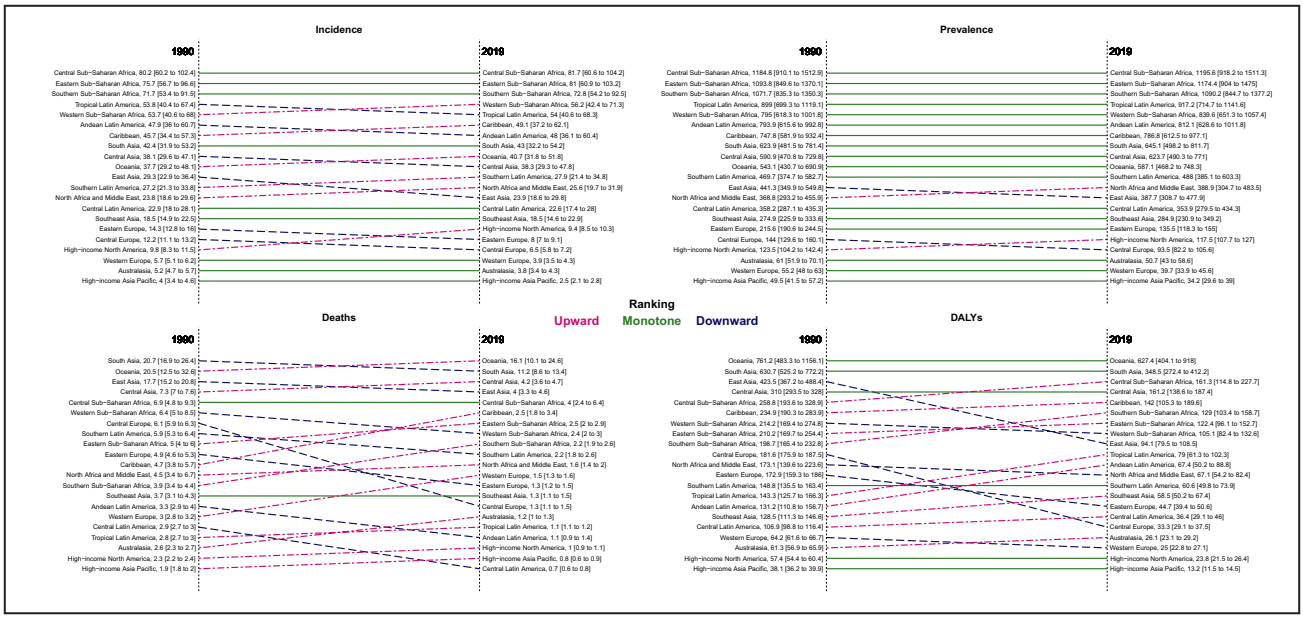

Figure 2. Regional age-standardized incidence, prevalence, deaths, and disability-adjusted life years (DALYs) of rheumatic heart disease in 1990 and 2019.

Across countries, Solomon Islands had the highest ASDR of RHD in all years from 1990 (30.9 [18.1–46.1] per 100 000 population) to 2019 (21.1 [10.9–31.2] per 100 000 population), despite a 31.8% (–54.2% to –4.6%) decrease in ASDRs since 1990. The second highest ASDR attributable to RHD was in Kiribati in 1990 and 2019 (Figure 3A). Commensurate with the ASDRs, the highest age-standardized DALY rate in 2019 was at the Solomon Islands, followed by Kiribati (Figure 3B). Finland and the Republic of Korea had the lowest ASDRs and age-standardized DALY rate for RHD in 2019.

The highest and lowest ASIR of RHD were in Uganda and Finland in 2019, with rates of 94.0 (68.4–128.3) and 1.5 (1.3–1.7) per 100 000 population, respectively (Figure 3C). The highest and lowest ASPR of RHD were among Eritrea (1370.1 [1054.6–1735.7] per 100 000 population) and Finland (18.0 [14.7–21.7] per 100 000 population) in 2019 (Figure 3D).

From 1990 to 2019, the ASDRs and age-standardized DALY rate of RHD decreased among all countries, except for 3 countries. The most decrease for ASDRs and age-standardized DALYs during the study period has been among Thailand (89.8% [–93.0% to –86.1%]) and Poland (86.7% [–88.7% to –84.6%]), respectively. The difference between the highest and lowest age-standardized rates for deaths and DALYs attributable to RHD decreased from 30.1 and 1177.2 in 1990 to 20.7 and 801.8 in 2019, respectively (Data S1).

Inequity Pattern in RHD Burden

In 2019, the age-standardized rates of RHD were higher among lower SDI countries. The low-SDI countries had ASIR, ASDR, and age-standardized DALY rates of 58.9 (44.4–74.2), 8.5 (7.0–10.2), and 275.5 (22.8–324.6) per 100 000 population, respectively, which were 10.0-, 7.7-, and 12.1-fold more than corresponding rates among high-SDI region. From 1990 to 2019, all age-standardized rates of RHD have shown a steep decline among countries of high-SDI, high-middle-SDI, and middle-SDI regions; however, only ASDRs and age-standardized DALY rate of RHD showed decreases in low-middle-SDI and low-SDI regions (Figure S1).

Considering the composition of DALYs attributable to RHD, expected age-standardized YLL rates for RHD declined profoundly as SDI increased. At the same time, age-standardized YLD rates for RHD demonstrate relatively little changes by SDI. At higher SDIs, the composition of disease burden shifted toward YLDs (Figure 4).

The analysis results on the age-period-cohort effect on incidence and deaths attributable to RHD worldwide are presented in Figure 5. The coefficient of age group effect on the incidence of RHD peaked in the age group of 15 to 19 years, with the rate of 0.98 (0.95–1.00), and started to decrease to the values as low as –1.06 (–1.14 to –0.97) in the age group of 50 to 54 years. The coefficient of age effect on deaths attributable to RHD showed increasing trends from the age group of 5 to 9 years (–1.83 [–1.92 to –1.75]) to the age

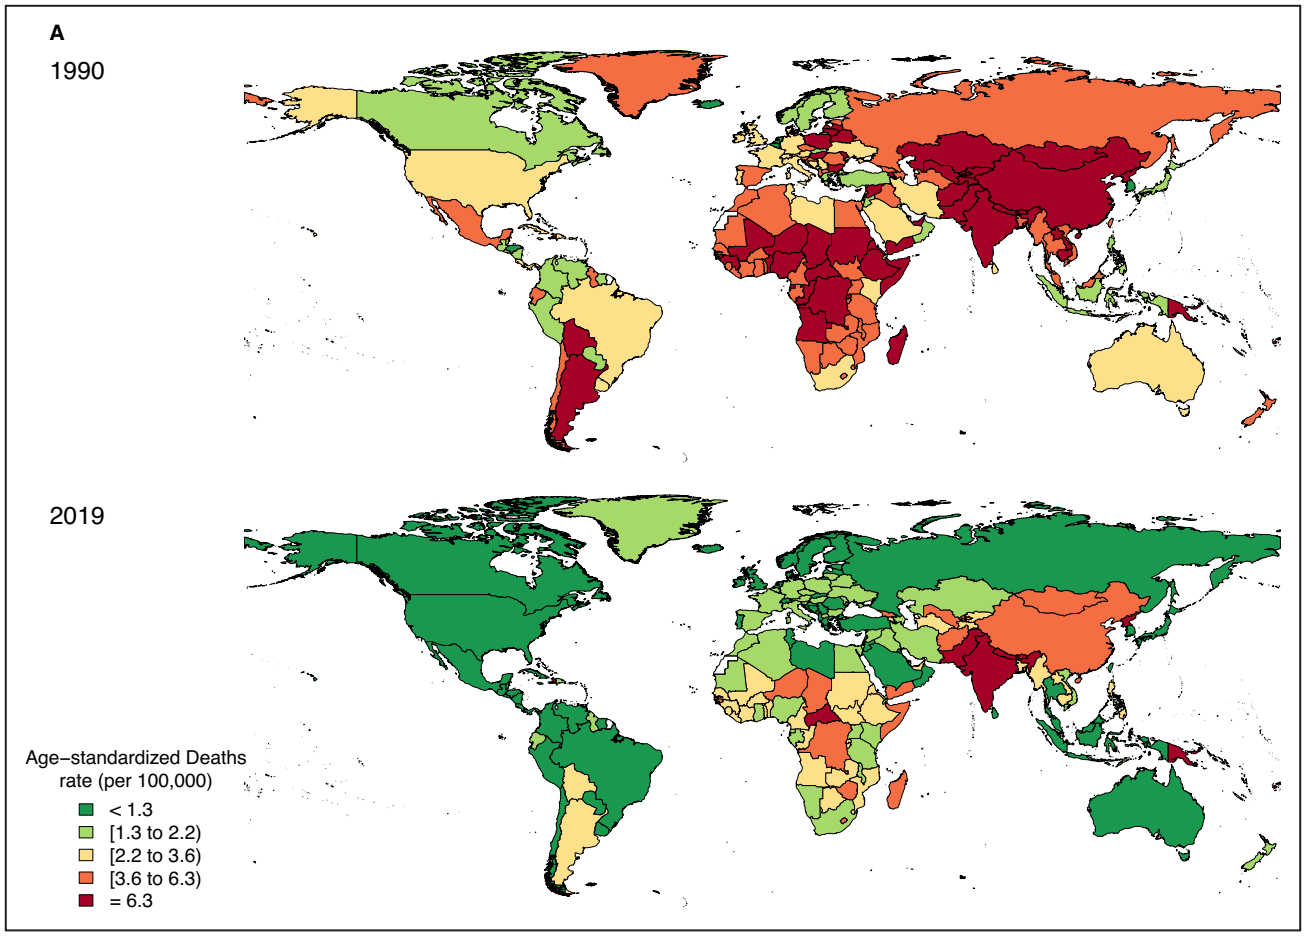

Figure 3. Age-standardized rheumatic heart disease epidemiological rates in both sexes in 204 countries or territories in 1990 and 2019: death (A), disability-adjusted life years (DALYs) (B), incidence (C), and prevalence (D).

group of ≥80 years (1.94 [1.91–1.97]). RHD had incessantly increasing trends in coefficients of period effect on incidence and mortality from 1990 to 1994 to 2015 to 2019. The coefficients of birth cohort effect on incidence of RHD showed a significantly increasing trend from 1960 to 1964 to 2015 to 2019; however, the birth cohort effect on deaths attributable to RHD showed unfailingly decreasing trends from 0.81 (0.75–0.86) in 1910 to 1914 to –1.23 (–1.48 to –0.98) in 2015 to 2019 (Table S3).

Age Pattern of RHD

Patterns in global rates of RHD by age were similar between men and women and across years from 1990 to 2019 and were consistently higher among women than rates among men. From 1990 to 2019, the death rate of RHD showed an increasing pattern by age and peaked at >85 years in both sexes. The DALY rate of RHD showed the current increasing trend by age at both 1990 and 2019. However, the DALY rate peaked at 75 to 79 years among women and 80 to 84 years in 1990. The age of the peaked DALY rate was at >85 years at both sexes. The global peak of incidence rate among women and men was 15 to 19 and 10 to 14 years, respectively. Nevertheless, the trends in the incidence rate of RHD rocketed up from the age group of 45 to 49 years at both sexes and peaked at the age group of ≥85 years again. The current dual trend was observed at age patterns of ASPRs of RHD for men and women in 1990 and 2019.

Age patterns in various rates of RHD showed an increasing trend by age in the high-SDI region and peaked at ≥85 years in all years from 1990 to 2019. Although the increasing trend by age is also witnessed at the death rate of all SDI regions and the peak age group of death rate was at ≥85 years for both sexes, and in both 1990 and 2019, the trend of disparate measures varies markedly across various SDI regions. The age trend of DALY rate among various SDI regions is similar to the death rate trend; however, the age pyramid base is wider than the death rate. Considering the pattern of incidence and prevalence rates of RHD by age, the lower the SDI, the wider the age pyramid base in both men and women in both 1990 and 2019,

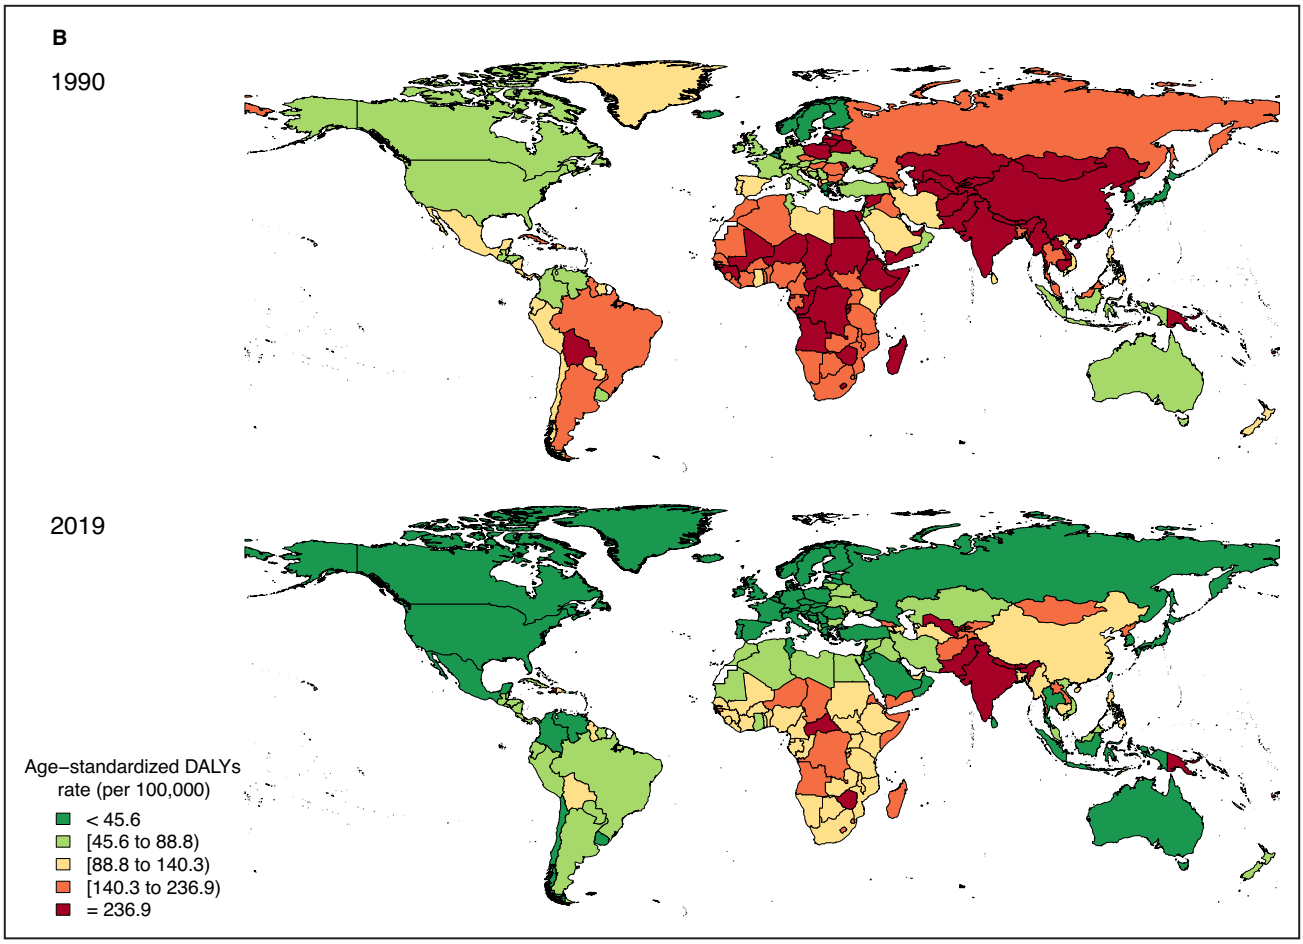

Figure 3. Continued

as the peak of incidence rate in the low-SDI region was at the age group of 10 to 14 years among men and women in 2019 (Figure S2).

DISCUSSION

In this study, multiple data sources and epidemiologic modeling techniques were used to estimate the global burden of RHD over the past 3 decades. The health-related burden of RHD has dramatically declined in affluent countries. Nevertheless, RHD continues to take a heavy toll on far too many people in lower-income countries, making it among the most neglected diseases relative to its burden worldwide. In this sense, the study results could be used by health care authorities in countries for resources allocation and hopefully drive efforts to reduce the disease burden further worldwide.

Globally, the ASIR and ASPR of RHD increased; however, the ASDR decreased during the study period. The increase in the new cases of RHD was majorly attributable to population growth and an increase in the incidence rate. Although YLLs and DALYs of RHD dramatically decreased, YLDs increased from 1990 to 2019. The burden of RHD was much higher among lower SDI countries. The age-standardized YLL and YLD rates for RHD significantly declined as countries' SDI increased.

The age-standardized DALY rate, although decreasing, has been higher among women than men. Although acute rheumatic fever is equally common among men and women, RHD occurs more commonly among women than men.[21] The reasons for this inequity in burden are yet to be understood; however, the roles of greater autoimmune susceptibility, exposure to infection, unequal access to primary and secondary acute rheumatic fever prophylaxis, and hemodynamic changes during pregnancy have been underscored.[22]

The burden of RHD varied significantly among countries. The age-standardized DALY, ASIR, and ASPR were lowest among the high-income superregion and highest among Southeast Asia, East Asia, and Oceania superregion, which also had the highest age-standardized death rates attributable to RHD. Central Sub-Saharan Africa was the first region regarding age-standardized incidence rate during the study period, consistent with other studies.[23]

Looking closer at Southeast Asia, East Asia, and Oceania superregion, the Oceania region had the

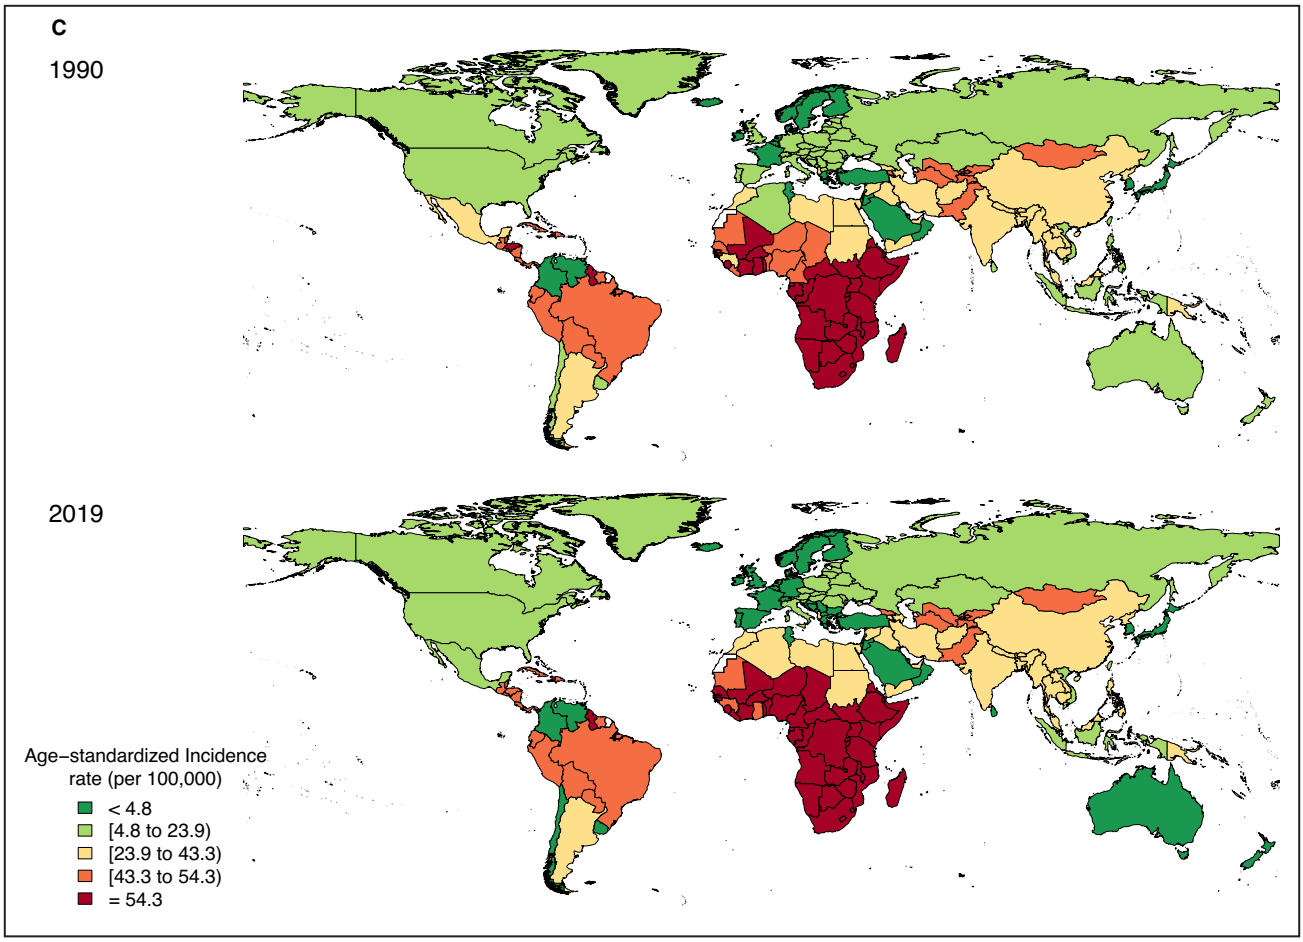

Figure 3. Continued

highest age-standardized DALYs and death rates attributable to RHD, which could be fueled by overcrowding, poor housing conditions, and improper health literacy. There is evidence that the actual number of deaths attributable to RHD could even be up to twice the records in vital registration systems, which could impose a burden much more than estimated.[24] Eradication of RHD calls for a centrally planned approach with a particular focus on prevention, early detection, and follow-up. Australia and New Zealand have spent millions to eliminate the burden of RHD among indigenous families and immigrants. Although there may be some evidence that genetic susceptibility may have a role in the significantly higher burden of RHD among Indigenous populations in the Oceania region,[25] socioeconomic and environmental conditions are the overwhelming significant modifiable determinants of RHD prevention.[26] The New Zealand government launched a program for the primordial and primary prevention of RHD in 2011, spending >$13 per capita, to increase awareness of rheumatic fever, reduce household crowding, and improve access to timely and effective treatment for strep throat infections.[27] The Australian government has invested $2 per capita in Rheumatic Fever Strategy during 2009 to 2021, resulting in no measurable reductions in the rates of rheumatic fever and RHD. Thus, they have recently launched RHD Endgame Strategy with a larger investment targeting all areas of control from primordial prevention to tertiary prevention to eliminate RHD in Australia by 2031.[28]

Improvements in housing and hygiene education have lessened the burden of RHD worldwide. Nevertheless, RHD remains the most acquired heart disease among people aged <25 years.[29] Given that the age group 15 to 19 years had the highest coefficient for age effect on RHD incidence, prompt medical interventions could substantially alleviate RHD mortality.[29] The burden of RHD was related to the socioeconomic development status of countries. Although both YLLs and YLDs attributable to RHD decreased as countries' SDI improved, the heterogeneities across countries based on SDI was more evident in YLLs. Higher YLLs attributable to RHD in low-SDI countries could be inadequate health infrastructure and poor health care services and management. The gaps between high-SDI countries and low-SDI countries were also reflected in the burden of RHD across various age groups. The DALYs attributable to RHD had an increasing trend by

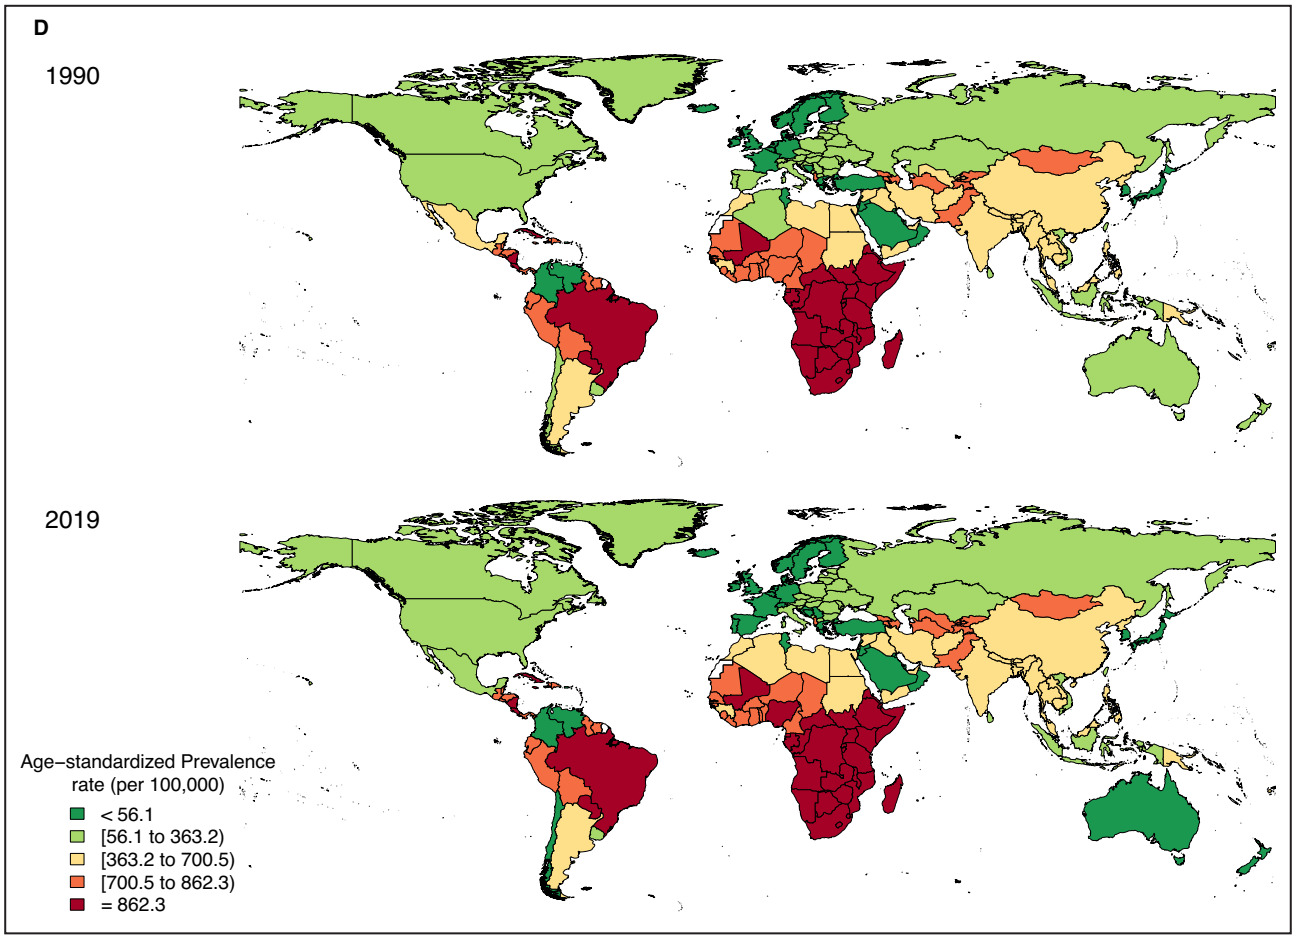

Figure 3. **Continued**

age in the high-SDI region and peaked at ≥85 years, which could show the cohort effect,[2] as reflected in the age-period-cohort effect in this study. Nevertheless, the incidence rate of RHD for the low-SDI region was at the age group of 10 to 14 years among men and women in 2019.

RHD, a complex consequence of acute rheumatic fever, is a febrile illness caused by group A streptococcus infection. The antibodies against the infection slowly damage the heart valves in RHD pathogenesis. The rheumatic fever per se is not likely to be fatal; however, untreated RHD could result in mortality.[30] RHD diagnosis still relies on a clinical diagnostic algorithm with no gold standard confirmatory test, which leaves the potential for imperfect specificity and sensitivity. This calls for further research to improve case detection, especially for use in moderate-/high-risk settings with limited resources.[31] Improvements in diagnosis in low-SDI countries could help policy makers better understand the problem severity, as there are many undiagnosed cases in such countries.[24]

The witnessed gaps and inequities call for concerted efforts to lessen the burden of RHD in areas with limited resources. Although low-SDI countries are witnessing a global shift of disease burden from communicable diseases to noncommunicable diseases,[32,33] they are still dealing with RHD, a neglected consequence of a communicable disease, which could add to their existing challenges.

Thus, there is an urgent need for investment and resource allocation to lessen RHD's burden. Given the level of technology, expenses, and the expertise required for tertiary prevention of RHD, the prevention of rheumatic fever recurrence among patients with previous rheumatic fever or RHD seems to be the most feasible measure among the mentioned prevention levels. In 2018, the World Health Assembly launched a coordinated global response to RHD and acute rheumatic fever and called for concerted efforts in prevention, treatment, and care,[14] the work plan of which is being developed. In the meantime, the WHO Benzathine Penicillin Technical Working Group endeavors to address global supply and demand issues for benzathine penicillin G for rheumatic fever prevention.[34] However, the disruptive effect of the COVID-19 pandemic on any progress is concerning.

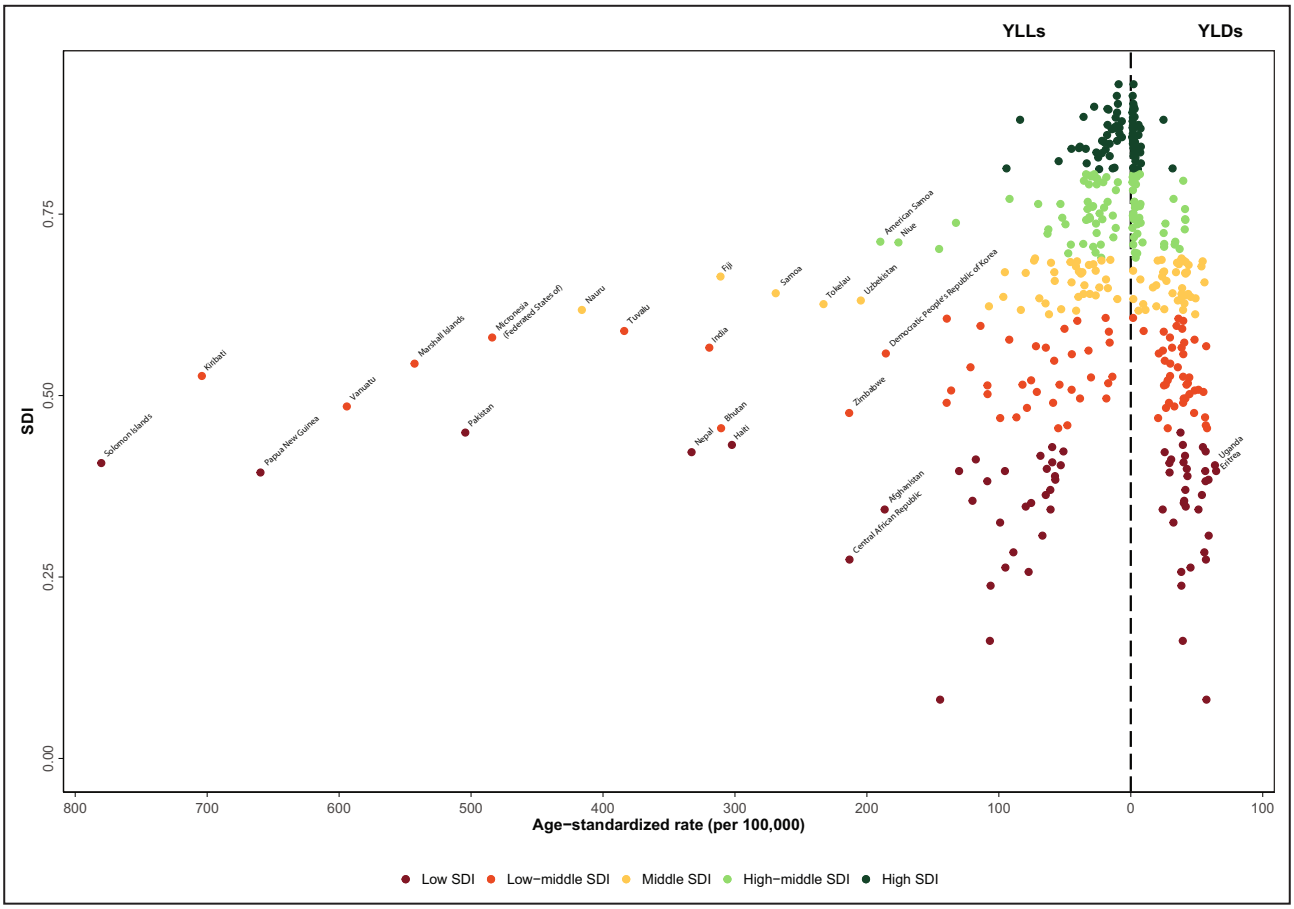

Figure 4. Expected relationship between age-standardized years of life lost (YLLs) and years lived with disability (YLDs) rates and sociodemographic index (SDI) for 204 countries.

The WHO emphasizes improved access to primary health care and extensive investment in a community and primary health care workforce trained in the prevention, diagnosis, and evidence-based management of group A β-hemolytic streptococcal pharyngitis and acute rhematic fever.[14] In this sense, public health authorities and donors need to use the existing evidence to allocate resources proportionate to disease burden and witnessed inequalities and support countries through exchange of expertise and training. As the required expertise and training are also currently lacking in low-SDI countries, the physicians' task for an antibiotic prescription could be shifted to community health workers, who could play a key role in delivering preventive medications via practical clinical algorithms, diagnostic tools, availability of appropriate antibiotics, and supportive supervision.[35]

Until there is an effective vaccine for RHD prevention, the WHO suggests following a multilevel approach against RHD: primordial prevention, including improving the socioeconomic status of populations at risk; primary prevention, including treating patients with strep throat using benzathine penicillin G; secondary prevention, including antibiotic prophylaxis among patients with previous rheumatic fever or RHD; and tertiary prevention, including medical/surgical treatment of RHD complications.[23,29]

Strengths and Limitations

This study presents estimates for incidence, prevalence, deaths, YLLs, YLDs, and DALYs attributable to RHD based on GBD 2019. It provides the opportunity to investigate the current situation and time trends of health metrics and measures worldwide during the past 3 decades to fill information gaps and implement action to address this avoidable disease. Nevertheless, the overall quality of GBD estimates fundamentally relies on the accuracy of data sources used in the modeling. The availability and reliability of registry data and the paucity of other RHD-specific data among countries with limited resources could be questionable, resulting in a need for modeling and data extrapolation. In this sense, the GBD study includes various modeling processes to overcome this limitation and presents

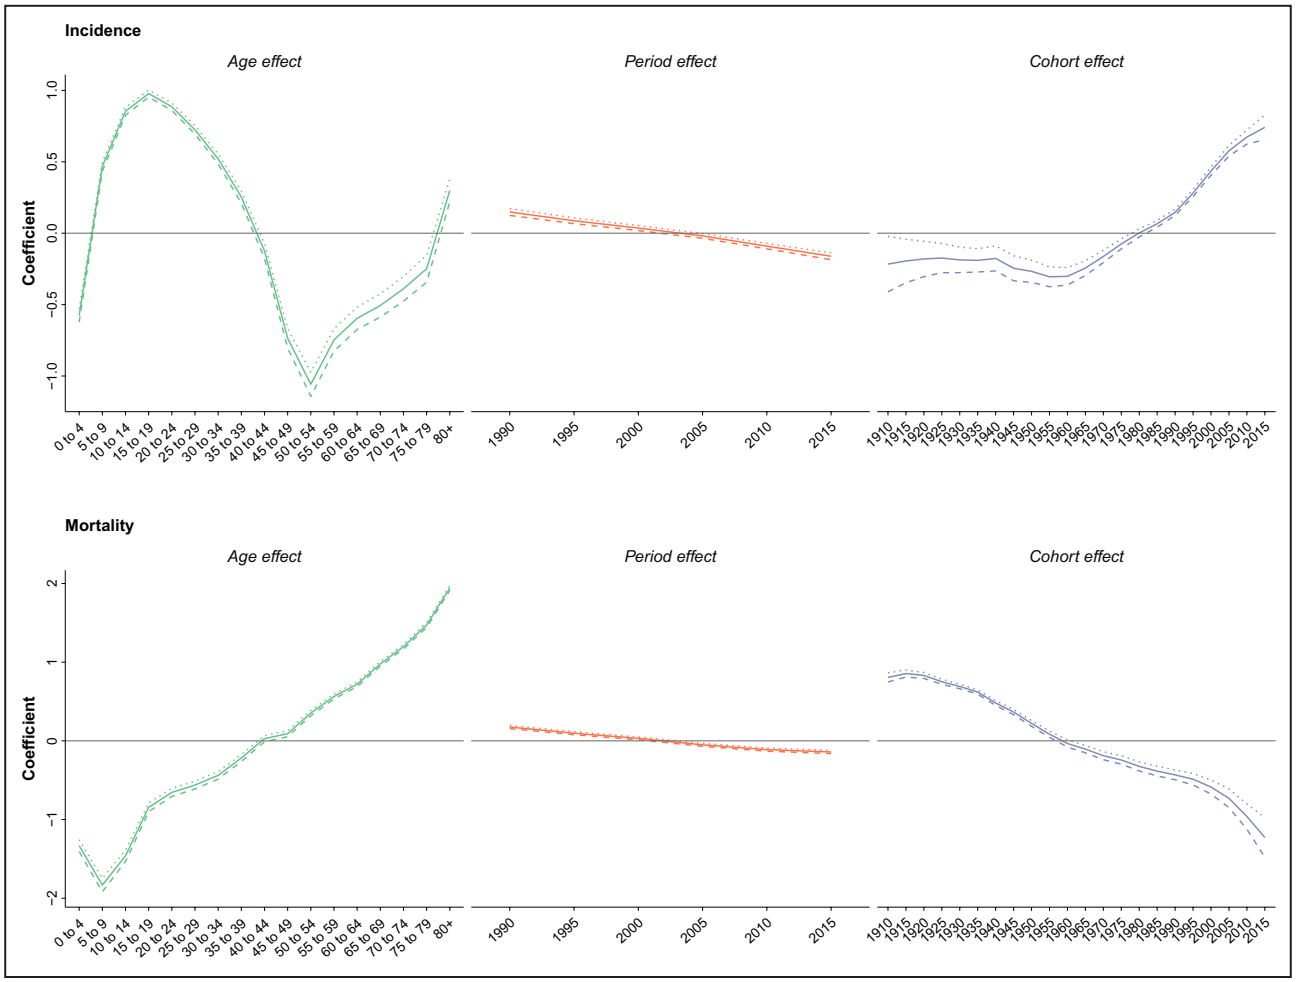

Figure 5. **Age-period-cohort effect on rheumatic heart disease incidence and death.**

metrics with 95% UIs. Moreover, the GBD does not provide subnational data estimates for all countries and thus makes it unfeasible to pick up within-country inequities by location and subpopulations.

CONCLUSIONS

Our study shows a divergence in the burden of RHD among countries based on SDI levels, which calls for including RHD in global assistance and funding. Indeed, many countries are still dealing with an unfinished infectious disease agenda, and there is an urgency to act now to prevent an increase in future burden from RHD.
