

## Succinylcholine: The Dilemma with the Evidence

**Comment on: Tejirian T, Lewis CE, Conner J et al. Succinylcholine: A Drug to Avoid in Bariatric Surgery. *Obes Surg* 2009; 19: 534-6**

To the editor:

We have read with interest the case report by Terijian and colleagues and the comment from Brodsky et al. [1, 2].

We fully agree with the authors that succinylcholine-associated myalgia might be a serious issue for many patients, especially for morbidly obese patients. But we were a little bit surprised about the authors' opinion that there are no proven strategies to reduce succinylcholine-associated myalgia significantly. The authors have cited a meta-analysis by Schreiber et al. that was published in 2005 in *Anesthesiology* [3]. In this article it has been shown that the relative risk of postoperative myalgia can be reduced significantly by using a pretreatment with low-dose non-depolarizing neuromuscular blockers or sodium channel blockers such as lidocaine. Currently, the paper represents the best available evidence on the prevention of succinylcholine-associated myalgia.

Furthermore, we agree that sugammadex, a new binding agent for the reversal of rocuronium and vecuronium, will improve the safety profile of these agents but we are not convinced that this will be the solution of all of our problems. In case of a rapid sequence induction, the anesthesiologist wants optimal intubation conditions within seconds and in this specific situation succinylcholine still

seems to be superior compared to high-dose rocuronium—according to a recent systematic review that was very well done by Perry et al. [4].

The dilemma of systematic reviews and meta-analyses might be that they cannot focus onto specific patient populations. This could be seen as a limitation of evidence-based approaches. On the other hand, it represents the best way—unless the contrary has been proven.

Another aspect emerges from this case report. After dramatic improvements in clinical anesthesia during the last 50 years, a "dirty drug" that may cause potentially fatal complications such as malignant hyperthermia or hyperkalemia still represents the "gold standard" for rapid sequence induction. Surely, a non-depolarizing agent with a comparable pharmacological profile but no side effects would be the best replacement. Unfortunately, it has not been found yet.
