Data extraction details

Structured data extraction

Initial population were drawn from MGB healthcare with at least one lung cancer related ICD codes (162, 1620, 1622, 1623, 1624, 1625, 1628, 1629, 20921, 2312, ICD10:C33, ICD10:C34.00, ICD10:C34.10, ICD10:C34.2, ICD10:C34.30, ICD10:C34.80, ICD10:C34.90, ICD10:C7A.090, ICD10:D02.20, ICD10:Z85.118, V1011).

Birthday, sex, and race/ethnicity were stored in the structured coded data. Birthday was used to calculate the age of diagnosis. Race was categorized into five categories: White, Asian, Black, Hispanic, and others. Common treatments for lung cancer patients including surgery, chemotherapy, radiation therapy, target therapy, and immunotherapy could be found in the prescribed medications and billing codes. Surgery and radiation therapy were extracted using ICD-9/10 and Common Procedural Terminology (CPT) codes. Chemotherapy, target therapy, and immunotherapy were extracted from ICD-9/10-CM, CPT, and medication codes. Common laboratory tests included complete blood count, metabolic panel, lipid panel, liver panel, hemoglobin A1C and urinalysis. The numeric value with its measurement dates were extracted using structured codes.

Unstructured data extraction using NLP tools

We used the published tool EXTEND to extract ECOG and BMI information. For other variables including cancer stage, histology, and mutation information, we developed a new tool named NICE to perform data extraction from clinical notes including discharge summary, progress notes (Figure 1). All dictionaries were shared (separate file). The flow chart of NICE was shown in eFigure 1.

Lung cancer concepts

For the extraction of lung cancer concepts, we built a dictionary containing all synonyms of the concept ‘lung cancer’ such as ‘lung cancer’ and ‘lung carcinoma’ using the Unified Medical Language System. All notes were processed to identify the positive mention of the ‘lung cancer’ concept via Named Entity Recognition (e.g., ‘lung cancer’ in a sentence like ‘The patient denies lung cancer history’ was ignored). Date information was also extracted if a date was mentioned in the same sentence that the concept of ‘lung cancer’ was located (e.g., “Lung cancer (HCC) 11/18/2014”). The date “11/18/2014” was assigned to the concept mention of ‘lung cancer’. The most mentioned dates of the ‘lung cancer’ concept was combined with ICD-9/10 codes time to choose the earlier time as the cancer diagnosis date.

Stage and histology type

To extract stage and histology type, we built dictionaries for both that are similar as those for the lung cancer concept. Then we processed notes to identify positive mention of stage and histology. Because stage information can also be mentioned for other diseases such as other cancers, sleep status, bed sore, and chronic kidney disease, we ignored the mention of stage with mention of any of these diseases in the same sentence. We also excluded the mention of histology if there was mention of a cancer other than lung cancer. The mention of stage and histology were categorized into three confidence levels: high, medium, and low. A high confidence level was assigned when the lung cancer concept appeared in the same sentence. A medium confidence level was assigned when the lung cancer concept appeared in the same note instead of the same sentence. We assigned a low confidence level to stage or histology concept if there was no mention of lung cancer concept in the same note. We built regular expression patterns for extracting TNM stage as additional stage information, and then converted TNM stage to clinical stage. For histological type, phrases were grouped into four categories: NSCLC, SCLC, adenocarcinoma, and squamous cell carcinoma. If at least two histological types were mentioned, the most commonly occurring phrases were selected. If the most commonly occurring type was NSCLC, we chose the most occurring subtype: adenocarcinoma or squamous cell carcinoma. If none of these subtypes were mentioned, the histological type was defined as non-small cell unspecified. For stage, phrases were extracted and grouped into the seven categories: stage I, stage II, stage III, and stage IV, extensive stage, limited stage, and metastatic.

Somatic mutations

Gene alterations that were listed in the NCCN guideline and have been identified that impact therapy selection including *EGFR*, *KRAS*, *ALK*, *ROS1*, and *BRAF*. For patients who received tumor diagnostic tests from MGB HealthCare System including the Snapshot assay, fluorescence in situ hybridization, and immunohistochemistry, we extracted results from the molecular pathology reports. The process of extraction was similar to that used for stage and histology, but we did not categorize the confidence level because the mention of these genetic variables in pathology notes was specific without ambiguation.

Smoking status

For smoking status, each patient was assigned as smoker or non-smoker, and was predicted using the classification model combining structured coded data and clinical notes. To develop the smoking algorithm, we adapted a standardized phenotyping process using NLP and machine learning (ref). We built the smoking algorithm for the entire data mart with 74,421 patients.

We considered six codified features: 1) diagnosis code for ever smoking; 2) EMR current smoking; 3) medical use of Bupropion; 4) nicotine replacement therapy; 5) medical use of varenicline; and 6) tobacco cessation counseling. We considered three most important smoking concepts: C0037369 (smoking), C0337664 (smoker) and C1519384 (tobacco smoking history). We processed free-text clinical notes using NLP to count the number of positive mentions of each smoking concept for each patient. In addition, we measured healthcare utilization as the total number of medical notes in each patient's EHR. To select the most informative features, we first constructed three surrogate labels using diagnosis code for ever smoking, main smoking CUI C0037369, and the combination of two former surrogates. We then repeatedly fitted lasso penalized logistic regression to each of three surrogate labels against all candidate features. Features that were selected >50% of the time were retained for subsequent supervised algorithm training.

Among the 74,421 patients, 4,922 were also from the BLCS, thus having the gold standard training labels for current smoker, past smoker, and non-smoker. Then the smoking labels were further categorized into either: smoker (including both current smoker and past smoker) or non-smoker.

We developed a smoking algorithm using lasso penalized logistic regression, which further reduced the number of variables in the model. Comparing against the chart review gold-standard, the performance characteristics of each algorithm was reported using the AUC, PPV, sensitivity, and specificity. Cross-validation with 70:30 splits averaged over 100 random partitions was used to correct for over-fitting bias. The algorithms assigned each patient their probability of being a smoker. Those with probabilities above a threshold that achieved 90% PPV were classified as smokers.

Of the 4,922 patients with gold standard labels, 4,314 (87.6%) were identified as smokers and 608 were identified as non-smokers. Six smoking features were selected as the most informative features, as shown in eTable 1. The six selected features were then fitted into the lasso model. The estimated regression coefficients are summarized in eTable 1. When compared with gold standard labels, the smoking algorithm achieved an AUC of 0.852 after cross-validation. With the probability threshold set to provide 90% PPV, the smoking algorithm identified 69,021 patients as smokers with 97.6% sensitivity.

BMI and ECOG

To calculate BMI, height and weight or calculated BMI recorded with measurement date were extracted from the structured data and clinical notes using the NLP tool EXTEND. ECOG performance status with the documented dates was extracted using EXTEND.

Prognostic model pre-selected variables

Demographic (age, sex, race), smoking status (smoker, nonsmoker), BMI, ECOG performance status, tumor characteristics (histological type, stage), history of COPD, history of asthma, history of type 2 diabetes, and common laboratory tests were collected. Laboratory tests were from complete blood count (CBC) and comprehensive metabolic panel (CMP). CBC includes WBC, neutrophil, lymphocyte, monocyte, and eosinophil and their ratio such as NLR, red blood count (RBC), RDW, HGB, hematocrit, platelet count (PLT), and mean corpuscular volume (MCV). Routine CMP panel includes albumin, total bilirubin, ALP, alanine aminotransferase (ALT) and aspartate aminotransferase (AST), blood urea nitrogen (BUN), creatinine, glucose, calcium, sodium, potassium, and chloride.

Sensitivity analysis for prognostic model

In main analysis, we coded missing as a separate group given that missing could itself be informative for general health status. In this sensitivity analysis, we used multiple imputations for the missing values and evaluated the final model performance. Time-dependent AUCs are 0.824, 0.824, 0.812, 0.810 and 0.808 for 1- to 5-year OS prediction, which are similar to our missing indicator methods.

eFigure 1. Flow Chart of Natural Language Processing Interpreter for Cancer Extraction (NICE)

The first step is to build dictionaries for variables of interest using UMLS. Then process narrative notes to identify data in notes with different confidence levels for each variable. Using knowledge-based rules to obtain final result for each variable.

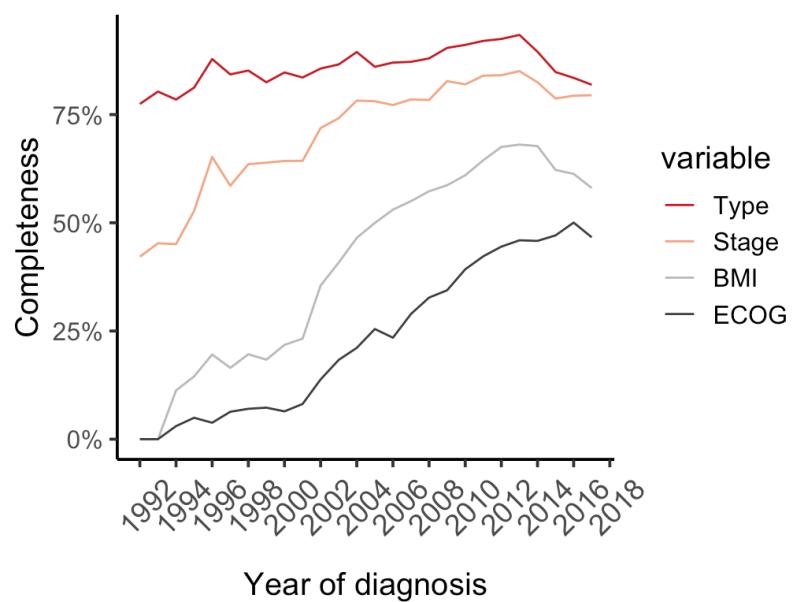

HCD-High confidence data, with mention of lung cancer concepts in the same sentence

MCD-Medium confidence data, with mention of lung cancer concepts in the same note

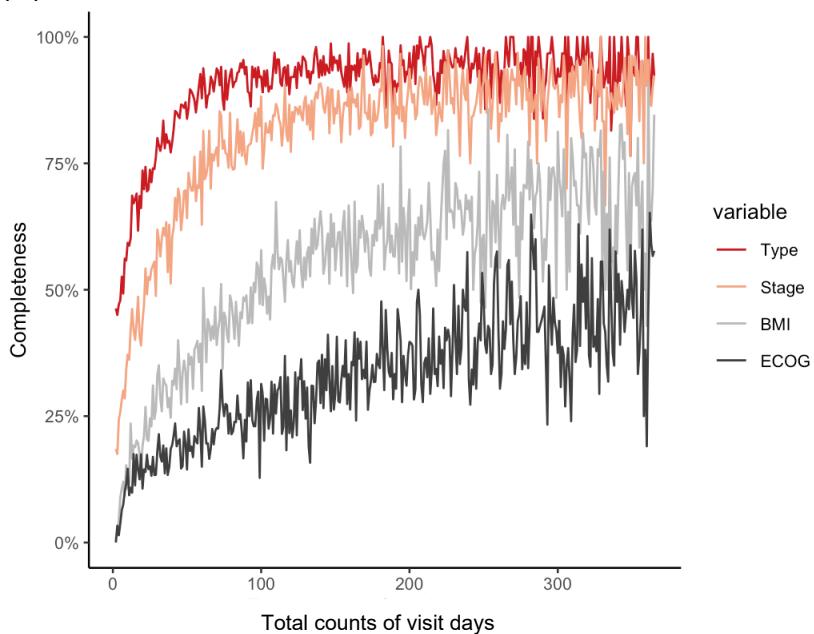

LCD-Low confidence data, with no mention of lung cancer concepts in the same note

eFigure 3. Histogram of Date Discrepancies for Extracted Diagnosis Date From Electronic Health Records Compared With Record Review and Boston Lung Cancer Study Cohort Diagnosis Date

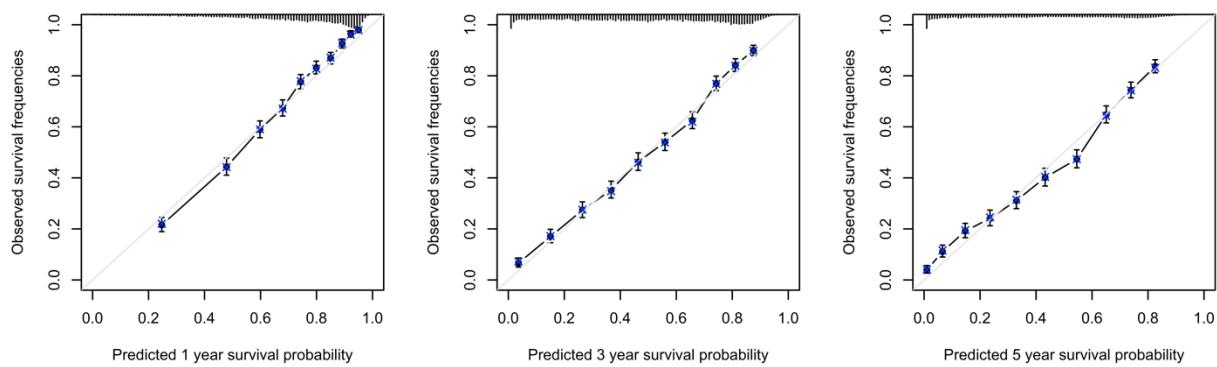

Positive deflections represent an extracted date that is later than the chart review/BLCS date. Outliers beyond ± 365 days (1 year) are not shown.

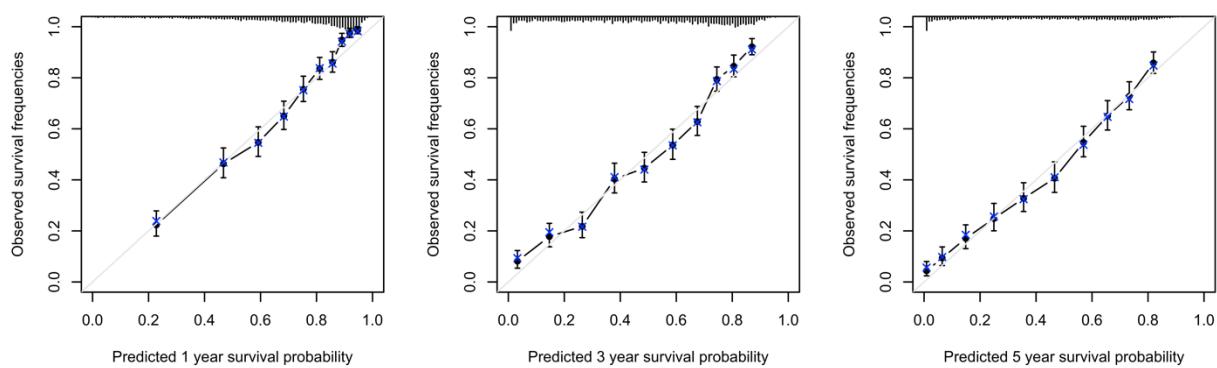

eFigure 4. Time-Dependent Area Under the Receiver Operating Characteristic Curves and 95% CIs for 1 to 5 Years in Testing Set

The final model included age, sex, smoking status, histological type, stage, BMI, albumin, ALP, creatinine, HGB, RDW, WBC, NLR, calcium, and sodium. The basic model included age, sex, histological type, and stage. 1000 bootstrap replicates were performed to estimate the confidence interval of AUC.

eFigure 5. Calibration Curves Comparing Predicted and Actual Survival Probabilities at 1, 3, and 5 Years for Training and Testing Sets

For each time point, patients were grouped into 10 intervals based on predicted survival probabilities. A plot along the 45-degree line would indicate a perfect calibration model in which the predicted probabilities are identical to the actual outcomes.
