From 18th Pediatric Rheumatology European Society (PReS) Congress  
Bruges, Belgium. 14-18 September 2011

## Background

Genetic contribution of TNF $\alpha$ -308 promoter and T676G TNF-RII polymorphism on response to TNF-blocking agents in JIA is not yet well established.

## Methods

Genomic DNA was extracted and TNF $\alpha$ -308 promoter and T676G TNF-RII polymorphism was evaluated using the PCR-RFLP method in 60 JIA patients treated with etanercept. Time cut of point for outcome data analysis was 4 years.

## Results

Average duration of etanercept therapy was 34.61±12.11 months. Disease subtype distribution was 6.78% systemic, 54.24% poly RF- and extended-oligo, 18.64% poly RF+, 16.95% ERA and 3.38 PsA. The distribution of TNF $\alpha$ 308 and T676G genotypes was not significantly different among JIA subtypes. TNF $\alpha$ 308 genotypes distribution was 6.78% AA, 30.51% GG and 62.71% GA while T676G genotypes were 59.3% TT, 8.3% GG and 26.4% TG. T676G genotype polymorphism did not significantly influenced outcome. ACR Pedi 30,50,70 and 100 improvement was significantly faster and sustained

in TNF $\alpha$ 308 GG-genotype patients compared to GA genotype (results shown in table.\*significant compared to 1 year; a-significant compared to GG). Treatment induced remission in 35.14%, had to be reintroduced due to disease worsening in 16.22%, disease was in remission under medication in 21.62% or still active in 24.32% GA patients and in 38.9%, 16.7%, 27.8% and 11.1% in GG patients, respectively. Patients with systemic or RF+ disease course were mostly treatment resistant in both genotypes. (Table 1)

## Conclusion

JIA patients with GG TNF $\alpha$ 308 genotype can achieve better outcome and etanercept treatment can be stopped earlier compared to GA genotype patients who need two years of treatment to achieve same results. TNF $\alpha$ 308 genotype could be useful clinical predictive biomarker for treatment response in all disease subtypes except systemic and RF positive JIA.
