Encephalitis with leucine-rich glioma-inactivated-1 (LGI1) immunoglobulin G (IgG) antibodies classically presents with cognitive impairment and characteristic faciobrachial dystonic seizures.¹ In a murine model, human LGI1 IgG caused reduction of K_v1.1 channels and α -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptor receptors resulting in neuronal hyperexcitability indicating probable pathogenicity of LGI1 antibodies.² LGI1 autoimmunity is associated with malignancy in less than 10% of cases, including small cell lung cancer, prostate and colon cancer, squamous cell skin carcinoma, and neuroendocrine pancreatic cancer.^{3,4} We present a case of LGI1 encephalitis only partially responsive to immunotherapy with eventual complete resolution after resection of a squamous cell lung carcinoma.

Case report

A 78-year-old woman was seen for evaluation of worsening cognition and brief spasmodic episodes affecting the arm and face. On examination, she had stereotyped episodes of grimacing and left arm posturing, without impairment of awareness, lasting 2–4 seconds, consistent with faciobrachial seizures. She also had dysarthria, hypophonia, and mild left hand bradykinesia. Her mental status examination showed impaired orientation to our clinic, impairment in delayed recall, and working memory deficits in reversed spelling and serial subtraction tasks.

A brain MRI showed an incidental CSF cyst on the anterior pole of the left lateral ventricle and bilateral subcortical microvascular changes, but no signs of limbic encephalitis. The CSF was normal with only mild protein elevation of 68 mg/dL and negative for JC virus and neurosyphilis. Continuous EEG monitoring demonstrated no EEG correlation with her dystonic events. She was hyponatremic, with sodium concentrations ranging from 127–132 mmol/L. Initial serologic testing was positive for antibodies to the voltage-gated potassium channel (VGKC) complex (0.11 nmol/L), but the results did not indicate specific protein targets (i.e., LGI1 or Caspr2). She was treated with high-dose IV immunoglobulin and methylprednisolone, and levetiracetam and clonazepam, but with only partial improvement of her dystonic seizures. She had moderate improvement in her cognitive functioning with partial improvement in delayed recollection and working memory. Follow-up testing for antibody specificity within the VGKC complex by a different laboratory was negative. However, 2 months later, repeated serum tested at the same laboratory using cell-based assay was positive specifically for LGI1.

Seven months after her initial presentation, a CT of the chest showed a right lung mass. Surgical resection demonstrated a moderately differentiated squamous cell carcinoma. After surgery, she had a complete resolution of faciobrachial dystonic seizures; her cognitive dysfunction also resolved, both subjectively and on follow-up examination. All previously applied neurologic therapies were discontinued. She had remained seizure free for over 1 year, through her most recent follow-up.

To explore the association of her squamous cell lung cancer with encephalitis, we tested sections from her paraffin-embedded tumor tissue for expression of LGI1 antigen. After deparaffinization, rehydration, antigen retrieval, and blocking, as previously described,⁵ the tissue sections were incubated overnight with a commercial rabbit polyclonal antibody against LGI1/EPT (Abcam 30868) 10 µg/mL diluted in 1:20 normal goat serum, followed by rhodamine-conjugated goat anti-rabbit IgG.⁵ Strong staining of many tumor cells was observed (figure, A). Incubation of tumor sections with the same rhodamine-conjugated secondary antibody, omitting the primary anti-LGI1, showed no staining of tumor cells (figure, B), confirming the specificity of the reaction. Immunostaining with LGI1-positive serum from an autoimmune patient with encephalitis diluted at 1:50 also showed that LGI1 was expressed in many tumor cells with a patchy membrane staining (not shown).

Figure Immunohistochemical staining of tumor sections for LGI1 (×40)

Deparaffinized sections from the patient's tumor immunostained with a commercial polyclonal anti-LGI1 antibody, followed by rhodamine-conjugated secondary antibody (A, top) or only with the same secondary antibody omitting the anti-LGI1 serum (B, bottom). Many LGI1-positive cells (red) are identified within the tumor (A); no tumor cells were stained, other than some connective tissue or vessels with the rhodamine-conjugated secondary antibody alone (B). LGI1 = Leucine-rich glioma-inactivated-1.

Discussion

We present an association of LGI1 autoimmune encephalitis with squamous cell lung carcinoma with dramatic resolution of all clinical phenomena after surgical resection. The case broadens the spectrum of paraneoplastic association with LGI1 encephalitis and demonstrates that the response to immunotherapy can be insufficient.

Although initial testing for the antibody was negative, the patient eventually tested positive for LGI1 antibodies confirming previous reports that LGI1 antibodies may initially show only seropositivity for antibodies to the VGKC complex.⁶ The connection of the encephalitis to the tumor was strengthened by finding that the tumor strongly expressed LGI1 antigen, although it was unclear which specific tumor cells express LGI1. A study of gene expression in *oral* squamous cell cancer has shown that LGI1 expression may be elevated in the surrounding mucosa of early squamous cell tumors, perhaps reflecting a mechanism of tumor suppression.⁷ The neurologic autoimmunity developed in our patient likely represents a paraneoplastic mechanism with cross-reactive autoimmunity triggered by LGI1 antigen expression within the neoplastic or the surrounding non-neoplastic tumor cells as supported by the complete resolution of the patient's symptoms after tumor resection.

Although still rare, the association of the typical neurologic phenotype of LGI1 encephalitis with cancer and the complete clinical response to tumor resection suggests an increased need to evaluate for malignancy in future cases, especially when the initial clinical response to immunotherapy is incomplete.

Acknowledgment

The authors express our appreciation to Sofia Akrivou and Dr. Harry Alexopoulos in Dr. Dalakas's neuroimmunology laboratory for performing the tissue immunostaining. Publication was made possible in part by support from the Thomas Jefferson University Open Access Fund.
