

Figure 3

VZV Risk Factors in Heart Transplant Recipients: Multivariable Analysis

Factor	HR (95% CI)
Age	1.1 (0.8-1.8)
Gender (M)	0.8 (0.3-2.4)
Race	
Black	Ref
White	1.9 (0.4-9.4)
Other	2.5 (0.4-17.4)
Immunosuppression at 1 yr	
Prednisone	0.4 (0.2-1.2)
Cyclosporine (vs. Tacrolimus)	1.4 (0.5-5.0)
MMF/MPA (vs. Azathioprine)	1.6 (0.6-4.2)
CMV	4.7 (1.7-13.5)

Conclusion. HT recipients are at highest risk for VZV reactivation. CMV infection before 1 year is associated with increased risk of VZV reactivation after 1 year in HT. This information may help design clinical trials of the recombinant zoster vaccine.

1555. A New Perspective About Disseminated Adenovirus Infection and Its Outcomes in Pediatric Solid Organ Transplantation

Coralee Del Valle Mojica, MD MPH¹; Sharon F. Chen, MD, MS¹ and Hayley Gans, MD, FPHS²; ¹Pediatrics, Stanford University, Stanford, California, ²Pediatrics, Stanford University School of Medicine, Stanford, California

Session: 151. Viruses and Bacteria in Immunocompromised Patients

Friday, October 5, 2018: 12:30 PM

Background. Adenovirus (AdV) in solid-organ transplants (SOT) was historically associated with increased morbidity and mortality. Detection of AdV at ≥2 sites is predictive of invasive disease in other immunocompromised populations; however, data is lacking for SOT.

Methods. All SOT in children ≤18 years from January 2005 to June 2017 (n = 1,024). We evaluated host and viral risk factors associated with disseminated AdV infection (defined as AdV from ≥2 sites or DNAemia alone) and the clinical spectrum of disease.

Results. Ninety-two patients had 116 AdV infections. Overall prevalence was 9% with one death. Thirty-nine percent of patients had disseminated infection and of those, 44% received cidofovir. Patients with disseminated infection were more likely to be ≤2 years compared with >2 years (P = 0.003), infected in first-year post-transplant compared with >1 year (P = 0.05), and to present with fever compared with no fever (P = 0.02). No difference was observed for organ subtypes, presence of gastrointestinal or upper respiratory tract symptoms, peak DNAemia, mean viral load (mean 3.9log₁₀ vs. 4log₁₀) between patients with dissemination compared with without dissemination. For patients who received a biopsy, dissemination was not different between patients with a positive biopsy vs. negative biopsy (46% vs. 54%). Cidofovir was given to 64% of the positive biopsy patients. No difference for age at infection or time to infection was observed between the treated and not treated groups.

Conclusion. Our data shows that younger age at infection, shorter time to infection and clinical fever are risk factors for disseminated adenovirus infection in pediatric SOT patients, supporting primary infection and enhanced immunosuppression as main factors that allow viral dissemination. Some patients with high viral loads and biopsy-proven disease were not treated with cidofovir with very low mortality, reflecting a broader spectrum of infection than previously recognized. Our data begins to define a high-risk clinical and viral phenotype for adenovirus dissemination, which can inform management strategies.

Session: 151. Viruses and Bacteria in Immunocompromised Patients

Friday, October 5, 2018: 12:30 PM

Background. Immune checkpoint inhibitors (ICIs) are innovative cancer immunotherapies used for solid-organ and hematologic malignancies. ICIs are known for their immune-related adverse events (irAE) but there are limited reports on infectious complications of immunosuppression for these complications. The purpose of this

study was to describe the spectrum of infections in patients with melanoma, renal cell carcinoma or non-small cell lung cancer receiving ICI.

Methods. Retrospective review of City of Hope patients with melanoma, renal cell carcinoma or non-small cell lung cancer on nivolumab, pembrolizumab, and/or ipilimumab from January to November 2017 and received two or more doses of ICI. Pt characteristics assessed: age, sex, prior chemotherapy, steroid use, and type of immunosuppression for irAE. Microbiology records were used to identify infections.

Results. Thirty-nine infectious episodes (35 bacterial, four viral) were identified among 111 patients. Four bacteremia (two *B. cereus*, *coagulase-negative staphylococcus*, 1 *S. aureus*), 12 urinary tract (10 Gram-negative rods, 2 Gram-positive cocci), one intra-abdominal, eight skin and soft-tissue infections (one *S. aureus*, one *Actinomyces radinge*, one *E. faecalis*, and one *E. cloacae*). There were two probable viral pneumonias (two rhinovirus, two enterovirus) and no fungal infections. Fourteen (12.6%) infections were defined as serious (requiring intravenous antimicrobials and/or hospitalization). There was no association between the specific malignancy or ICI used and risk of infection. Steroid use was significantly associated with serious infections: 12/14 (85.7%) vs. 27/95 (28.4%); P = 0.0003, and no patients had received infliximab or other immunosuppressant.

Conclusion. Bacterial infections were most common, and the only risk factor associated with serious infections in our study was steroid use. Type of ICI did not impact the rate of infection.

Session: 151. Viruses and Bacteria in Immunocompromised Patients

Friday, October 5, 2018: 12:30 PM

Background. HSV reactivation is a challenging complication of HM and HCT. ACV prophylaxis effectively decreases the incidence of symptomatic HSV episodes, but may contribute to development of ACV-R HSV disease in this population. Outcomes in patients with ACV-R HSV disease remain poorly characterized.

Methods. We identified adult HM patients and HCT recipients treated at Dana-Farber Cancer Institute who developed clinically significant ACV-R HSV disease between January 1, 2006 and March 1, 2018. HCT recipients typically receive 1 year of ACV prophylaxis after HCT, or longer in those with graft-vs. host disease. Clinical, microbiological and treatment details were collected.

Results. Nineteen patients had 27 episodes of ACV-R HSV disease during the study. Median age was 50 years (range 31–77); 15 (79%) were men. Fifteen (79%) were allogeneic HCT recipients and 4 (21%) had HM (3 CLL, 1 NHL). Thirteen (68%) had oral ulcers (HSV1), four (21%) had perineal ulcers (3 HSV2, 1 HSV1), one had HSV1 vesicles on the trunk and one had concurrent oral HSV1 and perineal HSV2 ulcers. Three patients had recurrent ACV-R HSV: two had one recurrence each and one had six recurrences. Of 19 first episodes of ACV-R HSV, 15 (79%) were confirmed by culture-based phenotypic resistance testing.

Most episodes (20/27, 74%) were treated with foscarnet at clinical diagnosis or after failure of high-dose val-ACV; four of these episodes were also treated with topical cidofovir without success before foscarnet. Three episodes resolved on high-dose val-ACV or IV ACV alone and three were treated with cidofovir or brincidofovir initially. Coinfection was present in 19 episodes (70%), most often bacterial pneumonia or blood stream infection. Twenty-two episodes (81%) resolved completely after a median of 36 days (range 10–88) of treatment. No patient died of HSV disease but five (26%) died before resolution of ACV-R HSV, a median of 25 days (range 1–117) after treatment started. Eight patients died after ACV-R HSV resolved, a median of 111 days (range 27–382) after treatment started. Among HCT recipients, six (37%) died within 12 weeks of diagnosis.

Conclusion. ACV-R HSV disease is an uncommon complication of HM and allogeneic HCT. While ACV-resistant HSV did not cause death in this cohort, death within 12 weeks of infection was common.
