# Bioelectrical impedance analysis-derived phase angle as a determinant of protein-energy wasting and frailty in maintenance hemodialysis patients: retrospective cohort study

Masakazu Saitoh<sup>1,2,3\*</sup> , Masumi Ogawa<sup>3</sup>, Hisae Kondo<sup>3</sup>, Kiichi Suga<sup>3</sup>, Tetsuya Takahashi<sup>1</sup>, Haruki Itoh<sup>4</sup> and Yoichiro Tabata<sup>3</sup>

## Abstract

**Background:** Phase angle (PA), measured by bioelectrical impedance analysis (BIA) has been studied as indicator of nutritional status or muscle function in hemodialysis (HD) patients. It remains unclear if the phase angle is associated protein-energy wasting (PEW) or frailty, which are common complication in hemodialysis patients. The aim of this study is to determine whether BIA-derived PA is a marker of PEW or frailty in HD patients.

**Methods:** This retrospective observational study included 116 adult HD patients (35% female, 64 ± 12 years of age) in a single dialysis center. Patients were classified according to the PA quartiles into four groups; 1) first quartile: PA < 3.7°, 2) second quartile: PA 3.7–4.1°, 3) third quartile: PA 4.2–4.9° and 4) fourth quartile: PA ≥ 5.0°. International Society of Renal Nutrition and Metabolism (ISRNM) criteria and Japanese version of Cardiovascular Health Study (J-CHS) criteria were used to identify PEW and frailty.

**Results:** The lower PA group was associated with a greater risk of PEW (35% vs. 24% vs. 21% vs. 3%;  $p = 0.032$ ), frailty (59% vs. 40% vs. 21% vs. 3%;  $p < 0.001$ ). In multivariate logistic regression analysis, the first quartile group was at a significantly greater risk of both PEW and frailty compared with the fourth quartile group after adjusting for other confounding factors.

**Conclusions:** Lower PA was associated with a greater risk of PEW and frailty in HD patients.

**Keywords:** Bioimpedance electrical analysis, Frailty, Hemodialysis, Phase angle, Protein energy wasting

## Background

Protein-energy wasting (PEW), defined as the loss of somatic and circulation body protein and energy reserves, is a common complication among hemodialysis (HD) patients [1]. Frailty can be defined as a biological syndrome of decreased reserve and resistance to stressors that results from cumulative decline across multiple physiological systems and is highly prevalent in patients with HD. HD patients accompanied by PEW or frailty are associated with accelerated biological ageing, and an increased risk of cardiovascular event (CV) and death [1, 2]. A more recent proposal suggests early screening and diagnosis of PEW and frailty are important in clinical practice among HD patients [1–3].

Bioimpedance electrical analysis (BIA) is a noninvasive, safe and quick methods, and validated assessment of hydration status and body composition. The clinical use of BIA in HD patients is currently increasingly used in dry weight and nutritional status management. Phase angle (PA) measured by BIA reflects the resistance and reaction of the body in response to the application of an external current. PA is the most clinically relevant impedance parameter, an index of cell membrane integrity and vitality. Phase angle is a direct measure of BIA and therefore not influenced by assumptions that can affect body composition or hydration assessments. A lower PA level indicates decreased cell integrity or cell death, whereas higher PA suggests large quantities of intact cell membranes [4]. Moreover, PA has been recently used as a tool for assessing disease progression as well as for predicting clinical outcome in many clinical situations [5]. However, the association between PA and PEW or frailty remains uncertain among HD patients. This study focused on HD patients, primarily to investigate the validity of BIA-derived PA in predicting PEW and frailty, and secondly to examine the association between PA and CV risk.

## Methods

### Subjects

The present study included 116 adult HD patients (35% female,  $64 \pm 12$  years of age) from a single unit of the Meisei-kai Toyo Clinic Yachimata, Chiba, Japan between January 2018 and March 2018. Patients were eligible to participate if they were over 18 years of age, had received maintenance HD at least 3 times per week for more than 6 months, and had no contraindications for BIA including patients with pacemakers or were not limbless. The exclusion criteria of present study were comorbidities active malignancy and recent hospital admission within 3 months that might influence nutritional or functional status. Study collaborators interviewed patients before or during a HD session, obtained recent clinical and laboratory data from medical records, and measured muscle

strength and physical performance prior to the start of the HD session. In addition, study collaborators measured the body composition using a BIA after a midweek dialysis session.

### Cardiovascular risk score

Cardiovascular (CV) risk score was calculated using new risk model developed by Japan Dialysis Outcomes and Practice Patterns Study (J-DOPPS) [6]. This CV risk model had a more accurate dose-dependent association with observed CV events than the Framingham risk score among HD patients. The J-DOPPS CV risk model contained only six variables: age, diabetes mellitus, history of CV events, dialysis time per session, phosphorus level, and albumin level, ranging from 0 to 20 points with higher scores reflecting greater risk of CV events.

### Diagnosis of protein-energy wasting

International Society of Renal Nutrition and Metabolism (ISRNM) recommended the diagnosis of PEW [7]. PEW involves 4 categories: (1) serum chemistry: low serum albumin, or total cholesterol; (2) body mass: decreased body mass index (BMI) or total body fat percentage or unintentional weight loss, (3) muscle mass: pre-dialysis serum creatinine appearance normalized by the body surface area (sCr/BSA), and (4) dietary intake normalized protein nitrogen appearance (nPNA). The cutoff values were as follows: serum albumin, 3.8 g/dL; BMI, 23 kg/m<sup>2</sup> or unintentional weight loss (5% over 3 months or 10% over 6 months); sCr/BSA, 380  $\mu$ mol/L/m<sup>2</sup>; and nPNA, 0.8 g/kg per day. The diagnosis of PEW was defined at least 3 of the 4 listed categories.

### Diagnosis of frailty

Frailty was evaluated based on the Japanese version of Cardiovascular Health Study (J-CHS) criteria consisting of 5 components: weight loss, exhaustion, low physical activity, slowness and weakness [8]. (1) Weight loss was evaluated using the question “Have you lost 2kg or more in the past 6 months?”. (2) Exhaustion was measured using the question: “In the past 2 weeks, have you felt tired without a reason?”. (3) Low physical activity was measured using the two questions: “Do you engage in moderate levels of physical exercise or sports aimed at health?”, and “Do you engage in low levels of physical exercise aimed at health?”. (4) Slowness was measured using usual gait speed: patients were asked to 5 m-walk at their comfortable pace using any walking aids to maintain balance and function. (5) Weakness was evaluated by measuring handgrip strength in the sitting position. The J-CHS comprises the following: (1) Weight loss: 1 point for “yes” to the question; (2) Exhaustion: 1 point for “yes” to the question; (3) Low physical activity: 1 point for “no” to both questions; (4) Slowness: 1 point

if gait speed < 1.0 m/s; (5) Weakness: 1 point if handgrip strength < 26 kg in men and < 18 kg in women. Summing up the J-CHS scores, we calculated a total J-CHS score; a cut off of  $\geq 3$  was used to identify frailty.

### Bioelectrical impedance analysis

BIA measurements was performed by seca mBCA515 (seca®, Hamburg, Germany), which is a multifrequency bioimpedance device. The 8-electrode technique enables segmental impedance measurement of the arm and legs. All the patients were in a standing position. The PA was calculated using the following equation:

$PA(\text{degree}) = \arctan(Xc/R) \times (180/\pi)$ , is related to body cell mass and soft tissue composition.

Quartiles were obtained for the PA (25th, 3.7°; 50th, 4.2°; 75th, 5.0), and the patients were classified in four groups: first quartile group ( $PA < 3.7^\circ$ ), second quartile

group ( $3.7 \leq PA < 4.2^\circ$ ), third quartile group ( $4.2 \leq PA < 5.0^\circ$ ), and fourth quartile group ( $PA \geq 5.0^\circ$ ).

To examine the PA values adjusting for age, sex, and body mass index, the PA values were converted into s.d. score by the following equation:

Standard deviation score (SDS) =  $(X - \text{average } X) / s. d.$

Where X is the observed value, average X is the mean of the normal value at the respective age, sex, and body mass index, and s.d. is the standard deviation from the mean. BIA-derived body components such as extracellular water (ECW) [9], total body water (TBW), fat mass and fat free mass were recorded, and ECW/TBW was calculated by the ratio of ECW and TBW.

### Statistical analysis

Continuous variables are expressed at mean  $\pm$  standard deviation and as counts and percentages as appropriate. For the comparison of continuous variables among PA

groups, one-way analysis of variance was used, and for categorical variables, the Pearson chi-square test was performed. To adjust for effects due to potential confounders for PA, multivariate logistic regression models of PEW, and frailty were performed, and odds ratios (ORs) and 95% confidence intervals (95% CI) were determined. The  $PA \geq 5.0^\circ$  (fourth quartile group) was considered the reference for this analysis. In the analysis for the CV event risk, we compared the CV event risk model score among PA groups using Kruskal-Wallis test. Statistical analyses were performed using SPSS software, version 21, and in all statistical calculations, a two-tailed  $p < 0.05$  was considered statistically significant.

## Results

The average age of HD patients in the analysis was  $64 \pm 12$  years; 35% of patients were female; dialysis vintage was  $7 \pm 6$  years; PA score was  $4.3 \pm 1.1^\circ$ , and PA SDS was  $-1.1 \pm 1.8$ ; 65% of the patients had PA SDS  $< -1$  s.d., and 17% had PA SDS between  $-1$  and  $0$  s.d and 18% had PA SDS  $> 0$  s.d..

The clinical characteristics of the study population according to PA groups are shown in Table 1. HD patients with lower PA were significantly older, had a higher proportion of females, and lower BMI, serum creatinine level, albumin level, modified creatinine index, and handgrip strength. Our findings demonstrated that 35% of patients in the first quartile group, 24% in the second quartile group, 21% in the third quartile group, and 3% in the fourth quartile group exhibited PEW based on ISRNM criteria ( $p = 0.032$ ). Moreover, the prevalence of frailty was 59% in the first quartile group, 40% in the second quartile group, 21% in the third quartile group, and 3% in the fourth quartile group ( $p < 0.001$ ). The remaining clinical variables were not significantly different among PA groups. We evaluated the prediction accuracy of several variables measured by BIA. The area under the curve (AUC) value of a PA is large in

predicting frailty and PEW compared with other values measured by BIA (Table 2).

Table 3 shows the results of logistic regression analysis of the predictive variables related to PEW in HD patients. The univariate logistic regression analysis showed that the first quartile group (OR 14.737, 95%CI 1.740–124.827,  $p = 0.014$ ) and second quartile group (OR 8.909, 95%CI 1.019–77.905,  $p = 0.048$ ) were at significantly greater risk of PEW compared with fourth quartile group. Moreover, multivariate logistic regression analysis showed that first quartile group remained a predictor of PEW after adjusting for other confounding factors, compared to the fourth quartile group (model 2: OR 10.967, 95%CI 1.124–107.014,  $p = 0.039$ ; model 3: OR 11.099, 95%CI 1.101–111.926,  $p = 0.041$ ).

Table 4 shows the results of logistic regression analysis of the predictive variables associated with frailty in HD patients. In univariate logistic regression analysis, the first quartile group (OR 40.727, 95%CI 4.805–345.219,  $p = 0.001$ ) and the second quartile group (OR 17.111, 95%CI 2.031–144.136,  $p = 0.009$ ) were at a significantly greater risk of frailty compared with the 4th quartile group. In multivariate analysis, the first quartile group (OR 36.770, 95%CI 3.906–346.140,  $p = 0.002$ ) and the second quartile group (OR 16.525, 95%CI 1.867–146.285,  $p = 0.012$ ) remained predictors of frailty after adjusting for age, sex, and HD vintage compared with fourth quartile group (model 2). Similarly, the first quartile group (OR 15.612, 95%CI 1.194–204.120,  $p = 0.036$ ) was significantly associated with frailty after adjusting for age, sex, HD vintage, diabetes mellitus, hemoglobin level, grip strength than the fourth quartile group (model 3).

Figure 1 shows the relationship between PA and four-quartile subgroups of CV risk model score among HD patients. The first quartile was significantly higher CV risk score compared with third and fourth quartile groups ( $p = 0.004$  and  $p < 0.001$ ).

## Discussion

PEW and frailty are common complication associated with functional decline, and worse prognosis in HD patients [7, 10, 11]. The present study demonstrated that a low PA measured by BIA as a simple alternative

screening tool is an independent predictor of PEW and frailty as well as CV risk score in HD patients.

The biological meaning of the PA remains uncertain; however, it seems to reflect body cell mass, or cell membrane function [5]. Increased ECW is associated with

PA Phase angle, HD Hemodialysis

**Fig. 1** Phase angle and CV risk model score developed by J-DOPPS among HD patients. The box plots display the 50th (H), 25th and 75th (Q1), 10th and 90th (–) percentiles and circles for the <10th and >90th percentiles of the variable. CV, cardiovascular; PA, phase angle

poor nutritional status, and reduced total body water (TBW), an indicator of lower body cellular mass. Therefore, an increase in the ECW/TBW may be explained by malnutrition or skeletal muscle mass loss, as well as by fluid overload status [12]. Our findings also demonstrated that lower PA tended to have a significantly higher ECW/TBW ratio among HD patients. Moreover, a low PA showed a tendency for association with lower BMI, hand grip strength, and higher ECW-TBW and C-reactive protein levels, which are included in the PEW or frailty diagnostic criteria and were consistent with results from prior studies [13, 14]. Moreover, a lower PA correlated with PEW, the highest OR in the multivariate models was 10.967 and 11.099 in the first quartile group compared to the reference group (fourth quartile group). Ruperto et al. subsequently confirmed that PA < 4° was an independent risk predictor for HD patients with PEW [15], and is in line with our results. Thus, we also recognized that a low PA was an important indicator of malnutrition and hydration in HD patients. In addition, we showed that a low PA was associated with low TBW as an indicator of skeletal muscle mass in HD patients. Moreover, low PA was a greater risk factor for frailty even after adjusting for other clinical indicators. Several prior studies have reported an association between low PA and frailty phenomenon in older subjects [16, 17], or cardiac surgery patients [18], although very few studies have focused on HD patients [19]. In the present study,

we also determined that low PA is a representative comprehensive biomarker of malnutrition, frailty, as well as hydration in HD patients.

Few studies have evaluated the association between PA and mortality or CV event in HD patients. More recently, Bansal et al. and Segall et al. demonstrated that PA was significantly associated with mortality in CKD patients [20] and HD patients [21]. Varan et al. reported a significant increase in the risk of death among HD patients with PA < 4°, even after adjustment of several nutritional indicators [22]. In present study, the first quartile group (PA < 3.7°) was at a significantly higher CV risk score compared with third (PA 4.2–4.9°) and fourth quartile (PA ≥ 5.0°) groups. However, given the relatively small number of patients and few events in present study, we could not perform analyses to identify factors related to all-cause mortality or incident of CV event.

Thus, we propose that regular screening would be essential to monitor the progression of PEW or frailty over time, and to avoid the development of the vicious cycle of PEW or frailty. Regular screening may help in the early identification of patients accompanied by PEW or frailty when they are the most treatable as well as provide prognostic information. We therefore suggest that PA could be a useful, simple indicator to predict PEW, frailty, and CV event risk among HD patients.

### Study limitations

Several limitations of our present study should be noted. First, our findings are limited to a relatively small number of patients at a single HD center, though most of the results are comparable to those from prior clinical studies. We have done sample size power calculation, a sample size of 122 patients was chosen based on the recommended method (median effect size 0.3, alpha error probability 0.05, power 0.8). Thus, our sample size is modest; further large number of studies are therefore needed in the future. Second, it has suggested that PEW is cachexia and should be termed kidney disease cachexia as a continuum with PEW first followed by cachexia. Our findings are limited to a small number of patients with severe PEW or kidney disease cachexia, therefore we could not assess the relationship between phase angle and severity of PEW including kidney disease cachexia. Future research needs to evaluate the diagnostic, prognostic, and predictive accuracy of phase angle on severe PEW or kidney disease cachexia status.

### Conclusion

PA could be a useful, simple indicator to predict PEW and frailty among HD patients. Lower PA was associated with a greater risk of PEW and frailty in hemodialysis patients.

### Abbreviations

BIA: Bioimpedance electrical analysis; BMI: Body mass index; BSA: Body surface area; CKD: Chronic kidney disease; CV: Cardiovascular; ECW: Extracellular water; HD: Hemodialysis; ISRNM: International Society of Renal Nutrition and Metabolism; J-CHS: Japanese version of Cardiovascular Health Study; J-DOPPS: Japan Dialysis Outcomes and Practice Patterns Study; nPNA: Normalized protein nitrogen appearance; ORs: Odds ratios; PA: Phase angle; PEW: Protein-energy wasting; SDS: Standard deviation score; TBW: Total body water

### Acknowledgements

The authors wish to thank the doctors, nurses, and clinical engineers who engaged in the treatment of our patients in Meiseikai Toyo Clinic Yachimata.

### Authors' contributions

SM provided the research design, data measurements and analysis, and wrote the manuscript. OM and KH provided the interpretation of data. TT provided the substantially contributed the analysis and revised the manuscript. SK, IH, and TY participated in the research design and substantially contributed to the study concept. The authors read and approved the final manuscript.

### Funding

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

### Availability of data and materials

The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

### Ethics approval and consent to participate

This study was approved by the institutional review board at the Meiseikai Toyo Clinic, Chiba, Japan, and informed consent was obtained before data collection. The ethics committee granted approval to waive the requirement for written informed consent for the additional follow-up from 2018 to 2020 because of the retrospective nature of this study.

### Consent for publication

Not applicable.

### Competing interests

The authors declare that they have no competing interests.

Springer Nature remains neutral with regard to jurisdictional claims in published maps and institutional affiliations.

**Ready to submit your research? Choose BMC and benefit from:**

- fast, convenient online submission
- thorough peer review by experienced researchers in your field
- rapid publication on acceptance
- support for research data, including large and complex data types
- gold Open Access which fosters wider collaboration and increased citations
- maximum visibility for your research: over 100M website views per year

**At BMC, research is always in progress.**
