Nb-doped and Al₂O₃ + B₂O₃-coated granular secondary LiMn₂O₄ particles as cathode materials for lithium-ion batteries

Chunliu Li,^{†ab} Linchao Zhang,^{†a} Junfeng Yang,^{id}*^a Zhuoming Xie,^a Tao Zhang,^a Jianxin Wang,^c Qianfeng Fang^{ab} and Xianping Wang^{*a}

In this work, to improve the cyclability and high-temperature performance of cubic spinel LiMn₂O₄ (LMO) as cathode materials, Nb⁵⁺-doped LiMn₂O₄ powders coated and uncoated with Al₂O₃ and/or B₂O₃ were synthesized *via* the modified solid-state reaction method. It was found that Nb⁵⁺-doped and B₂O₃ + Al₂O₃-coated LMO powders comprising 5 μm granular agglomerated fine primary particles smaller than 350 nm in diameter exhibited superior electrochemical properties with initial discharge capacity of 101.68 mA h g⁻¹; we also observed capacity retention of 96.31% after 300 cycles at room temperature (RT) and that of 98% after 50 cycles at 55 °C and 1C rate.

1. Introduction

Lithium-ion batteries (LIBs) have widespread applications in consumer electronic devices and potential applications in electric vehicles and hybrid electric vehicles on account of their high operating voltage and high energy density.^{1–3} To date, a variety of electrode materials have been developed.^{4–9} LiCoO₂ and LiFePO₄ are the most widely used cathode materials in commercial LIBs because of their good cycle life (>500 cycles); however, they have several drawbacks such as high cost, toxicity of Co for LiCoO₂, poor electronic and ionic conductivity, relatively low specific capacity and one-dimensional channels for lithium-ion diffusion for LiFePO₄.¹⁰ In this context, cubic spinel LiMn₂O₄ (LMO) as a cathode material has attracted continuous and considerable attention owing to its low cost, natural abundant resources of manganese, high safety, facile 3D Li⁺-ion diffusion pathways, and nontoxicity. However, the cycling performance of LMO degrades rapidly due to the Jahn–Teller distortion associated with high-spin Mn³⁺, dissolution of manganese into the electrolyte and undesirable electrode–electrolyte reaction, particularly at elevated temperatures (55 °C), which seriously restrict its application in commercial LIBs.^{11–13}

Various strategies have been attempted to solve these issues, and these mainly include surface coating, doping and

morphology control.^{14–22} Coating LMO particles with metal oxides or fluorides can improve their cycling performance and rate capability by decreasing the contact area between the electrolyte and electrode materials, therefore reducing Mn dissolution.^{14–17} Furthermore, ion doping of Nb, Al and Ni, respectively or collectively, can induce the formation of a high concentration of Mn⁴⁺ ions on the surface of LMO, thereby suppressing the Jahn–Teller distortion and eventually improving cycling stability.^{18–20} Moreover, the morphology of LMO particles has also been found to be a key factor in determining its electrochemical properties, for example, to study how spherical LMO exhibits better performance than polyhedral LMO.^{21,22} Hence, it is reasonably expected that through morphology control, coating and doping simultaneously, the electrochemical performance of LMO can be improved to a larger extent. Unfortunately, to the best of our knowledge, studies on their synergetic effects have not been reported so far.

In this work, Nb-doped LMO powders coated with Al₂O₃ and B₂O₃ were synthesized through a modified solid-state reaction. The effects of particle morphology, doping and coating on the electrochemical properties of LMO were investigated in detail.

2. Experimental

2.1 Material preparation

Four kinds of LMO samples were synthesized by a modified solid-state reaction. Stoichiometric amounts of Li₂CO₃, manganese oxides (MnO₂ or MnO₂ + MnO + Mn₃O₄) and Nb₂O₅ were mixed homogeneously by ball milling. Then, the resulting mixtures were sintered at 450 °C for 5 h and 780 °C for 20 h subsequently to obtain Nb-doped LMO. Thereafter, the mixtures were ground, mixed with Al(OH)₃ and/or B₂O₃, and sintered at 750 °C for 10 h. The selected sintering temperature

[†] These authors contributed equally to this work.

was 750 °C, which is higher than the melting point of Al(OH)₃ and B₂O₃; therefore, the mixture of liquid Al(OH)₃ and B₂O₃ with Nb-doped LMO facilitated the formation of a thin surface layer on LMO particles. The whole synthesis process is depicted in the following equations.^{23–27} The final obtained materials were labelled as LMOA, LMOB, LMOC and LMOD, as specified in Table 1.

2.2 Material characterization

The crystal structure of all samples was characterized by the X-ray diffraction (XRD) technique using a Rigaku SmartLab diffractometer with Cu K α radiation (40 KV, 250 mA) in the range of 10–90° with a step size of 0.02° s⁻¹. Lattice parameters of the as-prepared samples were acquired using the Jade 6.0 refinement software. The morphology and elemental composition were characterized by scanning electron microscopy equipped with EDS (SEM, S-3400N).

2.3 Electrochemical test

An organic-based slurry was prepared *via* mixing active materials, carbon black, and poly(vinyl difluoride) (PVDF) at a weight ratio of 80 : 10 : 10 in the *N*-methyl-2-pyrrolidone (NMP) solvent. The formed slurry was pasted on an aluminum foil and then dried at 120 °C for 12 h in a vacuum oven. The prepared electrodes were punched into \varnothing 12 mm disks and used as the working electrode thereafter. The loading mass density of the active material was about 8 mg cm⁻². CR2032 type coin cells were assembled in an argon-filled glove box with a lithium metal foil (Aldrich) as the counter electrode, Whatman filter paper (Alfa Aesar) as the separator, and 1 M LiPF₆ in EC/DMC/EMC (1 : 1 : 1 by volume) (Alfa Aesar) as the electrolyte. The cycling test was performed by using a Neware battery tester within the voltage range of 3.0–4.2 V *vs.* Li⁺/Li under the galvanostatic mode at different current densities (1C = 110 mA g⁻¹) at RT or 55 °C, respectively. Electrochemical

Fig. 1 XRD patterns of different LiMn₂O₄ samples: LMOA, LMOB, LMOC, LMOD.

impedance spectroscopy (EIS) measurement was carried out on a Chenhua CHI600E workstation between 10⁶ and 10⁻² Hz with amplitude of 10 mV.

3. Results and discussion

Fig. 1 displays the XRD patterns of Nb-doped LiMn₂O₄ with and without Al₂O₃ or Al₂O₃ + B₂O₃ coating. All the XRD patterns of the four samples matched well with those of single-phase spinel LiMn₂O₄; distinct diffraction peaks were observed from the (111), (311) and (400) crystal planes and relatively weak peaks were observed from the (222), (331), (511), (440), and (531) planes.^{5,28} No peaks of impurities were observed after doping and coating, which indicated that both B₂O₃ and Al₂O₃ layers existed in the amorphous state. Fig. 2 shows the SEM images of all samples. Nb-doped LiMn₂O₄ with MnO₂ as the Mn source and without the coating (LMOA) consisted of polygon- or pyramid-type particles of about 500 nm to few microns in diameter, with quite clean and smooth edges. After B₂O₃ coating (LMOB) or B₂O₃ + Al₂O₃ coating (LMOC) through sintering at 750 °C for 10 h, the edges of all the particles were passivated and obscure. However, their particle sizes exhibited different behaviors: significant increase for the sample LMOB with Al₂O₃ coating and almost no change for the sample LMOC with B₂O₃ + Al₂O₃ coating; this indicated the beneficial effect of the liquid B₂O₃ layer on suppressing the particle growth during sintering at 750 °C for 10 h. The EDS elemental mapping of O, Mn, Al, Nb and B in the selected area of sample LMOC (Fig. 3) revealed that Al and B are homogeneously coated on LMO

Table 1 The specific components of the LiMn₂O₄ samples

Sample	Mn oxides	Li source	Li : Mn	Nb : Mn	Coating
LMOA	MnO ₂	Li ₂ CO ₃	1.05 : 2	0.02 : 1.98	—
LMOB	MnO ₂	Li ₂ CO ₃	1.05 : 2	0.02 : 1.98	0.2 mol% Al ₂ O ₃
LMOC	MnO ₂	Li ₂ CO ₃	1.05 : 2	0.02 : 1.98	0.2 mol% Al ₂ O ₃ + 0.1 mol% B ₂ O ₃
LMOD	85Mn ₃ O ₄ + 10MnO ₂ + 5MnO (wt%)	Li ₂ CO ₃	1.05 : 2	0.02 : 1.98	0.2 mol% Al ₂ O ₃ + 0.1 mol% B ₂ O ₃

Fig. 2 SEM images of different LiMn_2O_4 samples: LMOA, LMOB, LMOC, LMOD.

microspheres. In contrast, the sample LMOD with the mixture of MnO , MnO_2 and Mn_3O_4 as Mn sources and $\text{B}_2\text{O}_3 + \text{Al}_2\text{O}_3$ as the coating consisted of granular secondary particles of about 5 microns in diameter, which comprised fine primary particles (smaller than about 350 nm in size) with obscure edges.

Fig. 4 shows the initial charge–discharge curves of all four samples at 1.0C rate in the voltage range of 3.0–4.2 V. It can be clearly seen that all samples exhibited similar voltage profiles in the initial discharge processes with two voltage plateaus at 4.0 V and 4.1 V, which were ascribed to the step-by-step Li^+ -ion deintercalation from the host oxide, as shown in eqn (6) and (7).^{29,30} The initial discharge capacities of LMOA, LMOB, LMOC

and LMOD were 109 mA h g^{-1} , 106 mA h g^{-1} , 102 mA h g^{-1} and 102 mA h g^{-1} , respectively, showing a decreasing trend with increasing coating content due to the inactive nature of these coatings toward Li^+ ions.

Fig. 5 shows the cycling stability of all samples at a current density of 1.0C between 3.0 and 4.2 V at 25 °C and 55 °C. At 25 °C (Fig. 5a), the Nb-doped and uncoated LiMn_2O_4 (LMOA)

Fig. 3 EDS mappings of the selected area in sample LMOC.

Fig. 4 The initial charge–discharge curves of LMOA, LMOB, LMOC and LMOD.

exhibited significant capacity fading with cycling; the specific discharge capacity quickly decreased to around 30 mA h g^{-1} after 130 cycles. After Al_2O_3 coating or $\text{Al}_2\text{O}_3 + \text{B}_2\text{O}_3$ coating, respectively, the cycling stability of Nb-doped LiMn_2O_4 could be improved significantly but was still not completely satisfactory, especially in the case of Al_2O_3 coating (LMOB), for which rapid capacity fading was observed after 230 cycles. By contrast, the sample LMOD, consisting of spherical secondary particles and with $\text{Al}_2\text{O}_3 + \text{B}_2\text{O}_3$ coating, displayed excellent cycling stability with capacity retention as high as 96.31% after the 300th cycle. At an elevated temperature of 55°C , the cycling stability of all samples was measured at 1.0C between 3.0 and 4.2 V (Fig. 5b). After 50 cycles, the capacity retention values of samples LMOA, LMOB, LMOC and LMOD were 95.40%, 93.25%, 94.57% and 97.98%, respectively. The superior cycling stability of sample LMOD to that of others could be attributed to their different morphologies because of the use of different manganese oxides as raw materials since all the other factors including Li/Mo ratio, crystal structure, Nb content and their coating composition were completely identical. Furthermore, by comparison with the reported results illustrated in Table 3, it could be seen that our $\text{Al}_2\text{O}_3 + \text{B}_2\text{O}_3$ -coated and Nb-doped granular LMO

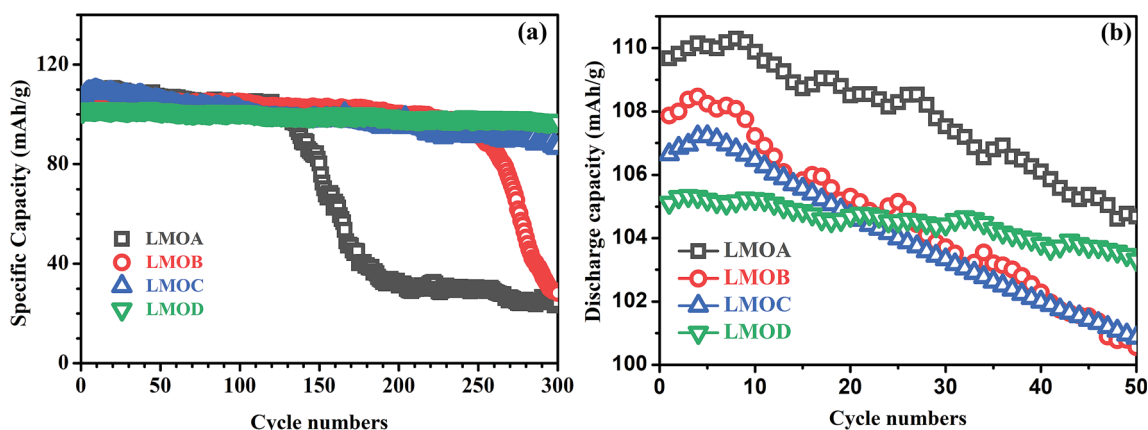

Fig. 5 The cycling performances of LMOA, LMOB, LMOC and LMOD at 25°C (a) and at 55°C (b) at a current density of 1C.

Fig. 6 The rate performances of LMOA, LMOB, LMOC and LMOD at various current densities.

secondary particles exhibited much better cycling stability at both 25°C and 55°C than pure LMO,^{19,31,32} Al(Mg, Ce, Ni, Mn, Nb)-doped LMO,^{12,18,19,31,33} and $\text{AlF}_3(\text{La-Sr-Mn-O}, \text{V}_2\text{O}_5, \text{ZrO}_2)$ -coated LMO, indicating the synergetically beneficial effect of doping, coating, and special morphology of granular secondary particles in our work.

Fig. 6 presents the normalized discharge capacity of all samples cycled at different current rates between 3.0 and 4.2 V (vs. Li/Li^+). Overall, their discharge capacities decreased gradually with increasing C-rate at first and then, the capacities increased with decreasing C-rate, reaching a minimum at the highest current density of 7C. Clearly, LMOB and LMOD presented better rate capability than LMOA and LMOC, especially at 7C rate. Fig. 7 shows the EIS graph of Nb-doped LMO with and without coating in the fully discharged state in the (a) 1st and (b) 100th cycle. All the Nyquist plots contain a semicircle in the higher frequency ranges and an inclined straight line in the lower frequency ranges. The diameter of the semicircle represents the charge-transfer resistance (R_{ct}) at the electrode/electrolyte interface, and the inclined straight line corresponds to the diffusion of lithium ions into the bulk of the electrode (Warburg impedance). The spectrum was fitted well

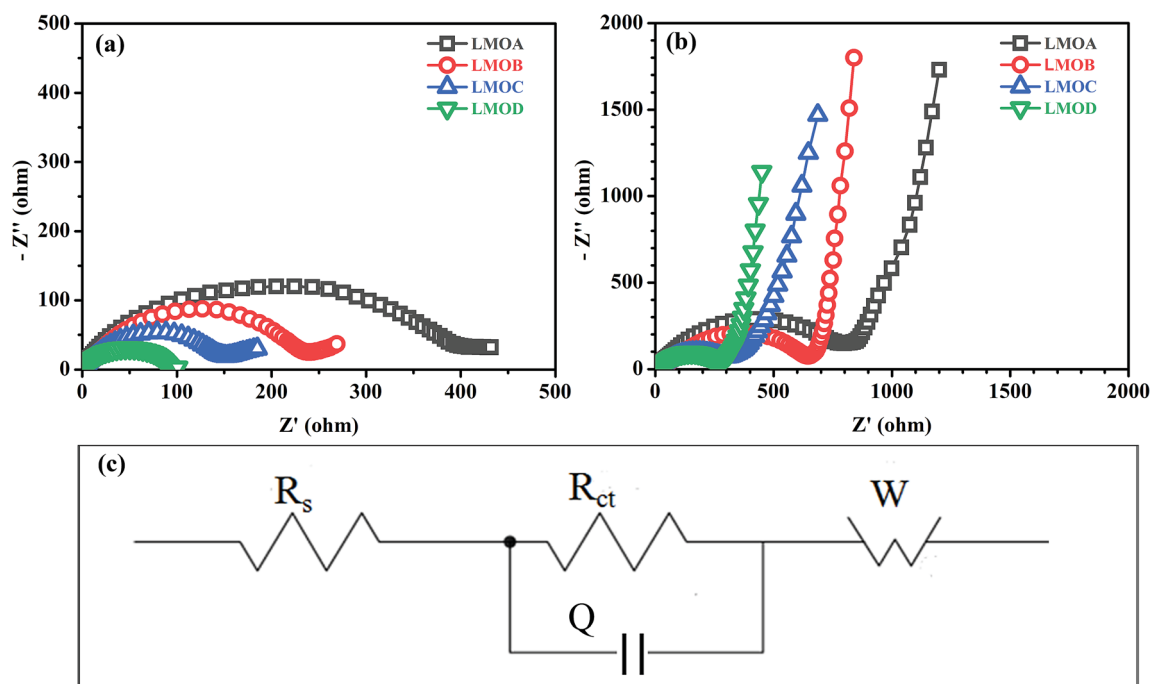

Fig. 7 Nyquist plots of samples LMOA, LMOB, LMOC and LMOD with an amplitude of 5.0 mV over a frequency range from 100 kHz to 0.01 Hz in the discharged state of 4.0 V: (a) in the first cycle; (b) in the 100th cycle; (c) the equivalent circuit.

Table 2 The fitting results of EIS spectra based on the equivalent circuit

Sample	1 st cycle		100 th cycle	
	R_s/Ω	R_{ct}/Ω	R_s/Ω	R_{ct}/Ω
LMOA	3.83	275.30	10.19	886.60
LMOB	2.95	249.40	6.79	624.00
LMOC	4.53	148.80	2.11	341.50
LMOD	2.41	91.90	2.52	302.50

on an equivalent circuit shown in Fig. 7c, where R_s , Q , R_{ct} , and Z_w represent the ohmic resistance of the electrolyte, constant phase element (CPE), charge-transfer resistance, and Warburg impedance arising from the diffusion of Li^+ ions in the

electrode, respectively. The values of R_s and R_{ct} are listed in Table 2. Notably, R_s in the case of sample LMOA without coating exhibited the largest increase after 100 cycles among the values of all samples, suggesting that surface coating can effectively inhibit the dissolution of an active material into the electrolyte, due to which the conductivity remains unchanged. The sample LMOD exhibited the smallest charge transfer resistance in both the 1st and 100th cycle among all samples, demonstrating its best electrochemical activity. The diffusion coefficient of lithium ions could be calculated from the plots in the low-frequency region according to the following two equations:^{14,34}

$$D_{\text{Li}} = \frac{R^2 T^2}{2A^2 n^4 F^4 C^2 \sigma^2} \quad (8)$$

Table 3 Comparison of the cycling performances of LMO between our work and literature

Sources	Performance	
	Initial capacity (mA h g^{-1}) and capacity retention after n cycles at RT	Initial capacity (mA h g^{-1}) and capacity retention after n cycles at 55 °C
Our work	101.7, 96.3% after 300 cycles	105.11, 98% after 50 cycles
LiMn_2O_4 (ref. 19)	104.2, 61.9 after 150 cycles	
Al-doped LiMn_2O_4 (ref. 31)	Unknown	93.1, 96 after 30 cycles
Mg-doped $\text{LiMg}_{0.08}\text{Mn}_{1.92}\text{O}_4$ (ref. 33)	99.3, 93.2 after 150 cycles	Unknown
Ce-doped $\text{LiMn}_{1.99}\text{Ce}_{0.01}\text{O}_4$ (ref. 12)	106, 85% after 150 cycles	Unknown
Nb-doped $\text{LiMn}_{1.5}\text{Nb}_{0.5}\text{O}_4$ (ref. 18)	115, 87% after 100 cycles	Unknown
Ni, Mn codoped $\text{LiNi}_{0.03}\text{Mo}_{0.01}\text{Mn}_{1.96}\text{O}_4$ (ref. 19)	114, 91.2% after 300 cycles	Unknown
La-Sr-Mn-O coated LiMn_2O_4 (ref. 35)	129.9, 90.6% after 500 cycles	129.9, 93.6% after 130 cycles
AlF_3 -coated LiMn_2O_4 (ref. 15)	103.4, 90% after 100 cycles	Unknown
V_2O_5 -coated LiMn_2O_4 (ref. 17)	113, 90% after 200 cycles	112.7, 79.7% after 100 cycles

Fig. 8 The plot comparison of Z' vs. $\omega^{-0.5}$ of samples LMOA, LMOB, LMOC and LMOD.

$$Z' = R_s + R_{ct} + \sigma\omega^{-0.5} \quad (9)$$

Here, R is the gas constant, T is the absolute temperature, A is approximately equal to the electrode area (cm^2), n is the number of electrons in the specific electrochemical reactions, F is the Faraday constant, and C is the molar Li^+ ion concentration; Z' is the real part of the impedance, ω is the angular frequency in the low-frequency region, and σ is the Warburg factor. Based on experimental results in the low-frequency zone, the relationship between Z'_{re} and the reciprocal square root of ω can be obtained, as depicted in Fig. 8. The σ values of samples LMOA, LMOB, LMOC and LMOD could be further concluded as 56.16, 38.55, 60.76 and 26.48, and the diffusion coefficients of lithium ions in these four samples were $1.02 \times 10^{-14} \text{ cm}^2 \text{ s}^{-1}$, $2.16 \times 10^{-14} \text{ cm}^2 \text{ s}^{-1}$, $8.69 \times 10^{-15} \text{ cm}^2 \text{ s}^{-1}$ and $4.58 \times 10^{-14} \text{ cm}^2 \text{ s}^{-1}$, respectively. Clearly, the sample LMOD exhibited the highest Li^+ ion diffusion coefficient, suggesting the beneficial effect of appropriate morphology and coating on increasing the Li^+ ion diffusion coefficient.

4. Conclusions

We successfully fabricated Nb-doped LMO with Al_2O_3 and/or B_2O_3 coatings and different morphologies by modified solid-state sintering. The morphology of Nb-doped LMO could be controlled *via* using different Mn oxides as precursors, on which the surface coating could be realized through mixing with $\text{Al}(\text{OH})_3$ and/or B_2O_3 and sintering at 750°C . During this, the liquid B_2O_3 layer could suppress LMO particle growth, whereas the Al_2O_3 layer played a negligible role. Eventually, Nb-doped and $\text{Al}_2\text{O}_3 + \text{B}_2\text{O}_3$ -coated granular LMO secondary particles, consisting of 350 nm spherical primary particles, were obtained with superior electrochemical performance; we also observed high capacity retention of 96.31% after 300 cycles at RT and that of 98% after 50 cycles at 55°C at 1C rate.
