## Abstract

**Background:** The early use of blood products has been associated with improved patient outcomes following severe hemorrhage or traumatic injury. We aimed to investigate the influence of pre-hospital blood products (i.e. plasma and/or RBCs) on admission hemostatic properties and patient outcomes. We hypothesized that pre-hospital plasma would improve hemostatic function as evaluated by rapid thrombelastography (rTEG).

**Methods:** We conducted a prospective observational study recruiting 257 trauma patients admitted to a Level I trauma center having received either blood products pre-hospital or in-hospital within 6 hours of admission. Clinical data on patient demographics, blood biochemistry, injury severity score and mortality were collected. Admission rTEG was conducted to characterize the coagulation profile and hemostatic function.

**Results:** 75 patients received pre-hospital plasma and/or RBCs (PH group; nearly half received both RBCs and plasma) whereas 182 patients only received in-hospital blood products (RBCs, Plasma and Platelets) within 6 hours of admission (IH group). PH patients had lower Glasgow coma scale (GCS) scores, more penetrating injuries, lower systolic blood pressures, lower hemoglobin levels, lower platelet counts and greater acidosis upon ED admission than the IH group (all  $p < 0.05$ ). Despite differences in type of injury and admission vitals indicating that the PH group had more signs of bleeding than the IH group, there were no significant differences in in-hospital mortality (PH 26.7% vs. IH 20.9%  $p = 0.31$ ). When comparing rTEG variables between PH patients transfused with 0, 1 or 2 units of plasma, more pre-hospital plasma transfusion was tendency towards improved rTEG variables. When adjusting for pre-hospital RBC, pre-hospital plasma was associated with significantly higher rTEG MA ( $p = 0.012$ ) at hospital admission.

**Discussion:** After adjusting for pre-hospital RBCs, pre-hospital plasma transfusion was independently associated with increased rTEG MA, as well as arrival indices of shock and hemodynamic instability. Besides more severe injury and worse clinical presentation, the group that received pre-hospital transfusion had early and late mortality similar to patients not transfused pre-hospital.

**Conclusions:** These data suggest that early administration of plasma can provide significant hemostatic and potential survival benefit to severely hemorrhaging trauma patients.

## Background

Death from injury has increased by 20% over the last decade and accounts for more deaths than malaria, tuberculosis and HIV combined [1]. Hemorrhage requiring massive transfusion secondary to trauma remains a major cause of potentially preventable deaths, and development of trauma induced coagulopathy (TIC) further increases the mortality rates of hemorrhaging patients substantially [2]. During the last decade a number of strategies and protocols have been developed and adopted to improve the management and delivery of care to trauma patients with severe hemorrhage. These strategies include: (i) damage control surgery, the use of abbreviated surgery to remedy hemorrhage and contamination with definitive surgery delayed until physiology has been restored [3]; (ii) limited use of crystalloid fluids, which can worsen coagulopathy through dilution of clotting factors and platelets [4]; (iii) hypotensive resuscitation, whereby normalization of blood pressure is delayed until hemorrhage has been surgically controlled [5]; and (iv) balanced blood product use, whereby packed red blood cells (RBCs), plasma and platelets are transfused in ratios of, or near to, 1:1:1 mimicking whole blood, which is associated with improved outcomes and may help alleviate TIC [6, 7]. Taken together, these are known as damage control resuscitation (DCR) [8]. As DCR developed, it became clear that early, aggressive resuscitation with blood products could lead to early correction of acidosis, coagulopathy, and hypothermia [9–11].

Rawdan and colleagues reported that moving thawed plasma from the blood bank to the emergency department enabling early balanced blood product transfusions, was associated with a reduction in overall blood product use and a 60% decrease in odds of 30-day mortality [12]. Based on this rapidly evolving experience, the Texas Trauma Institute at Memorial Hermann Hospital (Houston, TX) introduced the availability of two units of O RhD negative RBCs and two units of thawed AB plasma in appropriate temperature controlled containers on four Life Flight (LF) helicopters [13]. Recently, we reported that this novel practice of early hemostatic-resuscitation with blood products was associated with improved hemorrhage-resuscitation and patient outcomes (i.e. improved survival) when compared to trauma patients only receiving crystalloids en route to the hospital [13].

The objective of the present observational study was to investigate the association between pre-hospital administered RBCs and plasma and hemostatic function as evaluated by whole blood thrombelastography (TEG) on arrival at the trauma center as compared to that of patients not receiving pre-hospital blood transfusions. We hypothesized that patients receiving pre-hospital blood products, specifically pre-hospital plasma, would display improved hemostatic function as evaluated by TEG.

## Methods

### Setting and patients

The Texas Trauma Institute at Memorial Hermann Hospital is an American College of Surgeons verified Level I trauma center that is the primary teaching hospital for the University of Texas Health Science Center and operates a hospital-based helicopter program, Life Flight (LF). The helicopters carry two units of type O RBCs and two units of AB plasma for emergent use following established guidelines. This prospective observational cohort study included 257 trauma patients admitted directly from the scene of the injury to the highest level of activation at Memorial Hermann Hospital Texas Medical Center (MHH-TMC) between October 2012 and November 2013. The University of Texas Health Science Center at Houston institutional review board (IRB) approved this study (IRB# HSC-GEN-12-0059).

### Patient selection

All adult trauma patients ( $\geq 16$  years) who met criteria for full trauma team activation and received blood before arrival at ED (i.e. pre-hospital, PH group) or after hospital admittance within 6 h of ED arrival (i.e. in-hospital, IH group) were included in this study.

The criteria for exclusion were: pregnancy, prisoner, had a burned body surface area  $>20\%$  or enrolled in another study. Patients from whom we could not obtain a blood draw were excluded from analysis. Informed consent was obtained from the patient or a legally authorized representative within 72 h of admission. If the patients were discharged or died within 24 h, a waiver of consent was granted. In cases which consent could not be obtained, the patient was excluded from the study, and their blood samples were destroyed. Patient information on baseline demographics, clinical, physiologic, and laboratory tests were extracted from patient records and the institutional trauma registry.

### Sample collection

Blood samples were collected immediately upon hospital admission on all adult trauma patients ( $\geq 16$  years) who met criteria for full trauma team activation i.e., PH patients had samples drawn after PH blood transfusion whereas IH patients had samples drawn before any blood transfusion. In all cases, blood was drawn into citrated tubes for conducting the rapid-TEG assay.

### Rapid Thrombelastography (rTEG)

All rTEG specimens were run on a thrombelastograph 5000 (Haemoscope Corporation, Niles, IL). Admission rTEGs were performed using the accepted citrate reversal method. Specimens were collected in a small (3 mL) citrated tube, transported to the Emergency Department Stat Laboratory. The citrate was immediately reversed

by adding calcium chloride according to the recommendations of the manufacturer within the rTEG package insert. After this, TEG was performed within 5–10 min of blood sampling, using tissue factor and kaolin as activators. Staff laboratory technicians in the Memorial Hermann Hospital Emergency Department performed all the rTEG assays during the defined study period. These same technicians performed all the quality controls on the TEG analyzers, doing so every 8 h. Quality control was performed per the package insert from the manufacturer.

The rTEG generates several values that describe the hemostatic process: The first value generated is the activated clotting time (ACT), which is the time in seconds between initiation of the test and the initial fibrin formation (normal range, 86–118 s). Similar to the ACT, the r-value (also known as the reaction time (R-time), 0–1 min) expresses the time between the start of the assay and beginning of clot formation. The K-time (normal range, 1–2 min) is the time needed to reach 20-mm clot strength and the alpha ( $\alpha$ ) angle (normal range, 66–82°) determines the slope of the tracing that represents the rate of clot formation. The maximal amplitude (MA; normal range, 54–72 mm) is the greatest amplitude of the tracing and the G-value (normal range, 5,300–12,000 dynes/cm<sup>2</sup>) is a global measure of absolute clot strength (both enzymatic and platelet contributions) and is decreased in hypocoagulable states. LY30 (normal range, 0.0–7.5%) is the percent amplitude reduction at 30 min after MA, illustrating the amount of fibrinolysis.

### Statistics

Statistical analysis was performed using STATA (IC version 12.1, College Station, TX) and SPSS 22 (IBM Corporation, New York, US). Descriptive data are presented as medians with inter quartile ranges (IQR) or as % (proportions).

Non-parametric statistical tests (Mann-Whitney *U* test and Kruskal-Wallis) and Chi-square tests were used to evaluate group differences (PH vs. IH groups), as appropriate. *P*-values <0.05 were considered significant.

To investigate the association of pre-hospital RBCs and plasma on admission for rTEG MA, a parameter with significant predictive value for transfusion requirements and mortality [14–16], we conducted a linear regression analysis. Univariate and multivariate linear regression models were constructed for each group (PH, IH) and combined including both groups. Multivariate linear regression models were adjusted for admission vital differences between the PH and IH groups (systolic blood pressure (SBP), hemoglobin, platelet count and pH) as well as adjusting for mode of transport (i.e. LF or ambulance) and amount of PH-RBC and PH-Plasma in the model including both groups (PH and IH).

Furthermore we compared rTEG parameters in PH patients receiving plasma based on the amount administered (0, 1 and 2 units plasma) by ANOVA and Tukey post-hoc test.

## Results

### Patient characteristics

A total of 257 patients were included in the study, 75 (29%) patients received pre-hospital (PH) blood, whereas 182 (71%) patients only received blood in-hospital (IH) within 6 h of hospital admission. Eighty-six patients were transported by ground ambulance and 171 patients by LF, of which 44% received a PH blood transfusion (Table 1). The median age of the study cohort was 37 years, 81% were male, with a median injury severity score (ISS) of 26 (Table 1). Patients in the PH group demonstrated a higher incidence of penetrating injuries (45 vs. 25%, *p* = 0.002), field intubations (39 vs. 21%, *p* = 0.005), positive FAST exams and presented with lower GCS scores compared to patients in the IH group (Table 1). Additionally, patients receiving PH blood displayed significantly lower systolic blood pressure (SBP), hemoglobin, platelet count and more acidosis than IH, suggesting a more pronounced degree of hemorrhage and/or shock in the PH group. Lastly, patients receiving PH blood received more units of blood products within 6 and 24 h after admission (Table 1). Despite differences in type of injury and admission vitals indicating more severe injury and bleeding in the PH group, there were no significant differences in mortality (Table 1).

### Pre-hospital Plasma is associated with improved hemostasis

Despite the variations between the two groups, no significant differences were found in the median rTEG values, respectively for the PH vs. IH, for ACT (121 vs. 121), R-time (0.8 vs. 0.8), K-time (1.65 vs. 1.45), Angle (70 vs. 73) and Ly30 (1 vs. 1.4), upon arrival at the hospital. However, at hospital admission PH displayed significant lower median rTEG MA (62 vs. 64, *P* = 0.020) and G-value (8.1 vs. 8.69, *P* = 0.009) compared to IH patients. Table 2 shows the distribution of pre-hospital blood products transfused. Nearly half of the PH group received 1 unit of RBCs and plasma each (Table 2). When comparing rTEG values ACT, R-time, K-time,  $\alpha$ -Angle, MA, G and LY30 in PH patients receiving 0, 1 and 2 units of plasma pre-hospital unadjusted for PH RBC, patients receiving 2 units of plasma pre-hospital had the highest mean values of rTEG  $\alpha$ -Angle (70.57 vs. 67.51 vs. 72.00° for plasma = 0, 1 and 2 units, respectively), rTEG MA (58.73 vs. 57.30 vs. 62.55 mm for plasma = 0, 1 and 2 units, respectively) and rTEG G (5.93 vs. 7.36 vs. 8.41 dyn/cm<sup>2</sup> for plasma = 0, 1 and 2 units, respectively). Furthermore, patients receiving 2 units of plasma pre-hospital had lower average values of K-time (1.63 vs. 2.07 vs. 1.59 min for plasma = 0, 1 and 2 units,

respectively) and R-time (2.07 vs. 1.07 vs. 0.72 min for plasma = 0, 1 and 2 respectively). There was a significant difference in R-time between patients receiving no pre-hospital plasma compared to patients receiving 2 units of plasma ( $P = 0.023$ ).

#### Predictors of hemostatic competence

In the PH group, the unadjusted univariate linear regression demonstrated that pre-hospital plasma was

associated with significantly higher rTEG MA values (one unit increase in PH plasma was associated with ( $\beta$  coefficient) 13.95 mm, 95%CI [3.13, 24.77],  $p = 0.012$ ) higher MA at hospital admission in a model only adjusting for PH RBC. The interaction between PH RBC and plasma did not appear to have a significant effect on admission rTEG MA values (data not shown). When adjusting for pH, hemoglobin, platelet count, SBP, and in PH patients PH-RBC and PH-Plasma, higher pH and higher platelet count were independent predictors of rTEG MA in IH patients and higher pH, higher platelet count and PH-Plasma were associated with higher rTEG MA in PH patients (all  $p < 0.05$ , data not shown).

When conducting the analysis non-stratified (including both PH and IH groups in the same analysis), and instead adjusting for transportation (by LF or ambulance) and admission vital differences, and PH transfusion with Plasma and RBC, PH plasma transfusions were associated independently with higher rTEG MA values together with higher pH, higher SBP and higher platelet count (Table 3).

## Discussion

This study found that after adjusting for pre-hospital RBCs, pre-hospital plasma transfusion was independently associated with increased rTEG MA, as well as arrival indices of shock and hemodynamic instability. Acidosis and low platelet count were found to impede hemostatic potential evaluated by rTEG. Besides more severe injury and worse clinical presentation, the group that received pre-hospital transfusion had early and late mortality similar to patients not transfused pre-hospital.

Reduced clot strength, as evaluated by TEG, has repeatedly been associated with increased bleeding, transfusion requirements and mortality in severely injured trauma patients [16, 17]. In the present study, plasma transfusion PH was independently associated with higher rTEG MA values, also after adjusting for pre-hospital RBCs. Furthermore, patients in the PH group receiving the highest amount of pre-hospital plasma transfusions

differed in their hemostatic competence as evaluated by rTEG when compared to the patients in the PH group only receiving one or zero pre-hospital plasma. Given that the most severely injured and bleeding patients are expected to receive the highest amount of plasma pre-hospital, this suggests that pre-hospital plasma is more beneficial than pre-hospital RBCs for improving hemostasis in the acute/pre-hospital setting, in accordance with the coagulation factor and fibrinogen content in plasma compared to RBC.

Furthermore, PH patients were significantly different from IH patients. PH patients presented with more penetrating injuries, more positive FAST exams, lower systolic blood pressures, lower hemoglobin, lower platelet count, lower pH upon arrival to the trauma bay and lower rTEG MA and G, despite receiving pre-hospital RBC and/or plasma transfusions during transport. However, 52.7% of the IH patients were transported by LF where blood products are available; indicating that the prehospital blood transfusion by LF was not deemed necessary for these patients as they were not transfused. Furthermore, IH patients only received three RBCs and three plasma units within six hours of hospital admission, which suggests only moderate hemorrhage compared to eight RBCs and six plasma units in the PH group. Due to these differences, we stratified by group as well as conducting adjusted regression analyses. Regardless of group, however, acidosis and low platelet count were the strongest predictors of reduced hemostatic competence evaluated by rTEG MA values. This indicates that future analyses of rTEG should consider adjusting for pH and platelet count to make appropriate comparisons.

In addition, the acid buffer capacity of plasma is known to be 25–50 times better than crystalloids solutions [18], and despite the divergence between the two groups, the data shows no significant difference in the 6-h, 24-h, and the overall mortality. This indicates that pre-hospital plasma transfusion may lead to early correction of acidosis thereby mitigating coagulopathy, which

**Table 3** Admission rapid thrombelastography (rTEG) MA-value evaluated by linear regression in 257 adult trauma patients

Variable	Units	Univariate		Adjusted

Regression coefficients ( $\beta$ ) with 95% confidence intervals (95% CI) and *p*-values are displayed. *P*-values <0.05 are shown in bold. Predicted change in rTEG MA (mm) associated with: LF (yes) and one unit higher pH, Hemoglobin, Platelet count, SBP, PH-RBC and PH-Plasma

potentially can be translated into improved survival though this has to be investigated in future studies designed specifically to answer this question.

The study has several limitations. First, it should be noted that we could not obtain blood samples from “in-the-field”, prior to when the patient received pre-hospital transfusions. As such, we cannot definitively assess the effect of each transfusion and potential changes in the TEG values from “in-the-field” vs. hospital admission. Future studies are needed to evaluate these pre-hospital and pre-transfusion acute changes in clotting properties. Furthermore, another limitation is the relatively small sample size of 75 patients within the PH group and nearly half of these patients received one unit of RBCs and plasma pre-hospital. This emphasize the need for future studies investigating the relative benefits of adding RBCs to plasma in a larger number of patients, preferably sampling blood for pre-hospital analysis.

## Conclusion

In conclusion, after adjusting for pre-hospital RBCs, pre-hospital plasma transfusion was independently associated with higher rTEG MA. Acidosis (low pH levels) and low platelet counts were the strongest predictors of poor hemostasis evaluated by rTEG. Besides, more severe injury and worse clinical presentation, the PH group had early and late mortality similar to the IH group. Overall, these data imply that early administration of plasma may have beneficial effects on improving hemostasis, which may potentially translate into improved patient survival in future studies with larger sample sizes.

Submit your next manuscript to BioMed Central and we will help you at every step:

- We accept pre-submission inquiries
- Our selector tool helps you to find the most relevant journal
- We provide round the clock customer support
- Convenient online submission
- Thorough peer review
- Inclusion in PubMed and all major indexing services
- Maximum visibility for your research

Submit your manuscript at  
www.biomedcentral.com/submit
