Study of the reaction of ninhydrin with tyrosine in gemini micellar media

Dileep Kumar ^{*ab} and Malik Abdul Rub^c

This paper reports the study of the ninhydrin and L-tyrosine (Tyr) reaction in gemini micellar media. The aim of the study was to see the influence of different parameters on the reaction rate, including the influence of reactant concentration, temperature and pH. Spectrophotometric and conductometric techniques were employed to record the absorption of the product formed and cmc values as a function of the surfactants, respectively. The effect of varied surfactant concentrations on the reaction rate was also investigated. The quantitative treatment of the rate constant (k_{app}) vs. surfactant concentration was carried out on the basis of the pseudo-phase model suggested by Martinek *et al.*, Menger and Portnoy, and established by Bunton. Micellar binding parameters and thermodynamic parameters have been calculated and are discussed in detail. A plausible reaction mechanism that is consistent with observed kinetic data has been proposed.

1. Introduction

Surfactants consist of an amphiphilic chemical structure, having a preference toward interfacial adsorption at low concentrations of the surfactant in an aqueous medium. They self-associate to form an aggregated structure beyond a certain critical concentration. Their shape, size, and aggregated structure depend on different parameters that include surfactant concentration, salt, temperature, *etc.* A small range of concentration at which the formation of an aggregated structure occurs is called the critical micelle concentration (cmc), and this process of self-association of surfactant monomers into a micelle is referred to as micellization.^{1–4} Surfactants are used extensively in several industry and research fields.^{5–7} They find widespread use in household items and in the chemical industry due to their promising properties such as low cmc, high surface activity, super wetting ability, high dispersion, *etc.*^{8–10} The formation of a micelle, a characteristic property of surfactants, has various applications fundamentally as well as in applied fields. It is important in pharmaceutical technology as micelles play roles in several biochemical membranes and pharmacological systems due to their dual behavior (hydrophilic head and hydrophobic tail).^{11–14}

Ninhydrin is the name employed by Abderhalden and Schmidt¹⁵ for 1,2,3-triketohydrindene. They have given the

compound this name because of its peculiar color reaction with α -amino acids and amines. In 1910, ninhydrin, or what is more scientifically known as 2,2-dihydroxyindan-1,3-dione (as, in the presence of water, ninhydrin exists as its hydrate) was also called Ruhemann's reagent (the reagent was first discovered by Ruhemann) (Scheme 1).¹⁶

α -Amino acids react with ninhydrin at different rates, but they all give the same product of diketohydrindylidenediketohydrindamine (DYDA), known as Ruhemann's purple. To obtain better results, efforts are regularly being carried out involving CTAB surfactants, solvents and salts by researchers/scientists and the color of the product obtained has been affected.^{17–20} However, studies on the interaction of amino acids with ninhydrin in the presence of dimeric gemini surfactants are scarce. Researchers are still waiting for their advanced developments.

At the present time, there has been a fast increasing interest in proteins due to the number of their applications and uses in several aspects including in biochemistry and biotechnology.^{21,22} Amino acids play a significant role in our

Scheme 1 Structure of ninhydrin.

lives and have one of the most distinctive objectives of all medicines in living beings. They control the divergence of activity in the field of medical science, *e.g.* in metabolic process, information transfer, *etc.* Therefore, estimation of amino acids is highly significant in the evaluation of a protein structure.

Among the surfactants, gemini have been known for a long time, and they have been enormously studied by researchers.^{23–26} This is due to their superior properties and advanced applications. Gemini surfactants contain two heads (hydrophilic) and two tails (hydrophobic) in one molecule. That is, two conventional surfactant

Fig. 2 Observed rate constant (k_{Ψ}) against [ninhydrin] plots for the reaction of ninhydrin and Tyr in the presence of gemini surfactants: 16-6-16 (■), 16-5-16 (●), 16-4-16 (▲). Conditions: [Tyr] = 0.1 mM, [16-s-16] = 30×10^{-2} mM, temp. = 353 K and pH = 5.0.

Scheme 2 Tyr-ninhydrin reaction mechanism.

monomers are joined together *via* a spacer.^{27–31} Gemini surfactants show lower cmc, better surface activity, super wetting power and a low Krafft point over traditional single chain surfactants (single hydrophilic head and single hydrophobic tail).^{24,32–35} Gemini surfactants appeal for present consideration in surface science due to their unusual properties. They have been utilized in various fields for diverse purposes, *e.g.* in skin care, analytical uses, solubilizing agents, *etc.*^{36,37}

Numerous articles have been published in the scientific literature on the physico-chemical activities/properties of gemini surfactants. These observed that the gemini surfactants were superior on all fronts to the single surfactants.^{38–43} However, the impact of gemini surfactants on reaction rates has been paid relatively less attention and is required to be focused on more for further

development of the surfactants. Taking the above facts into consideration, we have synthesized and characterized three cationic gemini surfactants (designated as m-s-m; m (16) and s (4–6) refer to the alkyl chain length and the spacer, respectively). In order to obtain better insight and results, a study of the Tyr and ninhydrin reaction was conducted in gemini micellar media using a range of techniques and models and was discussed.

2. Experimental

2.1. Materials and equipment

Double-distilled conductivity water was utilized throughout the experiments. All stock solutions of Tyr, ninhydrin and the gemini surfactants were made in CH₃COOH-CH₃COONa buffer solution at

pH 5.0. L-Tyrosine (98.0%) was used as received from s.d. fine. CH₃COOH (99.0%), CH₃COONa (99.0%) and ninhydrin (99.0%) were employed as supplied from Merck without additional purification. *N,N*-dimethylcetylamine (>95.0%), 1,4-dibromobutane (>98%), 1,5-dibromopentane (>98%) and 1,6-dibromohexane (>97%) were bought from Fluka. Other chemicals used in the present study were of AR grade. To measure the pH, an ELICO pH meter was used. Alkanediyl- α,ω -bis(dimethylcetylammmonium bromide), 16-*s*-16, was synthesized *via* a procedure mentioned previously.^{44,45} The achieved products were purified several times using ethyl acetate. Product yields were found to be more than 90%. Afterwards, the products were placed in a vacuum oven. In addition, they were kept in vacuum desiccators containing phosphorous pentoxide (because they are excellent absorbers of H₂O) for more than 48 hours before their use. The identification of products was ascertained by elemental analysis and ¹H NMR.^{44,45}

2.2. Electrical conductivity

The electrical conductivity was measured as a function of the concentration of the surfactant. For this experiment, a Systronics conductivity meter (Ahmedabad, India) was utilized throughout the study. The experimental temperature was kept constant at 303 K and 353 K. The electrode cell used was made up of glass with the cell constant at 1.0 cm⁻¹. The electrode was calibrated by KCl within the required range of concentration. The intersection at two straight lines of the curve between the specific conductivities and the surfactant concentrations gives the desired cmc value.⁴⁶ The cmc value of the pure gemini surfactants determined in our present case is in good agreement with the data reported earlier.⁴⁷ The cmc values of the surfactants determined with and without ninhydrin and Tyr (*i.e.* water, water + ninhydrin + Tyr) are provided below:

- (a) [16-6-16] (mM): 0.043, 0.025 (at 303 K); 0.058, 0.045 (at 353 K)
 (b) [16-5-16] (mM): 0.034, 0.022 (at 303 K); 0.055, 0.030 (at 353 K)
 (c) [16-4-16] (mM): 0.032, 0.018 (at 303 K); 0.043, 0.020 (at 353 K).

2.3. Kinetic procedure and rate constant determination

A single beam UV-visible spectrophotometer (SHIMADZU-model UV mini 1240, Kyoto, Japan) was used for

Fig. 3 Observed rate constant against [16-*s*-16] plots for the reaction of ninhydrin and Tyr: 16-6-16 (■), 16-5-16 (●), 16-4-16 (▲). Conditions: [ninhydrin] = 5 mM, [Tyr] = 0.1 mM, temp. = 353 K and pH = 5.0.

spectroscopic measurements on the interaction of ninhydrin with Tyr in a surfactant medium. The volumes of Tyr, buffers and surfactant (if required) were kept in a round bottomed three-necked flask in a water bath at 353 K. Nitrogen gas was flowed through the mixture to create inertness inside the flask. The required quantity of ninhydrin solution was added to the flask to initiate the reaction. The absorbance of the product formed was recorded at definite time intervals at λ_{max} 570 nm. The rate constants (k_{app} , s^{-1}) in the gemini surfactants were determined by employing a program (computer based). All measurements were carried out in triplicate at least. The rest of the information on the kinetic methodology can be seen in the articles published earlier.^{48–51}

2.4. Spectra of the product formed

Spectra of the ninhydrin and Tyr reaction in two systems was noted on a UV-visible spectrophotometer. All the absorption spectra of the product formed were measured in a quartz cuvette (with a thickness of 10 mm and a slit width of 1 mm). Spectra were recorded in the wavelength range from 380 nm to 600 nm and are presented in pictorial form in Fig. 1. Graphitic profiles between A and λ showed that the absorbance was found to be greater in the surfactants compared to in aqueous solution at the same maximum absorption band ($\lambda_{\text{max}} = 570$ nm). This shows that the product formed in both media is the same.

3. Results and discussion

The observed rate constant values at various pHs in the presence of the surfactants evaluated are shown in Table 1. The concentration of the reactants (ninhydrin and Tyr) and the temperature were kept constant. Table 1 confirms that k_{app} increases up to pH 5.0, and beyond pH 5.0 there is almost no change in k_{app} . Therefore, all of the experiments were performed at pH 5.0.

Studies were performed at several initial concentrations of Tyr at 353 K by fixing other experimental parameters. The values of the rate constant were evaluated in the surfactants and are tabulated in Table 2. After a close look at Table 2, it can be easily concluded that the order of reaction is first-order with respect to Tyr as the rates do not depend on the initial concentration of Tyr (eqn (1)).

$$\text{Rate} = \frac{d[\text{DYDA}]}{dt} = k_{\text{app}}[\text{Tyr}] \quad (1)$$

Kinetic experiments were carried out in micellar media (gemini surfactants) at a different set of ninhydrin concentration by fixing the rest of the parameters. The rate constant increases with an increase in the ninhydrin concentration. The observed values of k_{app} are shown in Table 2. The curves between the rate constant and ninhydrin concentration were of non-linear feature and crossed through the origin. This is shown in Fig. 2. It can be safely concluded that the reaction showed fractional-order kinetics with respect to the ninhydrin concentration.

The influence of temperature has been studied on the title reaction by varying the temperature (range: 343 K to 363 K) with a fixed concentration of the reactants and fixed pH. The experiment was carried out in gemini micelles. The rate value increased with the increase in temperature. These data are presented in Table 1, and were used to determine different thermodynamic parameters with the help of the Eyring equation.

4. Mechanism

Ninhydrin reacts with various amino groups (except proline) at different rates, but they all produce the DYDA product.⁵² However, the amount of product formed in the reactions is dependent on several factors including reactant concentration, reaction medium, pH and temperature. In the current study, the mechanism of the reaction has been proposed for the study of ninhydrin and Tyr. This is shown in Scheme 2. By considering Scheme 2, the reaction proceeds through the attack of a lone pair of electrons of an amino nitrogen (tyrosine) on a carbonyl group (ninhydrin) to give a Schiff base. The Schiff base, being unstable, hydrolyses to give 2-aminoindanedione (B_1) and an aldehyde. Then B_1 reacts with another ninhydrin molecule to give DYDA.

5. Reaction in gemini surfactants

The k_{app} values evaluated at different concentrations of surfactants in the study of ninhydrin and Tyr are listed in Table 3 and are shown graphically in Fig. 3. The same respective first- and fractional-order paths in the tyrosine concentration and in the ninhydrin concentration were followed in the gemini surfactants as in those of in aqueous solutions. Fig. 1 confirms that the absorption maximum of the product stays the same in the surfactant system. This leads to the conclusion that the mechanism of reaction does not vary in any way between the two systems.

Quantitative treatment of k_{app} vs. [surfactant] may be elucidated using the model (pseudo-phase) suggested by Martinek *et al.*⁵³ and by Menger and Portnoy⁵⁴ that was established by Bunton.^{55,56} According to the pseudo-phase model, the reaction occurs in bulk aqueous and micellar pseudo phases. Under the set reaction situation, Scheme 3 can be presented as below.

Scheme 3 Study of the ninhydrin and Tyr reaction.

K_T and K_N refer to the respective tyrosine-micelle binding constant and ninhydrin-micelle binding constant. T and D_n stand for the concentration of Tyr and the micellized surfactant ($[gemini]_T-cmc$), respectively. k'_w and k'_m are the respective pseudo-first-order rate constants that refer to the bulk and micellar pseudo-phases.

Rate eqn (1) and Scheme 3 give eqn (2):

$$k_{\psi} = \frac{k'_w + k'_m K_T [D_n]}{1 + K_T [D_n]} \quad (2)$$

Eqn (2) results in eqn (3)

$$k_{\psi} = \frac{k_w [N] + (K_T k_m - k_w) M_N^S [D_n]}{1 + K_T [D_n]} \quad (3)$$

where, $[N]$ represents the ninhydrin concentration. $k_w = k'_w/[N_w]$ and $k_m = k'_m/M_N^S$ are the second-order rate constants.

M_N^S is the molar ratio of bound ninhydrin to the micellar head group and is presented by eqn (4),

$$M_N^S = \frac{[N_m]}{[D_n]} \quad (4)$$

M_N^S was determined by considering the equilibrium, as given by eqn (5) below.

$$K_N = \frac{[N_m]}{[N_w]([D_n] - [N_m])} \quad (6)$$

and the mass balance is:

$$[N] = [N_w] + [N_m] \quad (7)$$

Calculation of k_m (rate constant for a micellar medium) and K_T (tyrosine-micelle binding constant) from eqn (3) requires a cmc value of the gemini surfactants under the set of kinetic experimental conditions. The required cmc values have been determined using a conductivity technique. The values of k_m and K_T were calculated at several presumed values of K_N by a computer program. The obtained data are located in Table 1. Fitting K_T , k_m and K_N to eqn (3) supports the validity of the equation. Table 3 confirms the good agreement between k_{ψ} and $k_{\psi,cal}$, and this authenticates the validity of the proposed reaction mechanism.

Critical micelle concentration (cmc) is one of the most reliable and useful parameters. The cmc value is employed to establish a quantitative relationship between the physico-chemical parameters and the structure of the surfactant. In the present study, a rate constant has been evaluated for the title reaction below and above the cmc value of the surfactant solutions. A detailed account of the activity of the gemini surfactants is given below.

Considering segment I of Fig. 3, where the surfactant concentrations are below the cmc value, k_{ψ} should not change. However, the rate constant increased. The observed catalysis

may, therefore, be due to the formation of pre-micelles by the substrate. Pre-micelle formation and catalysis below the cmc value of the surfactants have been reported in earlier published articles.^{57,58}

Segment II (Fig. 3) shows that no reaction took place (*i.e.* the k_{ψ} value remained almost constant). Segments I and II of the k_{ψ} vs. $[16-s-16]$ plots where $[gemini]$ varies from 0 to 400×10^{-5} M are akin to their monomeric counterparts (single hydrophilic head and hydrophobic tail). This can be seen only when the substrates are absolutely micellar bound with the micellar assembly continually being unaffected.⁵⁹ The characteristic of segment II is unchanged for all surfactants and the rate constant follows the order 16-4-16 > 16-5-16 > 16-6-16 for all concentrations. This is not the first time where 16-4-16 among all the three gemini surfactants has given the best outcomes. 16-4-16 gave the best results previously as well.⁴⁴

After levelling-off, the k_{ψ} value increases further at higher gemini concentrations. Perhaps this is due to the association with a variation of micellar structures. It is well established that the surfactants self-associate into aggregates in aqueous solution above the cmc value. Generally, the aggregates are rotund, globular micelles. However, under appropriate conditions of concentration, salinity, temperature, the presence of counter ions, *etc.*, the spherical micelles can undergo uniaxial growth to form flexible worm-like micelles.⁶⁰ Furthermore, in the case of gemini surfactants, the extent of aggregate growth and the changes of the shapes of the micelles depend on the length of the spacer(s) as well. Cryo-TEM measurements from solutions of 16-s-16 clearly show the transitions upon increasing s with the sequence of structures of micelles being: vesicles + elongated micelles \rightarrow elongated micelles \rightarrow spheroidal micelles.⁶¹ Thus, the micellar growth is more pronounced the shorter the spacer unit, and this is most likely due to the increasing geometrical constraints in the formation of aggregates with decreasing length of the spacer unit. At higher $[gemini]$, variations in these micellar structures occur, which have been confirmed by 1H NMR spectral studies.⁶² Thus, variations in the micellar morphologies give a distinct reaction atmosphere (less polar); this is the consequence of increasing k_{ψ} sharply (Fig. 3). The same is true for all gemini surfactants and the difference is only in the extent of the k_{ψ} enhancement, and this depends on the spacer.

6. Thermodynamic parameters

Thermodynamic parameters were calculated within the temperature range of 343 K to 363 K using the Eyring equation in study of ninhydrin and Tyr in gemini micellar media. The thermodynamic parameters are listed in Table 1. Upon comparison of the data with aqueous solutions (Table 1), we find that ΔH^\ddagger reduces with a more negative ΔS^\ddagger in the presence of the gemini surfactants, compared to in aqueous solutions. This reduction in the parameters (ΔH^\ddagger and ΔS^\ddagger) takes place not only through the adsorption of both ninhydrin and Tyr on the micellar surface but also through the stabilization of the activated state. A meaningful mechanistic description of these apparent parameters is impossible because the rate constant,

k_{ij} , does not denote a single elementary kinetic step; it is a complex function of true rate, binding constants and ionization constants.

Looking at the data in Table 1, we can observe that gemini surfactants catalyze and accelerate the title reaction more than aqueous media. Furthermore, improvement in the values of thermodynamic parameters and rate constants using gemini surfactants takes place at concentrations *ca.* 67 times less than using cetyltrimethylammonium bromide (CTAB). Thus, the importance of the study is increased due to the use of very small quantities of the gemini surfactants that are required to perform the reaction. This is an important point to be noted regarding the use of gemini surfactants (cost effectiveness, as well as environmental toxicity).

7. Conclusions

In the current study, we have synthesized and characterized three cationic gemini surfactants (designated as m-s-m; where m and s refer to the alkyl chain length and the spacer, respectively). Experiments between ninhydrin and Tyr were performed in the gemini surfactants by studying the reaction using a UV-visible spectrophotometer. The study of ninhydrin and Tyr in gemini micellar media could be carried out successfully by the pseudo-phase model. 16-s-16 gemini surfactants were found to be extremely more valuable in applications in all respects than aqueous solution and traditional surfactants.^{63,64}

A key point to be noted is that, under the identical experimental situation, a much lower gemini concentration (below the cmc value) was adequate to catalyze and accelerate the rate than in the aqueous medium. This special feature of the gemini surfactants allows them to be used in low amounts in household items and in cosmetic purposes/products to overcome potential skin irritation. Gemini surfactants could be beneficial from the environmental toxicity point of view due to the low release of surfactant quantity.

Conflicts of interest

There are no conflicts of interest to declare.
