From 16th International Conference on Human Retroviruses: HTLV and Related Viruses
Montreal, Canada. 26-30 June 2013

Since 1997, the Interdisciplinary Research Group on HTLV-1/2 (GIPH) has been following individuals infected with HTLV in Minas Gerais, Brazil, in an open prospective cohort study. The HAM diagnosis is based on clinical parameters, with support of complementary exams to exclude other possible causes of myelopathy. The objective of this study was to evaluate the sensitivity and specificity of spinal cord MRI in HAM diagnosis. This was a cross-sectional study, conducted between March 17th and September 28th, 2012. The 120 HTLV-1 seropositive were included in the study. HAM was diagnosed on the basis of the World Health Organization diagnostic criteria. Cervical and thoracic MRIs were performed in sagittal and axial sequences fast spin-echo T2-weighted, without gadolinium. Blinded interpretation of MRIs was performed by radiologists who did not know clinical neurologic status of the participants. The mean age of the 120 individuals was 48.0 ± 12.8 years (range: 16.4 to 72.6 years) and 77 (64.2%) were women. Among all patients, 19 (15.8%) had a diagnosis of HAM. There was no statistically significant difference between the mean ages of the HAM and asymptomatic groups ($p = 0.7$). In the HAM group, 7 (36.8%) of them showed changes in MRIs compatible with the disease. On the other hand, 93 (83.0%) asymptomatic individuals have had normal MRIs. Spinal cord MRI demonstrated to be a diagnostic method with good specificity but low sensitivity in the diagnosis of HAM. It is possible that time

evolution of disease, as well as the degree of neurological impairment is directly related to the sensitivity of the method.
