ABSTRACT

Platelet-rich plasma (PRP) has been reported recently as a potential therapeutic approach for alopecia, such as androgenetic alopecia, but the exact mechanisms and effects of specific components of this recipe remain largely unknown. In this study, we identified that platelet factor 4 (PF4), a component of PRP, significantly suppressed human hair follicle growth and restrained the proliferation of human dermal papilla cells (hDPCs). Furthermore, our results showed that PF4 upregulated androgen receptor (AR) in human dermal papilla cells *in vitro* and via hair follicle organ culture. Among the hair growth-promoting and DP-signature genes investigated, PF4 decreased the expression of *Wnt5a*, *Wnt10b*, *LEF1*, *HEY1* and *IGF-1*, and increased *DKK1* expression, but did not affect *BMP2* and *BMP4* expression. Collectively, Our data demonstrate that PF4 suppresses human hair follicle growth possibly via upregulating androgen receptor signaling and modulating hair growth-associated genes, which provides thought-provoking insights into the application and optimization of PRP in treating hair loss.

INTRODUCTION

The hair follicle (HF) is able to repeatedly go through cycles of degeneration (catagen), rest (telogen), and regeneration (anagen) over all adult life. The hair follicle cycle depends on the capability of HF stem cells (HFSCs), residing in the bulge, to temporarily escape from their quiescent state to start the anagen phase. The activities of HFSCs are mainly regulated by the dermal papilla (DP) in the bottom of hair follicles (*Deng et al., 2015; Schneider, Schmidt-Ullrich & Paus, 2009*). The DPCs function as the signaling center to govern the

behaviors of HFSCs and their descendent cells to achieve hair regeneration ([Morgan, 2014](#)). Numerous signals from DP, such as Wnt/ β -catenin and BMP signals have been shown to be essential for the hair growth ([Deng et al., 2015](#); [Plikus, 2012](#); [Tang et al., 2016](#); [Li et al., 2012](#)).

Various hair loss disorders are mainly featured by the incapability of rebooting the growth phase of the hair follicle cycle. In androgenetic alopecia (AGA), elevated androgen receptor (AR) in DP cells is one of the causal factors for AGA ([Premanand & Reena, 2018](#)). The dysregulation of androgen receptor signaling affects the production of hair growth-associated paracrine signals in the DP cells. Disruption of these signals hampers HFSCs proliferation and differentiation, causing anagen shortening, thus leading to progressive miniaturization of hair follicles, which is a major feature of AGA ([Ceruti, Leiros & Balana, 2018](#); [Qi & Garza, 2014](#); [Shin et al., 2013](#); [Kwack et al., 2008](#)). As a consequence, DP cells are considered as the major therapy target for AGA. The existing therapies are mostly designed to restrain further hair loss, and the efficacy of new hair growth with these therapies are not dissatisfactory and obviously ameliorating effect is not always achieved ([Stevens & Khetarpal, 2019](#)).

PRP is a derivative of whole blood, also known as autologous conditioned plasma ([Mussano et al., 2016](#)). PRP was originally applied to the medical field as a promising hemostatic approach suitable for surgical setting and wound healing ([Cieslik-Bielecka et al., 2012](#); [Nicoli et al., 2015](#)). Recently, this technique has been explored in the field of dermatology including wound healing, scar revision, skin rejuvenation, fat graft and so on ([Emer, 2019](#)). Furthermore, PRP has also been demonstrated as an efficient cure to treat hair disorders, such as androgenetic alopecia, owing to its autologous, least injuries, less adverse effects, and more acceptable cost in comparison to hair implantation ([Strazzulla et al., 2018](#)). Evidence indicates that when injected into scalp, platelets in PRP become activated and secrete a series of cytokines and growth factors, like insulin like growth factor-1 (IGF-1), platelet-derived growth factor and epidermal growth factor from their alpha granules, which may promote hair growth ([Mussano et al., 2016](#); [Emer, 2019](#); [Cervantes et al., 2018](#)). However, the exact mechanisms and roles of specific components of PRP remain largely unresolved.

PF4, as an important member of the CXC chemokine family of small proteins, is one of the richest factors secreted to plasma after blood platelets activation. Even then, its level in plasma is only up to the nanogram level per milliliter ([Gleissner, Von Hundelshausen & Ley, 2008](#); [Chen et al., 2020](#); [Makarewicz-Wujec et al., 2020](#)). It has been reported to have an antiproliferative effect on fibroblasts and endothelial cells, but there is no report about its role in human hair growth. Here, we demonstrated that PF4, a component of PRP, notably suppressed human hair follicle growth and inhibited the proliferation of human derma papilla cells. Mechanically, we showed that PF4 promoted the expression of AR in human dermal papilla cells *in vitro* and via hair follicle organ culture. Among the hair growth-promoting and DP-signature genes investigated, PF4 reduced the expression of *Wnt5a*, *Wnt10b*, *LEF1*, *HEY1* and *IGF-1*, and increased the expression of *DKK1*, but did not alter the expression of *BMP2* and *BMP4*. Taken together, Our findings reveal that PF4 inhibits human hair follicle growth possibly by enhancing androgen receptor signaling

and decreasing hair growth-promoting genes expression, providing new insights into the application and optimization of PRP in the administration of hair loss.

MATERIAL AND METHODS

Human hair follicle isolation and culture

Scalp biopsies were acquired from occipital site of AGA individuals experiencing hair grafting surgery. The study was permitted by the Institutional Review Board of Xiangya hospital (IRB NO. 201611609), and informed consent from participants was obtained. The human hair follicles were isolated and cultured as previously described ([Luo et al., 2018](#)). Specifically, hair follicles were incubated with or without PF4 (R&D system, USA), and were photographed every two days. 90 hair follicles in anagen phase were obtained from 3 volunteers and incubated with different concentrations of PF4, and the measurements were repeated for triplicate with 30 hair follicles in total for each dose group.

hDPCs isolation and culture

The human DPCs were acquired and cultured according to previous strategy ([Gledhill, Gardner & Jahoda, 2013](#)). hDPCs at passages 2-5 were used in the present study. The hDPCs were digested with 0.1% trypsin and counted with a cell counter (JIMBIO FIL, China).

RNA collection and qPCR

Data were collected as previously described ([Luo et al., 2018](#)). Specifically, total RNA was acquired by TRIzol RNA extraction reagent (Thermo Fisher Scientific, USA). cDNA was obtained using the PrimeScript™ RT reagent Kit (Takara, Japan) according to the manufacture's instruction. qPCR was performed with SYBR Green Supermix (Bio-Rad, USA). The relative mRNA expression levels were figured by employing the delta CT means relative to GAPDH. The fold change for genes was normalized to control cell cultures. All primers for PCR are indicated in [Table S1](#).

Western blot assays

All procedures for western blot were conducted as previously described ([Deng et al., 2019](#)). Primary antibodies used were rabbit anti-Androgen receptor (1:1000, Cell Signaling Technology, USA) and mouse anti-Tubulin (1:1000, Cell Signaling Technology, USA).

Immunofluorescence

Immunofluorescence of cultured HFs was performed as previously described ([Chen et al., 2019](#)). Specifically, hair follicle frozen sections were fixed for ten min by paraformaldehyde (PFA), washed with PBS, and blocked for 60 min in blocking buffer (5% normal donkey serum supplemented with 0.3% Triton X-100). Primary antibodies were incubated for 12–16 h at 4 °C. Followed by washed with PBS, sections were stained with Alexa Fluor 488/594-tagged secondary antibodies (Thermo Fisher Scientific, USA) for 1 h at room temperature, then counterstained with nuclear staining reagent DAPI. Pictures were taken with a Zeiss Axioplan 2 microscope. Primary antibodies used were rabbit anti-Androgen receptor (1:200, Cell Signaling Technology, USA), rabbit anti-ki67 (1:500, Cell Signaling Technology, USA) and mouse anti-K15 (1:500, Thermo Fisher Scientific, USA).

ELISA

The hDPCs were incubated in 6-well plate (1 ml/well) after counted 50 cells/ μ l. DP cells were subjected into three groups, after cultured 48 h with PF4. Corresponding kits were used to test the bioactive factors of the supernatant. Wnt5a, IGF1 and BMP2 were measured by Wnt5a, IGF1 and BMP2 ELISA kits (CUSABIO) following the manufacturer's instruction, respectively.

Statistical analysis

Statistical analysis was performed by using GraphPad 8.0 and SPSS 18.0. Data are displayed as the mean \pm SEM. Statistical significance ($*P < 0.05$, $**P < 0.01$) was calculated using 2-tailed unpaired Student's *t*-test for the comparisons between two groups.

RESULTS

PF4 suppresses hair growth in cultured human HFs

To explore the effect of PF4, a component of PRP ([Hattori & Ishihara, 2017](#)), on hair growth, human HFs were acquired and incubated with or without PF4. The concentration of PF4 (0, 50, 100 ng/ml) was commonly used as previously described, and similar to or slightly higher than that in healthy human plasma, which may mimic the concentration of PF4 in PRP ([Srivastava et al., 2010](#); [Leiter et al., 2019](#)). Via hair follicle organ culture, we treated the isolated human hair follicles with or without PF4 for 8 days. Our results showed that PF4 significantly suppressed hair shaft elongation in cultured HFs ([Figs. 1A and 1B](#)). Moreover, we found that PF4 inhibited the proliferation of epidermal cells in outer root sheath (ORS) of hair follicles ([Figs. 1C and 1D](#)).

PF4 suppresses human dermal papilla cell proliferation

To determine the role of PF4 on the proliferation of cultured hDPCs, we administrated human dermal papilla cells with different doses of PF4 as described above. We showed that the quantity of hDPCs in the PF4-treated groups was obviously smaller than that in the control group, but the morphology of cells was not observably altered by PF4 treatment ([Figs. 2A and 2B](#)). By immunostaining of Ki67, a proliferative marker, we showed that PF4 repressed of DP cell proliferation *in vitro* ([Figs. 2C and 2D](#)). Collectively, these data suggest that PF4 inhibits the proliferation of hDPCs .

PF4 increases the expression of androgen receptor in hDPCs

Previous studies have indicated that androgen receptor (AR) signaling in the DP cells plays a vital role in the modulation of hair follicle growth and development of androgenetic alopecia ([Ceruti, Leiros & Balana, 2018](#)), we wondered whether PF4 affects the expression of AR in the dermal papilla cells. Surprisingly, we found that PF4 treatment remarkably enhanced AR expression in hDPCs at both mRNA and protein levels *in vitro* ([Figs. 3A and 3B](#)). In addition, by immunostaining, we showed that PF4 also increased the expression of AR in DP cells in organ-cultured hair follicle ([Fig. 3C](#)). Overall, these results demonstrate that PF4 promotes the expression of AR in the DP cells.

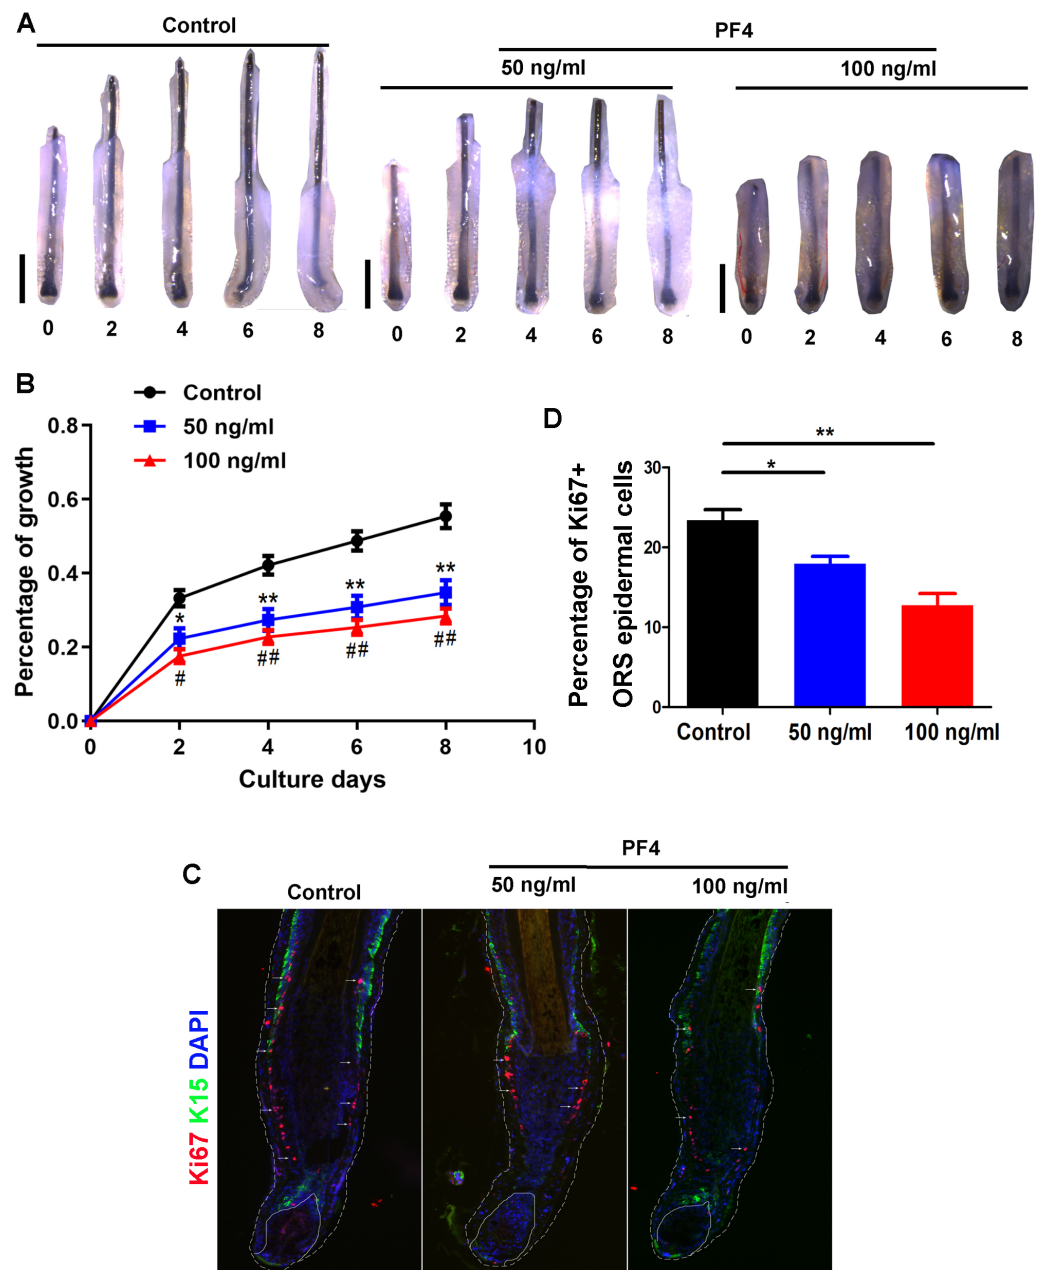

Figure 1 PF4 suppresses the elongation of hair shaft in cultured human hair follicles. Isolated human scalp hair follicles were cultured for 8 days in the presence of different doses of PF4. (A) Typical pictures of the hairs at day 0, 2, 4, 6, 8. (B) Data are presented as the percentage of growth (relative to day 0) of the hair follicles treated with PF4 (0, 50, 100 ng/ml). (C) immunostaining of Ki67 in hair follicles treated with PF4 (0, 50, 100 ng/ml) for 8 days. (D) Percentage of Ki67 positive cell in ORS of hair follicles treated with PF4. Data are reported as mean + SEM. Student's *t*-test was used to compare data. * $P < 0.05$, ** $P < 0.01$, comparison between 0 and 50 ng/ml. # $P < 0.05$, ## $P < 0.01$, comparison between 0 and 100 ng/ml. Scale bar = 1 mm.

PF4 declines the hair growth-promoting properties of hDPCs

To further examine the effects of PF4 on human DP cells, we detected the expression of various hair growth-promoting and DP-signature genes. We showed that PF4 treatment significantly declined the expression of *wnt5a*, *wnt10b*, *LEF1*, *HEY1* and *IGF-1*, and increased the expression of *DKK1*, but did not affect *BMP2* and *BMP4* expression in hDPCs at mRNA levels (Figs. 4A–4H). By elisa assays, we further confirmed that PF4 upregulated Wnt5a and IGF-1, but did not altered BMP2 at protein levels in human DP cells (Figs. 4I–4K).

DISCUSSION

Platelet-rich plasma (PRP) derived growth factors (GFs) positively influence tissue regeneration. The GFs of PRP stimulated proliferation of adipose tissue-derived stem cells to accelerate wound healing (Scioli et al., 2017; Emer, 2019). On the basis that PRP can

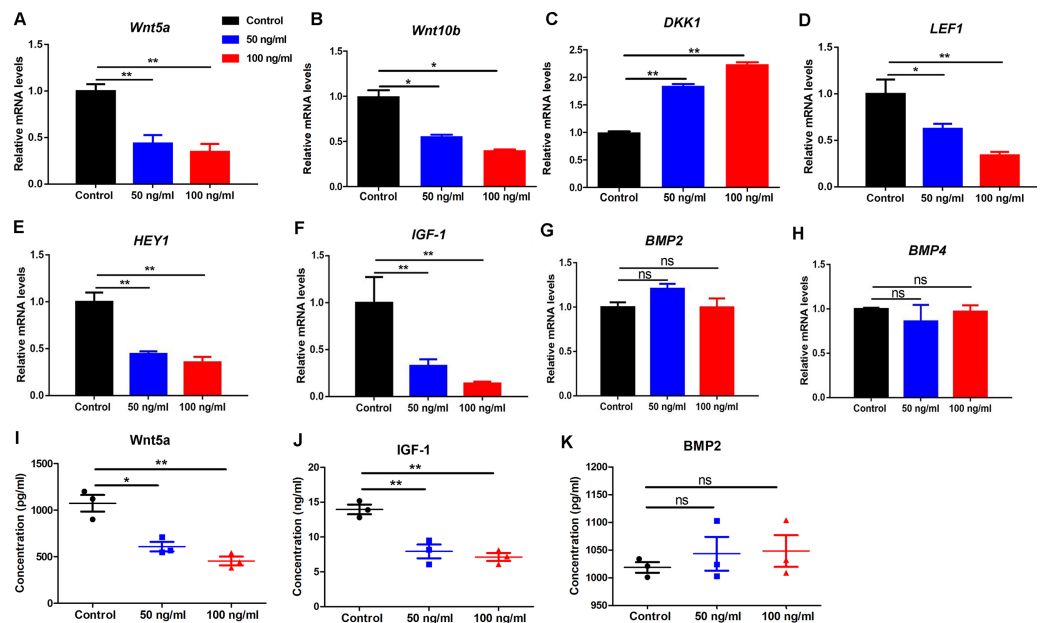

Figure 4 PF4 decreases the hair growth-promoting properties of hDPCs. (A–H) Effects of PF4 on hair growth-promoting and DP signature genes (*Wnt5a*, *Wnt10b*, *DKK1*, *LEF1*, *HEY1*, *IGF-1*, *BMP2* and *BMP4*) mRNA expression in human DPCs cultured for 24 h. promote wound repair, PRP was employed to treat hair loss (Stevens & Khetarpal, 2019; Strazzulla et al., 2018). Recently, PRP has been demonstrated as an effective alternative treatment with minimal side-effects for hair disorders (Strazzulla et al., 2018), but the exact mechanisms and effects of specific components of PRP have not been uncovered. In this study, we showed that platelet factor 4 (PF4), a component of PRP, significantly inhibited human hair follicle growth and restrained the proliferation of human dermal papilla cells. Mechanically, our data demonstrated that PF4 promoted the expression of androgen receptor (AR) in human dermal papilla cells *in vitro* and via hair follicle organ culture, and decreased the expression of *wnt5a*, *wnt10b*, *LEF1*, *HEY1* and *IGF-1*.

Though plenty of medicines are claimed to be effective for curing alopecia, the sexual-associated adverse-effects and efficiency are unpredictable (Varothai & Bergfeld, 2014; Rouso & Kim, 2014; Rogers & Avram, 2008). Recent evidence indicates that when injected into scalp, platelets in PRP become activated and release a number of growth factors and cytokines, such as PDGF, IGF-1 and EGF from their alpha granules, which may promote hair growth (Stevens & Khetarpal, 2019; Strazzulla et al., 2018; Cervantes et al., 2018). IGF-1 can stimulate proliferation of cycling Ki67 positive basal keratinocytes, and there is a higher number of Ki67 positive HFSCs in PRP-treated scalp tissue (Gentile et al., 2017; Cervelli et al., 2014). However, the precise effects of specific components in PRP on hair growth is still unclear. Surprisingly, in this study, we showed that PF4, a component of PRP, significantly inhibited human hair follicle growth via organ culture.

To our knowledge, our study is the first to identify a component in PRP which suppresses human hair growth. This finding suggests that though PRP is an effective therapy for hair loss, it is necessary to further optimize this recipe, and neutralization of certain negative factors, such as PF4, may worth a shot. Previous studies have revealed that AR activity in the dermal papilla cells governs the hair cycle and plays an important role in the development of AGA (Ceruti, Leiros & Balana, 2018; Inui & Itami, 2011). We now demonstrate that PF4 increases the expression of AR in human DPCs both *in vitro* and in cultured human HFs, which might be one of the mechanisms by which PF4 inhibits human hair follicle growth. Previous studies have clarified that anagen phase duration determines the hair length, which has become shorter and eventually results in the progressive miniaturization and disappearance of hair in AGA (Varothai & Bergfeld, 2014), and anagen onset largely depends on wnt/ β -catenin signaling (Lien *et al.*, 2014; Plikus & Chuong, 2014), whose activity in DP cells promotes the activation of HFSCs, thus triggering the growth of hair follicles (Morgan, 2014; Enshell-Seiffers *et al.*, 2010; Lei *et al.*, 2017; Lei & Chuong, 2016). Though PRP promotes hair follicle growth through wnt/ β -catenin signaling (Gentile & Garcovich, 2019), here our data show that PF4 significantly downregulated wnt-related genes in hDPCs. Previous study showed that androgen receptor could antagonize Wnt/ β -catenin signaling in skin cells (Kretzschmar *et al.*, 2015). In this study, we found that PF4 increased androgen receptor expression and suppressed Wnt-related genes. We speculate that PF4 regulates Wnt/ β -catenin signaling possibly via androgen receptor, but the precise mechanisms need to be figured out in the future.

Collectively, we report for the first time that PF4, a component of PRP which is an alternative therapy for AGA, significantly inhibits human hair growth via organ culture possibly through upregulating AR expression and decreasing hair-promoting genes. These data provide novel insights into the application and optimization of PRP in the treatment of hair disorders.

CONCLUSIONS

Our findings suggest that PF4 inhibits human hair follicle growth probably by promoting androgen receptor signaling and downregulating hair growth-promoting genes, providing thoughtful insights into the application and optimization of PRP in hair loss treatment.
