ABSTRACT

In vertebrates, homologous recombinational repair (HRR) requires RAD51 and five RAD51 paralogs (XRCC2, XRCC3, RAD51B, RAD51C and RAD51D) that all contain conserved Walker A and B ATPase motifs. In human RAD51D we examined the requirement for these motifs in interactions with XRCC2 and RAD51C, and for survival of cells in response to DNA interstrand crosslinks (ICLs). Ectopic expression of wild-type human RAD51D or mutants having a non-functional A or B motif was used to test for complementation of a *rad51d* knockout hamster CHO cell line. Although A-motif mutants complement very efficiently, B-motif mutants do not. Consistent with these results, experiments using the yeast two- and three-hybrid systems show that the interactions between RAD51D and its XRCC2 and RAD51C partners also require a functional RAD51D B motif, but not motif A. Similarly, hamster *Xrcc2* is unable to bind to the non-complementing human RAD51D B-motif mutants in co-immunoprecipitation assays. We conclude that a functional Walker B motif, but not A motif, is necessary for RAD51D's interactions with other paralogs and for efficient HRR. We present a model in which ATPase sites are formed in a bipartite manner between RAD51D and other RAD51 paralogs.

INTRODUCTION

DNA double-strand breaks (DSBs) represent a severe form of DNA damage that can lead to mutations and cell death if repaired incorrectly. Cells have evolved multiple mechanisms to repair DSBs, including the high fidelity process of

homologous recombinational repair (HRR) (1,2), which contributes significantly to the repair of DSBs in cycling cells (3), such as those generated at the replication fork during interstrand crosslink (ICL) removal. In vertebrates, HRR is highly conserved and mediated by the bacterial RecA ortholog, the Rad51 recombinase and five Rad51 paralogs (XRCC2, XRCC3, Rad51B, Rad51C and Rad51D). Though the biochemical functions of these paralogs in HRR are not well understood, they have been proposed to function in early steps (4–7) and in late steps (7–11) of recombination. The Rad51 paralogs are necessary for cellular resistance to DSBs (12,13), have no functional redundancy (14) and share limited sequence homology with Rad51 and with each other [~20% identity; reviewed in (15)]. The regions of highest sequence homology are the putative ATP-binding domains: the conserved Walker A and Walker B motifs (12,13,15,16).

In human cells, several RAD51 paralog complexes have been identified, among them the RAD51B-RAD51C-RAD51D-XRCC2 heterotetramer, and three heterodimers: RAD51B-RAD51C, RAD51D-XRCC2 and RAD51C-XRCC3 (4,17–24). The RAD51B-RAD51C and RAD51D-XRCC2 complexes were shown to bind to single- and double-stranded DNA and to hydrolyze ATP, an activity enhanced by DNA binding (4,19,25,26). The heterotetramer also exhibited ATPase activity and preferentially bound to Y-shaped DNA and synthetic Holliday junctions (27).

The Walker ATPase domain (28) consists of two separate motifs, A and B, crucial components of the nucleotide-binding site. The lysine residue in the GKT/S box of the Walker A motif is essential for ATP-binding and contacts the γ -phosphate of the nucleotide (29). The highly conserved aspartate/glutamate of the Walker B motif forms hydrogen bonds with the threonine/serine of the GKT/S box and with a bound water molecule (30) and facilitates nucleotide hydrolysis.

In human RAD51, non-conservative (no ATP binding) K133A substitution in the Walker A motif did not rescue the Rad51-deficient lethality of chicken DT40 cells while the conservative (ATP binding, but no hydrolysis) K133R substitution only gave a partially defective phenotype (31). In *in vitro* assays, human RAD51-K133R showed an increased stability of presynaptic filament formation and enhanced homologous pairing activity compared to the wild-type protein (32), but in a dominant-negative approach, expression of human RAD51-K133R in a mouse embryonic stem cell line specifically inhibited homology-directed DSB repair (33). In the Walker B motif of human RAD51, mutation in the highly conserved aspartate (D222A), but not V221A or S223A, was shown to eliminate protein function in the DT40 system (31). For the human RAD51 paralogs, mutations within the Walker A motif of RAD51C and XRCC3 were shown to greatly reduce cellular resistance to ICLs (34,35), but mutation in the Walker A motif in XRCC2 had little effect on complementing ability (36). Substitution of the conserved aspartate residue in the Walker B motif of human XRCC3 (D213N) resulted in increased spontaneous apoptosis and complete loss of gene-complementing activity for cell survival to ICL damage in the CHO *xrcc3* mutant (37,38). Evidence suggests that nucleotide binding and hydrolysis play important roles in the formation of RAD51 paralog complexes. For example, in XRCC3, the inability to hydrolyze bound ATP (i.e. a Walker A GRT substitution) blocks the interaction with RAD51C (35). A study of the paralog interactions of mouse Rad51D Walker A mutants has also been reported (39), and these results are discussed later.

In this study, Walker-motif mutants of RAD51D were tested for their ability to complement the MMC sensitivity of CHO *rad51d* knockout cells [hereafter written as *rad51d* cells; (2)]. Surprisingly, RAD51D mutants of the GKT box of the Walker A motif rescued the MMC sensitivity of *RAD51D* cells, whereas B-motif mutants did not complement. In addition, whereas A-motif mutations had little effect on the interaction of *rad51d* with binding partners XRCC2 and RAD51C, mutations in the B-motif disrupted these interactions. These results constitute the novel finding of a differential requirement for the Walker A and B motifs of a human ATPase.

MATERIALS AND METHODS

Cell culture

Parental CHO cells (strain AA8) and 51D1Lox and 51D1 (*rad51d*) derivatives (2) were grown in monolayer or suspension cultures in MEM- α medium supplemented with 10% fetal bovine serum, 100 μ g/ml streptomycin and 100 U/ml penicillin. For the experiments involving chronic MMC exposures and the generation of denatured and crude protein lysates from *rad51d* derivatives, cells were grown under selection in 700 μ g/ml hygromycin B.

Human RAD51D expression plasmids

The *RAD51D* cDNA was PCR amplified from plasmid pDS200 (40) and subcloned into pcDNA3.1/*hygro*

(Invitrogen) from HindIII to NheI. The entire *RAD51D* open reading frame (ORF) was verified by direct sequencing. Mutations were introduced using the QuickChange Site-directed mutagenesis II kit (Stratagene), and missense mutations were confirmed by direct sequencing of the entire ORF. Mutagenic primers were designed to create the following changes to the amino acid sequence of RAD51D: K113R, 5'-GGCCCAGGTAGCGGCCGC-ACTCAGGTATGTCTCTGTATGGC-3'; K113A, 5'-GGCCCAGGTAGCGGCCGCCTACTCAGGTATGTCTCTGTATGGC-3'; V203E, 5'-GGAACTGTGAAGGTGGAGGTTG-TGGACTCGGTCACTGCGG-3'; and D206A, 5'-GGAACTGTGAAGGTGGTGGTTGTGGCTTCGGTCACTGCGG-3' (only forward primers are shown; reverse primers had the complementary sequence).

Yeast two- and three-hybrid system

The yeast strain Y190-ura⁻ (40) was used for all yeast two- and three-hybrid experiments. For yeast two-hybrid analyses, Y190-ura⁻ was co-transformed with both a DNA-binding domain [pGBT9; (41)] and a transcription-activating domain fusion plasmid [pGAD424; (41)] and transformants were recovered on selective media (i.e. synthetic complete media lacking leucine and tryptophan: SC -Leu, -Trp). For yeast three-hybrid analyses, RAD51B was expressed from pVT100U, a yeast expression vector containing the *URA3* selectable marker (42) as described in (40). To test three-hybrid interactions, strains containing two plasmids, grown in SC -Leu, -Ura, were transformed with the third plasmid, derived from pGBT9, and selected on plates lacking leucine, tryptophan and uracil. Four independent colonies for all transformations were assayed qualitatively for β -galactosidase activity using X-gal filter assay (43). To quantify the strength of protein-protein interactions, liquid β -galactosidase assays were performed using *o*-nitrophenyl- β -galactopyranoside (Sigma) as a substrate as described (43). All quantitative β -galactosidase activity assays were performed on three to five independent colonies, each monitored in triplicate. Standard error of the mean (SEM) was determined among independent colonies. Yeast two-hybrid plasmids for *RAD51D*, *XRCC2* and *RAD51C* are described in (40). Mutations were introduced into the *RAD51D* using site-directed mutagenesis and mutagenic primers as described above. Mutations were introduced into the *XRCC2* ORF using the QuickChange site-directed mutagenesis II kit (Stratagene). Missense mutations were confirmed by direct sequencing of the entire ORF. Mutagenic primers for *XRCC2* were designed as follows: K54R, 5'-GGCCCAGAAGGAACAGGACGCAC-AGAAATGC-3'; K54A, 5'-GGCCCAGAAGGAACAGGA-GCTACAGAAATGC-3'; D149A, 5'-GCCTTTTGATTT-TGGCCAGCCTGTCAGCTTTTACTGG-3'; L148S, 5'-GCCTTTTGATTTTCAGATAGCCTGTCAGCTTTTACTGG-3'; (only forward primers are shown; reverse primers had the complementary sequence).

Whole cell protein extracts from transformed yeast strain Y190U-ura

To monitor the expression levels of Gal4-RAD51D in Y190U-ura⁻ transformants, whole cell protein extracts were generated according to published procedures (44). Western

blot analysis was carried out as described elsewhere (22), and filters were probed with 1:2000 diluted primary anti-RAD51D (Novus Biologicals). The signal for actin (dilution 1:300; Santa Cruz Biotech) was used as a loading control. Detection was carried out using horseradish peroxidase (HRP)-conjugated goat anti-rabbit secondary antibody (Jackson ImmunoResearch; 0.4 mg/ml). Filters were incubated with Supersignal WestPico substrate kit (Pierce Chemical) followed by exposure to Hyperfilm ECL (Amersham Biosciences).

Expression and purification of recombinant RAD51D and XRCC2 by affinity chromatography

For recombinant expression of GST-XRCC2 and His₆-RAD51D, respective cDNAs were inserted into the baculovirus transfer vector pFASTBAC™ DUAL (Invitrogen). The glutathione *S*-transferase (GST) ORF flanked by a PreScission Protease cleavage site was inserted upstream and in frame with the XRCC2 ORF. For PCR amplification of the RAD51D cDNA an N-terminal His₆-tag was built in the forward primer. Proteins were expressed in Sf9 insect cells and purified to 80% homogeneity. One L of insect cell culture was harvested at 72 h post-infection, and cells were pelleted at 1600 *g* (Sorvall GSA rotor) and resuspended in 20 ml of cell lysis buffer [20 mM HEPES (pH 8.0), 100 mM NaCl, 10% glycerol, 0.5 mM phenylmethylsulfonylfluoride (PMSF), 5 µg/ml aprotinin and 5 µg/ml leupeptin]. The cell suspension was incubated on ice for 20 min, sonicated and clarified by ultracentrifugation at 110 000 *g* (Beckman 70.1 Ti rotor) for 20 min. The supernatant was applied to a 5 ml Glutathione Sepharose 4 FF column (Amersham Biosciences) equilibrated with 10 column volumes buffer A [1 × phosphate buffered saline (PBS), 10% glycerol]. Bound GST-XRCC2:His₆-RAD51D complex was washed with 10 column volumes buffer A and eluted with buffer B [10 mM glutathione, 50 mM Tris-HCl (pH 8.0), 10% glycerol]. Peak fractions were pooled and dialyzed into PreScission Protease cleavage buffer [50 mM Tris-HCl (pH 8.0), 150 mM NaCl, 1 mM EDTA, 10% glycerol, 1 mM DTT, 0.5 mM PMSF, 5 µg/ml aprotinin and 5 µg/ml leupeptin] for subsequent cleavage by PreScission Protease according to the manufacturer's description (Amersham Biosciences). Following cleavage, the protein was diluted 1:1 with 100% glycerol and stored at -80°C.

Transfection of *rad51d* cells

Transfectants of *rad51d* cells (2) that stably express wild-type or mutant human RAD51D protein were created by electroporation (625 V/cm, 950 µF) using Gene Pulser II (Bio-Rad). A total of 1×10^6 cells were electroporated in 400 µl cytomix buffer using 10 µg of linearized plasmid (45). Twenty-four hours post-transfection, cells were plated into 10 cm dishes at $\sim 10^4$ cells/dish in 20 ml of medium containing hygromycin B (700 µg/ml) and incubated for 12 days for colony formation. Ten colonies were isolated and expanded for each transfected plasmid and analyzed for expression of the transgene by western blot analysis (22). Filters were probed with 1:2000 diluted primary anti-RAD51D (Novus Biologicals). The signal for the transcription factor QM (dilution

1:10 000; Santa Cruz Biotech) was used as a loading control. Detection was carried out using HRP-conjugated goat anti-rabbit secondary antibody (Jackson ImmunoResearch; 0.4 mg/ml). Filters were incubated with Supersignal WestPico substrate kit (Pierce Chemical) followed by exposure to Hyperfilm ECL (Amersham Biosciences).

Genetic complementation analysis

MMC sensitivity was determined by colony formation assay in 10 cm dishes. Exposure to MMC (Sigma) was conducted in 10 ml suspension cultures. For each dose, 1×10^6 cells were exposed to MMC for 60 min at 37°C, centrifuged and resuspended in fresh medium for plating. For each dose, 300 or more cells were plated in triplicate. After 12 days of growth, dishes were rinsed with saline, fixed with 95% ethanol and stained with Gram Crystal Violet. Colonies with >50 cells were scored.

To test for complementation directly in transfected cell populations, transfections were carried out as described above. Twenty-four hours post-transfection, cells were trypsinized and re-seeded at 4×10^4 cells/well in 6-well plates in regular growth medium containing hygromycin B without MMC, or with MMC at various concentrations. Colonies were fixed and stained after 12 days of growth. The surviving fraction of colonies was calculated as the ratio of the number of colonies in selection in MMC and hygromycin B to the number of colonies in the presence of hygromycin B only. For comparison purposes, untransfected AA8 were plated at 200 cells/well in regular growth medium lacking hygromycin B, both with and without MMC. In addition, *rad51d* cells were transfected with the empty vector control (pcDNA3.1/*hygro*) and plated at 4×10^4 cells/well in regular growth medium containing hygromycin B without or with MMC. The transfection efficiencies for all plasmids used were determined in a separate experiment. Plasmids were electroporated as described above and cells were plated 24 h post transfection in regular growth medium containing hygromycin B. The stable transfection efficiencies were found to be similar for all plasmids used and were $0.27 \pm 0.03\%$.

Immunoprecipitation

Immunoprecipitation was performed as described previously (22) using native cellular protein extracts from untransfected *rad51d* and AA8 cells and *rad51d* cells stably expressing either wild-type or mutant RAD51D. Immunoprecipitation was carried out using MagnaBind goat anti-rabbit IgG magnetic beads (Pierce) and anti-RAD51D antibody (Novus Biologicals) or control antibody (rabbit IgG, Santa Cruz Biotech). The polyclonal rabbit anti-human XRCC2 antibody for direct immunoprecipitation of hamster Xrcc2 was kindly provided by Dr P. Sung. Western blots were probed with 1:2000 diluted primary anti-RAD51D and 1:1000 diluted primary anti-XRCC2 antibody (Santa Cruz Biotech). Detection was carried out using HRP-conjugated goat anti-rabbit secondary antibody (see above) or bovine anti-goat secondary antibody (1:10 000; Santa Cruz Biotech). Filters were incubated as described above for analysis of RAD51D-expressing *rad51d* cells. To visualize co-immunoprecipitated hamster Xrcc2, filters were incubated with ECL-Advance (Amersham Biosciences).

RESULTS

Complementation of *rad51d* cells by ectopic expression of wild-type human RAD51D

Following transfection of *rad51d* cells [clone 51D1; (2)] with the wild-type RAD51D expression construct, colonies were selected for hygromycin resistance. To test whether these clones stably expressed the human cDNA, we picked 10 independent colonies and expanded them to mass cultures for western blot analysis. As shown in Figure 1A, seven of these clones stably expressed the transgene. Since the expression levels for RAD51D protein varied, one clone expressing a lower level of the protein (WT1; WT for wild-type) and one expressing a higher level (WT2) were selected to test whether ectopic expression of human RAD51D rescued the very high (~80-fold) MMC sensitivity of *rad51d* cells (2). Using the colony formation assay for cell survival, we found that both clones WT2 and WT1 were efficiently complemented; their MMC resistance was similar to that of the wild-type AA8 cells (Figure 2A and B, respectively). We also observed that the parent of 51D1, 51D1Lox, which contains functional *Rad51D* alleles prior to Cre-recombinase treatment (2), was slightly more sensitive to MMC (~2-fold; determined from D_{37} values) than AA8 cells or *rad51d* cells expressing wild-type human RAD51D (Figure 2A and B). We explain this observation in part by the fact that the endogenous hamster Rad51D protein level in AA8 cells (and possibly the human protein in clones WT1 and WT2) is higher than in 51D1Lox cells (2). However, due to interspecies variation in antibody recognition it is not possible for us to compare the protein levels in 51D1Lox cells (i.e. hamster Rad51D) to that in the transfectants (i.e. human RAD51D).

Complementation of *rad51d* cells by ectopic expression of RAD51D Walker A-motif ATPase mutants

We tested whether a conservative amino acid substitution (K113R; binds but does not hydrolyze ATP), or a non-conservative substitution (K113A; unable to bind ATP), in the GKT box of the Walker motif A influenced the ability of RAD51D to complement the *rad51d* mutant. We transfected *rad51d* cells with each mutant construct (GRT and GAT; see Figure 1E) and isolated 10 independent clones for each mutant. As shown in Figure 1B and C by western blot analysis, the protein expression levels of independent clones stably expressing either mutant of RAD51D varied. As with the cells expressing the wild-type RAD51D construct, for each mutant we choose a low-expressing clone (GAT2 and GRT3 (GRT2 was added in follow-up experiments); see Figure 1C and B, respectively), and a high expressing clone (GRT6 and GAT4; see Figure 1B and C, respectively). We found that stable expression of either mutant protein largely complemented MMC sensitivity of *rad51d* cells (Figure 2A and B). The degree of MMC resistance of the high-expressing lines (GRT6 and GAT4) was similar to that of AA8 cells and *rad51d* cells expressing wild-type RAD51D (WT2) (Figure 2A). For the low-expressing lines (GRT2, GRT3 and GAT2), complementation was less complete [~2- to 3-fold lower, as determined from the D_{37} values

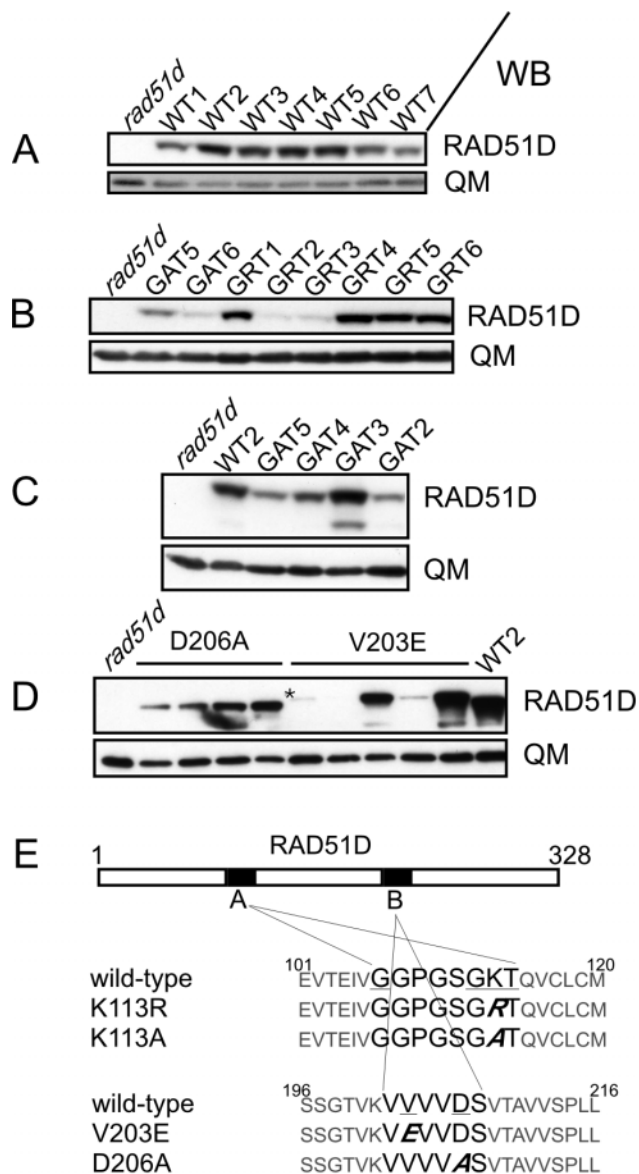

Figure 1. Representative western blots showing the expression levels for wild-type human RAD51D and its mutant forms in clonal isolates of stably transfected hamster *rad51d* cells. (A) *rad51d* clones expressing wild-type human RAD51D, Upper panel: anti-RAD51D antibody; lower panel: anti-QM antibody (loading control). Extract from untransfected *rad51d* cells is in left lanes of (A–D). (B) *rad51d* clones expressing RAD51D-K113R (GRT1–GRT6) or RAD51D-K113A (GAT5 and GAT6; loaded for comparison); lower panel as in (A). (C) *rad51d* clones expressing RAD51D-K113A (GAT2–GAT5) or wild-type RAD51D (WT2; loaded for comparison purposes); lower panel as in (A). (D) *rad51d* clones expressing RAD51D-D206A or RAD51D-V203E. Extract of clone WT2 (expressing wild-type RAD51D) monitored for comparison purposes; lower panel as in (A). The asterisk indicates that V203E runs with slightly slower mobility. ‘WB’ indicates antibody used in western blot analysis. ‘WB’ indicates antibody used in western blot analysis (A–D). (E) Domain structure of the RAD51D protein illustrating the amino acid substitutions introduced into the RAD51D cDNA. (A): Walker A motif; (B): Walker B motif. Highly conserved residues are underlined in the wild-type sequence. Amino acid substitutions introduced are bold italics. Numbers indicate residue location within the primary sequence of RAD51D.

(Figure 2B)]. However, these lower expressing lines were clearly no more sensitive to MMC than parental 51D1Lox cells that express reduced levels of hamster Rad51D [Figure 2B; (2)].

No complementation of *rad51d* cells by ectopic expression of RAD51D Walker B-motif ATPase mutants

Since we observed almost no abnormality in cellular phenotype for the Walker A-motif mutations, we hypothesized that the Walker B motif may predominately determine the function of RAD51D. To test this possibility, we mutated the highly conserved aspartate (D206) to alanine (D206A; see Figure 1E). For comparison purposes, we also made the previously uncharacterized V203E substitution within motif B of RAD51D. This valine was chosen for mutagenesis as it is

conserved among the human RAD51 paralogs RAD51B, RAD51C, RAD51D and XRCC3, and in mouse and hamster Rad51D. Both expression constructs (V203E and D206A) were separately transfected into *rad51d* cells, and cells were selected in the continuous presence of either hygromycin alone or hygromycin plus increasing concentrations of MMC. The extent of complementation for expression of *all* RAD51D constructs was assessed by comparing the number of colonies arising in hygromycin and MMC to the number of colonies arising in hygromycin alone. As shown in Figure 2C, ectopic expression of either RAD51D-V203E or RAD51D-D206A does not result in complementation of MMC sensitivity of *rad51d* cells measured by colony formation. Conversely, in this same method of analysis, expression of wild-type RAD51D, or the Walker A box mutants RAD51D-K113R and RAD51D-K113A resulted in high MMC resistance (Figure 2C) albeit expression of either K113R or K113A did not fully protect against killing. Whether these latter modest reductions are biochemically significant is unclear since the expression levels of the A-motif mutant proteins could be slightly lower than that of wild-type. As with the A-motif mutants, both B-motif mutants are expressed stably in *rad51d* cells (Figure 1D).

Inability of RAD51D Walker B mutants to interact with XRCC2 in the yeast two-hybrid system

As RAD51D B-motif mutants are unable to repair MMC-induced DNA damage, we investigated whether disruptions occur in the interactions between RAD51D and its known paralog partners. To do so, we employed the yeast two- and three-hybrid systems and tested whether mutant RAD51D would be able to interact with either XRCC2 or RAD51C. Each of the described forms of RAD51D (wild-type, K113R, K113A, V203E and D206A) was generated by site-directed mutagenesis using previously described vectors carrying wild-type *RAD51D* (40). First, each RAD51D protein was tested for binding to wild-type XRCC2 in both orientations (Figure 3A). The average strength of the RAD51D-K113R:XRCC2 interactions was 75 or 57% of the wild-type RAD51D:XRCC2 interaction (dependent on the orientation of the Gal4-fusion), and the average strength of

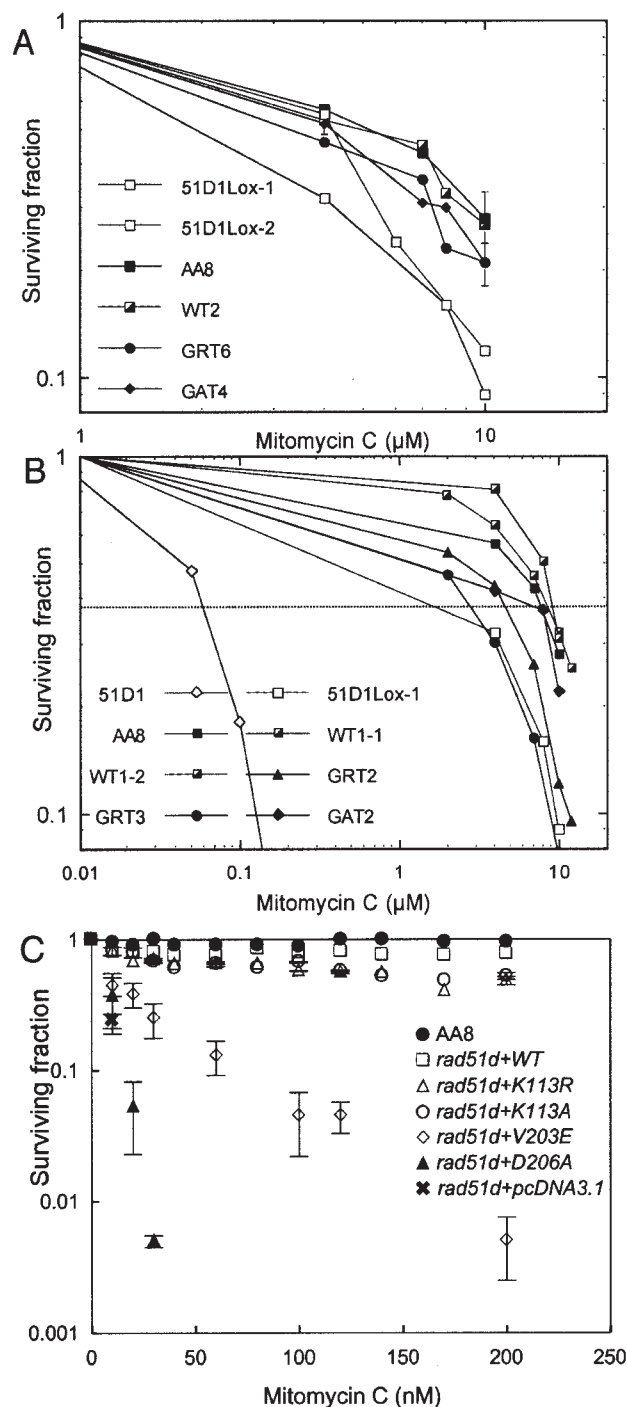

Figure 2. Cell survival determined by colony formation assay after acute or chronic exposure to MMC. (A) Parental lines and high-expressing transfectants carrying Walker A-motif mutations were exposed to MMC for 60 min. AA8, solid squares; 51D1Lox (*Rad51d*), open squares; 51D1 (*rad51d*) expressing wild-type human RAD51D (WT2), half-filled squares; 51D1 expressing Walker A-motif mutant, clone GAT4, solid diamonds; 51D1 expressing Walker A-motif mutant, clone GRT6, solid circles. (B) Parental, mutant (clone: 51D1) and low-expressing transfectants carrying Walker A-motif mutations were exposed to MMC for 60 min. Mutant 51D1 (*rad51d*), open diamonds; 51D1 expressing Walker A-motif mutant, clone GAT2, solid diamonds; 51D1 expressing Walker A-motif mutant, clone GRT2, solid triangle; 51D1 expressing Walker A-motif mutant, clone GRT3, solid circle; for AA8, 51D1Lox and 51D1 expressing wild-type RAD51D (here clone WT1) symbols same as in (A). Horizontal line indicates D_{37} survival. (C) Survival of colony-forming ability in response to continuous MMC exposure of *rad51d* cells and transfectants expressing either wild-type RAD51D (WT; open squares), K113R (open triangles), K113A (open circles), V203E (open diamonds), D206A (closed triangles). AA8 cells (closed circles) and *rad51d* cells transfected with the empty vector (pcDNA3.1/hygro; black cross) are shown for comparison. Error bars that are visible are ± 1 standard deviation from three independent experiments.

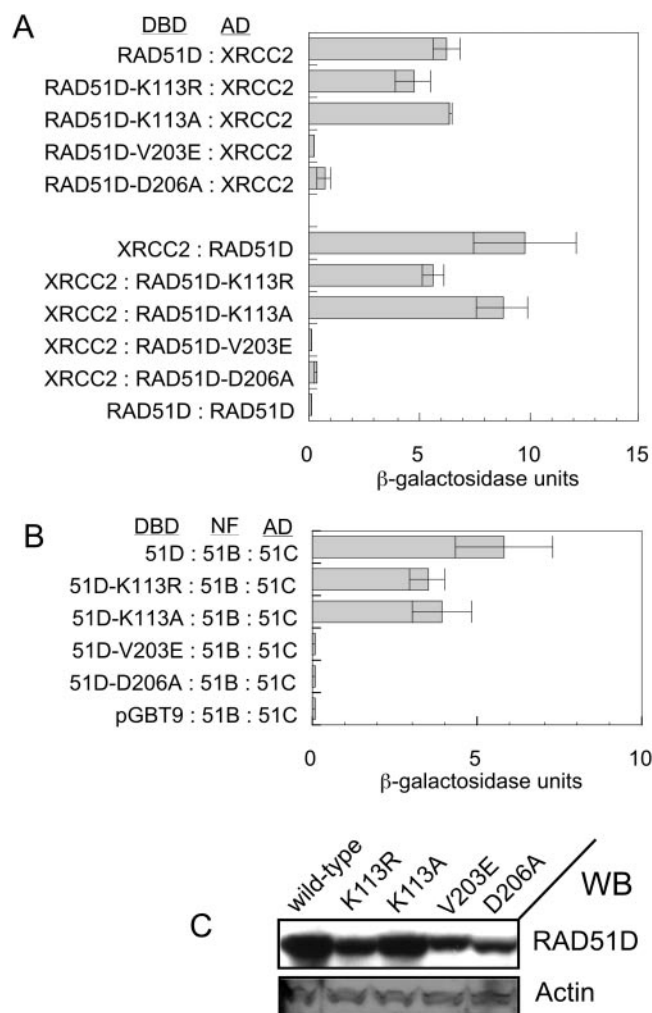

Figure 3. Yeast two- and three-hybrid analyses of the interactions of wild-type or mutant RAD51D with XRCC2 or the RAD51C:RAD51B heterodimer, respectively. (A) Quantitative assessment of the RAD51D:XRCC2 interaction: β -galactosidase units determined photospectrometrically by using *o*-nitrophenyl- β -galactopyranoside as a substrate (1 U corresponds to $\Delta\text{OD}_{420 \text{ nm}}/\text{min}/\text{mg}$ protein). (B) Quantitative assessment of the RAD51D:RAD51C interaction: β -galactosidase units determined as in (A). Results in (A and B) are from three to five different colonies for every interaction, each assayed in triplicate. Error bars represent ± 1 SEM; error bars that are not visible are too small to display. DBD = DNA binding domain of Gal4; AD = transactivating domain of Gal4; NF = non-fused protein (here: RAD51B). (C) Western blot to monitor the expression of Gal4AD-RAD51D wild-type and mutant forms in yeast Y190U-ura⁻ transformants. Three colonies for each transformation were tested, and a representative blot is shown. Upper panel, anti-RAD51D antibody; lower panel, anti-actin antibody loading control.

RAD51D-K113A:XRCC2 interactions was very close to wild-type levels (100 and 90%, depending on the orientation tested; see Figure 3A).

Strikingly, both B-motif mutants displayed greatly reduced interaction with XRCC2 in either fusion orientation (Figure 3A). The average strength of the RAD51D-V203E:XRCC2 interactions was determined to be at 1 and 3% of the wild-type interaction, and the average strength of the RAD51D-D206A:XRCC2 interactions was at 3 and 11% of the wild-type interaction (depending on the orientation tested). To ensure that the RAD51D mutants are produced

in amounts adequate to detect positive protein interactions in the yeast *two*-hybrid system, we tested the protein expression levels for Gal4-RAD51D and its mutant forms by immunoblotting of total protein extracts (Figure 3C). As for the wild-type, all mutant forms of the Gal-RAD51D fusions were produced at high levels in yeast. Although K113R, V203E and D206A were repeatedly expressed at slightly lower levels than the wild-type and K113A, the failure of XRCC2 to interact with V203E and D206A is not due to the unavailability of these mutant proteins in yeast. For example, even though K113R and V203E are expressed at similar levels, they differ greatly in their ability to interact with XRCC2 (see Figure 3A and 3C).

Inability of RAD51D Walker B mutants to interact with RAD51C in the yeast three-hybrid system

The interaction between human RAD51D and RAD51C, when tested in the yeast *two*-hybrid system, is comparatively weak, making it difficult to quantitatively assess protein-protein interactions that potentially are reduced even further. However, co-expression of RAD51B, in a non-fused form, has been shown previously to greatly enhance the strength of the RAD51D:RAD51C interaction in a yeast three-hybrid system (40). Furthermore, *in vivo* a stable RAD51D-RAD51C heterodimer has not been discovered, whereas RAD51D and RAD51C were shown to be part of the heterotetramer that also contains RAD51B and XRCC2 (20–22,24). For these reasons, we used the yeast three-hybrid system to assess the ability of either wild-type or mutant RAD51D to interact with RAD51C when RAD51B is co-expressed. We found that the average strength of interactions between Walker A K113R and RAD51C was reduced to 60% of the wild-type level, and the average strength of interactions between Walker A K113A and RAD51C was at 67% of the wild-type interaction (Figure 3B). Notably, the interactions between RAD51D Walker B mutants and RAD51C were virtually eliminated, not differing from the negative control (Figure 3B).

No co-immunoprecipitation of RAD51D Walker B mutants with hamster Xrcc2

To investigate *in vivo* complex formation between wild-type or mutant human RAD51D and hamster Xrcc2, we performed reciprocal co-immunoprecipitation in extracts from *rad51d* clones that stably express the ectopic proteins at similar levels. We found that hamster Xrcc2 is present specifically in anti-RAD51D immunoprecipitated complexes from clone WT2 (which overexpresses wild-type RAD51D) and not immunoprecipitated using IgG control antibody (Figure 4A). In addition, CHO cells appear to express two isoforms of Xrcc2 (as indicated by the double arrows in Figure 4A–C) that both bind to RAD51D. The faster migrating isoform displays the same mobility as recombinant human XRCC2 (Figure 4C), while the second isoform appears to be larger and migrates with a shift that corresponds to a 2–3 kD difference in molecular weight. It is likely, but not clear yet, that this larger form of hamster Xrcc2 may be a modified version of the protein. We also have observed both isoforms of Xrcc2 in V79 hamster cells but not in mouse mammary epithelial cells (data not shown). Importantly, Xrcc2 was present in anti-RAD51D immunoprecipitated

Figure 4. RAD51D wild-type and motif-A mutants allow complex formation with hamster Xrcc2 *in vivo*. (A) Crude extract from clone WT2 (overexpressing wild-type human RAD51D) immunoprecipitated with a polyclonal antibody against RAD51D. Precipitated RAD51D (upper panel) and co-precipitated Xrcc2 (lower panel) were detected by western blot analysis on the same membrane. A mock immunoprecipitate by incubation of WT2 extracts with IgG control antibody is shown in the far left lane. For comparison purposes, whole cell extract from clone WT2 is shown in the far right lane. Note: Xrcc2 is present in two isoforms in CHO cells [strain AA8 and derivatives; see also (C)]. 'HC' indicates cross-reacting heavy chain signal. 'IP' indicates antibody used for immunoprecipitation. 'WB' indicates antibody used in western blot. (B) Presence of Xrcc2 in anti-RAD51D immunoprecipitated complexes from clones WT2 (GKT), GRT6 (K113R) and GAT4 (K113A). Xrcc2 is not present in anti-RAD51D complexes from parental AA8 or *rad51d* cells (neither cell line expresses human RAD51D that is precipitated here). For comparison, crude extracts from human cells (HeLa; far left lane), WT2 cells (GKT; second lane from the right), and AA8 cells (far right lane) are shown. Upper and lower panels: western blot probed with Rad51D and XRCC2 antibodies, respectively. (C) Endogenous hamster Xrcc2 is expressed at higher levels in cell lines expressing complementing RAD51D (GKT, K113R, K113A) that is able to interact with Xrcc2. Upper panel: western blot probed with anti-XRCC2 antibody shows two Xrcc2 isoforms in Xrcc2 immunoprecipitated complexes from *rad51d*, K113R, K113A, D206A, V203E and GKT cell lines. Precipitated Xrcc2 from AA8 cells is shown for comparison (far left lane; note that only 1/16 of the precipitated complex relative to all other cell lines was loaded in order to avoid a very strong signal for Xrcc2). Two different concentrations of recombinant human XRCC2/(His)₆-RAD51D complex isolated from insect cells (second and third lanes from the left) and crude extract from clone WT2 (GKT; far right lane) are included. Lower panel: same blot probed with RAD51D antibody to detect human RAD51D that co-immunoprecipitated with hamster Xrcc2. Note: recombinant human His₆-tagged RAD51D migrated more slowly than human RAD51D.

complexes from *rad51d* cells overexpressing A-motif mutants (K113R and K113A), but absent in anti-RAD51D immunoprecipitated complexes from B-motif mutants (D206A and V203E; Figure 4B). Although reproducibly at lower levels compared to the wild-type expressing line (WT2; here: GKT), Xrcc2 was always present in anti-RAD51D immunoprecipitated complexes from clones GAT4 and GRT6, which overexpress Walker A K113A and K113R mutant protein, respectively. Anti-RAD51D immunoprecipitated complexes from parental AA8 and *rad51d* cells contained neither RAD51D nor Xrcc2, demonstrating the inability of the anti-RAD51D antibody to recognize the hamster Rad51D protein in AA8 cells and the absence of human RAD51D in *rad51d* cells.

In reciprocal experiments we analyzed anti-Xrcc2 immunoprecipitated complexes from all cell lines for the presence of RAD51D (Figure 4C). We found that the amounts of endogenous Xrcc2 directly precipitated by anti-XRCC2 antibody varied greatly among all cell lines tested (even though their expression levels for ectopic RAD51D were comparable; see Figure 1). Only small amounts of Xrcc2 were precipitated from extracts of *rad51d* cells and *rad51d* cells expressing Walker B-motif mutants D206A or V203E (Figure 4C). Significantly larger amounts of Xrcc2 were precipitated from cells overexpressing wild-type

RAD51D, K113R or K113A and from AA8 cells. (Note: for AA8 cells only 1/16 of the amount of the precipitated complex was loaded onto the gel, relative to all other cell lines). We reproducibly detected wild-type RAD51D (here: GKT), K113R and K113A in anti-Xrcc2 immunoprecipitated complexes (Figure 4C, lower panel). Not surprisingly, only small amounts of Walker B mutant proteins were present in anti-Xrcc2 complexes from *rad51d* cells overexpressing either V203E or D206A (Figure 4C). In sum, these results show that ectopically expressed wild-type RAD51D, or RAD51D with mutations in the Walker A motif, formed a stable complex with hamster Xrcc2. Conversely, motif-B mutants, although expressed at similar levels, had reduced levels of hamster Xrcc2, probably due to the inability to stabilize this protein as a RAD51D-Xrcc2 heterodimer (Figure 5C; see Discussion).

Greatly impaired interaction of XRCC2-K54A and RAD51D in the yeast two-hybrid system

As we observed little decrease in interaction between RAD51D A-motif mutants and Xrcc2/XRCC2 both *in vivo* and in the yeast two-hybrid system, we hypothesized that XRCC2's Walker A motif participates in nucleotide-binding within the XRCC2-RAD51D heterodimer. Interestingly, a

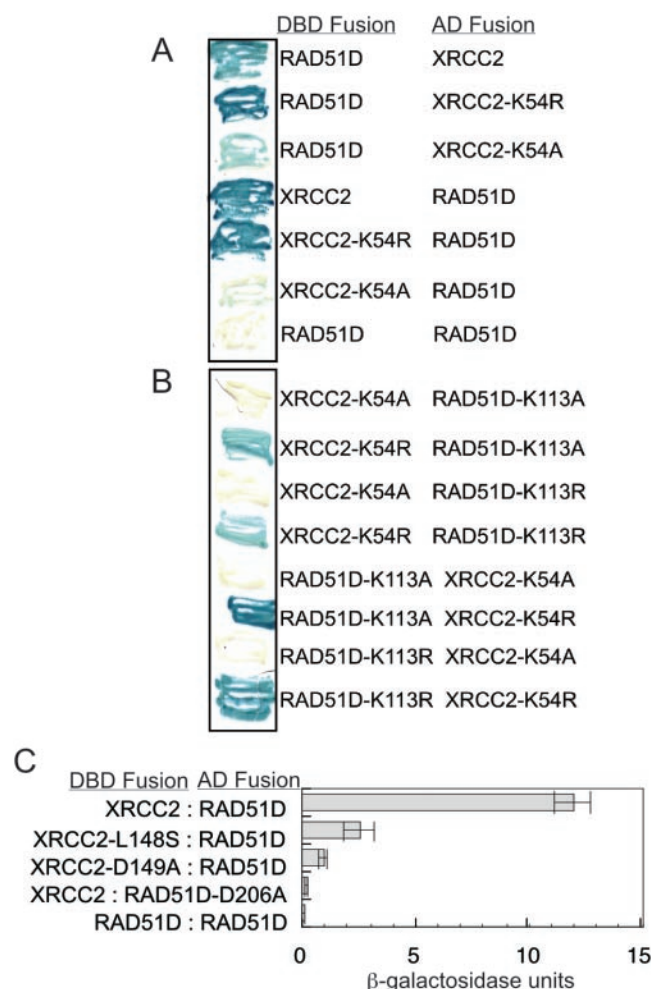

Figure 5. Yeast two-hybrid analysis of the interactions between Walker A/B mutants of XRCC2 and RAD51D. (A) Greatly impaired XRCC2-K54A interaction with wild-type RAD51D. Qualitative assessment: expression of β -galactosidase by X-gal filter assay; blue patches indicate the expression of interacting proteins; one representative colony is shown. (B) Pair wise analyses of the interaction between Walker A mutants from both XRCC2 and RAD51D. Qualitative assessment: as in (A). (C) Comparative analysis of the interaction between either XRCC2-L148S or XRCC2-D149A and RAD51D or between XRCC2 and RAD51D-D206A. Results are from three different colonies for every interaction, each assayed in triplicate. Error bars represent ± 1 SEM. DBD = DNA binding domain of Gal4; AD = transactivating domain of Gal4.

newly identified Rad51 paralog in *Schizosaccharomyces pombe*, Rlp1, having homology to human XRCC2 shows a conserved Walker A motif but no clearly defined Walker B motif (46). Therefore, we made the conservative K54R and non-conservative K54A substitutions in the Walker A motif of XRCC2, using previously described yeast two-hybrid plasmids (40), and assayed their interaction with wild-type RAD51D, RAD51D-K113R or RAD51D-K113A qualitatively and in both orientations by X-Gal filter assay (Figure 5A and B, respectively). XRCC2-K54A was greatly impaired in binding to wild-type RAD51D and mutant RAD51D (Figure 5A and B, respectively; light blue and white colonies). However, XRCC2-K54R was able to interact with wild-type RAD51D and both motif-A mutants of RAD51D (Figure 5A and B, respectively). In addition, we

introduced L148S or D149A amino acid substitutions within the Walker B motif of XRCC2 and assessed whether these XRCC2 mutants could interact with wild-type RAD51D in the yeast two-hybrid system. Both XRCC2-L148S and XRCC2-D149A were impaired in binding to wild-type RAD51D, although B-motif mutants of XRCC2 appeared to be less detrimental to the XRCC2:RAD51D interaction than B-motif mutants of RAD51D (Figure 5C; see Discussion).

DISCUSSION

To our knowledge we have described the first human ATPase with disparate requirements for two highly conserved Walker A/B motifs, both of which are generally crucial components of the nucleotide-binding site. Because of the complete loss of RAD51D function caused by amino acid substitution within its conserved B motif, the contrasting finding, of normal biological function for GKT substitutions within the A motif, was quite unexpected. Moreover, a recent study of mouse Rad51D using *rad51d* mouse cells, in which only A-motif mutants were examined, reached the opposite conclusion, 'that conservation of Walker Motif A is required for a physiological role of RAD51D' (39). Relative to the wild-type control, these authors reported $\sim 90\%$ decrease in cell survival after exposure to MMC for K113R and K113A mutants in bulk transfected cell populations. However, these investigators did not perform standard MMC dose-response measurements to calculate the dose-reduction factor of cell sensitivity associated with the mouse Rad51D mutant forms. Since we also observed a slightly increased sensitivity to MMC (calculated by dose-reduction factor) under some conditions for both acute and chronic exposures (Figure 2B and C), the only discrepancy between our survival data and theirs is the *extent* of reduced complementation by the A-motif mutants.

In addition, Gruver *et al.* (39) reported moderately impaired interactions of mouse Rad51D A-motif mutants with Xrcc2, but strongly impaired interactions with Rad51C in the yeast two-hybrid system. Although we also found greatly impaired interactions between the human RAD51D Walker A mutants and RAD51C in yeast two-hybrid experiments when monitored qualitatively (data not shown), in the yeast three-hybrid system we found that these interactions were only moderately affected when tested in the presence of RAD51B. As discussed in the Results above, we believe that the yeast three-hybrid system more closely reflects the *in vivo* interaction context.

Similar to our finding of gross defects associated with the B-motif D206A mutant of RAD51D, human XRCC3 substitution at the corresponding aspartate (D213N) dramatically reduced MMC resistance when expressed in hamster *xrcc3* irs1SF cells (37). As suggested by others (31,37), substitution of this highly conserved aspartate likely disrupts ATP binding and/or hydrolysis activity. Nonetheless, XRCC3 does behave differently from RAD51D in that both Walker motifs are critical for XRCC3's function (35,37).

We presented evidence that alterations in the Walker B motif of RAD51D (V203E or D206A substitutions) greatly impair RAD51D-XRCC2 complex formation. Co-immunoprecipitation clearly shows that, in the presence of

these non-complementing RAD51D mutant proteins, there is much less hamster Xrcc2 protein than under conditions where complementing RAD51D (i.e. wild-type or motif-A mutants) is available. It is important to note from these experiments that the *rad51d* knockout cell line itself (i.e. untransfected) also expresses greatly reduced levels of endogenous Xrcc2 protein when compared to its AA8 parent line, which expresses wild-type hamster Rad51D (Figure 4C). Our findings are consistent with several studies showing the stabilization of RAD51 paralogs by each other *in vivo* (7,22,47,48), but our data additionally demonstrate that the ability to interact directly is required for this stabilization. In addition, neither Walker B-motif mutant is able to interact with the RAD51B:RAD51C heterodimer in the yeast three-hybrid system.

The loss of RAD51D-XRCC2 and RAD51D-RAD51C interactions by disruption of nucleotide binding (V203E or D206A substitutions) raises the question of which biochemical defect (nucleotide binding or protein-protein interaction) is responsible for the cellular phenotype of high sensitivity to MMC. Our preferred view is that the role of the ATPase activity that is blocked by the V203E and D206A substitutions is to mediate a conformational change that promotes tight binding of RAD51D with XRCC2 and/or RAD51C. In this model ATPase site integrity and protein interaction are inseparable.

Reiterative changes in protein conformation are important for the assembly of multi-subunit protein complexes that function in DNA repair [for review see (49)]. Rad51 family members induce these conformational changes, necessary to fulfill protein function, by binding and hydrolysis of ATP [for review see (30)]. X-ray crystal structures (50–54) and electron microscopy reconstructions (53–55) of several Rad51 homologs have provided evidence that ATP-binding occurs at the subunit interface by contacting several highly conserved residues on neighboring subunits. We surmise that human RAD51D, through its Walker B motif, may rely on the A motif of another RAD51 paralog to form an active ATPase.

Overall, our results suggest that RAD51D must form a complex with XRCC2 and/or RAD51C to maintain cellular resistance to MMC. We showed that both interactions require a normal RAD51D Walker B motif, but not an intact A motif. We speculate that the binding of ATP to RAD51D occurs through its Walker B box as part of a bipartite nucleotide-binding site interacting with XRCC2 and/or RAD51C, as illustrated in Figure 6. In Figure 6A, the B motif of RAD51D interacts with the A motif of XRCC2. We showed that mutations in either of these motifs block the interaction; disruption of the XRCC2 A motif via K54A substitution (but not K54R substitution) greatly diminishes its binding to RAD51D in the yeast two-hybrid system (Figure 5A and B). One published observation is inconsistent with the idea that the RAD51D-XRCC2 interaction is important for efficient DNA repair. In that study, the XRCC2 A-motif K45A mutant showed only modest decrements in MMC resistance in *irs1* V79 cells transfected with mutant proteins (36) (although western blotting of these transfectants was not used to standardize the expressed XRCC2 protein levels). Moreover, in our yeast two-hybrid studies amino acid substitutions within the Walker B motif of XRCC2, though clearly affecting the XRCC2:RAD51D interaction, appear to be less deleterious to XRCC2:RAD51D complex formation in

Figure 6. Possible configurations of RAD51D interactions involving bipartite Walker A and B nucleotide binding motifs. (A) The RAD51D-XRCC2 heterodimer requires both the B motif of RAD51D and the A motif of XRCC2. (B) The RAD51D-RAD51C heterodimer requires the B motif of RAD51D; a requirement for the A motif of RAD51C is predicted but not yet been tested. Neither heterodimer requires the A motif of RAD51D. The possible role of the B motif of RAD51C has not been tested.

comparison with the RAD51D B-motif mutants (Figure 5C). Figure 6B depicts an ATPase site composed of the B motif of RAD51D and the A motif of RAD51C. Similar to our results for the B motif of RAD51D, mutations in the A motif of RAD51C also cause 80–100% loss of DNA repair efficiency (34). Although RAD51D-RAD51C interactions were not examined in that study, we found a severe RAD51D:RAD51C interaction defect in the yeast three-hybrid system for the RAD51D B-motif mutants (Figure 3).

In conclusion, we provide evidence that the Walker B motif of human RAD51D is critically important for complex formation with other RAD51 paralogs and for cellular resistance to ICLs. Since both Walker B-motif substitutions (V203E and D206A) yielded a similar phenotype, we propose that these substitutions not only abrogate ATP hydrolysis, but also simultaneously prevent one or more critical interaction(s) and conformational changes underlying RAD51D's participation in complexes, whose integrity is necessary for recombinational repair.

ACKNOWLEDGEMENTS

The authors are grateful to Drs M.-S. Tsai and M. Berardini for baculovirus transfer vector construction and help with protein purification.
