The solvothermal reaction of H_3BO_3 , KCF_3SO_3 , $\text{Mg}(\text{CF}_3\text{SO}_3)_2$ and pyridine led to a new alkali- and alkaline-earth-metal borate, $\text{MgK}_{0.5}[\text{B}_6\text{O}_{10}](\text{OH})_{0.5}\cdot 0.5\text{H}_2\text{O}$. Its structure features an intricate three-dimensional framework built from $[\text{B}_6\text{O}_{13}]^{8-}$ clusters, thus resulting in a six-connected achiral net with high symmetry. Each $[\text{B}_6\text{O}_{13}]^{8-}$ building block is composed of three trigonal BO_3 and three tetrahedral BO_4 units, with these BO_4 units being further connected to neighboring BO_3 units, giving rise to an oxoboron cluster of the general formula $[\text{B}_6\text{O}_{10}]^{2-}$.

1. Chemical context

As inorganic materials, borates are an important class of non-linear optical crystals, mainly because they can easily crystallize in non-centrosymmetric space groups and such structures often show a large second-harmonic generation response (Qiu *et al.*, 2021*a*; Qui & Yang, 2021*a*). The combination of BO_3 -trigonal and BO_4 -tetrahedral units makes it possible to form a variety of isolated anionic clusters. Extended chains, layers and three-dimensional frameworks can be formed between clusters through the dehydration and condensation of the terminal hydroxyl groups of oxoboron clusters (Wang *et al.*, 2017). In addition, negatively charged oxoboron clusters can also combine with a variety of counter-cations, making the structure of borates more complex and diverse. Here, single crystals of $\text{MgK}_{0.5}[\text{B}_6\text{O}_{10}](\text{OH})_{0.5}\cdot 0.5\text{H}_2\text{O}$ with alkali- and alkaline-earth metals have been obtained under solvothermal conditions.

2. Structural commentary

The asymmetric unit of the title compound consists of 2 B, 10/3 O, 1/3 Mg, 1/6 K, 1/6 OH, and 1/6 H₂O. The Mg, K, O4, O5 and O6 atoms are located on special positions with occupancy of 1/3 or 1/6, while the remaining B and O atoms are located at general positions with an occupancy of 1. Bond-valence-sum calculations show that Mg, K and B are consistent with the expected oxidation states (Brown & Altermatt, 1985; Brese & O'Keeffe, 1991). Three BO₄ units are joined together through corner-sharing of the O4 atom and three BO₄ units are connected with three neighboring BO₃ units to form a [B₆O₁₃]⁸⁻ oxaboron cluster (Fig. 1). To the best of our knowledge, this is the first example of a mixed alkali- and alkaline-earth-metal borate crystal with the [B₆O₁₃]⁸⁻ cluster anion. In this cluster, the B—O4 bonds are unique because their bond distances [1.529 (2) Å] are longer than other B—O bonds [1.359 (2)–1.453 (2) Å] in the BO₃ and BO₄ units. Each [B₆O₁₃]⁸⁻ unit is further connected to six other clusters by corner-sharing O atoms, resulting in a three-dimensional framework (Fig. 2).

3. Supramolecular features

In the title compound, the Mg and K atoms are six-coordinated, with Mg—O and distances in the range 2.332 (1)–2.374 (1) Å and K—O = 2.845 (1) Å. The three-dimensional structure is stabilized by a water cluster formed by O5—H5···O5, O5—H5···O6 and O6—H6A···O2 hydrogen bonds involving the water molecule, hydroxyl group and oxaboron cluster (Table 1). The channels of the compound are filled with ions/molecules (Mg²⁺, K⁺, OH⁻ and H₂O). The title structure is similar to previously reported analogues NH₄NaB₆O₁₀ (Wang *et al.*, 2014), K_{0.5}[B₆O₁₀]·H₂O·1.5H₃O (Qiu & Yang, 2021*b*), and NaRb_{0.5}[B₆O₁₀]·0.5H₃O (Qiu *et al.*, 2021*b*), so the simultaneous use of NH₄ and Na or K or Na and Rb or Mg and

K cations as templates has no effect on the crystallization of the oxaboron three-dimensional framework. However, after the introduction of Cl (Wu *et al.*, 2011) or Br (Al-Ama *et al.*, 2006), the new compounds crystallize in the trigonal space group *R*3*m* with a large second-harmonic generation response. The introduction of different anions can therefore play a key role in changing the crystalline structure to a non-centro-symmetric system.

4. Database survey

A search of the Cambridge Structural Database (CSD, version 5.43, update June 2022; Groom *et al.*, 2016) for the [B₆O₁₃]⁸⁻ oxaboron cluster gave 23 hits. The terminal oxygen atoms of this type of [B₆O_x] unit can be completely deprotonated [B₆O₁₃]⁸⁻, partially protonated [B₆O₁₁(OH)₂]⁶⁻ or completely protonated [B₆O₇(OH)₆]²⁻. Among the above 23 compounds, most of them are inorganic–organic hybrid solids, which contain transition-metal complexes and the [B₆O₇(OH)₆]²⁻ cluster (refcodes: CAFYIV, CAFYOB, Altahan *et al.*, 2021; CECWEM, Heller & Schellhaas, 1983; EMEHIP, Li *et al.*, 2016; HIXNAF, Jamai *et al.*, 2014; JOCCUC, JOCDAJ, Altahan *et al.*, 2019*a*; JUZLIC, Altahan *et al.*, 2020; MEBQUI, MEBRET, Altahan *et al.*, 2017; POJVIW, POJVOC, Altahan

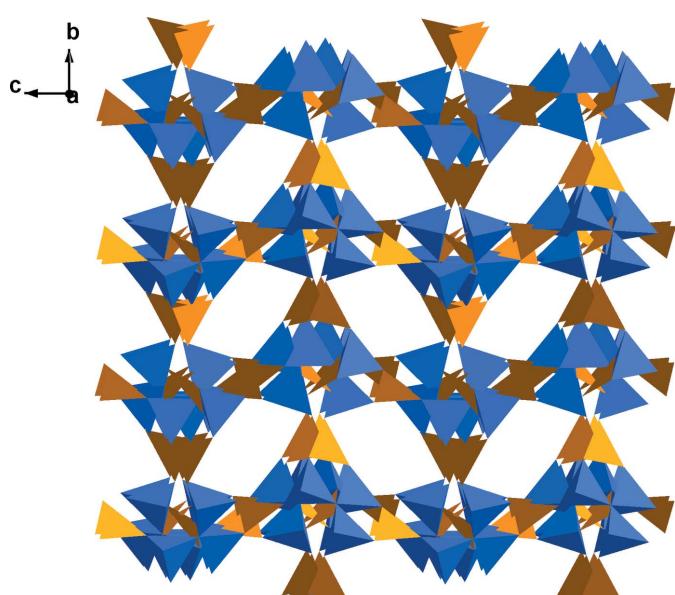

Figure 2

et al., 2019b; TAFROI, Natarajan *et al.*, 2003; VUVLOP, Jemai *et al.*, 2015; BATCUY, Jamai *et al.*, 2022; SAZVEY, Xin *et al.*, 2022). It is worth noting that this oxaboron cluster contains too many active hydroxyl groups and therefore tends to form isolated structures. In the crystal of $[\text{Cd}(1,2\text{-dap})]\cdot[\text{B}_6\text{O}_{11}(\text{OH})_2]\cdot\text{H}_2\text{O}$ (1,2-dap = 1,2-diaminopropane, refcode: LOZZUY, Deng *et al.*, 2020) and $\text{Cd}_3[\text{B}_6\text{O}_9(\text{OH})_2]_2\cdot2\text{NO}_3\cdot4\text{H}_2\text{O}$ (refcode: ZUXLIQ, He *et al.*, 2020), partially protonated $[\text{B}_6\text{O}_{11}(\text{OH})_2]^{6-}$ was successfully extended to layered structures *via* B—O—B bonds. In the crystal of $\text{NaRb}_{0.5}\cdot[\text{B}_6\text{O}_{10}]\cdot0.5\text{H}_2\text{O}$ (refcode: UCEXOT, Qiu *et al.*, 2021b), each completely deprotonated $[\text{B}_6\text{O}_{13}]^{8-}$ unit was linked to six nearest neighbors by bridging O atoms, leading to a 3D framework, similar to that of the title compound.

5. Synthesis and crystallization

A mixture of H_3BO_3 (0.618 g, 10 mmol), KCF_3SO_3 (0.188 g, 1 mmol) and $\text{Mg}(\text{CF}_3\text{SO}_3)_2$ (0.322 g, 1 mmol) was added to pyridine (3.0 mL). After stirring for 20 min, the resulting mixture was sealed in a 25 mL Teflon-lined stainless steel autoclave, heated at 488 K for 9 d, and then slowly cooled to room temperature and colorless block-shaped crystals $\text{MgK}_{0.5}[\text{B}_6\text{O}_{10}](\text{OH})_{0.5}\cdot0.5\text{H}_2\text{O}$ were obtained (yield 56% based on H_3BO_3). Infrared (KBr pallet, cm^{-1}): 3190vs, 1631s, 1360s, 1268m, 1188m, 1134m, 1099m, 964s, 845m, 781m, 741m, 718m, 630w, 564w, 540w, 480w, 455w.

6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 2. Hydrogen atoms were positioned geometrically ($\text{O}-\text{H} = 0.85 \text{\AA}$) and refined as riding with $U_{\text{iso}}(\text{H}) 1.2U_{\text{eq}}(\text{O})$.

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Refinement. The structure was solved by direct methods and refined by the full-matrix least-squares method on F^2 using the SHELXL programs (Bruker, 2006; Sheldrick, 2015*a*). All non-hydrogen atoms in the complex were refined anisotropically.
