

Complement 4 levels of a 4-year-old girl with angioedema

A 4-year-old girl was admitted due to erythema marginatum like pruritic rash over the entire body surface. She had a history of recurrent both arms swelling for 1 year prior to admission. However, she denied any history of allergic disease or family medical history. On the second day of admission, she developed a fever (38.5°C) and severe generalized abdominal pain, which improved on the next day. Subsequently, her hands and feet began to swell, suggesting angioedema (AE) (Table 1).

This study was approved by the Institutional Review Board (IRB) of the Catholic University of Korea, Daejeon St Mary's Hospital (IRB No. DC18ZESI0030).

What is the best screening test to exclude hereditary angioedema (HAE) on the 4-year-old girl with recurrent angioedema?

- ① C4
- ② C1-esterase inhibitor (C1-INH) activity
- ③ C1-INH level
- ④ Total IgE and specific IgE test

Test characteristics of the patient

The patient underwent testing for complement 4 (C4) levels because she had AE with a history of suspected recurrent AE

Table 1. Patient's laboratory values and reference ranges

Variable	Admission 1st day	Admission 3rd day	Reference range
Hemoglobin (g/dL)	13.2	-	11.5–13.5
White blood cell count (/μL)	13,700	-	5,000–14,500
Segmental neutrophil (%)	67.5	-	35–74
Lymphocyte	22.9	-	20–51
Eosinophil	0.3	-	0–5
Total protein	6.0	4.5	6.7–8.0
Albumin	4.0	3.1	4.0–5.0
AST (U/L)	38	23	0–31
ALT (U/L)	15	20	0–31
CRP	1.64	8.7	0–0.5
C3 (mg/dL)	-	93	86–160
C4 (mg/dL)	-	6.2	17–45
CH50 (U/mL)	-	3.5	23–46

AST, aspartate aminotransferase; ALT, alanine aminotransferase; CRP, C-reactive protein; C3, complement 3; C4, complement 4; CH50, 50% hemolytic complement.

events. C4 level is an important screening test for diagnosing AE associated with C1-INH.¹⁾ In this case, because C3 is normal and C4 is decreased, C1-INH activity and level test were performed. C1-INH activity was reduced under 50% of the normal range and the C1-INH level was decreased (Table 2). Hereditary angioedema has been associated with decreased C1-INH function in patients with recurrent edema involving the skin, intestine, and airway. HAE is an autosomal dominant disease caused by a mutation in the *SERPING 1* gene on chromosome 11 (11q12-q13.1), leading to a deficiency or functional inactivation of C1-INH.^{2,3)} Although type 3 HAE with normal C1-INH function is rarely reported, a majority of patients with HAE have decreased C1-INH function. Therefore C1-INH activity and level test are essential to confirm HAE. HAE is mainly classified as type 1 (80%–85%) and type 2 (15%–20%).^{4,5)} Type 1 HAE has low C1-INH level and activity, but type 2 HAE has normal or high C1-INH level and decreased activity.⁶⁾ C4 is always low in majority of patients. Algorithm for diagnosis recommends screening with C4 initially, followed by C1-INH activity and then level if required.^{7,8)} This patient could be diagnosed early with HAE by examination of C4 and C1-INH with recurrent AE. It is noteworthy that symptoms of HAE can also be expressed in young children, as in this patient. Furthermore, her symptoms such as arm swelling had started since the age of 3. Therefore, medical staff should actively suspect HAE and make efforts for early diagnosis by conducting C4 and C1-INH testing on even very young children.

Usefulness of genetic testing

HAE is an autosomal dominant disease with 25% *de novo* mutation.⁹⁾ Genetic testing is not essential for the diagnosis of

Table 2. Complement and C1 esterase inhibitor (C1-INH) levels of the patient and her mother

Variable	Patient (reference range)	Patient's mother (reference range)
C1-INH (mg/dL)	10 (21–39)	<2.9 (21–39)
C1-INH activity (%)	<25 (70–130)	<25 (70–130)
C3 (mg/dL)	93 (86–160)	106.7 (90–180)
C4 (mg/dL)	6.2 (17–45)	2.2 (10–40)
CH50 (U/mL)	3.5 (23–46)	<10 (32–58)

C3, complement 3; C4, complement 4; CH50, 50% hemolytic complement.

HAE, but is helpful in a confirming HAE from AAE.¹⁰⁾ It is also useful in diagnosing asymptomatic family members and in predicting the likelihood of disease development in offspring and in coping with future emergent situations.

Application of test results to this patient

Our patient and her mother showed reduced C4, C1-INH activity and level (Table 2). Therefore, they were diagnosed as type 1 HAE according to the diagnostic criteria.²⁾ They underwent genetic testing (Sanger sequencing), which revealed a missense mutation (c.1427C>T) of the *SERPING 1* gene.

Treatment and clinical course in the patient and her family

On-demand therapeutic agents consist of plasma-derived C1-INH (PdC1-INH, Berinert or Cinryze), recombinant human C1-INH (rhC-INH, Ruconest), Kallikrein-inhibitor (Ecallantide) and bradykinin-receptor antagonist (icatibant). Among them, PdC1-INH and icatibant is the approved drug for on-demand treatment in children. However, only icatibant is currently available in Korea, otherwise solvent detergent treated plasma or fresh frozen plasma can be used as second-line treatment. PdC1-INH is also preferred for long-term prophylaxis. When it is unavailable, antifibrinolytics (i.e., tranexamic acid) are preferred above androgens in children. Our patient did not present with AE after the initial diagnosis at 4 years old. However, colicky abdominal pain recurred every once or twice a month. The frequency of abdominal pain decreased sharply after 6 years old. She did not use any prophylaxis medication or on-demand medication. When the patient was 9 years old, the patient's mother was diagnosed with breast cancer and was given tamoxifen as part of her treatment regimen. Soon after medication, the patient's mother developed severe abdominal pain with hand swelling that lasted 24 hours, which recurred once a month. However, there was no urticaria and pruritus. Laboratory studies were performed and she was diagnosed with HAE, too (Table 2). Her mother started long-term prophylaxis with tranexamic acid and has terminated her prophylaxis after discontinuing tamoxifen because the incidence of abdominal pain was reduced.

If our patient was not diagnosed at an early age of 4 years old, the diagnosis of HAE might have been delayed because AE did not occur since then. In this respect, if HAE is suspected, an active diagnostic approach should be made.

Answer: ① C4
