Introduction: Non-alcoholic steatohepatitis (NASH) with fibrosis is the phenotype of non-alcoholic fatty liver disease (NAFLD) that carries the highest risk of developing end-stage liver disease and the associated serious complications including cardiovascular disease. In line with recent international and national Danish guidelines for the management of NAFLD patients, we established a community NASH clinic including a multi-disciplinary-team. We here report our initial experience and real-world outcome for medical evaluation of referred patients on suspicion of NASH.
Aims and Methods: During 2017, patients from Bispebjerg Hospital clinics with a suspicion of NASH were referred to the NASH clinic. Suspicion of NASH was based on having at least 2 of the following risk factors: BMI≥25 kg/m^2, diabetes, or persistent ALT > 50 U/l. Based on a general work-up algorithm and an individualized approach, routine and NAFLD specific examinations were performed to exclude other causes of chronic liver disease (CLD). To diagnose and assess NAFLD disease grade and fibrosis stage, structured interview including thorough medical history, anthropometric measurements, NAFLD (hepatic, metabolic and fibrosis) blood tests (no genetics), ultrasound, US-elastography and US-guided liver biopsy was offered as appropriate. NASH diagnosis and fibrosis stage was based on histopathology. NAFLD activity, NAFLD fibrosis and FIB-4 index scores were calculated. Numbers of patients, percentages of total (%), medians (upper range-lower range) and means ± standard deviation are reported, as appropriate.
Results: 55 adult patients were referred to the NASH clinic on suspicion of NASH. 12 patients (22%) were found to have non-NAFLD CLD (including alcoholic hepatitis, hepatitis B, hepatitis C and autoimmune hepatitis). 30 of the remaining 43 patients accepted further specific medical work-up on suspicion of NASH: mean age was 56 ± 13 years, 16/30 (53%) were female and 24/30 (80%) were white Caucasians. Comorbidity included 8/30 (27%) with hypertension, 10/30 (33%) with diabetes, 23/27 (85%) with dyslipidemia and 23/27 (85%) with overweight (mean BMI = 32 ± 5 kg/m^2). 11/30 (37%) of patients refused undergoing liver biopsy. In the remaining 19/30 (63%) patients a liver biopsy was performed: histopathology revealed simple steatosis (NAFL) in 5/19 (26%), NASH with no or mild fibrosis stage (F0-F1) in 6/19 (32%), NASH with moderate to severe fibrosis (stage F2-3) in 7/19 (37%) and NASH with cirrhosis (stage F4) in the remaining 1/19 (5%). NAFLD median activity score was 5 (3–8) in F0-F1 vs. 6 (3–7) in F2-3 NASH patients; NAFLD mean fibrosis score was −2.2 ± 0.4 in F0-F1 vs. −0.9 ± 2 in F2-3 NASH patients; and FIB-4 mean index was 1 ± 0.6 in F0-F1 vs. 2.5 ± 3 in F2-3 NASH patients. No complications were reported following liver biopsy.
Conclusion: In our NASH clinic, about a quarter of the referred patients were diagnosed with NASH, about a quarter were diagnosed with non-NAFLD and about a quarter with un-resolved potential CLD. One-half of the diagnosed NASH patients had different stages of fibrosis and will as such require further close monitoring and management via our local community NASH outpatient clinic. Finally, the applied non-invasive fibrosis blood based score systems correlated well to histopathological findings and appear useful in clinical practice.

Introduction: The aim of this study was to assess the clinical and diagnostic capabilities of the ^{13}C-methacetin breath test (^{13}C-MBT) in patients with chronic liver disease.
Aims and Methods: Using the ^{13}C-MBT, we examined 101 patients with various chronic liver disease (CLD). The study involved 55 men, 46 women aged 21 to 77 years, the median age was 47 years. In all patients, the degree of hepatic fibrosis was also determined by various clinical and laboratory methods such as puncture biopsy, fibrotests and elastometry. All patients were divided into groups according to the degree of fibrosis, and, subsequently, by the degree of functional reserve reduction: group F0 = 26 people, F1 = 23 people, F2 = 23 people, F3 = 12 people, F4 = 17 people.
Results: In our study, it was found that the differences in the ^{13}C-MBT data were in all the study groups. But statistically significant were differences in group 1 and 3, 1 and 4, 2 and 3, 2 and 4, 3 and 4 ($p < 0.05$ by chi-square, chi-square criteria with Yates correction for small groups).
Further, using the method of logical trees, threshold values of the cumulative dose were singled out in the first 30 minutes of the test. If CUM10 < 1%, the OR fibrosis 1-2 stage = 2.5, if CUM20 < 2.5, the OR severe fibrosis increases = 6.89, if CUM30 < 5.65, the OR of cirrhosis = 23.3, by based on these data, a formula was developed to evaluate liver fibrosis.
Conclusion: The results of the method of assessing fibrosis with ^{13}C-MBT in the determination of the degree of liver fibrosis, corresponded to the values of the liver biopsy, fibrotests, elastometry. N = 1a + 2b + 10c, where is the N- sum of scores, a is the coefficient calculated from the cumulative dose of ^{13}C for 10 min-1 in% (CUM10), b - the coefficient calculated from the cumulative dose of ^{13}C for 20 minutes in% (CUM20), c is the coefficient calculated from the cumulative dose of ^{13}C for 30 minutes in (CUM30), if CUM10 < 1%, then a = 1, if CUM10 > 1.00%, then a = 0 if CUM20 < 2.50%, then b = 1, and if CUM20 > 2.50%, then b = 0, if CUM30 < 5.65%, then c = 1, if CUM30 > 5.65%, then c = 0, and for N = 0, determine the degree of fibrosis of the liver as F0, that is, corresponding to the absence portal fibrosis, at a value of N = 1–3, the degree of liver fibrosis as F1-2, corresponding to the presence of portal fibrosis without septa and with a small number of septums, with a value of N = 10–13, determines the degree of fibrosis of the liver F3-4 corresponding to the presence of numerous septa without cirrhosis and cirrhosis. The invention is based on the first time we established constant relationship between the cumulative dose reduction indices ^{13}C at the 10th, 20th and 30th minute ^{13}C- metatsetinovogo performing the breath test and the risk of the presence of liver fibrosis in patients with CLD.

Introduction: Liver cirrhosis is a leading cause of morbidity and mortality. Insulin-like growth factor 1 (IGF-1) is a soluble protein mainly produced by the liver secondary to the growth hormone stimulation on hepatocytes. IGF-1 plays an essential role in growth, development, and overall cellular regulation in the human body in health as well as in the pathophysiology of various diseases.
Aims and Methods: The aim of the work is to study the relationship between insulin like growth factor 1 and the severity of liver cirrhosis.
Methods: The study included 69 patients with liver cirrhosis of various etiologies from Menoufia University Hospitals (Egypt) and 18 healthy volunteers as a control group. They underwent physical examination and laboratory investigations (CBC, liver profile {ALT, AST, serum albumin, bilirubin, PT %}, urea, creatinine, fasting glucose, postprandial glucose and serum IGF-1). Abdominal ultrasonography was done for all patients. Child-Pugh Score, MELD score and AST/Platelet ratio index (APRI score) were calculated for all patients.
Results: IGF-1 of cirrhotic patients (73.1 ± 42.3 ng/ml) was significantly lower than controls (243.2 ± 78.1 ng/ml) ($p = 0.0001$). IGF-1 was significantly lower in Child class C (46.11 ± 6.66 ng/ml) than Child class B (64.8 ± 4.4 ng/ml) and A (149.1 ± 43.8 ng/ml) ($p = 0.002$ and 0.0001 respectively). Also IGF-1 was significantly lower in Child class B than class A ($p = 0.0001$). IGF-1 was significantly lower in patients with MELD score < 20 (45.62 ± 6.72 ng/ml) than MELD score 10–19 (61.28 ± 13.85 ng/ml) and MELD score >10 (152.1 ± 44.30 ng/ml) ($p = 0.0001$). IGF-1 was significantly lower in patients with APRI < 1.5

(46.62 ± 7.103 ng/ml) than APRI 1–1.5 (68.52 ± 13.99 ng/ml) and APRI >0.5 (155 ± 45.24 ng/ml) (p = 0.0001).
In cirrhotic patients group, there were an inverse correlation between IGF-1 and APRI score (r = −0.49), MELD score (r = −0.78), Child score (r = −0.77) and bilirubin (r = −0.54) (p = 0.0001 for all). There were a strong direct correlation between IGF-1 and albumin (r = 0.71), PT% (r = 0.79) and platelet count (r = 0.58 (p = 0.0001 for all).
Conclusion: IGF-1 can be used as an index for evaluating the severity of cirrhosis as it is correlated with variables of hepatic dysfunctions like serum bilirubin, albumin and PT% and indices of hepatic dysfunctions and fibrosis like Child-Pugh score, MELD score and APRI score. Therefore, serial measurements of IGF-1 in cirrhotic patient can predict patients with decline of liver synthetic capacity.

Introduction: Chronic HCV infection (cHCV) is a leading cause of liver disease and transplantation worldwide and a major burden on public health.
Thus, early diagnosis and classification of the degree of liver fibrosis is crucial in clinical practice to determine the urgency and need for anti-HCV antiviral therapy.
Aims and Methods: To assess the metabolites that are associated with fibrosis stages in chronic HCV infection, using metabolomic method.
A total of 40 patients were included in the study, 30 diagnosed with cHCV infection and 10 controls. Fibrosis were assessed using Fibromax elaborated by Biopredictive (R) (Paris, France). The metabolomic techniques (high performance liquid chromatography coupled with mass spectrometry (LC-MS) and principal component analysis (PCA) was performed from serum and urine samples of each patient, to identify final products of various metabolic pathways correlated with liver fibrosis.
Results: Of the 30 patients with cHCV included in the study, 20 patients (66.6 %) had advanced fibrosis (F3-4). The metabolomic profile identified 5 metabolites (3 of serum and 2 of urine) that are associated severe fibrosis (F3-4):hexacosanoyl carnitine > 26416 (AUC 0. 717; Se 61%, Sp 80%; p = 0.03); aspartylaspartic acid > 228956 (AUC 0. 700; Se 70.00%, Sp 70.00%; p = 0.05); prostaglandin E2 (PGE2) > 4265917 (AUC 0. 695; Se 65.00%, Sp 70.00%; p = 0.04) and hippuric acid (u) >70056 (AUC 0.766; Se 63.16%, Sp 100%; p = 0.003), taurine (u) < 50172(AUC 0.772; Se 78.95%, Sp 77.78%; p = 0.008).
The combined use of the metabolites determined an AUC of 0.863, with Se 82.35 and Sp 88.89, p < 0.001.
Conclusion: The study emphasizes the significance of metabolomics profiling as a promising technology for the non-invasive assesment of HCV-related liver fibrosis.
Disclosure: This work was supported by a grant of the Romanian Ministery of Research and Innovation, CCCDI-UEFISCDI, project number PN-III-P1-1.2-PCCDI-2017-0221/59PCCDI/2018 (IMPROVE), within PNCDI III.

Introduction: The influence of hypergastrinemia on the motility and liver function is not well studied. The hypoacidity of gastric juice can occur in the case of prolonged use of proton pump inhibitors, atrophic gastritis, autoimmune processes etc. It leads to hypergastrinemia, decrease of pepsin activation, dysbiosis, motility violation.
Aims and Methods: The aim of our work was to study histological liver peculiarities due to the influence of hypergastrinemia, to estimate the severity of inflammation and to study the role of multiprobiotic in these conditions. We included 40 rats that were randomly divided into 4 groups with 10 rats in each. Group 1 (control) received intraperitoneanly 0.2 ml and per os 0.5 ml of water once per day during 28 days. Group 2 received 0.14 ml/kg multiprobiotic once per day during 28 days, Group 3 received 14 mg/kg omeprazole once per day during 28 days (model of prolonged hypochlorhydria). Group 4 received 0.14 ml/kg multiprobiotic + omeprazole in dose 14 mg/kg during 28 days. Of all of them the histological peculiarities of liver were studied, we measured the levels of IL-1, IL-4, IL-6, TNF-alpha. The expression of genes Nos2, Tgfb1, ChgA, Reg1a, Hgf was measured with semi-quantitative reverse transcription polymerase chain reaction with densitometry.
Results: A long-term suppression of gastric acid secretion leads to the violation of motility, hypergastrinemia, that increases dysbiosis. The inflammation was absent in the group that received multiprobiotic. In the group with marked hypochlorhydria IL-1 was increased in 4.7 times (p < 0.01), IL-6 was increased in 8.1 times (p < 0.01), during the histological examination leukocytes infiltration and edema were observed. The administration of multiprobiotic led to the increase of IL-4 and IL-10 in 2.1 and 2.7 times correspondingly. It was established the increase of relative gene nitric oxide synthase 2 (NOS2) expression in the liver and pancreas. In the liver was increased the expression of transforming growth factor beta 1 (TGFb1), chromogranin A (CHGA) and regenerating islet-derived protein 1 alpha (Reg1a). The expression of hepatocyte growth factor (Hgf) was absent that indicates on violations of molecular mechanisms of the regulation of antifibrotic processes.
Conclusion: The results of performed investigations clearly indicate the development of inflammation which is associated with the progression of oxidative stress in liver upon these experimental conditions. As the result of these disturbances, the damage of functional status and further possible formations of fibrosis in liver can occur. The leading role of pathogenic microbiota in violation of structural and functional state of liver upon long-term suppression of gastric acid secretion were established.

Introduction: Cell therapy with mesenchymal stem cells (MSCs) is expected as a new therapeutic strategy, and large numbers of MSCs can be isolated from the amnion noninvasively. Sclerosing cholangitis is a chronic cholestatic disease, characterized by inflammation, obliterative fibrosis of bile ducts, stricture formation and progressive biliary destruction leading to cirrhosis. Many factors are involved in the development of sclerosing cholangitis; however, the effective medical therapy for sclerosing cholangitis has not been established. Therefore, a new strategy to delay or prevent disease progression of sclerosing cholangitis is urgently required.
Aims and Methods: We investigated the effects of human amnion-derived MSCs (hAMSCs) and conditioned medium (CM) obtained from hAMSC cultures in rats with sclerosing cholangitis. Sclerosing cholangitis was induced by the intragastric administration of 100 mg/kg alpha-naphthylisothiocyanate (ANIT) twice weekly for 4 weeks. ANIT is a toxin that targets intrahepatic bile ducts, and it is used to generate animal models of sclerosing cholangitis. hAMSCs were cultured in dishes until reaching a subconfluent state. After washing, cells were further cultured with serum-free medium for 48 hours and consequently, CM was collected. One million hAMSCs suspended in 200 μL of phosphate-buffered saline or 200 μL of CM were intravenously injected through the penile vein on days 15 and 22. All rats were sacrificed on day 29. In each animal, the left lobes of the liver were evaluated via histological, immunohistochemical, and mRNA expression analyses.
Results: Biliary hyperplasia, peribiliary fibrosis, and inflammation in Glisson's sheath were induced by ANIT. Histological scoring demonstrated that hAMSC transplantation and CM administration significantly suppressed biliary hyperplasia. The number of necrotic lesions was significantly decreased by hAMSC transplantation. In addition, immunohistochemical examination demonstrated that hAMSC transplantation and CM administration significantly improved

biliary hyperplasia, peribiliary fibrosis, and inflammation in Glisson's sheath. Accordingly, mRNA expression of CK19, MMP-9, TNF-α, and MCP-1 in the liver was also significantly decreased by hAMSC transplantation and CM administration.
Conclusion: hAMSC transplantation and CM administration ameliorated biliary hyperplasia, peribiliary fibrosis, and inflammation in Glisson's sheath in a rat model of sclerosing cholangitis. hAMSCs and CM may represent new modalities for treating sclerosing cholangitis.

Introduction: Liver steatosis is often suspected in patients with hyperferritinemia.
Aims and Methods: To study the BMI and alcohol consumption of patients referred for HF to 6 hospitals in the Basque country, Spain. To study the prevalence of hepatic steatosis determined by MRI in these patients.
A prospective study of 312 consecutive with HF (>200μg/L women; 300 μg/L men) was conducted from December 2010 to April 2013. The presence of liver steatosis was determined by MRI 1.5 Tesla system. We systematically performed T1-weighted in-phase and opposed-phase imaging to determine the presence or not of liver steatosis. BMI and alcohol consumption were determined in all the patients in the study.
Results: 312 patients (272 men/ 40 women) were included. Mean age 55 (SD 13.5); Mean ferritin 729.6 (SD 449.6), mean TSI 40.8 (SD 15.8); In 286 patients a MR study for the presence of liver steatosis was performed: 196 no steatosis; 90 liver steatosis (31.47%). When we study if BMI and liver steatosis were directly related, liver steatosis was more frequent in the BMI > 30 group; BMI < 25-11/52(21.15); BMI25-30: 23/105(21.90%); BMI>30-45: 56/129(43.41%)/286; the results obtained were statistically significant ($p = 0.000$). Relationship with alcohol comsumption was also evaluated. Alcohol consumption was directly related with the presence of liver steatosis: 43/196 patients (21.94%) -no alcohol-mild consume-; 32/90 (35.56%) moderate/ heavy drinker. The results were statistically significant ($p = 0.015$).
Conclusion: BMI and alcohol consume are directly related with the presence of liver steatosis in patients referred for hyperferritinemia in our country.

Contact E-Mail Address: agustincastiella@yahoo.es
Introduction: The dysmetabolic syndrome with iron overload (DIOS) is characterized by producing hyperferritinemia (HF) with slight elevation of the hepatic iron concentration, together with one or more diagnostic factors of metabolic syndrome (MtS): obesity, hypertension, dyslipidemia, and/or abnormal metabolism of glucose or BMI> 25 kg/m^2. It is associated up to 50% with NAFLD/NASH. The diagnosis is made discarding the usual causes of hepatic iron overload.
Aims and Methods: To study the cases of DIOS in a cohort of patients with hyperferritinemia sent to 6 hospitals in the Basque Country and to determine its relationship with mutations of the HFE gene and with hepatic steatosis.
A prospective study of consecutive patients with HF (>200μg/L women; 300 μg/L men) and/or TSI>45%, confirmed in 2 determinations, was conducted from December 2010 to April 2013. Dysmetabolic iron overload syndrome (DIOS) was diagnosed (1) when LIC>36, one or more MtS criteria (2) or BMI >25. Exclusion criteria: C282Y/C282Y, LIC>80-phenotypic hemocromatosis-, alcohol >40 g/day men/>20 g/day women, viral infection (HCV, HBV), oral iron, blood transfusions. LIC was determined by MRI 1.5 Tesla system (SIR method) (3). We systematically performed T1-weighted in-phase and opposed-phase imaging to determine the presence or not of liver steatosis (4). We studied HFE gene mutations in all the patients.
Results: 312 patients (272 men/ 40 women) were included. Mean age 55 (SD 13.5); Mean ferritin 729.6 (SD 449.6), mean TSI 40.8 (SD 15.8); 82 patients were diagnosed with DIOS. H63D/H63D 19 (23.17%), C282Y/H63D 11 (13.41%), C282Y/wt 5 (6.10%), H63D/wt 21 (25.61%), wt/wt 25 (30.49%). When we compared the results with those of Basque general population (5), the differences were statistically significant for H63D/H63D ($p = 0.002$) and C282Y/H63D ($p = 0.009$) mutations.
In 286 patients a MR study for the presence of liver steatosis was performed: 196 no steatosis; 90 liver steatosis (31.47%). There were 71 DIOS patients (from 82) with MR for LS determination: 13 with LS (18.31%), 58 without LS (81.69%). From 215 patients without DIOS and with MR: 77 LS (35.81%), 138 without LS (64.19%). When we compared the patients from DIOS group with MR and the group without DIOS and MR, LS was more frequent in the group without DIOS ($p = 0.006$).
Conclusion: HFE gene mutations H63D/H63D and C282Y/H63D are more associated with DIOS patients than with general population in our country; liver steatosis is more frequent in patients without DIOS than in patients with DIOS.
Disclosure: Nothing to disclose

[2]*MedGene Lab., Seoul, Korea (Republic of)*

Contact E-Mail Address: dr.sohnkm@gmail.com
Introduction: Nonalcoholic fatty liver disease (NAFLD) is related closely to risk factors for coronary artery disease (CAD), but it is unclear whether NAFLD independently contributes to asymptomatic individuals. Coronary artery calcium (CAC) scanning is the predictor of coronary events. We investigated the association of coronary artery calcification with NAFLD in asymptomatic adults.
Aims and Methods: This is the cross-sectional study performed in Hansol Hospital Healthcare Center. NAFLD was defined as cases with the typical ultrasonographic findings without excessive alcohol consumption, medications causing hepatic steatosis or other chronic liver diseases. CAC was evaluated using the Agatston method.
Results: We enrolled 312 subjects (mean age, 46.8 ± 8.7 years; 60.7% males) without known liver disease or a history of ischemic heart disease. NAFLD was found in 27% of the enrolled 312 subjects and CAC > 100 with moderate-high risk of CAD was found in 10.3% of subjects. Male gender (odds ratios (OR), 2.857; 95% confidence intervals (CI), 1.169–6.147), diabetes mellitus (OR, 2.739; 95% CI, 1.092–5.638), increased age (OR, 1.208; 95% CI, 1.071–1.316), and NAFLD (OR, 1.862; 95% CI, 1.065–3.592) were the independent factors that increased the risk of CAC > 100 in binary logistic regression.
Conclusion: NAFLD is associated with increased coronary artery calcification independent of traditional risk factors. The assessment of CAC may be useful in identifying NAFLD patients at risk of future cardiovascular events even in asymptomatic individuals.
Disclosure: Nothing to disclose

P0010 A POTENTIAL LINK BETWEEN POLYCYSTIC OVARY SYNDROME AND NON-ALCOHOLIC FATTY LIVER DISEASE: AN UPDATE META-ANALYSIS

X. Wang[1], J. Wu[2]
[1]*Changzhou No. 2 People's Hospital, Affiliated with Nanjing Medical University, Gastroenterology, Changzhou, China*
[2]*Changzhou No. 2 Hospital, Affiliated with Nanjing Medical University, Changzhou, China*

Introduction: Polycystic ovary syndrome (PCOS) itself accounts for a high risk of developing non-alcoholic fatty liver disease (NAFLD). Alternatively, other specific factors in women with PCOS may contribute to this association, which presently remains unknown.
Aims and Methods: We aimed to shed some light into this issue, and thereby performed this meta-analysis. Relevant studies that were published before May 2017 were identified and retrieving from PubMed and Web of Science databases. Data were extracted, and the pooled odds ratios (ORs) and 95% confidence intervals (95% CIs) were calculated.
Results: A total of 17 studies were included into this analysis. Compared to the control group, the risk of NAFLD in the PCOS group was higher (OR = 2.25, 95% CI = 1.95–2.60). When stratified by BMI and geographic location, these results indicated that the frequency of NAFLD risk was significantly higher amongst obese subjects (OR = 3.01, 95% CI = 1.88–4.82), non-obese subjects (OR = 2.07, 95% CI = 1.12–3.85), subjects from Europe (OR = 2.00, 95% CI = 1.58–2.52), subjects from the Asia-Pacific Region, (OR = 2.32, 95% CI = 1.89–2.84) and subjects from America (OR = 2.96, 95% CI = 1.93–4.55), respectively. In addition, PCOS patients with hyperandrogenism (HA) had a significantly higher risk of NAFLD than controls (OR = 3.31; 95% CI = 2.58–4.24). However, there was no association between PCOS patients without HA and higher risk of NAFLD (OR = 1.46; 95% CI = 0.55–3.87).
Conclusion: In summary, women with PCOS are more likely to develop NAFLD. Furthermore, PCOS itself is not a major factor leading to the disease. An excess in androgen levels, which is the main feature of PCOS and is interrelated to IR, might be a contributing factor to the development of NAFLD in PCOS patients. These findings have clinical implications for NAFLD screening in hyperandrogenic women with PCOS.
Disclosure: Nothing to disclose

P0011 UDCA EFFICASY IN THE TREATMENT OF NON-ALCOHOLIC FATTY LIVER DISEASE

I. Pirogova[1], S. Yakovleva[1], T. Neuymina[1]

Introduction: Dyslipidemia, insulin resistance, steatosis and fibrosis play a key role in the pathogenesis of NAFLD.
Aims and Methods: We aimed to evaluate the effect of UDCA in combination with of lifestyle modification on liver steatosis and fibrosis, insulin resistance (IR) and dyslipidemia in obese patients with NAFLD.
90 obese (BMI > 30, Mediana - 32) patients (men 49) with NAFLD were included in the study. The median (Me) age - 45.6 years. All patients had cytolysis (> 2 norms) and \ or Fibrosis (F) and Steatosis (S) > 1 stage by FibroScan 502 TOUCH with XL probe for obese patients and CAP technology. Blood lipid spectrum, IR, signs of inflammation were evaluated. Body metabolism (M) assessed by method of indirect calorimetry and impedancemetry (IM). It was done to prescribe the appropriate diet (minus 500 kkal/day with low level of carbohydrates ≤100g\day) in combination with exercises (plus 500 kkal/day). 63 patients were prescribed a diet in combination with daily aerobic exercise and UDCA 15 mg/kg/day (group 1), remaining 27 patients were recommended a daily aerobic exercise (group 2). Follow up period - 6 months.
Results: According to IM data in both groups there was a decrease in body weight (Me = 7% of baseline), basal metabolism (Me = 10%), fat mass in Me = 14%. At the same time muscle mass increased - with a parallel increase in muscle mass- metabolically active body mass-Me = 8. According to M evaluation there was an increase in respiratory exchange ratio by 12% with an increase in oxygen consumption (+ 15%) and a decrease in the o CO2 production (+13) in both groups, a decrease in the metabolic age by 5 years (Me). Metabolic parameters correlated (r > 0.3) with value of insulin, glucose, total cholesterol, LDL, S, F. There was a 25% decrease in Me of ALT, $p < 0.001$ (1st group), and 12% of the 2nd group ($p < 0.05$); reduction of AST by 36% and 8% respectively ($p < 0.001$), GGTP-36% and 27% respectively ($p < 0.001$), glycated Hb-20% and 11%, respectively ($p < 0.05$); insulin 16% and 14% respectively ($p < 0.02$), HOMA - 16% and 8% respectively ($p < 0.04$); total cholesterol 10% and 5% respectively ($p < 0.001$); triglycerides −27% and 10% respectively ($p < 0.05$); LDL 22% and 10% respectively ($p < 0.05$); S (dB/m^2) −19% and 13% respectively ($p < 0.05$); F -reduction in 1 stage (Metavir) in 40% of patients in group 1 only.
Conclusion: The UDCA administration in combination with of lifestyle modification in obese patients with NAFLD results in significant reduction of liver inflammation, insulin resistance and dyslipidemia compared with non-pharmacological therapy only.

Introduction: Colorectal cancer (CRC) is one of the most common cancers and the leading causes of cancer-related death worldwide; however, the prevalence of colorectal neoplasm in young adults with obesity and the associated risk factors have not been clarified. We aimed to investigate the association of non-invasive fatty liver indexes with the colorectal neoplasm among young population.
Aims and Methods: From Jan, 2013 to Dec, 2016, 1,132 asymptomatic young people aged younger than 50-year-old receiving the health check-up colonoscopy in Health Management Center of Far-Eastern Memorial Hospital were enrolled. The ability of the fatty liver index (FLI), lipid accumulation product (LAP) and non-alcoholic fatty liver disease (NAFLD) fibrosis score to predict obesity and colorectal neoplasm was assessed.
Results: The mean age of the population was 39.2 ± 6.69 years old and 52.6% was male. Colorectal neoplasms were diagnosed in 15.5% of the population (tubular adenoma 87.5%, tubulovillous adenoma 8.52%, high-grade dysplasia 3.98%). Subjects with colorectal neoplasm tended to be older, male predominant, with higher body mass index, waist circumference, serum triglycerides, fasting blood glucose, alanine aminotransferase, aspartate aminotransferase, gamma-glutamyltranspeptidace (γ-GT), and higher FLI, LAP and NAFLD fibrosis scores. Male sex, age and γ-GT were strongly associated with colorectal neoplasm than other variables (OR 1.536, 1.029 and 1.007, respectively; $p = 0.017$, 0.030 and 0.001, respectively). Using the multivariate analysis, the FLI (≥60, OR 1.830; $p = 0.004$) and LAP score (Men > 48.09, Women > 31.77, OR 1.489; $p = 0.045$), but not NAFLD fibrosis score ($p = 0.270$), can be representative indicators to predict colorectal neoplasm in young adults.
Conclusion: Among average-risk young adults, increasing risk for colorectal neoplasm was found to be associated with higher FLI and LAP scores, suggesting that the screening colonoscopy before 50 years of age with high fatty liver indexes might be beneficial.

P0013 MOLECULAR INVERSION PROBE ASSAY TO IDENTIFY NOVEL GENES ASSOCIATED WITH POLYCYSTIC LIVER DISEASE

L.F.M. van de Laarschot[1], R.H.M. te Morsche[1], A. Hoisschen[2], W.R. Cnossen[1], R. Roepman[2], J.P.H. Drenth[1]

Contact E-Mail Address: liyanne.vandelaarschot@radboudumc.nl
Introduction: Polycystic liver disease (PLD) is an inherited disorder associated with the development of numerous liver cysts. The genetic spectrum of PLD currently consists of six genes related to autosomal dominant PLD (ADPLD) and two genes related to PLD in patients with autosomal dominant polycystic kidney disease (ADPKD). Contrary to ADPKD patients, the genetic background of the majority of ADPLD patients remains unknown. Identification of these genes is important for understanding of pathways leading to liver cysts as well as possible genotype-phenotype associations. The aim of our study was to identify novel genes associated with PLD.
Aims and Methods: We deployed molecular inversion probe (MIP) analysis for the discovery of genetic variants in 26 genes in a cohort of unrelated PLD patients. We developed probes for 5 known genes associated with PLD and 21 genes chosen for their association with liver or kidney cysts in literature. Variants identified using the MIP assay were filtered before validation using Sanger sequencing. The validated variants were then selected based on novelty or SNP frequency < 0.001, in silico prediction using bioinformatics prediction tools (PolyPhen-2; SIFT), and absence of pathogenic variants in known PLD-genes. If available, family members were screened to test for disease segregation.
Results: We included 625 unrelated patients with the primary phenotype of PLD. After the first filter steps of the MIP results we identified 280 variants in 15 genes not previously associated with PLD. For six remaining genes no variants were identified that complied to all filter steps. Sanger sequencing of these 280 variants lead to validation of 85 variants in 10 genes. Sixty-five of the non-validated variants occurred in the remaining 5 genes. Of the validated variants, 49 variants are either known SNPs with allele frequency < 0.001 (n = 36), have not been described before (n = 11), or frequency data is not available (n = 2). These 49 variants were all predicted to be likely pathogenic or pathogenic by in silico prediction and are found in 9 genes.
Conclusion: We identified 49 variants in 9 genes in a large international cohort of PLD patients. These are all novel or rare variants predicted to have deleterious effect on their corresponding protein. These genes are possibly associated with PLD and are excellent candidates for further functional studies to provide evidence for their relation with PLD.

Introduction: Human liver is known as one of the target organs for estrogens, with mitogenic activity. Bisphenol A (BPA), is an artificial environmental endocrine disrupting chemicals (EDCs) that leaches from polycarbonate plastics that consequently leads to low-dose human exposure. The BPA environmental exposition was hepatic damage and worsening of non-alcoholic fatty liver disease (NAFLD). BPA is considered to be a xeno-estrogen and it can bind to estrogen receptors (ERs). Estrogens play important roles in the cell proliferation and invasion of estrogen dependent human neoplasms.
Aims and Methods: The aim of this study was to investigate the low dose of BPA effects on cell proliferation, oxidative stress and impaired synthesis of steroid hormones in human hepatocellular carcinoma cell line HepG2.
Cells were exposed to non-toxic BPA concentration (0.025 and 0.05 μM) for 48 and 72 h. Cell viability was assessed by adding 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) assay. The level of Thiobarbituric Acid-Reactive Species (TBARS) was assessed as markers of lipoperoxidation. The effect of BPA on the expression of p-ERK, ERK, Caspase 3 and aryl hydrocarbon receptor (Ahr) was determined by Western blot analysis. The analysis of steroids extracted from cell culture medium were performed by mass spectrometer analysis.
Results: BPA was able to induce a significant increase of both cell proliferation ($p = 0.0013$) and TBARS concentration ($p = 0.0003$) after 48 hours of incubation. Moreover BPA increased the protein expression of key molecules involved in the regulation of proliferation and survival, as Erk, p-Erk and AKT, and reduced the expression of caspase 3. Low dose of BPA induced an increase estrogen/testosterone ratio compared to untreated cells. The major representative peaks present in the media of BPA-treated HepG2, obtained by mass spectrometry, were: 17β-estradiol 3-sulfate ($353.1 \pm 1 m/z$), methoxyestrone 3-sulfate ($381.3 \pm 1 m/z$), 17-hydroxyprogesterone ($331.3 \pm 0.2 m/z$), estrone ($269 \pm 1 m/z$),16α-oxoestrone ($283.3 \pm 1 m/z$), testosterone sulfate ($367.4 \pm 1 m/z$) and cholesterol ($393 \pm 1 m/z$).
Conclusion: In the present study we demonstrated that treatment of HepG2cells with low doses BPA elicited: 1) increase of proliferation rate; 2) regulation of ERK/MAPK and PI3K/AKT pathways probably binding to ERα 3) increase of oxidative stress 4) induction of oxidative metabolism of estrone.

P0015 TRANSIENT ELASTOGRAPHY, APRI AND FIB-4 SCORES FOR STAGING OF FIBROSIS AND CIRRHOSIS IN WILSON DISEASE

R. Paternostro, A. Stättermayer, M. Trauner, P. Ferenci, A. Ferlitsch
Medical University of Vienna, Internal Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria

Contact E-Mail Address: rafael.paternostro@meduniwien.ac.at
Introduction: Data on the predictive capability of cirrhosis through transient elastography (TE) in Wilson disease (WD) is scarce. Furthermore there is no data regarding its value to monitor therapy. Aim was therefore to assess whether TE is a suitable tool to identify cirrhosis in patients (i) newly diagnosed and (i) under treatment for WD.
Aims and Methods: Patient with WD underwent TE (results in kPa) either at the time of diagnosis or during a regular outpatient visit during treatment. Data are shown only for patients in whom a liver biopsy was available. Furthermore data on initial liver biopsy results and non-invasive fibrosis scores (APRI, FIB-4) were recorded.
Results: 55 patients were included in the study. Of those 6 were de novo patients [Male: 50%, Age: 34 ± 10, TE: 10,9 kPa (3.5–34.8), Cirrhosis at LBX: 50%] and 49 patients [Male: 49%, Age: 40 ± 14), TE: 7.4 kPa (3.5–15.4), Cirrhosis at LBX:36.7%] had received various length of treatment with chelators. Significantly more patients under treatment were found with TE values < 12kPa (93.6% vs. 62.5%; $p = 0.009$) irrespective of initial biopsy results. Moreover the APRI classification found no patients (0%) with cirrhosis in the treated group (vs. 33.3% in the no-treatment group, $p < 0.001$). No non-cirrhotic patient worsened under treatment according to the APRI classification (cirrhosis: 0%). In untreated patients, TE, APRI and FIB-4 values almost correctly classified patients with cirrhosis, whereas in treated patients with cirrhosis at LBX (n = 18) only 16.7%, 5.6% and 27.8% where classified with cirrhosis according to TE > 12kPa, APRI and FIB-4 scores respectively (see Table 1) suggesting a potential reversible effect of therapy on the course of the disease.
Conclusion: In conclusion, TE and non-invasive fibrosis scores are valid tools to discriminate cirrhosis in newly diagnosed WD patients. In cirrhotic patients on long-term treatment TE, APRI and FIB-4 were mostly below the threshold for advanced fibrosis, indicating that decoppering therapy prevents progression of liver disease.
[Table 1]

Introduction: A recently created ultrasonographic score (*Ultrasonographic fatty liver indicator* (US-FLI)) allows the grading steatosis severity using ultrasound (US) and correlates with its histological features when assessed with liver biopsy.
Aims and Methods: We aimed to assess the correlation of US-FLI with the controlled attenuation parameter (CAP) in patients with non-alcoholic fatty liver disease (NAFLD).
Initially, inter-observer agreement for the score was assessed between 3 physicians using a sample of 31 patients. Later, 96 patients with NAFLD were included and several anthropometric, clinical and analytical parameters were assessed and US and transient elastography was performed.
Results: Physicians showed an excellent absolute agreement regarding the total score, with an average Interclass Correlation Coefficient of 0.972 (95% CI 0.949–0.986).
Patients had a median US-FLI of 6 ± 3 points and a mean CAP of 311 ± 48 dB/m. Comparing US-FLI with CAP, and considering the previously defined cutoff for steatosis > S1 (268dB/m) and > S2 (280dB/m), we verified that US-FLI had a good discriminative capacity for both grades, with areas under the curve (AUC) of 0.88 ($p < 0.001$) and 0.90 ($p < 0.001$), respectively. We also verified that a US-FLI≤3 points had a negative predictive value of 100% for steatosis > S2 and that values of US-FLI ≥6 points had a positive predictive value (PPV) of 94.0% for steatosis > S2.
When comparing the clinical score *Fatty Liver Index* (FLI) for the same CAP cutoffs, it showed a weak discriminative capacity for both grades with AUC of 0.65 ($p = 0.030$) and 0.66 ($p = 0.017$). When comparing AUC for US-FLI and FLI scores, we verified that these were significantly diferente for both cutoffs ($p < 0.001$).
Conclusion: US-FLI has an excellent reproducibility and a good discriminative capacity for the different steatosis grades. Scores ≤3 points allow us to exclude significant steatosis and scores ≥6 points have a PPV of 94.0% for steatosis > S2. US-FLI was significantly superior to the clinical score FLI in the discrimination between steatosis grades.
Disclosure: Nothing to disclose

P0017 IDENTIFYING THE NEXT TREATMENT FOR POLYCYSTIC LIVER DISEASE USING A DRUG SCREENING LIBRARY

L.F.M. van de Laarschot, A. van Spijk, K. van der Ende, R.H.M. Morsche, J.P.H. Drenth
Radboud University Medical Center, Gastroenterology and Hepatology, Nijmegen, Netherlands

Contact E-Mail Address: liyanne.vandelaarschot@radboudumc.nl
Introduction: Autosomal dominant polycystic liver disease is caused by genetic defects in *PRKCSH* in the majority of patients. Pharmaceutical treatment of polycystic liver disease is aimed at curtailing cyst volume and limited to the use of somatostatin analogues. Disadvantages of somatostatin analogues are the moderate efficacy, common frequency of side effects, and high costs. There is an urgent need for a safe treatment that decreases cyst proliferation, and hence

Abstract No: P0015

	N	kPa	kPa >12	APRI median	APRI classification: cirrhosis	FIB-4 median	FIB-4 classification: F3/4
No-cirrhosis in untreated patients	3	5.3	0 (0%)	0.21	0 (0%)	0.39	0 (0%)
Cirrhosis in untreated patients	3	34.8	3 (100%)	2.15	2 (66.7%)	7.46	2 (66.7%)
Cirrhosis at time of Dg. in treated patients	18	7.9 (3.5–12.4)	3 (16.7%)	0.39 (0.23–1.27)	1 (5.6%)	1.25 (0.49–4.28)	5 (27.8%)
No cirrhosis at time of Dg. in treated patients	31	6.9 (3.5–15.3)	2 (6.5%)	0.25 (0.17–0.83)	0 (0%)	0.88 (0.28–4.23)	2 (6.5%)

cyst volume. The aim of our study is to design a diagnostic pipeline that is able to identify pharmaceutical compounds that target pathways related to hepatic cystogenesis: cell proliferation and fluid secretion caused by decreased calcium and subsequently increased cAMP levels.[1]

Aims and Methods: The Selleckchem FDA-approved drug screening library contains 1442 compounds with a wide spectrum of therapeutic targets. *PRKCSH* knockout H69 cholangiocytes were used as *in vitro* model for polycystic liver disease. Cells were incubated with compounds at 10 microM concentration for 24 hours in triplicate. Proliferation was measured as absorbance after addition of WST-1 proliferation reagent (Sigma-Aldrich) for 3 hours. Compounds changing proliferation >20% compared to DMSO controls were selected for incubation in wildtype H69 cholangiocytes. Compounds showing >50% of proliferation compared to control and >20% absolute difference between knockout and wildtype H69 cells were identified as most promising. Compounds were further tested for their effect on cyclic AMP levels after 24 hours incubation using ELISA (Cayman).

Results: 1278 compounds showed proliferation rates of 80–120% relative to control in *PRKCSH* knockout H69 cholangiocytes. 26 compounds increased proliferation >120% of control and 138 compounds decreased proliferation below 80% of control proliferation rate. These 164 compounds were further tested in wildtype H69 cholangiocytes, while octreotide was added as reference. 18 compounds showed proliferation >50% of control proliferation rate and >20% absolute difference between knockout and wildtype H69 cholangiocytes. These compounds were then screened for their effect on cyclic AMP levels. Of these, 3 compounds reduce proliferation more in *PRKCSH* knockout cells than wildtype cells and decreased cyclic AMP levels. These included 2 anti-cancer drugs and 1 antimicrobial agent. Octreotide showed no difference in proliferation between incubated cells and controls, nor between knockout and wildtype cells. As expected octreotide reduced cyclic AMP levels in both cell lines.

Conclusion: We identified 3 FDA approved drugs that reduce proliferation rates in *PRKCSH* knockout cholangiocytes without large effect on proliferation rates in wildtype H69 cells. These drugs show reduction of cyclic AMP as well. Target pathways of these compounds differ from somatostatin analogues, and may become future pharmaceutical options for patients unresponsive to current treatment.

Introduction: Alpha-1 antitrypsin deficiency (A1AD) is an autosomal codominant disease associated with an increased risk of liver and lung disease in adults. The association between liver disease and homozygosity for the mutant Z allele (PiZZ) is well-established, however, contribution of other genotypes to the pathogenesis of adult liver disease is unclear. Moreover, the clinical course of liver disease in adults with A1AD remains poorly understood. Research is required to identify patients at risk of developing liver disease at an early stage.

Aims and Methods: Multicenter cross-sectional case-control study, including adult A1AD patients treated in Pulmonology departments of 10 hospitals (3/12 hospitals excluded with < 5 patients). Data pertaining pulmonary function, A1AT replacement therapy, A1AT phenotype/genotype, lung transplant and imaging were retrospectively collected. Clinical, demographic, laboratorial, family and personal history (including paediatric manifestations), and liver stiffness (LS), measured by transient elastography (TE, Fibroscan), data were prospectively collected at time of enrolment. Significant liver fibrosis was defined by LS≥7.1kPa. Controls were recruited within a prospective epidemiological study in the general adult population.

Results: We evaluated 218 A1AD patients and 199 controls. Our study comprised 59 PiZZ, 114 PiZ heterozygotes (55 MZ, 54 SZ, 4 MheerlenZ, 1 ZQ0s), 21 PiS (10 SS, 11 MS), 17 PiMmalton/PiMpalermo (PiMma/Mpa) carriers and 7 other rare genotypes. Cases and controls did not differ in terms of age, obesity (BMI > 30 kg/m^2), AUDIT score, serum lipids, glycaemia or CAP. Cases had significantly higher serum levels of ALT, AST and GGT ($p < 0.0001$). There was a significantly higher number of smokers in controls than patients ($p = 0.001$).

Median A1AT serum level in patients was 58 mg/dL (IQR 30) being lowest in PiZZ (27) and PiMma/Mpa patients (23). 16% of patients (34) underwent IV augmentation therapy, mainly Pi*ZZ patients, while 4 patients had undergone successful lung transplantation and 8% (18) needed regular oxygen therapy. 14% of patients were previously admitted in a Pulmonology department due to exacerbation of lung disease.

LS was defined 8.5% in controls and 17.4% in A1AD ($p = 0.007$) being highest in PiZZ (7.2 ± 4.8kPa) and PiZ heterozygotes (6.0 ± 7.2kPa). Liver fibrosis was detected in 17.4% (38/218) of patients. The genotype-specific prevalence was: PiZZ 36%(21/59), PiZ- 11,4%(13/114), PiMZ 17% (8/48), PiMma/Mpa 18%(3/17) and PiS carriers 5% (1/21), $p = 0.001$. Advanced liver fibrosis was verified in 1 control (0.5%) and 6% patients ($p = 0.002$), namely: 10% PiZZ, 5% PiZ- and 6% PiMma/Mpa. Liver fibrosis was significantly associated ($p < 0.05$) with male sex, BMI, ALT, AST, GGT, ALP, albumin, platelet, INR, CAP, glycaemia and diabetes. Laboratory liver scores (APRI and FIB-4) had a fair correlation with elastography.

Conclusion: Akin to PiZZ, PiZ heterozygoty, in particular PiMZ, is associated with liver fibrosis development. Moreover, our results suggest that rare A1AD variants, as PiMmalton also promote liver fibrogenesis. Routine laboratory tests are not predictive of significant liver fibrosis, highlighting the need for other non-invasive methods such as TE in A1AD patients follow-up.

Introduction: Cirrhosis is characterized by a hyperdynamic circulatory state and altered vascular reactivity to circulatory and paracrine agents. Vascular hyporeactivity to vasoconstrictors has been suggested to play a role in human and animal models of portal hypertension. The studies of 5-HT$_{2A}$ receptor stimulation and post receptor signaling mechanisms have revealed conflicting results. Our study aims to investigate the role of 5-HT$_{2A}$ receptors and post-receptor signaling mechanisms in vascular hypo-responsiveness in a rodent model of cirrhosis.

Aims and Methods: Cirrhosis was induced in Sprague-Dawley rats by administering CCl_4 at a dose of 1.5 mg/kg (subcutaneously), twice weekly for 8 to 10 weeks. The control rats were administered olive oil. At week 10, rats were dissected to isolate aortae and liver tissues. Aortic preparations were mounted in tissue bath assembly for the assessment of vasoconstrictor effects of α-methyl 5-HT, a 5-HT$_{2A}$ receptor agonist 5-HT$_{2A}$ agonist. The mRNA levels of 5-HT$_{2A}$ receptors were carried out using real-time PCR, while the levels of ROCK$_2$ protein were measured using an enzyme-linked immunosorbent assay. Histology of Liver tissues was studied to confirm the presence of cirrhosis.

Results: In isolated aortae of control animals, α-methyl 5-HT, caused a concentration-dependent (0.1–10 μM) vasoconstriction with maximum effect of 99.94 ± 32.51% (mean ± s.e.m) relative to K (80 mM) contraction. In cirrhotic rat aortae, it also caused concentration-related vasoconstriction at similar range with attenuated maximum contractile effect of 44.52 ± 32.55% at 100 μM. Treated and untreated tissues challenged with graded concentrations of α-methyl 5-HT were tested to quantify the mRNA levels of 5-HT$_{2A}$ and ROCK$_2$ protein. Expression of 5-HT$_{2A}$ mRNA and ROCK$_2$ protein levels showed a decreasing trend in cirrhotic aortic tissues vs. control. Histological features of hepatic tissues confirmed the development of cirrhosis in diseased rats showing evidences of fibrosis and nodule development.

Conclusion: These data suggests that the resultant hypo-responsiveness in isolated aortic preparations of cirrhotic animals is due to attenuated activity/affinity of 5-HT$_{2A}$ receptors which was evident by suppressed vascular contractile response to 5-HT$_{2A}$ receptor agonist in cirrhotic animals vs. control. Though no significant difference was observed in the expression of mRNA levels of 5-HT$_{2A}$ and downstream ROCK$_2$ protein levels, a clear downward trend was noticed in both. Thus, this study provides an evidence to the contributing role of 5-HT$_{2A}$ receptors in vascular hypo-responsiveness in cirrhotic animals.

Introduction: Previous large-scale genetic studies identified single nucleotide polymorphisms (SNPs) of the *TM6SF2* and *MBOAT7* genes as risk factors for alcoholic liver cirrhosis and non-alcoholic fatty liver disease. In this study, we tried to evaluate whether *TM6SF2* (*rs58542926, rs10401969*) and *MBOAT7* (*rs641738, rs626283*) SNPs are associated with the risk of hepatic fibrosis or liver cirrhosis of different aetiology in an Eastern European population.
Aims and Methods: The study was conducted at the Department of Gastroenterology, Lithuanian University of Health Sciences Hospital, and included 334 patients with liver cirrhosis, 128 patients with liver fibrosis, and 550 controls. SNPs were genotyped by quantitative PCR, using TaqMan allelic discrimination assays.
Results: Genotype distributions of *TM6SF2* (*rs58542926, rs10401969*) and *MBOAT7* (*rs641738, rs626283*) SNPs were in Hardy-Weinberg equilibrium. The *TM6SF2 rs58542926* and *rs10401969* alleles and genotypes had similar frequencies in controls, liver fibrosis and cirrhosis groups ($p > 0.05$). The distribution of *MBOAT7 rs626283* and rs641738 genotypes did also not differ between the 3 groups ($p > 0.05$). Overall, none of the 4 analysed SNPs (*rs58542926, rs10401969, rs641738, rs626283*) was associated with the presence of hepatic fibrosis or liver cirrhosis in our population.
Conclusion: Our study showed no significant associations between *TM6SF2* (*rs58542926, rs10401969*) and *MBOAT7* (*rs641738, rs626283*) gene polymorphisms and liver fibrosis, alcohol or hepatitis C virus-induced liver cirrhosis in an Eastern European population. These findings point to a predominant role of exogenous risk factors for disease progression in these patients.

Introduction: Increased hepatic vascular resistance (HVR) due to architectural distortion and intrahepatic vasoconstriction is the primary factor for the development of portal hypertension in liver cirrhosis. Oxidative imbalance in cirrhotic livers, by decreasing nitric oxide (NO) bioavailability, contributes to increasing HVR and portal pressure (PP). Cyclooxygenase-2 (COX-2) is up-regulated in cirrhotic livers and correlated with fibrosis degree and PP.
Aims and Methods: To investigate the antioxidant capacity of celecoxib, a selective COX-2 inhibitor, and its effects on intrahepatic resistance during the development of portal hypertension in cirrhotic rats. *In vivo* study, peritoneal injection of thioacetamide (TAA) was employed to induce liver cirrhosis for 16 weeks. 36 male *Sprague-Dawley* rats were randomly assigned to the control, TAA, and TAA+celecoxib groups. TAA-cirrhotic rats received celecoxib or its vehicle by gastric gavage for last 8 weeks. PP, portal blood flow (PBF) and HVR were measured before sacrificed. Oxidative stress levels were evaluated by *in situ* superoxide (O_2^-) fluorescent staining and activity of superoxide dismutase (SOD). cGMP and arachidonic acid metabolomics in liver homogenate were quantitated. Hepatic expressions of pivotal molecules in NO bioavailability (eNOS, AMPK, nitrotyrosine), oxidation/antioxidation (NOX4, SOD) and COX pathway (COX2, EP2, TXA2R) were analyzed by RT-qPCR or Western blot. *In vitro* study, the recombinant plasmid with COX-2 or empty vector were transfected into LSECs (SK-Hep1) and hepatocytes (L02). After treatment with PGE2, AH6809 (EP2 antagonist), U46619 (TXA2R agonist), Terutroban (TXA2R antagonist), Dorsomorphin (AMPK inhibitor) and GKT137831 (NOX4 inhibitor), *in situ* O_2^- levels and protein expressions were evaluated.
Results: Celecoxib administration significantly decreased PP by 22.8% (12.51 ± 0.69 vs. 16.20 ± 0.84 cmH_2O, $p < 0.05$) and HVR by 31.6% (0.91 ± 0.05 vs. 1.33 ± 0.10 $cmH_2O \cdot mL^{-1} \cdot min$, $p < 0.05$), with a significant increase in PBF (13.83 ± 0.83 vs. 12.25 ± 0.75 mL/min, $p < 0.05$). Compared with the TAA group, celecoxib ameliorated oxidative stress by enhancing SOD activity ($p < 0.05$) and suppressing NOX4 expression ($p < 0.05$). Consistently, the up-regulation of hepatic O_2^- level and nitrotyrosine protein induced by TAA was significantly inhibited after celecoxib administration ($p < 0.05$). Furthermore, treatment with celecoxib increased hepatic cGMP level (0.59 ± 0.14 vs. 0.44 ± 0.09 pmol/mgprot, $p < 0.05$) by accelerating the phosphorylation levels of eNOS and AMPK. COX-derived metabolites showed that PGE2 and TXA2 were significantly increased in TAA-cirrhotic rats ($p < 0.05$), and remarkably decreased after celecoxib treatment ($p < 0.05$). The mRNA and protein levels of COX-2, EP2 and TXA2R were significantly down-regulated by celecoxib administration ($p < 0.05$). In cultured SK-Hep1 and L02 cells, COX-2 plasmid, PGE2, U46619 and Dorsomorphin significantly decreased phosphorylation level of AMPK ($p < 0.05$) and increased NOX4 expression ($p < 0.05$). The effects caused by PGE2 or U46619 could be inhibited after the blockage of EP2 or TXA2R ($p < 0.05$). GKT137831 down-regulated NOX4 expression ($p < 0.05$) without affecting AMPK phosphorylation.
Conclusion: Therapeutic administration of celecoxib efficiently decreased HVR and PP in TAA-cirrhotic rats. These effects may due to the acceleration of NO generation and the suppression of NO scavenging by superoxide radical. Inhibition of COX-2 by celecoxib significantly reduced ROS generation in LSECs and hepatocytes by suppressing PGE2/TXA2-EP2/TXA2R-AMPK-NOX4 pathway.

Introduction: The von Willebrand factor (vWF) is a marker of endothelial dysfunction that is closely associated with the degree of hepatic dysfunction in the cirrhotic patient. Thus, it is assumed that there is a correlation between vWF level and the prognosis of the cirrhotic patient.
Aims and Methods: We aimed to evaluate the role of vWF as a predictor of short and medium-term mortality in patients with decompensated liver cirrhosis; to determine its prognostic accuracy and to compare it with the Child-Pugh (CP), MELD and CLIF-AD prognostic scores.
Prospective study including patients admitted for acute decompensation of cirrhosis between July 2016 and October 2017. The value of vWF-antigen, CP, MELD, CLIF-AD was determined. In-hospital, as well as 30, 90, 180 and 365-day mortality was calculated. The accuracy of vWF and each of the scores in the prediction of mortality was evaluated and compared.
Results: 41 patients included, 90.2% male, mean age 61 ± 9.6 years. MELD 15.74 ± 6.62, CP 9.98 ± 1.54 and CLIF-AD 53.34 ± 9.98. The mean value of vWF was 594.69 ± 344.52 (reference value 42–176.3%), presenting significantly higher values in patients who died at admission as well as at 30, 90, 180 and 365 days (829.5 ± 164.32 vs. 557.39 ± 347.78, $p < 0.05$; 797.36 ± 191.66 vs. 539.48 ± 352.51 $p < 0.05$; 752.64 ± 217.91 vs. 542.6 ± 357.69, $p < 0.05$; $702\text{-}26 \pm 192.09$ vs. 548.39 ± 395.36, $p < 0.05$; 729.32 ± 214.43 vs. 455.58 ± 236.27, $p < 0.05$). The area under the curve (AUC) of vWF as predictor of in-hospital and 30-day mortality was 0.831 and 0.815, respectively, $p < 0.01$, not presenting values significantly higher than CP, MELD and CLIF-AD scores. The best cut-off value of vWF to predict in-hospital and 30-day mortality was 636.
Conclusion: The vWF constitutes a mortality predictor independent of the CP, MELD and CLIF-AD scores, identifying decompensated cirrhotic patients with poor short term prognosis. Thus, it is a promising biological marker, requiring more studies in order to be integrated into a new prognostic score.

P0023 GRAM-NEGATIVE BACTERIA INDUCE CELL-CYCLE ARREST AND INTESTINAL EPITHELIAL BARRIER DESTABILIZATION - AN *IN VITRO* MODEL FOR THE STUDY OF BACTERIAL TRANSLOCATION IN LIVER CIRRHOSIS

M. Haderer, L. Wächter, E. Aschenbrenner, K. Pollinger, S. Schlosser, C. Kunst, M. Müller-Schilling
University Hospital Regensburg, Department of Internal Medicine I, Gastroenterology, Endocrinology, Rheumatology and Infectious Diseases, Regensburg, Germany

Contact E-Mail Address: marika.haderer@ukr.de
Introduction: Patients suffering from liver cirrhosis display impaired intestinal characteristics compared to healthy individuals, indicated by a suppressed immune system with bacterial overgrowth and a reduced microbial diversity. Of special importance an increased permeability of the intestinal epithelial barrier due to liver cirrhosis is observed. Together, these changes promote bacterial translocation, driving spontaneous bacterial peritonitis (SBP) - one of the most harmful complications of liver cirrhosis. Up to now, a molecular mechanism explaining bacterial translocation in this setting has not been elucidated. To uncover under lying pathomechanisms, an *in vitro* model using Caco-2 intestinal epithelial cells was established. Effects of bacterial stimulation were evaluated

regarding changes in cell-cycle regulation and *tight junction* composition of Caco-2 cells.
Aims and Methods: Caco-2 - human intestinal epithelial cells were cocultured at day 6 post confluence with *Escherichia coli* (*E. coli*) and *Klebsiella pneumoniae* (*K. pneumoniae*) at MOI 0 - 10 for up to 4 hours. To clarify whether observed effects were due to living bacteria, bacterial components like *lipopolysaccharide* (LPS) and bacterial metabolites in form of supernatant of an *E.coli* overnight culture were also used for stimulation. Heat-inactivated bacteria served as reference. Changes in cell-cell-contact proteins (oocludin and E-cadherin) were analyzed by Western blot and fluorescence microscopy. Moreover, effect on cell-cycle regulation was examined by flow cytometry.
Results: Bacterial stimulation of Caco-2 cells with *E.coli* or *K. pneumoniae* resulted in a G1 arrest with up to 11% more cells in Go/G1 phase compared to the unstimulated control. Coincubation with *K. pneumoniae* at MOI 5 resulted in a decreased production of occludin, while *E.coli* reduced both protein levels of occludin and E-cadherin. Bacterial metabolites in the supernatant of the overnight culture reduced protein levels around 30%, but less strong compared to vivid bacteria with a downregulation of 50% compared to unstimulated cells. In contrast, heat-inactivated bacteria and LPS however failed to induce changes on the level of cell-cell-contact proteins.
Conclusion: Gram-negative bacteria such as *E.coli* and *K.pneumoniae* are capable of regulating cell-cell-contact-forming proteins of intestinal epithelial cells and therefore impair integrity of the epithelial barrier. Furthermore, presence of both bacteria resulted in a G1 cell-cycle arrest. Both effects might be part of a bacterial mechanism to escape intestinal immune responses and promote bacterial translocation followed by the development of SBP.
Disclosure: Nothing to disclose

P0024 INFLAMMATORY ACTIVITY IN ASCITIC FLUID OF LIVER CIRRHOSIS PATIENTS - ON THE WAY TO NOVEL POTENTIAL BIOMARKERS FOR DIAGNOSIS OF SPONTANEOUS BACTERIAL PERITONITIS

S. Scherm, M. Haderer, E. Aschenbrenner, K. Pollinger, S. Schlosser, C. Kunst, M. Müller-Schilling
University Hospital Regensburg, Internal Medicine I, Regensburg, Germany

Contact E-Mail Address: sophia.scherm@stud.uni-regensburg.de
Introduction: Spontaneous bacterial peritonitis (SBP) is defined as bacterial infection of ascitic fluid without any intra-abdominal, surgically treatable focus. It is a well-known and severe complication in decompensated liver cirrhosis with a 1-year-mortality of 93%. Although SBP pathogenesis is still not yet fully understood, bacterial translocation of intestinal bacteria from the gut to mesenteric lymph nodes into the ascitic fluid is regarded to be the underlying mechanism. Intestinal bacteria translocating into ascitic fluid are mostly gram-negative bacteria, most common is *Escherichia coli*. According to the German S3-Guideline "Ascites, spontaneous bacterial peritonitis, hepatorenal syndrome", diagnosis of SBP is assured with detection of more than 250 polymorphonuclear (PMN) cells per µl. Since patients need an immediate antibiotic treatment, molecular markers indicating a beginning SBP need to be identified to be able to improve early diagnosis of SBP.
Aims and Methods: To identify novel potential biomarkers for SBP, ascitic fluid was collected from patients suffering liver cirrhosis at the University Hospital of Regensburg. Protein levels of the potential biomarkers lactoferrin, C3a, IP-10, IL-6, IL-8 and IL-10 withinascitic fluids were analyzed by ELISA. Total protein content of ascitic fluid was measured by BCA protein assays.
Results: In total, 69 ascitic fluid samples from 41 different patients were analyzed. The range of age in our cohort was between 36 and 77 years at date of paracentesis. 78% (32 patients) of the cohort were male and 22% (9 patients) were female. The development of liver cirrhosis in our population was alcohol-toxic (58.5%), cryptogenic (19.5%), nutritive-toxic (7.3%), viral (4.9%), autoimmune (2.4%), PBC (2.4%), non-alcoholic steatohepatitis (2.4%) and Budd Chiari Syndrome (2.4%). In 11.6 % (8) of the samples diagnosis of SBP was confirmed with the definition of $>$ 250 PMN/µl. The use of aPMN cell count of more than 100 PMN/µl ascitic fluid detected SBP in 13 samples (18.8%). Lactoferrinlevels in ascitic fluid with SBP (1006 ng/ml) were higher than in ascitic fluid without SBP (75ng/ml). Follow-up samples indicated that lactoferrin concentrations were elevated in early stages of SBP and coincided with the course of the disease and therapeutic response. In contrast C3a levels in infected ascitic fluids (511 ng/ml) was reduced compared to healthy controls (974 ng/ml) and correlated with the course of disease. IP-10 was detected in all samples, but did not display any correlation with disease activity. Also relevant amounts of cytokines such as IL-6, IL-8 and IL-10 were detected in ascitic fluid of liver cirrhosis patients. However, these parameters did not display any relation with the early onset of SBP.
Conclusion: Lactoferrin and C3a are molecular components of ascitic fluid which levels are in relation with the course of SBP. Moreover, a variety of other inflammatory molecules and cytokines is present in ascitic samples. These results highlight the tremendous inflammatory activity in ascitic fluids of liver cirrhosis patients and provide a potential platform for a new perspective of SBP and an earlier diagnosis and treatment of SBP in hospital or ambulant patient care leading to a reduced mortality.

P0025 OUTCOMES OF LARGE-VOLUME PARACENTESIS IN CIRRHOTIC PATIENTS WITH SPONTANEOUS BACTERIAL PERITONITIS

H.A.B. Siddiqui, S.H. Alishah, R. Azmat
[1]*Aga Khan University Hospital, Medicine, Karachi, Pakistan*

Contact E-Mail Address: dr.basit.siddiqui@gmail.com
Introduction: Pakistan ranks second among highest prevalent countries for chronic hepatitis C with a prevalence of 5.2%. Here we have an exponential increase in chronic liver disease patients, so burden of morbidity and mortality is high due to lack of transplant centres. Spontaneous bacterial peritonitis (SBP) occurs in 10–30% of cirrhotic patients and is associated with high mortality rate among hospitalized patients and its associated incidence of acute kidney injury (AKI) and hepatorenal syndrome (HRS). Large-volume paracentesis (LVP) decreases the burden of infective fluid. Outcomes of LVP in SBP patients has not been clearly addressed in previous studies. Furthermore, in the abcense of more viable therapeutic options for preventing kidney impairment in SBP, the managment really looms around time and need for renal replacment therapy (RRT). This study will assess the outcome of LVP in patients with SBP, both in terms of mortality, length of stay and effect on renal function.
Aims and Methods: This cross-sectional study was conducted in the Medicine Unit of Aga Khan University Hospital. A total of 113 patients with diagnosed SBP were assessed. Among these patients 61 underwent LVP while 51 were managed conservatively. LVP was done as per routine practice of safety and monitoring. All the patients received intravenous albumin and hydration as per protocol. Baseline and 48 hours clinical outcomes (including creatinine and ascitic fluid total leucocytes (TLC) count) were compared including a number of other parameters. The development of AKI and post-paracentesis induced circulatory dysfunction (PPCD) were also assessed and model for end-stage liver disease (MELD) and Child-Turcotte-Pugh (CTP) scores were also calculated.
Results: There was statistically significant improvement in post 48 hours creatinine among patients undergoing LVP ($p < 0.001$) whereas no significant improvement was seen in patients without LVP (p 0.32). Similar improvements were seen for special care unit stay and total length of stay in patients with LVP, need for RRT and incidences of AKI and HRS amnong both groups.
Conclusion: LVP in patients with SBP translates into significantly positive outcomes in terms of length of hospital stay, spceial care unit stay, need for RRT and development of AKI and HRS. Hence LVP is recommended as a favoured therapeutic option.
[Outcome of LVP in SBP]

Introduction: Liver biopsy is the gold standard for assessing hepatic fibrosis in patients with chronic hepatitis C virus infection, but it is invasive and has many sequelae.
Aims and Methods: This study was performed to verify the role of the aspartate aminotransferase-to-platelet ratio index (APRI) and fibrosis 4 (FIB-4) tests as non-invasive alternatives to liver biopsy.
Our study included 757 patients with a median age of 42.6 ± 10.3 years. All patients underwent liver biopsy for fibrosis stage estimation, and the APRI and FIB-4 tests were performed. The liver biopsies were scored using the METAVIR system: 13 patients were F0 (1.7%), 356 (47%) were F1, 227 (30%) were F2, 160 (21%) were F3, and 1 (0.1%) was F4.
Results: For predicting fibrosis stages $F \geq 3$, APRI and FIB-4 had a specificity of 90% at cut-off values of 1.1 and 2.7, respectively, and a specificity of 95% at cut-off values of 1.67 and 3.3, respectively. The area under the receiver operating characteristic curve (AUC) was 0.663 (95% confidence interval [CI], 0.617–0.709) for APRI and 0.673 (95% CI, 0.627–0.719) for FIB-4. For predicting $F \geq 2$, APRI and FIB-4 had a specificity of 90% at cut-off values of 0.94 and 2.4, respectively, a specificity of 95% at cut-off values of 1.14 and 2.7, respectively. The AUC was 0.642 (95% CI, 0.603–0.681) for APRI and 0.676 (95% CI, 0.638–0.714) for FIB-4.
Conclusion: For the non-invasive prediction of liver fibrosis stage, using higher cut-off values for APRI and FIB-4 is advised to improve the specificity
Disclosure: Nothing to disclose

P0028 HEALTH-RELATED QUALITY OF LIFE IN PRIMARY BILIARY CIRRHOSIS

D. Popovic[1,2], V. Nikolic[2], K. Bojovic[2,3], J. Jovic[4], L. Markovic Denic[2], T. Milosavljevic[1,2], T. Milovanovic[1,2]

Introduction: Primary biliary cirrhosis (PBC) is a chronic autoimmune disease, characterized by progressive inflammation, destruction of intrahepatic bile ducts and cholestasis. Symptoms of PBC, especially itching and fatigue, lead to a reduction in Health-Related Quality of Life (HRQoL). HRQoL can be determined using general or disease-specific questionnaire. Further studies investigating the HRQOL of patients with PBC, demonstrated an urgent need for a disease specific instrument, separate from other chronic liver disease and general quality of life questionnaires including the chronic liver disease questionnaire (CLDQ) and the short form health survey-36. Therefore, the first disease specific quality of life questionnaire for PBC, the PBC-40, was created.
Aims and Methods: A cross-sectional study was conducted for period of 9 months in 3 tertiary institutions. The study included consecutive patients with PBC. The diagnosis of PBC was based on a significant elevation of antimitochondrial antibody titre, biochemical cholestasis and/or pathohistological finding. The data on the anamnestic and clinical characteristics of the patients were collected. HRQoL was assessed using of a validated PBC-40 questionnaire. Descriptive and analytical statistics are used. The t-test and One-way ANOVA were used to estimate the significance of the difference, while Pearson's correlation was used for correlation estimation. The determination of predictor variables of the total PBC-40 score was performed using multiple regression analysis.
Results: The study included 94 patients, with an average age of 59.26 ± 10.04 years. Of the total number of patients, 97.9% ($n = 92$) were women.
The score for the "Itch" domain is significantly higher (worse) in patients of the age ≤ 56 years than in older patients (5.36 ± 4.16 vs. 3.65 ± 3.66) ($p = 0.043$). Patients with edema have lower HRQoL for the domains "Emotional" (11.80 ± 3.11 vs. 7.09 ± 3.14) ($p = 0.002$) and "Social" (29.60 ± 9.99 vs. 19.83 ± 8.78) ($p = 0.018$). The score for the "Social" domain is significantly lower in patients on diuretics therapy (27.93 ± 9.33 vs. 19.00 ± 8.38) ($p = 0.018$). The score for the "Itch" domain positively correlates with the values of alkaline phosphatase (ALP) ($r = 0.335$; $p = 0.020$), gamma glutamyl transferase (GGT) ($r = 0.303$; $p = 0.040$) and alanine aminotransferase (ALT) ($r = 0.231$; $p = 0.028$). The "Fatigue" domain positively correlates with the value of ALP ($r = 0.274$; $p = 0.010$), while the domain "Social" correlates with prothrombin time ($r = 0.264$; $p = 0.024$). The value of the score for the "Emotional" domain significantly negatively correlates with serum albumin value ($r = -0.242$; $p = 0.033$).
A significant regression equation was obtained to determine the prediction of the total PBC-40 score ($F(1, 61) = 8.258$, $p = 0.006$) for $R^2 = 0.119$. Significant predictor of the total PBC-40 score is value of GGT ($\beta = 0.315$, $p = 0.006$).
Conclusion: HRQoL in patients with PBC are affected by: age, edema, diuretics, and some laboratory parameters. Significant predictor of total PBC-40 is GGT.
Disclosure: The study was conducted on the same sample as the validation of the Serbian version of the PBC-40 questionnaire (1).

P0029 EFFECT OF THE PROPRANOLOL THERAPY ON THE INCIDENCE OF HEPATOCELLULAR CARCINOMA IN PATIENTS WITH CIRRHOSIS: A RETROSPECTIVE OBSERVATIONAL STUDY IN A TERTIARY CENTER

N. Suna, D. Özer Etik, S. Öcal
Başkent University, Ankara, Turkey

Contact E-Mail Address: nurettinsuna.44@hotmail.com
Introduction: Hepatocellular carsinoma (HCC) is the most frequent type of the primary malign tumors of the liver and at the same time it is the third most common cause of mortalities among all kind of cancers. Despite the recent advances in this field, new strategies are need for prevention of HCC.
Aims and Methods: The objective of this study is to determine the effect of propranolol on the incidence of HCC regarding patients with cirrhosis caused by various etiologies in our center.
Data from patients with cirrhosis caused by different etiologies (who were registered in a HCC surveillance program in our center between June 2011 and December 2017) were retrospectively studied and comparatively (patients taking propranolol therapy and those without propranolol therapy) analyzed.
Results: Total 231 patients (135 male (58.4%) and 96 female (41.6%)) were included in this study. The median age was 58.1 +/- 14 years and average cirrhosis period was 7.7 +/- 4 years. 153 (66.2%) patients had used propranolol and other 78 (33.3%) had not used. HCC progression was observed in 36 patients (15.6%). HCC evolution in patients undergoing propranolol treatment was 7.8% (12 patients) in response to 30.8% (24 patients) in those who were not taken propranolol ($p < 0.001$). According to this result, the incidence of HCC was 5.22 times greater in patients not taking propranolol with respect to those undergoing propranolol therapy.
Conclusion: Although the cirrhosis etiologies and onset phase of the illness were similar in both groups, HCC incidence was importantly lower in propranolol group with respect to the non-propranolol group. This result shows that propranolol theraphy has a protective effect on HCC in patients with cirrhosis.

P0030 LIVER CIRRHOSIS AND LEFT VENTRICLE DIASTOLIC DYSFUNCTION: RETROSPECTIVE STUDY

J. Šarnelytė, I. Stundienė, J. Valantinas
Vilnius University, Faculty of Medicine, Clinic of Gastroenterology, Nephro-Urology and Surgery, Vilnius, Lithuania

Contact E-Mail Address: sarnelyte.julija@gmail.com
Introduction: Patients with liver cirrhosis are reported to have a hyperdynamic circulation, which manifests as a high cardiac output, decreased systemic vascular resistance, and widespread arterial vasodilatation. Based on studies, cirrhosis is associated with cardiovascular abnormalities. A definition "cirrhotic cardiomiopathy" had been proposed in 2005. It states that "cirrhotic cardiomyopathy is a form of chronic cardiac dysfunction in patients with cirrhosis, characterized by blunted contractile responsiveness to stress, and/or altered diastolic relaxation with electrophysiological abnormalities in the absence of other known cardiac disease."
Aims and Methods: The aim of a research was to evaluate the association between diastolic dysfunction of letf ventricle and the severity of cirrhosis. 150 patients with diagnosed liver cirrhosis, waiting for the liver transplantation, were retrospectively analyzed between 2006 and 2015 at Vilnius University Santaros Clinics. Etiology of cirrhosis, Child-Pugh classification, Model for End-Stage liver disease score, echocardiographic indicators of diastolic dysfunction, concentrations of bilirubin, creatinine and albumin, international normalization ratio were recorded. Diastolic dysfunction was divided into 3 grades by increasing severity by American Society of Echocardiography 2016. Data were analyzed by SPPS v.19. A $p < 0.05$ was considered as statistically significant.
Results: Final statistical analysis included 47 patients. The majority of patients were men (66%), patients' mean age was 48.5 ± 1.175 years. All patients in our study had liver cirrhosis. Hepatitis C virus infection was the most common etiology of cirrhosis (38.3%). Normal diastolic function was presented in 20 (42.6%), first grade dysfunction in 7 (14.9%), second grade in 18 (38.3%) and third grade in 2 (4.3%) cirrhotic patients. There was a significant relation between diastolic function and age ($p = 0.039$; $r = 0.3$), Model for End-Stage liver disease ($p = 0.007$, $r = 0.4$).
Conclusion: According to the relation between diastolic dysfunction and Model for End-Stage liver disease score, we recommend cardiac assessment in patients with higher Model for End-Stage liver disease scores.

Introduction: Bleeding from ruptured esophageal varices (EV) is the most severe complications of patients with liver cirrhosis and portal hypertension. Upper endoscopy is the golden standard for diagnosis of esophageal varices. Non-invasive diagnosis of esophageal varices in cirrhotic patients is beneficial because it help us to select the patients likely to have esophageal varices to do endoscopy for them.
Aims and Methods: The aim of this study was to assess esophageal varices by noninvasive parameters in patient with liver cirrhosis using some clinical, laboratory and ultra-sonographic parameters.
Methods: The study included 120 patients with liver cirrhosis of various etiologies from Menoufia University Hospitals (Egypt) and 20 healthy volunteers as controls. They underwent physical examination and laboratory investigations (CBC, liver profile {ALT, AST, serum albumin, bilirubin, PT %} and creatinine). Abdominal ultrasound and upper endoscopy were done for all patients. Child-Pugh score, MELD score, AST/Platelet ratio index (APRI score), Platelet count/spleen diameter ratio (PC/SD) and NIEC Index were calculated for all patients.
Results: Serum albumin at cutoff less than 3.65gm/dl is significant in prediction of EV with sensitivity 70% and specificity 86.2%. Platelet count at cutoff less than 99000/mm^3 is significant in prediction of EV with sensitivity 87.5% and specificity 55%. PC/SD ratio at cutoff less than 919.6 is significant in prediction of EV with sensitivity 57.5% and specificity 95%. APRI score at cutoff cut off greater than 1.14 is significant in prediction of EV with sensitivity 68.8% and specificity 65%. Spleen longitudinal diameter at cutoff more than 140.5 mm is significant in prediction of EV with sensitivity 73.8% and specificity 70%. Portal vein diameter (PVD) at cutoff more than 15.2 mm is significant in prediction of EV with sensitivity 62.5% and specificity 90%. Prothrombin time at cutoff more than 15.1 second is significant in prediction of EV with sensitivity 63.8% and specificity 82.5%. NIEC Index at cutoff more than 25.4 is significant in prediction of variceal bleeding risk with sensitivity 90% and specificity 50%. Platelet count at cutoff less than 74000/mm^3 is significant in prediction of variceal bleeding risk with sensitivity 82.5% and specificity 55%. PC/SD ratio at cutoff 851.6 is significant in prediction of variceal bleeding risk with sensitivity 45% and specificity 90%. Multiple logistic regression analysis of risk factors of development of esophageal varices revealed that serum albumin, prothrombin time, PC/SD ratio and PVD are significant predictors for development of esophageal varices. Multiple logistic regression analysis of risk factors of variceal bleeding revealed that NIEC index is the most significant predictor for variceal bleeding.
Conclusion: Non-invasive predictors for presence of esophageal varices in patients with liver cirrhosis provide a method for selecting patients for endoscopic screening based on laboratory, clinical and ultrasonographic variables such as serum albumin, platelet count, PC/SD ratio, APRI score, SLD, PVD, prothrombin time and Child-Pugh score. Therefore, the number of unnecessary endoscopies will be reduced. NIEC Index, platelet count and PC/SD ratio can provide information help in prediction of variceal bleeding risk in patients with liver cirrhosis.

P0032 LONG-TERM PREVENTION OF OVERT HEPATIC ENCEPHALOPATHY IS POSSIBLE WITH LACTULOSE ALONE BUT MORE EFFECTIVE IF COMBINED WITH RIFAXIMIN: A SYSTEMATIC REVIEW WITH NUMBER NEEDED TO TREAT ANALYSES OF RANDOMISED CONTROLLED TRIALS

M. Schuchmann[1], N. Mason[2], **M. Hudson**[3]
[1]*Department of Medicine, Medical Director, Klinikum Konstanz, Constance, Germany*

Introduction: Overt hepatic encephalopathy (OHE) is a serious complication of liver cirrhosis and it occurs in 30–40% of these patients. Frequent hospitalisations and a high mortality rate make prevention essential. Thus, patients should be offered the most effective treatment available. Previous systematic reviews have aggregated both treatment and prevention plus different time scales. This more focused systematic review analysed the long term OHE-preventive efficacy of lactulose versus its combination with rifaximin. An NNT analysis was also performed to understand the clinical relevance of the efficacy outcomes.
Aims and Methods: PubMed was searched for titles and abstracts published by 16 November 2017. Search terms were: 'hepatic encephalopathy + rifaximin' and 'hepatic encephalopathy + lactulose'. Randomised controlled trials with long-term (≥6 months) effectiveness and/or safety/tolerability endpoints for lactulose and/or rifaximin were selected for NNT analysis if statistically significant between-group differences were reported in the rate of OHE recurrence. Studies of primary prophylaxis and different dosing regimens of rifaximin were excluded.
Results: A total of 570 articles including 201 with primary clinical data were identified. Long-term treatment was reported in 8 articles for lactulose alone and in 19 articles for rifaximin, alone or in combination with lactulose. NNTs were calculated from 5 studies (Table 1). Lactulose prevented OHE episodes versus placebo or nothing, NNT [95% CI]: 3.28 [2.15, 6.90] and 3.68 [2.33, 8.75]. Combining lactulose with rifaximin prevented OHE episodes more than lactulose alone, NNT [95% CI]: 3.28 [2.27, 5.90] and 4.21 [2.93, 7.46]. Rifaximin alone offered additional prevention for some patients versus its combination with lactulose, NNT [95% CI]: 6.88 [3.50, 203.90].
Conclusion: In the systematic literature review of the long-term prevention of OHE, further clinical benefit is shown by adding rifaximin to lactulose than with lactulose alone. The number needed to treat to prevent a further recurrence of OHE improves the clinical relevance of this outcome.
[Table 1. Long term prevention of overt hepatic encephalopathy]

Study	Duration (months)	Treatment A	Treatment B	Number needed to treat, mean [95% CI]
Sharma 2009	12	Lactulose	Placebo	3.68 [2.33–8.75]
Agrawal 2012	14	Lactulose	Placebo	3.28 [2.15–6.90]
Bass 2010	6	Lactulose+rifaximin	Lactulose	4.21 [2.93–7.46]
Bajaj 2015	6	Lactulose+rifaximin	Lactulose	3.28 [2.27–5.90]
Neff 2012	12	Rifaximin	Lactulose+rifaximin	6.88 [3.50–203.90]

Introduction: For many patients the first presentation with cirrhosis is a non-elective admission with decompensation. In the UK, approximately only one-third survive. Prognostic scores including markers of liver synthetic function and complications of liver disease already exist (MELD, MELD sodium and Child Pugh score). The aim of this study was to develop a statistical model to identify those most at risk of death within 3 months of their first diagnosis, using both liver and more general metrics, that are recorded routinely in primary care in the UK population.
Aims and Methods: The data source used for this study was the Clinical Practice Research Datalink (CPRD) with corresponding Hospital Episode Statistics (HES). Data included demographics, diagnoses, symptoms, investigations, referrals and prescriptions, and routine hospital inpatient data. Incident cases of patients with cirrhosis were identified between 1998 and 2014. Cases were ≥18 years at diagnosis. Explanatory co-variates were included in a logistic regression model: age, gender, BMI, blood pressure, sodium, albumin, alcohol status and various measures of prior clinical morbidity to predict mortality within 3 months of diagnosis. Markers of coagulation were not included as they are not routinely measured in general practice. The model was validated using a confusion matrix and a receiver operator characteristic (ROC) curve.
Results: Of 17,012 subjects, 32% of patients died within 3 months of first diagnosis of ESLD. The most influential variable was ascites (aHR = 2.56 (2.34–2.81)) followed by a history of end stage renal disease (aHR = 1.81(1.65–1.98)). Patients with sodium < 125mmol/L had an aHR of 1.49 (1.02–2.18), albumin < 34 g/l had an increased aHR of 1.46 (1.32–1.62) and those with variceal bleeds had an increased aHR of 1.42 (1.11–1.81). The model had 64% accuracy and the ROC curve indicated that the model was correctly predicting mortality.
Conclusion: It was possible to create and validate a reliable model to characterise those people who are most likely to die within the first 3-months following incident diagnosis of cirrhosis, using parameters commonly recorded in routine clinical practice.

Introduction: The objective of this study was to develop a time-dependent, statistical model to identify key factors that relate to mortality as cirrhosis progresses. MELD and MELD sodium are reliable measures of mortality risk derived from patients in the US. This study set out to see if the same key factors predict outcome in a population of patients with cirrhosis in the UK. The model considered a number of directly and indirectly recorded test results, and morbid effects whilst adjusting for damage to various organs.

Aims and Methods: The data source used for this study was the Clinical Practice Research Datalink (CPRD) with corresponding Hospital Episode Statistics (HES). Data included demographics, diagnoses, symptoms, investigations, prescriptions and routine hospital inpatient data. Incident cases of patients with cirrhosis were identified between 1998 and 2014. Cases were ≥18 years at diagnosis. Explanatory co-variates were included in a time-dependent Cox regression model including; age, gender, body mass index, systolic blood pressure, estimated glomerular filtration rate, sodium, albumin, bilirubin, units of alcohol consumed per week, cumulative number of liver admissions, cumulative number of infection admissions and presence of renal complications. All variables were included in the model as categorical variables in order to include all patients.

Results: The Cox regression model gave adjusted hazard ratios (aHR) for all variables included. The variable that had the greatest value in predicting death was sodium values less than 125mmol/L with aHR of 3.2 (95% CI; 2.5–4.2). Patients that were admitted for a renal complication had an increased aHR of 2.6 (95% CI; 2.1–3.3) and those with albumin >34 g/L had an increased aHR of 2.4 (2.18–2.67). Those with bilirubin >50 umol/L had an increased aHR to 1.74 (1.51–2.01) and those with an eGFR of 15–30 ml/min had an increased aHR of 1.64 (1.32–2.05). The model was validated using receiver operator curves (ROC) at 2, 3, 5 and 10 years following diagnosis of cirrhosis.

Conclusion: It was possible to build a reliable statistical model to forecast the likelihood of all-cause mortality in cirrhotic patients confirming the significance of hyponatraemia and renal dysfunction in the prognosis of patients with cirrhosis.

Introduction: The role of rifaximin in the prevention of spontaneous bacterial peritonitis (SBP) is not well studied.

Aims and Methods: The aim of this meta-analysis was to evaluate the role of rifaximin in the prevention of SBP.

A computerized literature search for relevant clinical trials was conducted during August 2017. Data on Frequency of SBP, the success rate of prevention of SBP, mortality rate, hepatorenal syndrome, septic shock, hepatic encephalopathy, and GIT bleeding were extracted and pooled as risk ratio (RR) with their 95% confidence interval (CI) in a meta-analysis model. Heterogeneity was assessed by Chi-square test.

Results: 6 studies involving 973 patients were included in the final analysis. The pooled effect estimate showed that the rifaximin plus norfloxacin group had less incidence of SBP (RR 0.58, 95% CI [0.37, 0.92], p = 0.02) and hepatic encephalopathy (RR 0.38, 95% CI [0.17, 0.84], p = 0.02) than the norfloxacin-based regimen group. No significant difference between rifaximin and norfloxacin in terms of frequency of SBP and success rate of primary prevention of SBP (RR 0.49, 95% CI [0.24, 1.01], p = 0.05; RR1.21, 95% CI [0.95, 1.55], p = 0.13, respectively).

Conclusion: Based on our analysis, Rifaximin is a promising drug and appears to be a good alternative to norfloxacin in prevention of SBP.

P0036 EFFECTS OF FOOD AND CALCIUM CARBONATE ON PHARMACOKINETICS OF LUSUTROMBOPAG, A NOVEL THROMBOPOIETIN RECEPTOR AGONIST

T. Katsube, T. Wajima, T. Fukuhara, T. Kano
Shionogi & Co., Ltd, Osaka, Japan

Contact E-Mail Address: takayuki.katsube@shionogi.co.jp

Introduction: Thrombocytopenia (TCP) is a common complication in chronic liver disease (CLD) patients, and hence TCP patients with CLD may benefit from access to approved pharmacotherapeutic options that will help raise platelet counts prior to undergoing planned invasive procedures. Lusutrombopag (LUSU) is a small-molecule orally active thrombopoietin receptor agonist discovered by Shionogi & Co., Ltd., and currently approved for use in Japan in this patient population. The aim of these studies was to assess the effects of food and calcium carbonate on the pharmacokinetics (PK) of LUSU in healthy subjects because a potential of drug-food interactions will affect the PK profiles and may inadvertently reduce or increase the drug effect. Not having a consistent treatment effect in raising platelet counts, CLD TCP patients may experience a delay or avoidance of a necessary invasive procedure.

Aims and Methods: 3 single-dose, open-label, and crossover studies were conducted. In Study 1, 18 healthy subjects were administered LUSU 2 mg as a 2-mg tablet in the fasted or fed state or the solution in the fasted state. In Study 2, 15 healthy subjects were administered LUSU 0.75 mg as 3 0.25-mg tablets in the fasted or fed state, or the fasted state with co-administration of calcium carbonate 4000 mg. In Study 3, 15 healthy subjects were administered LUSU 4 mg as a 4-mg tablet in the fasted or fed state. The PK parameters were estimated from plasma concentrations of LUSU in each treatment and compared between the treatments.

Results: Mean (90% confidence intervals) ratios of maximum plasma concentration and area under the plasma concentration-time curve were: for fed versus fasted, 0.90 (0.86–0.95) and 0.92 (0.89–0.96) in Study 1, 0.97 (0.86–1.09) and 1.02 (0.94–1.11) in Study 2, and 0.92 (0.84–1.00) and 0.91 (0.86–0.96) in Study 3, respectively; for calcium versus fasted, 1.08 (0.96–1.21) and 0.99 (0.91–1.07) in Study 2, respectively. No clinically significant effect of food or calcium carbonate on the bioavailability of LUSU was demonstrated. Each treatment was well tolerated.

Conclusion: No specific restrictions are required for LUSU administration with regard to meals (including those with dairy products), mineral supplements, or co-administration of antacids.

Disclosure: This study was supported by Shionogi & Co., Ltd. The authors, Takayuki Katsube, Toshihiro Wajima, Takahiro Fukuhara, and Takeshi Kano, are all employees of Shionogi & Co., Ltd.

P0037 INFECTIONS IN THE CIRRHOTIC PATIENTS AND THE IMPACT OF PROTON PUMP INHIBITORS

Introduction: Liver cirrhosis (LC) is associated with a state of immunosuppression resulting in elevated risk of infection. Infections in the cirrhotic patient are one of the main causes of decompensation of the disease associating with high morbidity and mortality. Recent studies suggest that the use of proton pump inhibitors (PPI) increases this risk.

Aims and Methods: To characterize infections and agents isolated in patients with LC, to evaluate the impact of PPI therapy on the risk of infection and the impact of infection in the mortality rate.

Retrospective study of cirrhotic patients admitted for more than 48h in a tertiary center between 2014–2015. Group 1- with infection; group 2- without infection. Patients with hepatocellular carcinoma were excluded. We compared both groups for the outcomes: impact of Infection in transplant-free survival and impact of PPI on the risk of infection.

Results: 202 patients were included and 290 hospitalizations were analyzed. 77.7% were male with mean age of 60.3 ± 11.8 years. Infection was present in 187/290 hospitalizations (64.5%) (group 1). In both groups the most frequent etiologies of LC were: alcoholic (group 1- 51.6%, group 2- 61.8%) and HCV infection (group 1- 16.7%, group 2- 13.2%). At admission, group 1 presented higher severity of disease decompensation (group 1- Child-Pugh score B-48.4% and C-42.1% vs. group 2- Child-Pugh score B-53.4% and C- 24.3%[U1]). The most prevalent infections were: urinary tract (n = 90/187, 48.1%), pneumonia (n = 58/187, 31.0%) and spontaneous bacterial peritonitis (SBP) (n = 48/187, 25.7%). Sepsis was present in 32.1% (n = 60/187). Gram-negative agents were the most prevalent microorganisms in urinary infection (50%) and SBP (18.8%). PPI therapy was associated with higher prevalence of infection (75% vs. 65.6%, p = 0.016). We found no significant correlation between PPI and mortality rate (56.8% vs. 43.2%, p = 0.362). We found a trend for higher infection rate in patients under SBP prophylaxis (77.8%, n = 49/63 vs. 69%, n = 138/200, p = 0.205), including multiresistant strains (26.5% vs. 22.1%, p = 0.558).

Group 1 showed a trend to higher mortality rate (59.1% vs. 40%, p = 0.130). Mortality was also correlated with sepsis, bilirubin value, MELD-Na^{+} score and ECOG score (p = 0.05).
[U1]
Conclusion: Cirrhotic patients present a high rate of infections and this group present higher mortality rate. Our results suggest that PPI therapy is in fact, associated with higher risk of infection, which should lead us to be more strict in the indications of PPI's in these patients.
Disclosure: Nothing to disclose

P0038 ABCPS: A NEW SCORE PREDICTING IN-HOSPITAL MORTALITY IN CIRRHOTIC PATIENTS

C. Arieira[1,2,3], T. Cúrdia Gonçalves[1,2,3], F. Dias de Castro[1,2,3], J. Magalhães[1,2,3], C. Marinho[1,2,3], J. Cotter[1,2,3]

Contact E-Mail Address: catia_arieira@hotmail.com
Introduction: Cirrhotic patients have high rates of hospital readmissions and mortality. Recently, a new score - ABCPS - has emerged and allows predicting in-hospital mortality in cirrhotic patients. To date, there are no cut-off values defined for this score.
Aims and Methods: The aim of the study was to evaluate the power of ABCPS in predicting in-hospital mortality and to define cut-off values for this score.
Retrospective study, including patients hospitalized for decompensated cirrhosis within 9 years. The ABCPS Score was calculated using the formula: 0.04 + 0.03 x albumin + 0.05 + 0.02 x Creatinin + 0.04 + 0.04 x Bilirubin + 0.05 + 0.28 x Potassium + 0.04 x 0.07 x Sodium.
Results: 362 patients included, 271 (74.9%) males with mean age of 57.4 ± 11.7 years. The majority of patients (85.9%) had alcoholic cirrhosis.
Ascites was present in 80.4% patients, hepatic encephalopathy in 39.8%, acute kidney injury in 31.8%, variceal bleeding in 12.4%, spontaneous bacterial peritonitis in 28.7%, other infections in 3% and hepato-renal syndrome in 3.6%.
The mean hospitalization time was 11.7 ± 10.5 days. In-hospital mortality was found in 85 patients (23.5%). The mean value of ABCPS was 2.17 ± 1.88.
The area under ROC curve (AUC) that predicts mortality for ABCPS score was 0.645 and the cut-off predictor for mortality was > 2.16 with sensitivity of 53% and specificity of 77%.
Patients with ABCPS > 2.16 presented higher mortality (39.1% vs. 16.2%, p < 0.001).
Conclusion: The ABCPS score is a tool to be used in the evaluation of cirrhotic hospitalized patients for its ability to predict in-hospital mortality. This study also allowed to determine cut-off values for this score.

P0039 VALIDATION OF EXPANDED BAVENO VI CRITERIA FOR PREDICTING ESOPHAGEAL VARICES

M. Sousa, S. Fernandes, A.P. Silva, S. Leite, J. Rodrigues, J.C. Silva, A.C. Ribeiro Gomes, J. Carvalho
Centro Hospitalar de Vila Nova de Gaia e Espinho, Vila Nova de Gaia, Portugal

Contact E-Mail Address: mafalda_m_p_sousa@hotmail.com
Introduction: According to Baveno VI, patients with chronic liver disease with platelets > 150,000 uL and liver stiffness measured by elastography < 20kPa can avoid upper endoscopy. These criteria were widely validated presenting high specificity but low sensitivity. Recently, Augustin S et al proposed expanded Baveno criteria (platelets > 110,000 uL and liver stiffness < 25).
Aims and Methods: Retrospective study of patients with chronic liver disease submitted to elastography between January 2013 and December 2015. Small varices with red wale marks or large varices were considered as high risk varices. The aim this study was to validate Baveno's expanded criteria in our center.
Results: A total of 104 patients were included; mean age 57 years, 69% male. The etiology of chronic liver disease was hepatitis C in 80%, alcohol in 12%, hepatitis B in 4% and other causes in 5%. The prevalence of varices was 25%.
Baveno's expanded criteria had a sensitivity of 92% and a specificity of 74% for the prediction of esophageal varices (100% and 62% Baveno's classical criteria). If we considered only high-risk varices the sensitivity of expanded criteria was 100% and sensitivity was 65% (100% and 50% classic criteria).
Conclusion: The expanded Baveno's criteria present similar sensibility as classic criteria but with higher specificity. In clinical practice, it continues to correctly identify patients with varices but decreases the number of potential screening endoscopies.
Disclosure: Nothing to disclose

P0040 RESISTANCE PATTERNS IN HOSPITAL-ACQUIRED URINARY TRACT INFECTIONS IN PATIENTS WITH LIVER CIRRHOSIS: SINGLE-CENTER EXPERIENCE

Introduction: Decompensated cirrhosis patients are inherently immunocompromised and highly susceptible to bacterial infections due to translocation of gut flora and altered defense mechanisms. Healthcare-associated infections with multi-drug resistant (MDR) bacterial uropathogens in patients with cirrhosis have increased significantly over the last decades.
Aims and Methods: The aim of our study was to investigate rates of antimicrobial resistance among cirrhotic patients with hospital-acquired (HA) urinary tract infection (UTI) and to determine factors that significantly impact outcome associated with MDR infection.
Retrospective single-center surveillance analysis of microbiological isolates obtained from decompensated cirrhosis patients with HA UTI, defined as event on-set > 48 hours after admission, with pyuria and monomicrobial growth ≥ 105 CFU/ml on urine culture. Microbial susceptibility testing was performed using the Kirby-Bauer disk diffusion method. Isolated pathogens were classified as MDR if resistant to ≥ 1 drug from ≥ 3 groups of antibiotics. *In vitro* resistance to empiric therapy defined therapy failure. Independent predictors for MDR UTIs were identified with multivariate logistic regression.
Results: A total of 65 patients were included in the analysis. The mean age was 60.8 ± 11.3 years (range 39–84 years), 48 (73.8%) were males. All patients had decompensated liver disease, 21 (32.3%) CP class B, and 44 (67.7%) CP class C, with a mean MELD score of 21.88 ± 6.07, and a mean CLIF-C AD score of 88.34 ± 10.26. Ascites was seen in 55 (84.6%) patients, and 32 (49.9%) had hepatic encephalopathy either at admission or during hospitalization. 15 patients (23%) had a diagnosis of DM. 33 patients (50.8%) were catheterized. *Enterococcus* spp was the most common pathogen (52.3%), followed by *Klebsiella* spp (14.4%) and *Escherichia coli* (9.2%). 35 (53.8%) isolates were MDR. *Enterococcus* spp were more commonly non-MDR (n = 22, 64.7%, p = 0.003); Enterobacteriacae were mainly MDR strains (n = 18, 81.1%, p = 0.001). VRE was isolated on 7 occasions (20.6%), and 16 of the Enterobacteriacae isolates (72.7%) were ESBL-E. The overall resistance rates to ceftriaxone, ciprofloxacin, imipenem and meropenem were 93.1%, 80.0%, 47.2%, and 45.4%, respectively. Resistance to amikacin and gentamcin were 33.3% and 48.6%. Resistance to vancomycin and nitrofurantoin were 23.2% and 60.0%. Therapy failure was more frequent in patients with MDR UTIs (p = 0.039). In regression analysis, age > 65 years (OR 6.328, 95% CI 1.662–24.097, p = 0.007), cephalosporin prophylaxis (3.611, 1.815–17.239, p = 0.042) and hepatic encephalopathy (4.986, 1.437–17.304, p = 0.011), were independent predictors for MDR UTI.
Conclusion: Increase in antimicrobial resistance to commonly used antibiotics for treatment of bacterial infections in patients with cirrhosis contributes to high mortality and morbidity associated with these infections. It emphasizes the significance of early recognition and proper management of these infections by choosing appropriate antibiotic in order to reduce morbidity and mortality.

Introduction: Chemokines are major mediators of leukocyte trafficking into the sites of the immune response. Chemokine-induced signaling is mediated by a group of G protein-coupled receptors, They participate in defense against

microbial infection. Several functional polymorphisms of chemokine and chemokine receptor genes have been described that are able to deregulate chemokine system and, therefore, in HCV infection it was assumed that these polymorphisms may be associated with persistence or clearance of the virus.
Aims and Methods: This study was performed to investigate the association of single nucleotide polymorphisms (SNPs) of chemokines and chemokine receptor with the susceptibility to HCV infection in Egyptian families.
Methods: A total of 3014 subjects comprising 845 Egyptian families were recruited from The Upper and Lower Egypt governorates and were classified into 3 groups: 1460 patients with chronic HCV (CHC), 108 subjects with spontaneous virus clearance (SC), and 1446 subjects taken as a healthy control group. All subjects were genotyped for rs13900 C/T SNP of CCL2 gene, rs3817655 T/A SNP of CCL5 gene, and (rs743660 G/A, rs1799864 G/A) SNPs of CCR2gene using allelic discrimination real time PCR (RT-PCR) technique.
Results: The carriage of the allele A of CCR2 rs743660 and the allele A of CCR2 rs1799864 were significantly higher in the CHC (OR = 4.03 and OR = 1.97, respectively, $p < 0.0001$) when compared with both SC (OR = 4.03 and OR = 1.97, respectively, $p < 0.0001$) and control groups (OR = 1.42 and OR = 2.13, respectively, $p < 0.0001$) while the carriage of allele C of CCL2 rs13900 and the allele T of CCL5 rs3817655 were significantly higher in SC group when compared with both CHC (OR = 0.19 and OR = 0.24, respectively, $p < 0.0001$) and control group (OR = 0.65 and OR = 0.45 $p < 0.0001$ respectively)
Conclusion: Susceptibility to HCV infection is associated with A alleles of both(rs743660 and rs1799864 G/A) of CCR2 gene while SC of HCV is associated with C allele of rs13900 of CCL2 gene, and T allele of rs3817655 of CCL5 gene in the Egyptian families.
Disclosure: Nothing to disclose

Introduction: Globally, there are 50 million infections per year from the dengue virus (DV) spread over 100 countries. With the documented dispersion of dengue fever, physicians from temperate climates such as Europe are finding more often travellers with this infectious disease that frequently affects the liver, sometimes with major impact. Indeed, DV has been implicated as an important cause of acute liver failure (ALF) in endemic countries. In addition, the secondary dengue mosquito, *Aedes albopictus*, has established in the Mediterranean region and the primary, *Aedes aegypti*, is on the verge of invading the southernmost parts of Europe.
Aims and Methods: We aimed to characterize the DV-induced hepatic alterations and the associated eventual mimickers of chronic liver disease.
Retrospective study in a southern-European hospital to identify all patients with a positive IgM antibody for DV in the last 6 years, using the laboratory data at the time of admission or first evaluation. In addition, diagnosis was further confirmed through positive DNA and/or a highly suggestive clinical picture and epidemiological context.
Results: Out of 2138 anti-DV IgM requests, we identified 1282 individuals with a positive result, including 279 under an age of 18 years old. Of the 1003 adults, 61.6% were female and the mean age was 45.2 years ± 16.7. Laboratory results revealed median adult haemoglobin levels of 13.9 g/dL ± 1.37, haematocrit 41.4% ± 4.05, leukocytes 4400/μL ± 2160, lymphocytes 31.5% ± 12.54, AST 112 U/L (13–1033), ALT 107 U/L (8–1220), total bilirubin 0.63 mg/dL (0.14–5.68), GGT 112 U/L (9–957), ALP 78 U/L (23–469), albumin 39 g/dL (20–51), urea mg/dL 26.9 ± 12.02, creatinine mg/dL 0.95 ± 0.22 and prothrombin time (PT) 14.9 seconds ± 4.02 (for an upper limit of normal (ULN) of 12.5 s). 62% of adult patients had AST > ALT while 68.7% had thrombocytopenia and only 4.1% of the tested patients had hyperbilirubinemia. A higher PT on admission was associated with a lower platelet count (mean = $133x10^3$/μL; $p = 0.003$) while a low albumin was significantly associated with higher age ($p = 0.019$), lower haemoglobin (0.001), ALP ($p = 0.023$) and sodium ($p = 0.027$).
Conclusion: Dengue virus hepatitis should be considered in any patient with fever within 14 days after any trip to tropics or subtropics, taking into account that the virus frequently induces thrombocytopenia in addition to elevation of transaminases that may be very significant, prolongation of PT/INR and rarely hyperbilirubinemia.
Dengue should also be considered in the differential diagnosis of acute liver failure and as an acute component of chronic liver disease, in the appropriate setting.

P0043 THE RELATION OF QUANTITATIVE INDICATORS OF PLASMACYTOID DENDRITIC CELLS IN THE BACKGROUND OF APPLICATION OF VARIOUS TREATMENT REGIMENS IN PATIENTS WITH CHC

O.N. Khokhlova[1], L.V. Serebrovskaya[1], V.V. Makashova[2], L.A. Ivanova[1], A.R. Reizis[2]

[2]*Central Research Institute of Epidemiology, Federal Supervision Servise, Moscow, Russian Federation*

Contact E-Mail Address: x.olia79@mail.ru

Introduction: The special role of plasmocytoid dendritic cells (pDCs) in the immunopathogenesis of CHC puts them in the first place, not only as the main producers of IFN, but also as direct participants in the interaction between innate and acquired immune responses. Therapeutic regimens using direct-acting antiviral agents (DAAs) have revolutionized the treatment of CHC patients, but long-term interaction of the immune system with the hepatitis C virus forms a close immunological relationship in the adaptation process, which leads to a change in the functioning both at the cellular and systemic levels. Changing the cellular response against the background of the therapy can dramatically affect the work of the immune system as a whole.
Aims and Methods: We examined 45 patients taking different regimens of CHC therapy. 27 of them received standard therapy and 18 people received DAAs. The amount of pDCs was determined by flow cytometry using monoclonal antibodies CD123 and CD 303.
Results: Quantitative indicators of pDCs have been reduced in all patients with CHC and vary depending on the type of CHC therapy. In patients treated with IFN, the absolute number of pDCs is 2 times lower (abs.−3.5) in comparison with the group receiving DAAs (abs.−6.2; $p = 0.007$). In the application of DAAs reduction of the absolute number of pDCs noted only on 4th week, whereas at the end of therapy (12 weeks - DAAs and 48 weeks - IFN) quantitative indicators pDCs did not differ (IFN: %−0.18, abs.−5.1; ADF: %−0.17, abs.−8.3; $p > 0.05$). According to catamnesis (patients examined after 12 months after the end of treatment CHC) pool pDCs after the use of drugs IFN was restored and did not differ from the indicators in healthy individuals (IFN: %−0.18, abs.−8.4; healthy: %−0.27, abs.−10.25; $p > 0.05$). The number of pDCs in DAAs as at the end of therapy, and in the history (%−0.18, abs.−9.5; $p > 0.05$) did not differ from those of healthy people.
Conclusion: pDCs values vary and depend on the type of therapy being performed. The use of DAAs leads to rapid eradication of the HC virus antigen from the body, which affects the dynamics of the pDCs pool and can lead to delayed changes in the immune system. Further observation and detailed study of this issue are needed.

Introduction: Patients with thalassemia are at risk for infections such as Hepatitis C Virus (HCV) due to their repeated blood transfusions; meanwhile, the treatment of thalassemia patients who develop HCV infection is a controversial issue.
Aims and Methods: Although the effectiveness of Direct-Acting Antivirals (DAAs) on HCV infection has been confirmed, their side-effects as well as effects on hematological factors due to the resultant need for blood transfusion remain to be further understood.
This study examined 61 patients with major beta thalassemia and HCV infection who had a history of interferon treatment failure. The patients underwent a 24-week treatment with Sofosbuvir (SOF) and Daclatasvir (DAC). To assess the response to treatment, SVR12 was used. At the end of the study, the need for blood transfusion and serum ferritin were evaluated
Results: A total of 98.4% of the subjects responded to the treatment, and only one patient with genotype 1b did not respond positively. No significant complications necessitating treatment cessation were observed, and all the subjects tolerated the treatment well. The level of liver enzymes showed a significant reduction 12 weeks after the treatment. The need for blood transfusions in

patients before treatment was averagely 1.595 ± 0.65 bag per month, which received 1.593 ± 0.64 bags after treatment (p = 0.9). This regimen did not affect the amount of anemia in patients and did not differentiate the need for blood transfusions. The rate of hemoglobin before treatment was 9.5 ± 1.42 g/dl, which reached 9.6 ± 1.6 g/dl after treatment (p = 0.54). Ferritin levels decreased significantly in patients after treatment, and from 1948.08 ± 1539.54ng/ml to 1315.73 ± 1207.67ng/ml (p = 0.001).

Conclusion: The combination of Sofosbuvir and Daclatasvir is an effective and tolerable treatment regimen without affect the amount of anemia in patients and did not differentiate the need for blood transfusions.

Disclosure: Nothing to disclose

Introduction: Little real-world data has been reported for Asians who have received interferon-free regimen with direct-acting antivirals for chronic hepatitis C.

Aims and Methods: Our large, multicenter, real-world cohort study of Japanese chronic hepatitis C patients was done to assess the effectiveness of Japan-approved direct-acting antiviral (DAA) treatment for patients who were both treatment-naïve and -experienced with or without compensated cirrhosis. This multicenter cohort consisted of 2,063 (GT1: 1,312, GT2: 751) consecutive Japanese patients who initiated a 12-week course of the following DAA treatment. Patients with under aged 20 years, decompensated cirrhosis, or co-infection with HBV/HIV were excluded: GT1: Sofosbuvir (SOF)/Ledipasvir (LDV) (n = 1,101), Ombitasvir (OBV)/Paritaprevir (PTV)/Ritonavir (r) (n = 106), Elbasvir (EBR)+Grazoprevir (GZR) (n = 223), GT2: Sofosbuvir (SOF)+Ribavirin (RBV) (n = 751). For GT1 patients, NS5A gene amino acid positions 31(L31I/F/M/V) and 93 (Y93C/F/H/N/S) were measured by direct-sequencing. These resistance associated variants (RAVs) were examined at baseline and at the time of relapse.

Results: The sustained virological response (SVR) rate of the GT1 patients who underwent SOF/LDV was 98.7%, only 14 relapsers (1.3%) were found, by intention-to-treat analysis. SVR rate of those with cirrhosis plus RAVs was 87.5%; ratio among all was just 6% (n = 53). The 14 relapsers included 5 with failure of Daclatasvir+Asunaprevir. The SVR rates of the GT1 patients who underwent OBT/PTV/r and EBZ+GZR were 98.1% and 99.1%, respectively, by intention-to-treat analysis. The SVR rate of the GT2 patients who underwent SOF+RBV was 96.4%, 27 non-SVR patients (3.6%) were found, by intention-to-treat analysis. SVR rate of those with cirrhosis plus treatment-experience was 86.0%; ratio among all was just 6.7% (n = 50).

Conclusion: Japan-approved DAA treatment for both HCV GT 1 and GT2 was exceptionally effective. However, NS5A RAVs undermined the virological effect for cirrhosis GT1 patients, and RBV-experience did the effect for cirrhosis GT2 patients.

P0046 RISK OF RECURRENT HEPATOCELLULAR CARCINOMA AFTER HEPATITIS C VIRUS ELIMINATION FOLLOWING DIRECT-ACTING ANTI-VIRAL TREATMENT

Introduction: Direct-acting antiviral agents (DAAs) have improved the treatment response for chronic hepatitis C virus (HCV) infection. Several predictive factors of de novo hepatocellular carcinoma (HCC) after sustained virological response (SVR) have been reported, including liver cirrhosis and serum alpha-fetoprotein (AFP) level.

Aims and Methods: The aim of this study was to evaluate the risk of recurrent HCC among patients with prior HCC who achieved SVR by DAAs. This retrospective multicenter study consisted of 759 consecutive patients who achieved SVR by treatment with interferon-free DAA regimens (Daclatasvir/Asunaprevir, Ombitasvir/Paritaprevir/ritonavir, Sofosbuvir/Ledipasvir, Elbasvir/Grazoprevir, Sofosbuvir/Ribavirin). Of these, 75 patients had prior HCC. The Kaplan-Meier method and Cox proportional hazard analysis were used to estimate the cumulative HCC incidence and predictive factors of developing HCC.

Results: The 1-, 2-, 3-year cumulative rates of HCC were 9.8%, 30.6%, 70.8% for the patients with prior HCC, while 1.1%, 2.9%, 7.4% for those without prior HCC (log-rank test: p < 0.001). Among the 75 patients with prior HCC who achieved SVR by DAAs, the median age was 73 years and 36 (48%) had cirrhosis. Median duration from the first HCC diagnosis to the initiation of antiviral therapy was 28.4 months and 29 (38.7%) had received HCC treatments two or more times. During the follow-up period (median: 23 months), 30 of 75 (40%) patients with prior HCC developed recurrent HCC. Univariate analysis showed that higher serum AFP level at the end of treatment (EOT-AFP), lower platelet count, longer duration from the first HCC and HCC treatments 2 or more times were associated with recurrent HCC. Multivariate analysis extracted only EOT-AFP as independent predictor of recurrent HCC (hazard ratio 1.02, 95% confidence interval 1.01–1.04, p < 0.001). In contrast, liver cirrhosis, sex, age and metabolic features were not associated with recurrent HCC. The 1, 2, 3-year cumulative rates of recurrent HCC were 23.7%, 50.8%, 75.4% for the patients with EOT-AFP 5.9ng/mL or more and 6.7%, 15.2%, 50.1% for those with EOT-AFP less than 5.9ng/mL, respectively (log-rank test: p = 0.012). The 1, 2, 3-year cumulative rates of recurrent HCC were 18.0%, 37.2%, 77.1% for cirrhosis patients and 5.3%, 24.6%, 62.9% for non-cirrhosis patients, respectively (log-rank test: p = 0.20).

Conclusion: For the patients with prior HCC, the risk of recurrent HCC after HCV elimination was very high. Serum EOT-AFP was significant predictor of HCC recurrence. However, even in the patients with low EOT-AFP or those without cirrhosis, the rate of recurrent HCC was still high. Duration and number of treatment from the first HCC may influence the rate of recurrent HCC. The patients with prior HCC should be considered for careful ongoing HCC surveillance.

Introduction: Chronic HCV infection in patients with extrahepatic cancer results in mutual ill effects with respect to natural history and successful treatment of both the diseases. Availability of DAA make it possible to treat patient concomitantly for both HCV infection and cancer.

Aims and Methods: To assess the outcome of HCV treatment with DAA in patients with extrahepatic cancers either on treatment or completed treatment. A retrospective audit of Chronic HCV patients referred to Hepatology clinic in a leading cancer centre in India for the period of April 2015-December 2017 was done. Data were collected regarding demography, cancer site, cancer treatment, prior anti HCV treatment, current anti HCV treatment, adverse events, possible events of drug-drug interaction, status of underlying liver function and treatment response for anti HCV therapy. Treatment of HCV was prescribed in accordance with current AASLD/EASL guidelines and that of cancer as per NCCN/ESMO guidelines. Patient with Haemoglobin less than 10 gm/dl, Ribavirin (RBV) was avoided.

Results: Out of total 48 patients assessed 7 patients could not be followed up, 2 died during treatment and in 1 patient anti HCV treatment stopped before completion due to cancer progression. 38 patients were included in the analysis. 6 (16 %) patients were cirrhotic (Child Pugh A, n = 5; Child Pugh B-8, n = 1). 1 patient

Abstract No: P0047

Parameters	**n = 38**
Age in years (Mean ± SD)	45.53(± 14.23)
Male/ Female	17(45%)/21(55%)
Genotype 1/3/4	10(26%)/27(72%)/1(2%)
Mean Baseline RNA (IU/ml)	> 500000 IU/ml
Concurrent cancer	Hematolymphoid, n = 10 (ALL, n = 4; Chronic myeloproliferative disease, n = 1; Plasma cell leukemia, n = 1; Plasmacytoma, n = 1; Non-Hodgkin's lymphoma, n = 2; Multiple myeloma, n = 1). Breast, n = 5. Genitourinary, n = 9 (Cervix cancer, n = 5; Ovarian cancer, n = 2; Uterine cancer, n = 1; Urinary bladder, n = 1). Gastrointestinal, n = 7 (Stomach adenocarcinoma, n = 4; Stomach GIST, n = 1; Colon cancer, n = 2). Head and neck region, n = 3 (Buccal mucosa squamous cell cancer, n = 2; Thyroid cancer, n = 1). Musculo-skeletal, n = 4 (Osteosarcoma, n = 1; Fibromatosis, n = 1; Rhabdomyosarcoma, n = 1; Paediatric neuro-ectodermal tumour, n = 1)
Comorbid conditions	Diabetes, n = 2; Hypertension, n = 2; Ischemic heart disease, n = 1
Anti HCV therapy	Sofosbuvir+Daclatasvir, n = 15 (39%); Sofosbuvir+Ledipasvir, n = 10 (26%); Sofosbuvir+Daclatasvir+Ribavirin, n = 3 (8%); Sofosbuvir+Velpatasvir, n = 4 (10%); Sofosbuvir+Ribavirin, n = 6 (15%)
Concurrent chemotherapy (n = 14)	CAPOX, n = 1; Paclitaxel-Carboplatin, n = 1; Paclitaxel, n = 2; Imatinib, n = 3; R-CHOP, n = 2; FOLFIRI, n = 1; Cyclophosphamide-Adriyamycin, n = 1; Gemcitabine-Carboplatin, n = 1; VCD,n = 2
Adverse events requiring drug modification of HCV therapy	Anaemia, n = 4 (44% among those receiving RBV, Overall 10%)
Adverse events not requiring drug modification of HCV therapy or cancer therapy	Dyspepsia, nausea or vomiting, n = 6 (15%); Constitutional, n = 2 (5%); Skin rash, n = 1 (2%)

was treatment experienced with PEG-IFN and RBV. Most common associated extrahepatic malignancies are hematolymphoid, gynaecological and gastrointestinal. 7 patients had HBV coinfection and all of them received concomitant anti HBV therapy and none had HBV flare. 1/3rd of patients received cancer therapy concomitantly with anti HCV therapy. The rest were under surveillance post cancer treatment. All 38 patients had achieved ETR and SVR 12. Overall adverse event rate was 34%. Most common being anaemia requiring modification of ribavirin therapy (n = 5). Other adverse events noted were skin rash, dyspepsia, nausea, occasional vomiting or constitutional symptoms, none of which required modification for either anti HCV therapy or cancer therapy. No drug -drug interaction was noted.
[Table 1]
Conclusion: Real-life data of concomitant cancer chemotherapy and DAA is scarce. This study demonstrates that SVR rate is excellent (100%) in this cohort of patients with chronic HCV infection. Concomitant cancer therapy and DAA are safe. Adverse events are not serious among most of the patients and usually does not mandates cessation of either cancer or HCV therapy. 90% of patients could tolerate full dose of RBV.

Introduction: miR-122 has the advantage of being hepato-specific. It plays a key role in HCV replication and its knockout in animal model proved to promote de novo hepatic carcinogenesis. To date miR-122 role in HCV-related HCC remains a matter of debate
Aims and Methods: The aim was to investigate the difference in expression levels of circulating miR-122 in cirrhotic HCV patients with and without hepatocellular carcinoma (HCC). We included 41 HCV-related cirrhotic patients recruited from Ain Shams University hospitals' clinics and in-patient department. Patients were divided into 2 groups: I) non-HCC group of 14 patients with different Child-Turcotte-Pugh (CTP) classes, II) HCV-related HCC group of 27 patients having different patterns of tumor aggression - classified using CT/MRI imaging features into low and high aggressive HCC patterns, defined as: a) Low aggression/ small sized focal HCC = single lesion < 2 cm or ≤ 3 nodules < 3 cm each, b) High aggression patterns either multicentric HCC (> coexisting 3 nodules) or infiltrative HCC (ill-defined large sized HCC with no focal mass formation).

Abstract No: P0048

			Plasma miR-122 level (Ct value)		p value
			Mean	**SD**	
Age:	56.68 ± 7.35				0.317
Gender	Males (n = 31)	- Females (n = 10)	31.80–29.74	5.8–5.5	0.325
Study groups	Non-HCC (n = 14)		27.99	3.9	**0.002 (t = −3.26)**
	HCC (n = 27)		33.02	5.8	
CTP class	All patients				0.074
	Non-HCC group	Class A (n = 7)	27.05	2.8	0.691
		Class B (n = 6)	29.05	5.3	
		Class C (n = 1)	28.27	–	
	HCC group	Class A (n = 10)	30.79	6.1	0.321
		Class B (n = 5)	33.83	6.7	
		Class C (n = 12)	34.53	5.06	
Imaging criteria of tumor	Small sized focal HCC (n = 7)		27.49	5.69	**0.005 (F = 6.68)**
	Multicentric HCC (n = 9)		33.63	4.5	
	Infiltrative HCC (n = 11)		36.03	4.5	
ALT					0.060
AST					0.084
AFP					0.139

RNAs were extracted from plasma using (mirVana PARIS kit). Reverse-transcription (TaqMan microRNA RT Kit) and miRNA-specific stem-loop primers (has-miR-122) done according to instructions of the manufacturer. For real-time PCR, TaqMan MicroRNA Assay probe was used. The cycle threshold (Ct value) defined as the number of cycles required for the fluorescent signal to cross the threshold in qPCR and inversely correlates with the miRNA level
Results: There were significantly lower levels of circulating miR-122 in patients with HCC compared to non-HCC patients ($p = 0.002$). However, no significant differences were found regarding different CTP classes among all patients ($p = 0.074$), or within each group: HCC ($p = 0.69$) and non-HCC groups ($p = 0.32$). Regarding tumor aggression there were significantly lower levels of miR-122 for multicentric or Infiltrative HCC as compared to small sized focal HCC ($p = 0.02$, 0.001 respectively). No significant differences were found in respect to patients' gender, and no correlation was found with age, ALT, AST, or alpha-fetoprotein (AFP).
[Table 1: summary of miR-122 levels in our study.]
Conclusion: There were significantly lower miR-122 levels in patient with HCC on top of HCV related cirrhosis than patients with no HCC regardless of liver cirrhosis status, moreover, the levels were significantly lower in high aggressive patterns of HCC as compared to low aggressive patterns.

Introduction: The optimal goal of HCV treatment is to achieve SVR 12 weeks after treatment (SVR12). However, this term was appraised with the emergence of occult C infection (OCI) by detecting HCV-RNA in peripheral blood mononuclear cells (PBMCs), and/or other compartment.
Aims and Methods: To determine the prevalence of OCI in PBMCs in patients achieved SVR after sofosbuvir/daclatasvir therapy and to determine the different predictors of OCI persistence.
A cross-sectional study enrolled all consecutive patients with SVR12 between January 2017 to August 2017 post Sofosbuvir 400mg/ Daclatasvir 60mg for 12 weeks. Patients were either treatment naive or experienced to previous Interferon/ribavirin regimen. All patients were HCV genotype 4, compensated cirrhosis.
Basic laboratory and liver stiffness score measurements were done. PBMCs were obtained using Ficoll-Hypaque density gradient of EDTA anticoagulated blood according to the manufacturer's instructions (Lymphoflot, Biotest,Dreleich, Germany). HCV-RNA was tested for isolation from PBMCs in all patients.
Results: HCV RNA was detected in PBMC in 5 (3.9%) patients out of 128, all of them are experienced to Sofosbuvir/ Daclatasvir regimen, with advanced fibrosis score F3/F4 3/2 and have raised ALT at pre-treatment tests. Logistic regression analysis comparing OCI with Non OCI revealed Pre-treatment prolonged prothrombin time, low albumin level and advanced fibrosis are the most significant predictor of presence of OCI.
Conclusion: Occult hepatitis C infection post DAAs therapy is not uncommon finding and should be raised in patients with high fibrosis score and/or with non-normalized ALT post-treatment.
Disclosure: Nothing to disclose

P0050 DIRECTLY ACTING ANTIVIRALS ARE SAFE, EFFECTIVE AND NOT ASSOCIATED WITH TUMOR RECURRENCE IN HCV PATIENTS WITH NON-HEPATIC CANCER

L. Lamonaca[1], V. Boccaccio[2], A. Lleo De Nalda[1], R. Ceriani[2], L. Rimassa[3], N. Personeni[3], M. Colombo[2], S. Bruno[1], A. Aghemo[1]

Introduction: Patients with chronic HCV infection can be cured of their disease with 8–12 weeks of DAA therapy. However, in patients with a history of hepatocellular carcinoma (HCC) there are concerns regarding an increased risk of HCC recurrence after sustained virological response (SVR) to DAA therapy. Although the reasons are still unclear, an altered immune control of pre-existing neoplasia deriving from the rapid clearance of the virus has been hypothesized. Little is known about the recurrence rate of non-hepatic tumors in HCV patients who received DAA.
Aims and Methods: Our aim was to evaluate the recurrence rate of non-hepatic neoplasia in consecutive HCV patients treated with DAA.
We included all consecutive HCV patients treated with DAA from February 2015 to January 2017 with solid non-hepatic tumor diagnosed in the 5 years before the start of antiviral therapy. For breast cancers no time limit was fixed. Patients with hematological malignancies were excluded. All tumors had achieved complete control before starting DAA treatment.
Results: 313 HCV patients were treated with DAA and 20 (6.4%) had a positive anamnesis for solid non-hepatic tumor. 6 patients had a history of breast cancer, 4 gastrointestinal tumors, 2 non-melanoma skin cancer, 5 uro-genital cancers, 1 spinocellular carcinoma of the oral cavity, 1 pituitary and 1 lung tumor. Median time from cancer diagnosis to DAA was 3.7 years and patients were followed-up for a median of 22.38 months after DAA therapy. No patient underwent DAA treatment concomitantly with chemotherapy. Median age at DAA therapy was 67.66 years and 45% were men. 65% were genotype 1, 15% genotype 2, 10% genotype 3 and 10% genotype 4. 70% had evidence of cirrhosis, well compensated in everyone (CPT score A). An SVR was achieved in 19 patients (95%), and no serious adverse events were reported. During a median of 22.38 months after DAA therapy no patient included in the study had cancer recurrence.
Conclusion: HCV treatment in patients with solid non-hepatic tumors is safe and effective. Although findings are preliminary, an SVR to DAA therapy was not associated with any case of tumor recurrence.

Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

Contact E-Mail Address: gulturkilkay@gmail.com
Introduction: The success rate of anti-viral treatments of hepatitis C infection now approaches 100%. Therefore, it is important to conduct community screenings and raise awareness. Pre-operative hepatitis serology is routinely considered in most countries of the World.
Aims and Methods: We aimed to detect the prevelance of anti-HCV and HCV-RNA positivity rate in patients undergoing pre-operative HCV screening and also the awareness rate of having chronic hepatitis C infection in these patients. Patients who had pre-operative anti-HCV testing in surgical clinics of our hospital were screened from 2013 to 2017. All patients who were positive were questioned for HCV-RNA positivity and whether they were treated for hepatitis C. Hospital records were screened for HCV-RNA results. Treatments reports were reached through the integred database system of social security with our hospital. HCV-RNA untested patients were called by phone and asked whether they were aware of being anti-HCV positive.
Results: During 5 years, 21897 patients were screened for hepatitis C. A total of 125 patients (0.57 %) were found to be positive (58M, 67F, mean age 59.1 ± 15.7) HCV-RNA was tested in 76 of these patients, 22 were HCV- RNA negative(29%), 24 were positive and treatment-naive, 19 were positive and treatment experienced. From 125 patients with Anti-HCV positivity, 49 patients had no HCV-RNA assay (39%), we called them by phone and noticed that just 5 (10 %) patients knew that he/she was anti-HCV positive.
Conclusion: Anti-HCV positivity was detected in approximately 0.6% of 21897 patients who were operated in surgical departments of a tertiary medical center. Approximately 40% were not tested for HCV - RNA and most of these patients were not aware of being Anti-HCV positivity. Testing hepatitis C serology before surgery seems that do not contribute to catch new patients. Surgeons need to be more aware towards chronic hepatitis C infection.

Introduction: The IBD are frequently associated to the extra intestinal manifestation: dermatologic, ophthalmic, hepato-biliary. We observed a high prevalence of hepato-biliary manifestation in IBD (up to 50%) and one of the most serious complication is PSC. We also noted various pathogenesis of these hepato-biliary abnormality; the common pathogenesis of IBD, direct or indirect complication of IBD.
Aims and Methods: The aim of our study is, first of all, to assess the frequency of hepato-biliary manifestation on the IBD, and secondly to study clinical, advancement characteristics of IBD and liver disease occurrency. In our study, we have removed the abnormal transient liver test and the drug which caused hepatitis. This retrospective study concerned the population with IBD of the occurrence's liver disease during period: 2000 - 2013. Initially, all the patients get a clinical, biological and morphological investigation, and also a clinical, biological and endoscopic during active colitis. All the patients with permanent abnormal liver test got a complementary and etiologic investigation.

Results: We observed 686 patients with IBD; 459 Crohn's disease and 227 ulcerative colitis with a mean age of 42,5 years (24 years - 61 years). During the follow up, we noted 3.2% liver disease, among them: 13 cases of Crohn's disease (8 male - 5 female), 9 cases of ulcerative colitis (6 male- 3 female). 18 cases of liver disease was reveal by abnormal liver test, 3 cases by portal hypertension, and one by jaundnice. All the investigation were determinated :14 PSC, 3 steatosis, 1 peliosis, 1 overlap syndrome (HAI + PSC). Clinical and morphological characteristic study revealed that hepato-biliary manifestation are more common for male patient and also in ileo-colonic, pan-colitis forms. The IBD is the most of the time chronically active with growing period for more than 5 years.
Conclusion: The hepato-biliary manifestation are rare, they are generally revealed by abnormal liver test which occurred the most often on long lasting and extensive IBD and PSC represented the most frequent etiology.

Introduction: In patients with primary biliary cholangitis (PBC), bilirubin (BILI) is a recognized marker of disease progression and a strong predictor of survival. Recently, the Global PBC Study Group reported the risk with elevated BILI extends into the normal range with a cutoff of 0.67x ULN identifying patients at risk. Obeticholic acid (OCA) is indicated for treatment of PBC in patients with an inadequate response or intolerability to ursodeoxycholic acid.
Aims and Methods: The aim of this retrospective analysis was to evaluate the effect of OCA on BILI in this patient subpopulation. OCA has been evaluated in patients with PBC in 1 12-month Phase 3 double-blind (DB) placebo (PBO)-controlled trial (POISE) and 2 3-month Phase 2 PBO-controlled trials (201 and 202). Patients were eligible to continue treatment in open-label extensions (OLE) with all patients receiving OCA. Patients from the Phase 2 and 3 studies with baseline (BL) total BILI (TBILI) ≥0.67x ULN were evaluated for change in TBILI over 12 months in the following manner: 1) DB comparison of OCA vs. PBO at 12 months in POISE and 2) DB+OLE OCA use totaling 1 year of treatment (POISE randomized to PBO, evaluated at 12 months OLE; Phase 2 randomized to OCA for 3 months, evaluated at 9 months OLE; and Phase 2 randomized to PBO, evaluated at 12 months OLE).
Results: The analysis included patients with TBILI ≥0.67x ULN at their OCA BL: POISE, n = 51; 201, n = 7; and 202, n = 7. In patients with BL TBILI ≥0.67x ULN, TBILI increased after 12 months of PBO treatment, and decreased after 12 months of OCA (Table 1). In the DB phase of POISE, of the 7 PBO-treated and 9 OCA-treated patients with abnormal TBILI at BL, 14% of PBO-treated and 78% of OCA-treated patients attained normal TBILI levels after 12 months. Further, of 10 PBO-treated and 20 OCA-treated patients with normal TBILI at BL, 60% of PBO-treated and 15% of OCA-treated patients worsened to abnormal TBILI after 12 months.
Conclusion: Patients treated with OCA had a trend toward reduction of TBILI compared with those treated with PBO. These data suggest that OCA may reduce progression of patients with more advanced liver disease.
[Table 1. Mean (SD) Change From BL in TBILI (μmol/L) in Patients with BL TBILI ≥0.67x ULN]

12 Month Treatment	PBO	OCA				
Phase	DB			OLE		
Study	POISE			201	202	POISE
Dose (mg)	–	5 to 10	10	10 or 50	10, 25, or 50	5 to 10
n	17	15	14	7	7	17
Mean (SD) change from BL to TBILI	2.6 (6.5)	−3.3 (3.6)	−4.0 (7.8)	−8.1 (6.4)	−10.1 (8.1)	−1.6 (7.9)

OCA BL is defined as: - OCA-randomized patients: if time from last visit in DB to first visit in OLE ≤30 days, mean of evaluations prior to first DB dose is used; if ≥30 days, last assessment prior to first dose in OLE is used; the initial OLE visit is included as a BL evaluation. -PBO-randomized patients: last assessment prior to first dose in OLE is used; initial OLE visit is included as baseline evaluation.

Disclosure: This study was funded by Intercept Pharmaceuticals, Inc.

P0054 DEVIATIONS IN PERIPHERAL BLOOD SUBPOPULATIONS ARE CONNECTED WITH THE PRESENCE OF PRURITUS IN PRIMARY BILIARY CHOLANGITIS PATIENTS

A. Michalak[1], H. Cichoż-Lach[1], A. Kowalik[1], E. Grywalska[2], J. Roliński[2], B. Kasztelan-Szczerbińska[1]

Introduction: Primary biliary cholangitis (PBC) constitutes an autoimmune liver disease characterized by progressive destruction of small- and medium-sized intrahepatic bile ducts. The role of particular peripheral blood (PB) subpopulations in the course of PBC remains still uncertain. Bile acids, endogenous opioids, autotaxin and lysophosphatidic acid (a potent itch neuron activator) seem to have a key role in the pathogenesis of cholestatic pruritus in PBC patients. However, there is a growing body of evidence that PB subsets are of great importance in pathological appearance of this liver disease.
Aims and Methods: The aim of our study was to assess the relationships between analyzed peripheral blood cell subsets and the presence of pruritus in patients with newly diagnosed PBC. The frequencies of PB subpopulations were measured by flow cytometry in 34 previously untreated female patients with PBC. 19 participants from research group presented pruritus. The control group consisted of 20 healthy age- and sex-matched volunteers. The diagnosis of PBC was based on the commonly known criteria. The severity of pruritus was assessed according to Visual Analogue Scale (VAS) questionnaire and the mean result was 4.1/10 points. The degree of severity of PBC was evaluated by histologic stages of PBC. This parameter was described in all patients and they were divided into 4 groups, according to histologic stages of PBC (I - portal stage - 7 patients, II - periportal stage - 16 patients, III - septal stage - 9 patients and IV - cirrhotic stage - 2 patients). Before the initiation of treatment of PBC, lymphocyte subsets, values of PB cell count parameters, and immunoglobulin serum levels were measured.
Results: PBC patients complaining of pruritus had significantly lower percentages of CD3+/CD16+CD56+ NKT-like cells ($p = 0.04$) and CD3+ T lymphocytes ($p = 0.03$) than PBC patients without pruritus. Additionally, PBC patients with itch presented significantly lower absolute counts of CD4+/CD3+ cells ($p = 0.01$) and CD3+CD25+ cells ($p = 0.03$) in comparison to PBC patients without itch. Percentages of CD3+/CD16+CD56+ NKT-like cells and absolute counts of CD3+CD25+ cells were significantly higher in PBC patients compared to controls ($p < 0.01$). There were no significant differences in percentages of CD3+ T lymphocytes and absolute counts of CD4+/CD3+ cells between research and control group.
Conclusion: The results obtained in our survey suggest that deviations in PB subsets might be involved in the pathogenesis of cholestatic pruritus in PBC patients and this issue should be undoubtedly clarified in further studies.

P0055 A NOVEL UK REGIONAL REAL-WORLD REGISTRY FOR PRIMARY BILIARY CHOLANGITIS (PBC) ALLOWING DATA LINKAGE FROM PRIMARY AND SECONDARY CARE

M. Pericleous[1,2], C. Kelly[1,2], S. de Lusignan[2], A. Ala[1,2]

Introduction: PBC is a model autoimmune liver disease affecting approximately 35/100,000 population. Data for PBC and rare diseases appears scarce, fragmented. Coordinated efforts are required to bring various datasets together to provide integrated care for patients. A real-world registry linking primary and secondary care for PBC does not exist.
Aims and Methods: Following ethical approval, a regional observational feasibility study was set up collecting data from 3 regional hospitals and 10 primary care providers (General Practice surgeries) in the region of Surrey South East England, UK which has a population 1.1 million. From primary care, data was collected using READ codes and 725 data points were collected for each patient. In secondary care, data was collected from multiple sources including histology, fibroscan, immunology, biochemistry, virology, endoscopy, patient workflow systems, patient notes/letters, radiology and hospital coding departments. A total of 286 data points were collected for each patient. The datasets from primary and secondary care were linked for each patient using a unique patient identifier (NHS number) which was hashed using a pseudonymisation algorithm.
Results: A total of 375 patients with confirmed PBC were identified in primary and secondary care giving a regional PBC prevalence of 34.1/100,000 population. All patients from primary care were successfully linked to secondary care providing a holistic overview of the patients' journey and the disease's natural history.

Conclusion: Our novel method of establishing a rare disease registry for PBC is able to link datasets from various sources which are otherwise found in disjointed silos. Our registry is collecting more data points than existing PBC registries and does not rely on manual data entry from time-stretched clinicians and nurses which can affect data quality and lead to errors. This robust methodology has enabled us to generate real-world data on a large number of PBC patients and better understand the natural history and regional impact of this rare condition. Moreover, it will inform the development of regional frameworks for integrated care which are currently lacking for PBC and for rare liver diseases. This work will complement the efforts of larger consortia including UK-PBC and GlobalPBC.

Introduction: At present, many studies are still controversial for the response of acute presentation-AIH (A-AIH) after immunosuppressive treatment. Some studies reported that acute presentation-AIH had a worse response than chronic AIH (C-AIH) due to its more severe liver injury
Aims and Methods: Our study analyzed the effectiveness of standard treatment (corticosteroids alone or combined with azathioprine) between A-AIH and C-AIH. First, we collected patients prospectively according to the International Autoimmune Hepatitis Group (IAIHG) revised score and the experience of hepatologists. Patients who had a probable diagnosis (IAIHG score $\geq$10) of AIH were included in our study. And all of these patients were treated with standard treatment. Patients who were concurrent with other liver diseases or used other immunosuppressive agents were excluded. Then, all the patients were divided into the A-AIH group and the C-AIH group. Patients in A-AIH group needed to meet at least 1 of the following conditions: (1) total bilirubin $\geq$ 5mg/dL; (2) alanine aminotransferase $\geq$ x 10 upper limits of normal (ULN), or (3) aspartate transaminase $\geq$ x 10 ULN. Finally, the complete biochemical remission rate, time of reaching complete biochemical remission and mortality of the 2 groups were retrospectively analyzed.
Results: 88 patients were included in our study, of which 48 patients were in the A-AIH group and 40 patients in the C-AIH group. The follow-up period was 0.3–33.1 months. There was no statistical difference in the rates of complete biochemical remission between A-AIH group and C-AIH group (50%, 55%, $p = 0.640$). The median time of reaching complete biochemical remission was 3.2 (1.3, 9.2) months in A-AIH group, while that in the C-AIH group was 2.4 (1.3, 4.6) months, and there was still no significant difference ($p = 0.474$). During the follow-up, 9 patients were dead owe to hepatic decompensation, of which 5 (10.4%) patients were A-AIH and 4 (10%) patients were C-AIH ($p = 1.000$).
Conclusion: Although the serum bilirubin and aminotransferase were obviously increased in A-AIH patients, the response after standard treatment of A-AIH may not be significantly different from that of C-AIH. Moreover, the different level of serum biochemical indicators may not be the most important factor influenced prognosis for neither A-AIH or C-AIH.

P0057 URSODEOXYCHOLIC ACID FOR THE TREATMENT OF PRIMARY BILIARY CIRRHOSIS/CHOLANGITIS AND PRIMARY SCLEROSING CHOLANGITIS: ARE OUR PATIENTS UNDERDOSED?

Y. Abbey, M. Olsen, M. Farrant, A.V. Gunasekera
Ashford and St Peter's Hospitals NHS Foundation Trust, Gastroenterology, Chertsey, United Kingdom

Contact E-Mail Address: yvonneabbey@doctors.org.uk
Introduction: Ursodeoxycholic Acid (UDCA) is used to treat the cholestatic liver diseases primary biliary cirrhosis/cholangitis (PBC) and primary sclerosing cholangitis (PSC). Current guidance states an optimum dose of UDCA is 13–15mg/kg in PBC, with the same dose used but not specifically recommended in PSC. A survey undertaken by the PBC Foundation in 2013 implied a third of patients were underdosed. Optimal dosing of UDCA leads to improved biochemical reposes in both PBC and PSC patients, and delayed disease progression and reduced transplant rates in PBC.
Aims and Methods: The objective of this study was to assess whether locally, our patients are optimally dosed on UDCA (using the upper end 15mg/kg) and whether this has had any impact on their biochemical response to treatment.
A database of outpatient correspondence was searched for the terms "primary biliary cirrhosis", "primary biliary cholangitis" and "primary sclerosing cholangitis". 85 patients were identified with a confirmed diagnosis of PBC or PSC (antibody positive or biopsy proven). 7 patients were excluded from the study as they had not yet been commenced on UDCA, leaving 78 treated patients (59 PBC, 19 PSC). Using the most recently documented weight around time of diagnosis/commencement of treatment, optimum doses of 15mg/kg were calculated for each patient and compared to the actual dose prescribed. Biochemical response was assessed using the Barcelona Criteria - either greater than 40% reduction in alkaline phosphatase (ALP) or normal after 1 year of UDCA treatment.
Results: Of the 78 patients, 33 (42%) were found to be at least optimally dosed at 15mg/kg, with 45 patients (58%) underdosed on UDCA. In the optimally dosed group, 19 patients (58%) showed biochemical response, and 9 patients (27%) had a worsening of their ALP (1 identified as non-compliant). The remaining 5 patients (15%) had a normal ALP at the time of commencing, which remained normal to date.
In the suboptimally dosed group, 20 patients (44%) showed biochemical response, with 16 patients (36%) having a worsening in their ALP and 9 patients (20%) having had a normal ALP at diagnosis which again remained normal to date. 71% of patients with PBC responded to UDCA compared to 53% of those with PSC.
Conclusion: This study shows that a higher proportion of our local patient group diagnosed with PBC or PSC are underdosed with UDCA than optimally dosed. We have demonstrated in this group that UDCA appears effective in improving biochemical response to treatment or at least maintaining a normal ALP, when used at the optimum dose, supporting a drive towards ensuring patients are prescribed 15mg/kg of UDCA. Interestingly there was still a partial response to treatment despite underdosage, and all patients who had normal baseline ALP maintained this regardless of UDCA dose. This may generally imply efficacy of UDCA in the treatment of PBC and PSC. Looking at potential reasons for underdosing, it was identified in some cases that patients' weight had changed (mainly increased) but not led to a subsequent adjustment of UDCA dose, raising the importance of regularly reviewing the dose (especially if there has been no adequate biochemical response), as well as reviewing compliance. Lastly the results suggested a better response to UDCA overall in PBC compared to PSC, correlating with current literature. It would be useful to perform this analysis again following dose adjustment for the suboptimal group, and reviewing the dose for our optimally dosed but non-responsive group, in the hope that a positive effect is seen leading to an improvement in their overall outcome.

P0058 DIAGNOSIS OF TYPICAL FOCAL NODULAR HYPERPLASIA IN THE LIVER - USE OF A NOVEL ULTRASONIC VASCULAR DOPPLER TECHNIQUE

M. Sawatzki[1], D. Semela[2], J. Neuweiler[2], B. Stephan[2]

Introduction: Examination of vascular structures and flow dynamics is important in order to differentiate benign from malignant focal liver lesions (FLL). Diagnostic ultrasound in combination with contrast-enhanced ultrasound (CEUS) has a high accuracy and diagnostic value for FLL (1,2). CEUS ideally allows the visualization of the very specific spoke wheel pattern in the arterial phase and is standard of reference (SOR) in the diagnosis of FNH smaller 3 cm (3). Conventional colour Doppler has limitations in visualizing microvasculature and low velocity blood flow. Superb Micro-Vascular Imaging (SMI) is a novel ultrasound Doppler technique with high resolution imaging, minimal motion artefacts and high frame rates. SMI has not been studied in FNH lesions, which have a unique vascular supply that is diagnostic in most cases. Diagnosis of this benign FLL is important to avoid unnecessary biopsies and surgical procedures. In contrast to hepatocellular adenoma, the management of FNH is conservative because there is no risk of malignant transformation, no risk of bleeding and no need to stop contraception (4,5).
Aims and Methods: The diagnostic value of the novel SMI technique for diagnosing FNH lesions in comparison to CEUS was studied. SMI offers a unique algorithm allowing visualization of microvasculature with low velocity flow without the need of a contrast agent. SMI analyzes clutter motion and uses a new adaptive algorithm to identify and remove tissue motion and reveal true blood flow. CEUS was performed as standard of reference by using 1.5 ml intravenously injected contrast agent (sulphur hexafluoride microbubbles) and was performed according to international guidelines (1). Representative still images and video clips were recorded.
Results: We present a case series of 5 female patients between 25 and 55 years with FNH. CEUS revealed in almost all cases FNH with typical early centrifugal arterial spoke-wheel enhancement without washout up to 5 minutes after injection of the contrast agent. We could demonstrate the excellent visualization of

the spoke wheel-like vessels by SMI (without contrast agent and independently to time response). SOR was resection/histology (n = 2), MRI (n = 1) and follow-up 12–18 months (n = 2).

Conclusion: FNH is the second most common benign liver tumor after hemangioma. FNH is diagnosed by CEUS, CT or MRI using intravenous contrast agents. This is the first european experience demonstrating the excellent clinical value of SMI to diagnose typical FNH with spoke-wheel-like vessels. SMI is an easy to use, intuitive imaging tool without the need of contrast agent that offers a detailed visualization of small, low-velocity vessels within FNH lesions. In the presented cases, SMI was able to provide the same diagnostic imaging criteria for FNH as CEUS in the arterial phase. In contrast to SMI, CEUS and especially CT and MRI require early arterial contrast enhancement, which may be missed due to a short detection period of sometimes only a few seconds.

Introduction: Noninvasive methods have been used for the assessment of hepatic steatosis in patients with nonalcoholic fatty liver disease (NAFLD). Magnetic resonance derived measures, such as proton density fat fraction (PDFF) and fat fraction (FF), and transient elastography based controlled attenuation parameter (CAP) of liver fat and volume are emerging as non-invasive, accurate imaging biomarkers.

Aims and Methods: We performed this systematic review and meta-analysis to compare the efficacies and accuracies between magnetic resonance technique and transient elastography for evaluation of hepatic steatosis in NAFLD patients. PubMed, the Cochrane Library, Embase and Web of science were searched to gather studies, relating to accuracies of MR technique or TE for evaluating grading of steatosis (S0-S3) diagnosed by liver biopsy. We compared the sensitivity, specificity, positive likelihood ratio, negative likelihood ratio and hierarchical summary receiver operating characteristic (HSROC) curves of these 2 methods for grading of steatosis. The clinical utilities of MR technique and TE were also evaluated.

Results: 19 articles with a total of 1558 NAFLD subjects were included. As for diagnostic accuracy of MR based PDFF, the summary sensitivities and specificities values were 0.92 (95% CI, 0.88–0.95) and 0.93 (95% CI, 0.88–0.97) for ≥ S1, 0.76 (95% CI, 0.71–0.80) and 0.88 (95% CI, 0.84–0.91) for ≥ S2, and 0.73 (95% CI, 0.68–0.78) and 0.89 (95% CI, 0.86–0.92) for ≥ S3. The HSROCs were 0.96 for ≥ S1, 0.91 for ≥ S2, and 0.89 for ≥ S3. Following a positive measurement (over the threshold value) for ≥ S1, ≥ S2, and ≥ S3, the corresponding post-test probabilities for the presence of steatosis (pretest probability was 50%) were 93%, 87% and 87%, respectively; if the values were below these thresholds (negative results), the post-test probabilities were 14%, 7%, and 7%, respectively. The diagnostic accuracy of MR based fat fraction(FF) for stage ≥ S1, the summary sensitivity was 0.92 (95% CI, 0.87–0.95), and the specificity was 0.82 (95% CI, 0.76–0.87). Besides, the HSROC is 0.9260. For diagnostic accuracy of TE-CAP detecting stage ≥ S1, ≥ S2, ≥ S3, the summary sensitivity was 0.79 (95% CI, 0.67–0.89), 0.80 (95% CI, 0.75–0.84), 0.81 (95% CI, 0.78–0.84), and the specificity was 0.83 (95% CI, 0.80–0.96), 0.74 (95% CI, 0.70–0.78), 0.66 (95% CI, 0.59–0.73), respectively. Following a positive measurement (over the threshold value) for ≥ S1, ≥ S2, and ≥ S3, the corresponding post-test probabilities for the presence of steatosis (pretest probability was 50%) were 86%, 76% and 71%, respectively; if the values were below these thresholds (negative results), the post-test probabilities were 16%, 18%, and 18%, respectively.

Conclusion: MR technique and TE both provide standardized non-invasive approaches for staging hepatic steatosis in NAFLD patients. Compared with TE based CAP, MRI derived PDFF is significantly more accurate for evaluating dichotomized grades of steatosis, especially in those obese patients, which probably offer the best diagnostic performance and may be used instead of invasive liver biopsies.

Introduction: Portal hypertension is the main cause of bleeding from ruptured esophageal and gastric varices that may lead to death. Timely and accurate diagnosis of portal hypertension is of primary importance on the choice of treatment strategies and on the judgment of prognosis. Hepatic venous pressure gradient (HVPG) has been accepted as the gold standard for evaluating portal pressure [1]. But this method is limited in clinical applications because of its invasiveness, expensiveness, high requirements for equipment and techniques, and difficulty in follow-up. To explore and verify noninvasive methods in diagnosing portal hypertension becomes a hot issue in medical research. Real-time shear wave elastography (SWE) is a newly developed technique used to evaluate tissue elasticity. Previous studies suggested that SWE has excellent performance in the diagnosis of liver fibrosis and cirrhosis in chronic hepatitis B ([2]). Moreover, SWE may be more reliable in patients with ascites than noninvasive methods. Based on previous study results, the objective of this project is to further explore the diagnostic accuracy of SWE and its derived models in assessment of portal hypertension, aiming to provide new ideas and alternatives for clinical noninvasive evaluation of portal hypertension.

Aims and Methods: To assess the diagnostic accuracy of liver and spleen stiffness by shear wave elastography (SWE) and its derived models in assessment of predicting clinically significant portal hypertension (CSPH) and severe portal hypertension (SPH).

Clinical data of 135 cirrhotic patients who underwent assessment of portal pressure and endoscopic examination before starting prophylactic treatment were consecutively collected. Liver stiffness measurement (LSM) and spleen stiffness measurement (SSM) was measured with SWE by repeated performance 5 times per patient and the average values of stiffness were collected. The correlation between LSM, SSM and hepatic venous pressure gradient (HVPG) were assessed. The diagnostic accuracy of LSM, SSM and composite scores as the liver stiffness-spleen diameter to platelet ratio score (LSPS) and the portal hypertension (PH) risk score were evaluated, and also compared with other noninvasive parameters including the aspartate-to-platelet ratio index (APRI) and the platelet count/spleen diameter ratio. CSPH and SPH were defined as a HVPG ≥ 10 mmHg and ≥12 mmHg.

Results: A total of 104 patients were eligible for analysis. CSPH and SPH were detected in 84 patients (80.7%) and 74 patients (71.2%) respectively. LSM and SSM were significantly corrected with HVPG in overall, CSPH and SPH patients ($r1 = 0.627$, 0.554 and 0.412; $r2 = 0.665$, 0.565 and 0.476, respectively; all $p < 0.001$). The AUROC of LSM, SSM and LSPS and the PH risk score was 0.72 (95% Cl, 0.49–0.95), 0.78 (95% Cl, 0.51–0.93), 0.76 (95% Cl, 0.51–0.96), and 0.73 (95% Cl, 0.55–0.88) for CSPH and 0.77 (95% Cl, 0.51–0.97), 0.79 (95% Cl, 0.55–0.94), 0.81 (95% Cl, 0.58–0.98), and 0.80 (95% Cl, 0.59–0.93) for SPH, respectively. The diagnostic performance was significantly better than that of other noninvasive parameters. The cut-off values of LSM for determining CSPH and SPH were 16.1 kPa (Sensitivity, 81%; Specificity, 80%) and 23.5 Kpa (Sensitivity, 83%; Specificity, 81%), respectively. The cut-off values of SSM for determining CSPH and SPH were 25.3 kPa (Sensitivity, 83%; Specificity, 79%) and 33.4 Kpa (Sensitivity, 82%; Specificity, 80%), respectively.

Conclusion: In cirrhotic patients with hepatic B virus, LSM and SSM and composite scores by SWE is a reliable non-invasive diagnosis tool to predict CSPH and SPH.

Introduction: Many complications can occur during Transjugular Intrahepatic Portosystemic Shunt (TIPS) implantation procedure. However, the most relevant clinical complication is hepatic encephalopthy (HE).
Aims and Methods: The aim of this study was to assess TIPS indications, sucess rates and related complications. The secondary goal was to identify predictive factors of HE after TIPS.
We present a restrospective unicenter cohort study from October 2007 to January 2018 including patients undergoing TIPS procedure on a Portuguese referral center. Portal pressure gradients before and after TIPS were only recorded from January 2015.
Results: 180 patients were included (76.1% male; mean age 55.03 ± 10.99 years (21–79 years)). Portal pressure gradients were recorded in 61 patients.
Primary liver disease was alcoholic in 59.44%, alcoholic/viral in 15%, viral in 11.1% and due to other causes in 10.56%. The indications for TIPS were: refractory ascitis (52.78%), recurrent upper gastrointestinal bleeding (17.78%), acute upper gastrointestinal bleeding (11.1%), hepatic hydrothorax (0.56%) and Budd-Chiari syndrome (0.56%). 17.22% of the patients had more than 1 indication for TIPS procedure.
Technical success rate was 91.67% (n = 165). Hemodynamic success rate (since January 2015) was 82.86% in patients with refractory ascitis and 100% in patients with upper gastrointestinal bleeding.
3.33% had immediate TIPS-related complications: hemoperitoneum (1.11%); haemorrhagic shock (0.56%); porto-biliary fistula (0.56%); cervical haematoma (0.56%) and anestesia complications (0.56%).
After TIPS, 49.44% (n = 89) patients with refractory ascitis had improved and 5.56% (n = 10) patients had a rebleending episode. HE after TIPS was seen in 44.4% (n = 80) of the patients (26.7% newly installed, 13.3% maintained and 4.4% worsened). It was found that patients with HE "de novo" or worsened were older (58.2 vs. 53.6, p = 0.09).
Higher severity scores (MELD and Child-Turcotte-Pugh) and non-sclerosis hemostasis were not associated with a higher occurrence of HE (p > 0.05). However, a portal pressure gradient ≤5mmHg demonstrated a higher risk of HE (10/16 Vs 13/45, p = 0.017).
Conclusion: The success rates were over 80%. HE was a frequent complication. Older age and portal pressure gradient≤5mmHg were associated with a higher risk of HE after TIPS.

Introduction: Several studies showed that VTQ (Virtual Touch Quantification) provides additional information regarding FLLs stiffness and it is useful when differentiating between malignant and benign FLLs.
Aims and Methods: We aimed toevaluate inter-observer reproducibility of a point shear wave elastography- pSWE [using Acoustic Radiation Force Impulse Quantification (ARFI)]: VTQ (Siemens) for the evaluation of focal liver lesions stiffness.
We performed a prospective study including 44 patients diagnosed with focal liver lesions (FLLs) after an ultrasound examination admitted to the Department of Gastroenterology of SCJUT between January 2017-December 2017: 23 men (52.3%) and 21 women (47.7%), mean age 65.3 ± 11.1 years. A total of 48 FLLs were examined.
Elastographic measurements (EM) were obtained in 48 FLLs using VTQ (Siemens). 2 examiners with different levels of experience in ultrasound-based elastography, performed EM using VTQ on each subject: 10 measurements in the liver parenchyma and 10 measurements in each focal liver lesion. Medians and interquartile ranges (IQRs) were calculated (m/s). We used the interclass correlation coefficient (ICC) with 95%b lower and upper limits of agreement (LOA) to assess the inter-observer reproducibility of VTQ.
Results: A total of 48 lesions were evaluated. The lesions were: 32/48 (72.7%) hepatocellular carcinomas, 7/48 (14.5%) hemangiomas, and 9/48 (18.7%) metastases. The total mean values obtained were: 1.62 m/s in HCCs, 2 m/s in hemangiomas and 2.62 m/s in metastases. The agreement between the novice and the experienced examiner was excellent: 0.950 (95% CI: 0.91–0.972).
Conclusion: The excellent ICCs for the median values show that ARFI technique with VTQ for evaluating FLL stiffness is a reproducible method and could provide significant complementary information regarding the tissue stiffness, useful for the differential diagnosis of focal solid liver lesions.
Disclosure: Nothing to disclose

Introduction: Sarcopenia may affect patients with liver cirrhosis. It is associated with a poorer quality of life and higher morbidity and mortality.
Aims and Methods: We aimed to evaluate the value of ultrasound measured psoas major (PM) and rectus abdominis (RA) thickness in predicting survival of patients with liver cirrhosis**.** 61 patients were included in a prospective study in a 16-month period and followed-up for at least 6 months. Sarcopenia was assessed using surrogate parameters - handgrip strength (HGS), mid-arm muscle circumference (MAMC) and SGA (subjective global assessment) score.
Results: There were 40 men, with a mean age of 58.03 ± 10.8 years. 26.22% of patients were Child-Pugh A, 45.9% B and 27.86% C. Patients were followed-up for 11.9 ± 5.63 months.
Mean RA (mRA) was 8.73 ± 2.57mm. RA thickness moderately correlated with MAMC (r = 0. 596, p < 0.0001) and HGS (r = 0.515, p < 0.0001) and decreased with increasing SGA class (A 10.6 ± 2.8mm, B 8.3 ± 1.9mm, C 6.5 ± 1.9mm, p < 0.0001).
Survival at 6 months was independently predicted by MELD-Na score (OR 1.305, p = 0.005). Survival during follow-up was independently predicted by mRA (HR 0.701, p = 0.011, AUROC 0.732) and ascites (HR 1.876, p = 0.026, AUROC 0.732). A cut-off of mRA less than 6.75mm had 50% sensitivity and 93% specificity to predict mortality in patients with liver cirrhosis.
Conclusion: As a surrogate marker of sarcopenia, ultrasound measured rectus abdominis muscle may predict survival in patients with liver cirrhosis.

Introduction: Prevalence of type II diabetes has significantly increased in the last decade.
Type II diabetes and nonalcoholic fatty liver disease (NAFLD) are frequently associated.
Aims and Methods: The aim of the present study was to assess the severity of liver fibrosis and steatosis in a cohort of type II diabetic patients, using non-invasive methods: Transient Elastography (TE) and Controlled Attenuation Parameter (CAP) before and after the CAP adjustment algorithm was applied. The study included 576 type II diabetic patients, who were prospectively randomized. All were evaluated by means of TE and CAP (FibroScan EchoSens). A cut-off value of 10.5 kPa [1] was used to define clinically relevant fibrosis (F≥3). We used the following cut-off values [2]: for S2 (moderate steatosis) - 255 dB/m, and 290 dB/m for S3 (severe steatosis) - We corrected the CAP values according to the presence of diabetes (we deducted 10 dB/m) and according to the degree of obesity (we deducted 4.4 dB/m for each BMI > 25 kg/m^2 and added 4.4 dB/m for each BMI < 25 kg/m^2) [1, 3].
Results: Out of 576 diabetics screened, we excluded those with associated viral hepatitis, those with an AUDIT-C score ≥8 and those with unreliable LSM. The final analysis included 403 subjects (59.3% women, BMI = 31.6 ± 6 kg/m^2) with reliable LSM obtained using both probes. Moderate and severe steatosis by means of CAP was found in 18.9% and 61.5% cases respectively. After correction, we found moderate steatosis in 22.1% cases and severe steatosis in 52.6%

cases. We found no significant differences regarding the proportion of patients with moderate steatosis after the algorithm was applied (18.9 vs. 22.1%, $p = 0.26$), but we found significant differences regarding the proportion of severe steatosis, (61.5% vs. 52.6%, $p = 0.01$). Clinically relevant fibrosis was detected by means of TE in 13.6% (55/403) of subjects.
Conclusion: In type 2 diabetes patients it is necessary to use an algorithm for correction in order to avoid overestimation of the degree of steatosis and fibrosis.
Disclosure: Nothing to disclose

Introduction: The microvascular invasion (MVI) in hepatocellular carcinoma (HCC) patients is a poor prognostic factor for survival after liver transplantation and/or resection. Any correlation between MVI and segmental location of HCC has yet to be studied.
Aims and Methods: Our aim is to evaluate the location of HCC and its correlation with the presence of microvascular invasion, recurrence of HCC and portal vein thrombosis (PVT) in explanted liver. Another objective of the study is to assess the treatment history (ablation or transarterial chemoembolization (TACE)) and size of the tumor with respect to the risk of MVI.
This is a single-center, retrospective chart review, including 98 patients with the age of 18 years and older who had liver transplantation in our institute between 2012 and 2017. We reviewed the radiological images of the HCC, the pathological findings of the explanted liver and the follow up imaging after transplantations.
Results: 98 patients with the diagnosis of HCC underwent liver transplantation between 2012 and 2017. The mean age of the cohort was 63 ± 8.2. Males represented 75% of the cohort and 25% were females. Caucasian race was representing 75% of the cohort. The average MELD score was 13.5+/- 6.5. The most common etiology of cirrhosis was chronic hepatitis C virus infection followed by alcohol abuse and non-alcoholic steatohepatitis (NASH) with percentages of 50%, 23% and 10% respectively. Microvascular invasion was found in 16% of the patients while recurrence of HCC and PVT was found in 6% and 17% of the cohort respectively.
MVI was found in 10 single HCC and 6 multifocal HCC. Right sided HCC had more MVI when compared to the left and multilobar HCC with percentages of 11%, 2%, 3% respectively.
Localization of HCC in segment 8 was associated with the highest percentage of MVI when compared to all other segments. The risk of MVI in segment 8 was 3.5 times higher than the risk of the other segments ($p = 0.002$) while no vascular invasion was found in segments 1, 3 and 5. The risk of vascular invasion in the untreated HCC is 3 times the risk in treated HCC ($p = 0.03$).
[Table 1]

HCC	Microvascular invasion	Odd ratio	P-value
Single	10	1.5	0.3
Multifocal	6	0.6	0.3
Size > 2 cm	10	0.4	0.6
Segment 4	1	1.3	0.6
Segment 6	2	2	0.19
Segment 8	6	3.5	0.002
Segment 2	1	1.3	0.7
Treated	6	0.3	0.03
Untreated	10	3.0	0.03

Conclusion: Our data indicate that the risk of microvascular invasion is higher in segment 8 HCC and in the untreated HCC. The size and the number of the HCC were not associated with an increased risk of microvascular invasion.

Introduction: Hepatocellular carcinoma is a common health burden in cirrhotic patients with HCV infection. New direct-acting antivirals substantially improved the cure rate to above 90%. However, cancer risk persists even after 10 years of viral cure. Several risk-predictive host factors e.g., advanced liver fibrosis, older age, co-morbid metabolic diseases such as diabetes, persisting hepatic inflammation, and elevated alpha-fetoprotein were associated with HCC development. Transient Elastography is a widely available non-invasive marker of fibrosis which can be a reliable method of fibrosis assessment and risk stratification.
Aims and Methods: We aimed to evaluate Liver stiffness measurement by transient elastography as a predictor of HCC development after direct acting antiviral drugs (DAAs).
All patients with HCV related fibrosis who did FibroScanTM before treatment with DAAs were included retrospectively. Liver, renal function tests, CBC, INR, alpha-fetoprotien, abdominal ultrasonography, Triphasic CT, and FibroScanTM were performed at the National Liver Institute, Menofia University from January 2015 to December 2016. Patients who had a Transient Elastography measurement before treatment with DAAs were included and divided into 2 groups; Group (I) patients who developed de novo HCC and Group (II) are those who did not developed HCC after DAAs.
Results: Patients who developed de novo HCC after DAAs (group I, 30 patients) had higher serum AST levels (68.3 ± 38.2 vs. 48.7 ± 32.4 U/L), lower platelet count (131.5 ± 55.6 vs. $179.5 \pm 69.8 \times 10^3$ /μL) and older age (59.5 ± 6.4 vs. 51.3 ± 10.5 years) than patients who did not develop HCC (group II, 90 patients) with $p < 0.05$. Group I patients had a statistically significant higher liver stiffness measurement (LSM) by FibroscanTM (32.1 ± 10.7 vs. 15.5 ± 11.5 kPa, $p = 0.001$) than patients who did not develop HCC. With a cutoff of 18.5 kPa being the most predictive value of de novo HCC development after treatment of chronic HCV infection with DAAs (90.0% sensitivity, 80.0% specificity, 55.0% PPV, 97.3% NPV, 80.0% accuracy).
Conclusion: The measurement of liver stiffness by FibroScanTM could be a reliable method for risk stratification and prediction of de novo HCC development after DAAs in cirrhotic patients.

Introduction: HCC is a major type of primary liver cancer and one of the most frequent human malignant neoplasms. It is estimated to cause more than a quarter of a million deaths each year throughout the world. The increased prevalence of HCC is related to the prevalence of hepatitis B virus and hepatitis C virus infections. Because of the very high prevalence of HCV in the Egyptian population, it accounts for most chronic liver disease and HCC cases.
Aims and Methods: This study was conducted to verify the reliability of serum peroxiredoxin-3 (PRDX-3) as a marker for diagnosis of HCC
The study included 20 patients with liver cirrhosis (cirrhotic group) and 20 patients with liver cirrhosis and HCC (HCC group) from Menoufia University Hospitals (Egypt) and 10 healthy volunteers as a control group. They underwent physical examination and laboratory investigations (CBC, liver profile {ALT, AST, albumin, bilirubin, PT %}, blood urea, serum creatinine, AFP and serum peroxiredoxin-3 (PRDX-3)). Abdominal ultrasonography was done for all patients. HCC is further confirmed by triphasic CT.
Results: AFP level of HCC group (846.7 ± 820.2 ng/dl) was significantly higher than cirrhotic group (17.1 ± 14.1 ng/dl) and controls (4.5 ± 1.1 ng/dl) ($p = 0.0001$). Serum PRDX-3 level of HCC group (285.1 ± 127.8 ng/dl) was significantly higher than cirrhotic group (120.4 ± 72.6 ng/dl) and controls (46.9 ± 19.1 ng/dl) ($p = 0.0001$). Serum PRDX-3 in cirrhotic group was significantly higher than that of controls ($p = 0.0001$).
At a cut off value of 162 ng/ml, serum PRDX3 showed a high AUC of (0.877) with sensitivity of 84.2%, specificity of 79.8%, compared to AUC of AFP (0.721) with sensitivity of 70.1%, specificity of 60%. The combined use of PRDX3 and AFP raised the sensitivity to 90% and the specificity to 84% with diagnostic accuracy of 91.2%. There was positive correlation between PRDX3 and serum AFP level ($r = 0.88$ and $p = 0.0001$) and the focal lesion size ($r = 0.61$ and $p = 0.004$).
Conclusion: PRDX-3 is more sensitive and more specific than AFP in diagnosis of HCC. Serum PRDX-3 level could be a valuable marker for detection of HCC in patients with liver cirrhosis.

[2]*National Liver Institute, Menoufia University, Shebine Elkom, Egypt*

Contact E-Mail Address: elshaarawy.omar@stadtmission-hd.de

Introduction: ALBI score eliminates the need for the subjective variables required in the CTP grade. The addition of tumor characteristics from TNM classification resulted in ALBI-T score. ALBI grade 2 showed a wide range of patients, Ogasawara sub classification of ALBI grade 2 classifies patients more precisely.
Aims and Methods: We accrued data from the HCC clinic at National Liver Institute, Menoufia University. We had access to a data set of a cohort of 1910 patients diagnosed with HCC and fulfilled the inclusion criteria. Patients were followed up from the time of diagnosis to the date of death or date of data collection if they remained alive. Modified ALBI-T was obtained through using new grading of ALBI score (grade 1 to 4 instead of grade 1 to 3) obtained through Ogasawara sub-classification of ALBI grade 2 and using it in calculating ALBI-T score. We compared our score to other scoring systems as CTP, TNM, BCLC, ALBI, PALBI, ALBI incorporated BCLC and ALBI-T scores.
Results: For 1910 patients, the mean age was 57 years, 1575 were males. At presentation, 50.6% were CTP A, 36.1% were CTP B and 13.4 % were CTP C. Most of the patients were ALBI grade 2 (63.2%), 17.8 % were ALBI grade 2A while 45.5% were ALBI grade 2B. ALBI grade 1 & 3 were 12% & 24.7% respectively. The overall median survival was 13 months; the median survival was better in patients with ALBI grade 1 than ALBI 2 & 3 (28.6, 14 and 5.8 months respectively, $p < 0.001$). Moreover, the median survival for ALBI grade 2A patients was better than ALBI 2B (18.6 vs. 13 months respectively, $p < 0.001$). ALBI-T grades 0 & 1 patients had better median survival than those of ALBI-T grades 2, 3, 4 & 5 (42, 24.4, 17, 8.9, 5 and 3 months respectively ($p < 0.001$)). On adding the ALBI sub classification proposed by Ogasawara, the modified ALBI-T showed significant improvement in the median survival of modified ALBI-T grades 2, 3, 4, 5 and 6 to be 28.6, 20.9, 13.9, 8 and 4 months respectively. On comparing our model to CTP, TNM, ALBI, BCLC, ALBI (modified), PALBI, ALBI based BCLC and ALBI-T, it showed significantly better AUC (0.818 vs. 0.643, 0.620, 0.709, 0.713, 0.719, 0.734, 0.749 and 0.803, respectively).
Conclusion: Modified ALBI-T classifies patients with HCC more precisely than other scoring systems.
Disclosure: Nothing to disclose

Introduction: The prognosis of hepatocellular carcinoma is influenced by severity of liver disfunction. Child-Pugh (CPS) and MELD scores have considerable limitations.
Recently the prognostic value of albumin-bilirubin (ALBI) [1] grade has been evaluated in patients undergoing HCC treatment with different modalities, but not specifically in patients undergoing TACE [2]. Moreover, the pALBI grade, that includes platelet count, is a surrogate marker of portal hypertension [3].
Aims and Methods: ALBI and pALBI are proposed to be objective scores of liver function reserve which could adequately stratify patient survival.
The aim of this research is to study the role of ALBI and pALBI in predicting outcome for HCC patients who underwent transcatheter arterial chemoembolization (TACE).
We retrospectively evaluated the prognostic significance of ALBI and pALBI in patients undergoing TACE recorded in the Ita.Li.Ca. database, and compared it with other prognostic systems, including MELD, CPS, hepatoma arterial-embolization prognostic (HAP) and mHAPII.
Results: 2283 TACE performed in 1012 consecutive patients between January 2008 and December 2016 were evaluated. Patients had a median MELD of 9 and belonged to all BCLC stages; 1168 TACE were perfomed in BCLC-A, 696 in BCLC-B and 419 in BCLC-C stage. Median overall survival in the whole population was 33.9 months.
Considering all TACE procedures, irrespective of the BCLC stage, the ALBI grade and pALBI grade were significant predictors of overall survival ($p = 0.001$ and $p < 0.0001$ respectively), similar to the HAP and the mHAP scores ($p < 0.0001$). When patients in different BCLC stages were considered, ALBI was a significant predictor of OS only in BCLC-C ($p < 0.001$) patients treated with TACE, pALBI was a significant predictor of OS in BCLC-B ($p = 0.001$) and BCLC-C ($p < 0.001$) similarly to HAP and mHAPII.
Similar data were obtained when only the first TACE procedure was considered in each patient (total of 901 patients, 460 BCLC-A, 259 BCLC-B and 182 BCLC-C). Considering all BCLC stages, ALBI was a significant predictor of overall survival ($p = 0.001$) similar to the pALBI, HAP and mHAPII scores ($p = 0.003$). When different BCLC stages were considered, ALBI, pALBI and HAP were significant predictors of OS in BCLC-C ($p = 0.008$, $p = 0.003$ and 0.008 respectively), whereas mHAPII was not significant. PALBI was also a significant predictor of OS in BCLC-B ($p = 0.005$).
Conclusion: ALBI and pALBI offer additional simple and objective methods of assessing liver function in HCC and may be useful for selecting patients more likely to survive after TACE, especially ALBI in those belonging to the BCLC -C stage whereas pALBI in BCLC-B and BCLC-C stage.

Introduction: The debate on the matter of HCC recurrence risk and its aggressiveness in patients who have a history of previously and successfully treated HCC underwent DAAs treatment is still open.
Aims and Methods: The present real-life multicenter, prospective study aims to investigate the impact of new DAAs therapies in HCV patients with a previous successfully treated HCC, in terms of neoplastic recurrence. From March 2015 to March 2017, 101 consecutive HCV patients with prior HCC underwent DAAs treatment were enrolled. The assessment of neoplastic recurrence was used as primary outcome, while a secondary outcome was the evaluation of baseline characteristics predicting HCC recurrence.
Results: 83% of patients were in Child-Pugh class A, and 89% had a history of HCC BCLC stage 0/A, while 35% of patients had a prior HCC recurrence. 91% of the patients achieved SVR. The median time between the HCC 1st diagnosis and DAAs-starting was 17.2 months (range 10.1–37.2), while the median time from the last successful HCC treatment to DAAs starting was 10 months (range 5.8–16.6). 31 HCC recurrences were observed from DAAs-starting in a median observational follow-up of 24.7 months (range: 2–36.9). The cumulative rate of recurrence was 20.5/100 person-year (95% C.I. 13.9–29.0). The 6-, 12- and 24-months HCC recurrence rates from the last HCC treatment were 1%, 8.9% and 25.6%, respectively. Higher BMI (HR 1.27, 95% C.I. 1.05–1.52), lower age (HR 0.93, 95% C.I. 0.87–0.98) and DAAs treatment failure (4.17, 95% C.I. 1.23 - 14.29) were significantly associated with higher risk of HCC recurrence, both at univariate and at Cox multivariate analysis.
Conclusion: Patients without HCC recurrence are characterized by lower BMI, older age and higher SVR rate. These data suggest that the absence of well-known HCC risk factors reduces the HCC recurrence rate also in patients underwent DAAs.
Disclosure: Nothing to disclose

P0071 EVALUATION OF SERUM ENDOGLIN LEVEL AS A NEW DIAGNOSTIC BIOMARKER FOR HEPATOCELLULAR CARCINOMA

Introduction: Hepatocellular carcinoma is the most common primary malignant tumor of the liver. It occurs most commonly on top of a cirrhotic liver which in Egypt is prevalence is due to chronic HCV infection. Diagnosis of HCC at earlier stages improves patient outcomes. Currently, the most commonly used methods for screening and diagnosing HCC are ultrasound imaging and serum α-fetoprotein (AFP) concentration measurements, but the diagnostic value of AFP is recently challenged due to its low sensitivity and specificity.

Aims and Methods: The aim of the study is to evaluate the value of serum endoglin as a noninvasive biomarker in diagnosis of HCC versus serum AFP in liver cirrhosis patients.

The study was conducted upon 90 subjects who were divided into 3 groups: group I included 40 patients with liver cirrhosis and hepatocellular carcinoma, group II included 30 patients with liver cirrhosis without HCC, group III had 20 healthy subjects as controls. Group I was also divided into 2 subgroups, Group Ia represents patients with AFP less than 200ng/ml and Group Ib represents patients with AFP more than 200ng/ml. For all participants, thorough clinical examination, blood picture, liver function tests, HCV antibody, HBsAg, alpha fetoprotein (AFP), and serum endoglin were performed. Abdominal ultrasound, abdominal triphasic computed tomographic (CT) scan.

Results: In this study, the serum levels of Endoglin and alpha fetoprotein were highest in patients of group I with HCC compared to those with liver cirrhosis and the control groups with significant difference. Serum AFP and Endoglin was found to be positively correlated with number of hepatic focal lesions. However, it did not increase significantly with tumour size, vascular invasion. At a cut off value 220ng/ml, the diagnostic sensitivity and specificity of AFP for selective detection of HCC over the cirrhotic group was 67.5% and 100% respectively. At a cut off value 1125pg/ml the diagnostic sensitivity and specificity of Endoglin for selective detection of HCC over the cirrhotic group was 90% and 76.67% respectively. When combining both markers together the sensitivity increased to 100% with a specificity of 100%.

Conclusion: Serum Endoglin is a promising tumor marker that may be used with serum AFP as noninvasive technique to aid diagnosis of HCC.

Introduction: Previous reports suggested an unexpected high rate of hepatocellular carcinoma (HCC) occurrence and recurrence following antiviral treatment using direct acting antiviral (DAA).

Aims and Methods: We aim to synthesis evidence about effect of DAA on the occurrence and recurrence of HCC.

A compute literature search for PubMed, Cochrane CENTRAL, EMBASE, Web of Knowledge, and SCOPUS was carried out. We included prospective cohort studies and clinical trials that the reported the rate of occurrence or recurrence of HCC following DAA treatment in patients with HCV. Data were extracted and analyzed using Open-Meta (Analyst) software for windows. Rates were pooled as relative risk (RR) in a random-effect model using Mantel Haenzel (M-H) method.

Results: Seven prospective cohort studies were included in the present review with a total of 1438 HCV patients. The pooled HCC occurrence rate in the DAA group was 2.7% (95% CI [0.015, 0.038]). The pooled HCC recurrence rate in the DAA group was 13.6% (95% CI [0.059, 0.214]); while the two-arms meta-analysis showed that the DAA group was associated with less risk of HCC recurrence compared to the control group (RR = 0.55, 95% CI [0.32, 0.96], p = 0.04). Pooled effect estimates did not differ significantly after subgrouping the patients according to DAA regimens. All pooled analyses were homogenous.

Conclusion: The present meta-analysis showed that the rate of HCC occurence or recurrence following DAA regimens is low.

Disclosure: Nothing to disclose

P0073 PROGNOSTIC VALUE OF ALBUMIN BILIRUBIN SCORE AND ALBUMIN BILIRUBIN RATIO IN HEPATOCELLULAR CARCINOMA PATIENTS TREATED WITH TRANS-ARTERIAL CHEMOEMBOLIZATION

H. Elalfy[1], T. Besheer[1], M. Abd El Maksoud[1], M. Hassany[2], **A. Mohammed El Nakib**[1]

Introduction: Albumin bilirubin score (ALBI) is a recently reported, simpler, more objective, and evidence-based alternative to the Child-Pugh (CP) score and Barcelona clinic liver cancer (BCLC) for prediction of survival and prognosis in hepatocellular carcinoma (HCC). Albumin bilirubin ratio is a novel method for detection of early recurrence of HCC after management.

Aims and Methods: This study aimed to validate prognostic value of both albumin bilirubin score and albumin bilirubin ratio in hepatocellular carcinoma patients treated with conventional transarterial chemoembolization (cTACE). The study enrolled 78 HCC patients with BCLC stage (A,B) underwent cTACE, all of them have complete response (CR) according to mRECIST criteria. ALBI score was measured before cTACE using this equation - $0.085\times$ (albumin g/l) $+ 0.66 \times \log$ (bilirubin µmol/l) while the ratio between albumin (g/l) and bilirubin (µmol/l) was mathematically calculated before TACE. Follow-up of the patients was done every 6 months for 36 months using dynamic imaging, liver, kidney functions and AFP.

Results: Early HCC recurrence (within the first 6 months) was observed in 28 patients, ALBI score was significantly associated with early tumor recurrence (p = 0.001). Albumin Bilirubin ratio also was significantly associated with early tumor recurrence (p = 0.001). The Roc curve for ALBI score for detection of early recurrence of HCC after cTACE (at cut off value 0.637, sensitivity is 100% and specificity is 77%), for Albumin Bilirubin ratio (at cut off value 0.885, sensitivity is 95.2% and specificity is 71.4%). Both ALBI score and albumin bilirubin ratio were significantly positively correlated with Child Pugh score, BCLC staging and model for end stage liver disease (MELD) score (p = 0.001).

Conclusion: ALBI score and albumin bilirubin ratio could be used as prognostic indices in HCC management and help in assessing early recurrence of HCC following TACE with high sensitivity and good specificity in comparison to other well-known scores like BCLC and Child -Pugh scores.

Introduction: Portal hypertension is determined both by 'static' fibrosis and 'dynamic' hemodynamic components. The correlation of fibrosis area and portal pressure has not been systematically assessed in different animal models and in human liver disease of different etiologies. Thus, we evaluated the correlation of collagen-proportionate area (CPA) with portal pressure (PP) in animal models and with hepatic venous pressure gradient (HVPG) in patients with cirrhosis.

Aims and Methods: Carbon tetrachloride (CCl_4) or bile duct ligation (BDL) models were used to mimic toxic or biliary cirrhosis in rats, respectively. Portal pressure was measured by direct cannulation of the portal vein. Patients underwent HVPG measurements and transjugular liver biopsy. Liver samples were stained by chrome-aniline-blue (CAB) or picro-sirius-red (PSR) and CPA was quantified by ImageJ software.

Results: Portal pressure correlated with CPA both in BDL ($R = 0.844$, $p < 0.001$) and in CCl_4 ($R = 0.866$, $p < 0.001$) animals. The 'linear fitting' curve was steeper in BDL ($PP = 2.303*CPA + 4.045$) as compared to CCl_4 ($PP = 1.520*CPA + 4.794$). Animals outside the 75% confidence interval of the expected PP (based on CPA) might have pronounced 'dynamic' components, e.g. in endothelial dysfunction, splanchnic blood flow or portosystemic shunting. Similarly, in (n = 18) patients, HVPG correlated with CPA ($R = 0.339$, $p = 0.17$) yielding a 'predicted' HVPG (mmHg) of $0.663*CPA + 11.8$. In patients with 25% higher HVPG as expected by the CPA-formula, we recorded higher vWF-Ag (368 ± 3 vs. $233 \pm 50\%$; $p = 0.048$), IL6 (23 ± 8 vs. 8 ± 4 ng/L; p = ns), and bile acids (34 ± 18 vs. 7 ± 3 µmol/L; p = ns) than in patients with 25% lower HVPG as expected. More patients will be presented at congress.

Conclusion: CPA as the 'static' component of PHT correlates with PP/HVPG, with model-specific and etiology-dependent correlation estimates. Outliers to this curve imply profound alterations of 'dynamic' components of PHT, such as endothelial dysfunction, significant collateralization, bacterial translocation or a deranged gut-liver axis. Identification of outliers refines the assessment of vascular and hemodynamic dysfunction and may allow for personalized therapy of PHT.

Introduction: The portal cavernoma (PC) follows a chronic thrombotic occlusion of the portal vein. PC is rare event and scanty data are available on its incidence of thrombotic recurrence, complications of portal hypertension, survival and causes of death and no data are available to identify those patients in which lifelong anticoagulation is necessary to prevent recurrent thrombosis.

Aims and Methods: The aim of the study was to analyze the long-term prognosis of patients with PC.

The study was prospective and follow-up study of patients initially managed for portal cavernoma from January 2008 to June 2017. Patients with cirrhosis, cancer or Budd Chiari syndrome were excluded. Portal hypertension was managed according to Baveno V recommendations. Anticoagulant therapy has been indicated according to current recommendations. All recurrent thrombosis, gastrointestinal bleeding, adverse events of anticoagulant therapy and death were registered.

Results: In this study 131 patients were included and followed up for a median time of 51.5 months. Of the 131 patients, 69 were men and 62 women, with a median age of 46.2 (23–81) years. PC was an incidental finding in 25 (19%) patients; 46 (35.2%) patients presented with abdominal pain; 60 (45.8%) patients presented with bleeding from portal hypertensive sources. Esophageal and/or gastric varices were present at diagnosis in 78 (59.5%) patients. Prothrombotic disease was identified in 75 (57.2%) patients. Among the factors identified, the most common were chronic myeloproliferative disease (CMD, 25.2%) and protein S deficiency (14.9%). 95 (72.5%) patients received long-term anticoagulation therapy. During the follow-up, 91 patients had no hemorrhagic or thrombotic events. The incidence rate of esophageal varices was 25%; 15 (11.4%) patients suffered from 23 episodes of gastrointestinal bleeding with no deaths. 6 patients had ascites and 15 patients had symptomatic cholangiopathy effectively treated with UDCA. New venous thrombotic episodes occurred in 11 (8.4%) patients of which 71% were in the splanchnic area. There was no case of occurrence or recurrence of intestinal infarction under anticoagulation therapy. 5 patients had latent CMD progression and 1 patient died of acute myeloid leukemia. No serious bleeding or death related to anticoagulant treatment was registered. Survival rates at 1, 3, and 5 yr were 100%, 99.2%, and 97.6%, respectively.

Conclusion: The long-term prognosis of patients with portal cavernoma is good, 70% of patients have a stable evolution. The combination of anticoagulants and the treatment of portal hypertension is effective in preventing thrombotic recurrence and management of bleeding complications.

Introduction: Dysfunctional nitric oxide (NO) and cGMP signalling results in increased intrahepatic resistance in cirrhotic portal hypertension (PHT). PHT contributes to major complications such as variceal bleeding or ascites. Currently medical treatment of PHT is limited to non-selective beta-blockers, while there is no available treatment for liver fibrosis. We investigated the soluble guanylyl cyclase (sGC) stimulator riociguat (RIO) and activator cinaciguat (CINA) and phosphodiesterase-5 inhibitor tadalafil (TADA) in bile duct ligated (BDL) rats.

Aims and Methods: Male Sprague-Dawley rats underwent BDL or sham-operation. Starting 1 week after surgery, RIO (0.5mg/kg), CINA (1mg/kg), TADA (1.5mg/kg) or vehicle (VEH) were gavaged for 3 weeks. Portal pressure (PP), mean arterial pressure, heart rate and splanchnic/portal blood flow were measured. Liver fibrosis, hepatic inflammation and hepatic cGMP levels were assessed.

Results: Cirrhotic BDL-VEH rats showed significant increase in PP (13.07 ± 0.97mmHg) compared to healthy controls. In BDL animals RIO (9.96 ± 0.7mmHg, $p = 0.021$) and TADA (10.27 ± 0.86mmHg, $p = 0.050$) treatment decreased PP without affecting systemic hemodynamics. Intrahepatic vascular resistance was reduced by RIO (2.86 ± 0.25 vs. 4.85 ± 0.54mmHg/min*mL, $p = 0.005$). Hepatic hydroxyproline content was reduced by RIO and TADA treatment (RIO:350 ± 30µg/g, $p = 0.003$; TADA: 282 ± 50µg/g, $p = 0.003$ vs. BDL-VEH: 503 ± 20µg/g liver), whereas fibrotic chrome-aniline-blue stained area decreased only by RIO ($2.14 \pm 0.3\%$ vs. $4.15 \pm 0.53\%$, $p = 0.011$). Both, RIO and TADA therapy decreased transaminases AST (RIO: −36%, $p < 0.001$; TADA: −24%, $p = 0.006$) and ALT (RIO: −32%, $p = 0.035$; TADA: −27%, $p = 0.053$). In line, BDL-RIO rats presented less hepatic *Il6* expression (−56%, $p = 0.053$), indicating a reduction of necroinflammation. Furthermore, hepatic cGMP levels were significantly increased by RIO, but not by TADA or CINA. In cirrhotic BDL rats, 1mg/kg CINA caused weight loss, hypotension and increased lactate levels.

Conclusion: The sGC stimulator riociguat and the PDE5 inhibitor tadalafil showed beneficial effects in cirrhotic rats by reducing liver fibrosis and decreasing portal hypertension. High dosing of sGC activators such as 1mg/kg cinaciguat may be associated with toxicity in cirrhosis.

[2]*Faculté de Medecine IBN Al Jazzar Sousse, Sousse, Tunisia*

Contact E-Mail Address: harbi.raida@gmail.com

Introduction: The diagnosis of portal hypertension at a subclinical stage is important because of major prognostic and therapeutic consequences. In the latent stage, non-invasive imaging and endoscopic exploration play a major role in the positive diagnosis. The aim of this work is to study the concordance between Esophagogastroduodenoscopy (EGD) and non-invasive imaging examinations in the positive diagnosis of infra-clinical portal hypertension.

Aims and Methods: This is a retrospective study that included all patients with infra-clinical portal hypertension syndrome between January 2010 and August 2017. A clinical or latent infra-clinical portal hypertension is referred to any elevation of pressure in the portal system which is not complicated with digestive hemorrhage. Data collection was done from patients' medical records. All patients included in the study had EGD and x-ray examination by abdominal ultrasound (+ doppler) or abdominal CT scan.

Results: 183 patients were included in the study. There were 102 men and 81 women. The average age was 58 [15–81 years]. The syndrome of portal hypertension was secondary to cirrhosis in the majority of cases (90.7%), a portal cavernoma in 11% of the cases, a Banti syndrome in 2 patients and a tumor of the head of the pancreas in a patient. The main etiologies of cirrhosis were viral hepatitis B (33.3%) and C (16.7%), autoimmune origin (4.2%) and nonalcoholic steatohepatitis (8.3%). EGD revealed signs of oesophageal varices, gastric varices and or hypertensive gastropathy in 87.4% of cases. Signs revealed by radiological examinations were splenomegaly (79.2%), portosystemic diversion pathways (33.3%), portal trunk dilatation (50%) and portal flow reversal (54%). The concordance between the existence of signs of endoscopic portal hypertension and the radiological abnormalities that identify the portal hypertension syndrome was: 65% for splenomegaly, 52% for portosystemic diversions, 68% for portal dilatation and 59% for reversing the portal flow.

Conclusion: Consistent with the results of previous studies, concordance between endoscopy and imaging data in the diagnosis of portal hypertension remains moderate. All the interest lies in facing these 2 diagnostic methods to increase the chances of diagnosing portal hypertension at an early stage and avoid its complications.

Introduction: Firstly, difficult bile duct stones were removed by mechanical lithotripsy. But, if this failed, the electrohydrulic (EHL) or laser lithotripsy (LL) could be performed.

Aims and Methods: We performed the first prospective randomized controlled study to compare the efficiency and safety of LL and EHL in multicenter of South Korea.

Between 2014 and 2016, a total of 122 patients who underwent LL or EHL was enrolled from 12 centers. All patients had failed to remove stones by conventional endoscopic stone extraction method including mechanical lithotripsy because huge stone, inaccessible major duodenal papilla, or intrahepatic bile duct (IHD) stone. For laser lithotripsy, we used holmium laser technology. Main outcome measures included complete stone clearance, procedure times and post-procedure complications.

Results: 31 patients received LL and 33 received EHL. Those in the LL treatment were older, had longer procedure times (EHL33.3 ± 13.8 min, LL 47.9 ± 25.7 min, p = 0.006). There were no significant differences in stone size (EHL 15.0 ± 7.6 mm, LL 13.1 ± 4.4 mm, p = 0.235), number of sessions (EHL 2.4 ± 1.1, LL 3.0 ± 1.6, p = 0.113), stone location between the 2 treatment groups. Rate of complete clearance (EHL 90.9%, LL 96.8%, p = 0.333) and complications (EHL 15.2%, Holmium 19.4%, p = 0.656) were not different between the groups. Main complications included bleeding (n = 3), infection (n = 7), and pancreatitis (n = 1), although there were no differences in complications between the 2 treatments, and no severe complications were observed. Recurrence rate was 22.6% (14/62), although no differences were seen in either LL or EHL treatment groups (EHL 57.1%, Holmium 42.9%, p = 0.638). IHD stone was significantly associated with recurrence compared to common bile duct (CBD) stones (Odds ratio = 1.957, 95% confidence interval = 1.017–3.767, p = 0.045).

Conclusion: Although both LL and EHL were safe and effective in the treatment of refractory CBD stones or intrahepatic stones, LL had longer procedure. However, the number of session was not different. Further large comparative studies are warranted

P0079 LONG-TERM OUTCOME OF ENDOSCOPIC PAPILLARY LARGE-BALLOON DILATION FOR BILE DUCT STONES

T. Murabayashi, Y. Kanno, K. Ito, S. Koshita, T. Ogawa, K. Masu, H. Kusunose, T. Sakai, K. Yonamine, Y. Kawakami, Y. Fujii, K. Miyamoto, F. Kozakai, Y. Noda
Sendai City Medical Center, Department of Gastroenterology, Sendai, Japan

Contact E-Mail Address: murabayashi@openhp.or.jp

Introduction: Endoscopic papillary large-balloon dilation (EPLBD) has been reported to be safe and effective for large, multiple common bile duct (CBD) stones. However, long-term outcome of EPLBD for such difficult stones has not been sufficiently determined.

Aims and Methods: The aim of this study was to evaluate long-term outcome of EPLBD for CBD stones. 102 consecutive patients who had undergone endoscopic CBD stone removal with EPLBD, which was defined as papillary dilation with a balloon having a diameter ≥ 12 mm between October 2011 and December 2015 were identified using a prospectively maintained database. Patients with previous history of surgical choledochoduodenostomy or endoscopic papillectomy, those with benign biliary stricture, and those in whom stones were not completely removed were excluded for evaluation of long-term outcome. Postal or telephone surveys were conducted for patients who did not undergo periodical follow-up. Patients who rejected or inappropriately replied to the survey were also excluded. The main outcome measurement was the recurrence rate of CBD stones after complete stone removal with EPLBD during a follow-up. Risk factors for such recurrence were secondarily analyzed. In addition, other complications in the biliary system, such as acute cholecystitis and acute non-calculous cholangitis, and the patient survival period were analyzed.

Results: Complete stone removal with EPLBD was achieved in 99 patients (96.1%). After elimination according to the above-mentioned criteria, 93 patients were finally included in the retrospective analyses for long-term outcome. The mean follow-up period after the successful procedure was 33.7 ± 16.6 months. CBD stones recurred in 16 patients (17%) during the follow-up period. The mean time to recurrence was 12.7 ± 12.7 months. Univariate analyses revealed that a large CBD diameter, multiple stones, and a large stone size were significant risk factors for stone recurrence. Multivariate analysis using the cox proportional hazard model indicated that a large CBD diameter was the only significant risk factor for the recurrence (hazard ratio, 1.25 [95% confidence interval, 1.04–1.50], p = 0.019). Acute cholecystitis and acute non-calculous cholangitis were observed in 5 (5%) and in 3 (3%) patients, respectively. In the 19 patients (20%) who died during follow-up, the causes of death did not involve biliary events.

Conclusion: The long-term outcome of EPLBD for CBD stones, including stone recurrence, acute cholecystitis, and acute cholangitis, was found to be acceptable. A large CBD diameter was the independent risk factor for stone recurrence.

Disclosure: Nothing to disclose

P0080 BILIRUBIN LEVEL AT ADMISSION AS PREDICTOR OF CONCOMITANT CHOLEDOCHOLITHIASIS IN PATIENTS WITH ACUTE CHOLECYSTITIS AND RATE OF READMISSION FOR BILIARY COMPLICATIONS IN PATIENTS WITH DELAYED SURGERY FOR SUSPECTED BILIARY DUCT OBSTRUCTION

C. Lara Romero, M. Belvis Jiménez, M.L. Cadena Herrera, J. Romero Vazquez, P. Cordero Ruiz, F. Bellido Muñoz, Caunedo Álvarez
University Hospital Virgen Macarena, Gastroenterology Department, Seville, Spain

Contact E-Mail Address: carmenlararomero@gmail.com

Introduction: Laparoscopic cholecystectomy (LC) is the gold standard treatment in acute cholecystitis (AC). Concomitant choledocholithiasis incidence is 4–20%. Confirming choledocholithiasis often delays LC and leads to initial conservative management of the acute episode. Biliary endoscopic sphincterotomy and bile duct clearance, followed by LC is actually the most common treatment, although the appropriate management of these patients still remain controversial.

Aims and Methods: The aim of this study was to identify admission and maximum bilirubin levels in patients with AC and its capability to predict the presence of concomitant choledocholithiasis. The second aim was to assess the rate of readmissions for biliary complications in these patients treated conservatively due to the suspect of choledocholithiasis.

Data was retrospectively collected from hospitalization medical reports between June 2015 and October 2017 at Virgen Macarena University Hospital. Tokyo guidelines criteria were used for AC diagnosis and American Asociation for Gastroenteroly (ASGE) criteria for assessing high risk suspect of choledocholithiasis (common duct stone in abdominal ultrasound (US), bilirubin > 4 mg/dL, bilirubin > 1.8 with bile duct dilatation in US and/or cholangitis). Patients under 18 years old, benign or malignant biliary ducts stenosis, previously abnormal liver function tests, previous hepatobiliary surgery, gastrectomy and/or cholecystostomy were excluded. Data were analyzed using SPSS software.

Results: 88 patients with AC were included. 59% were male, ASA score II and III were the most common (31.8 and 37.5% respectively). Delayed programed LC was performed in 64 patients (72.7%). Surgery was ruled out on 19 patients (21%). Only 5 underwent LC on the acute episode (5.7%). Choledocholithiasis was confirmed in 39.8% of cases either with US or abdominal magnetic resonance. In patients with normal biliary ducts in US, admission and maximum bilirubin levels were significantly higher when concomitant cholecholithiasis was present (table 1). The bilirubin level at admission found to be predictor for choledocholithiasis was 7.1mg/dL (sensitivity 80% and specificity 81.6%), OR 1.8 [IC 95%(1.1–2.9); p = 0.14], AUC = 0.87 [IC 95%(0.75–0.98), p = 0.008]. Median time of Hospitalization days was 9.5 (IC 95% 8.77–14.28). Median time for programmed cholecystectomy was 68 days (IC 95% 59.29–109.22) for 44 patients, while 20 patients were still waiting for cholecystectomy 4 months after the acute episode. Readmission for biliary complications was observed in 24.1% of patients who didn't undergo LC on the acute episode (second episodes of AC, cholangitis and biliary acute pancreatitis were reported), 3 of them required urgent surgery.

Conclusion: In the majority of patients with AC, surgical intervention was delayed due to the suspicion of concomitant choledocholithiasis. However, in less than 40% of cases the diagnosis was confirmed and the requirement of endoscopic treatment was needed. This resulted in a readmission rate for biliary complications higher than 20% in patients treated conservatively.

Admission Bilirubin cutoff found to be predictor of common biliar duct obstruction in this study was higher than established on ASGE guidelines. Considering that the appropriate management of this patients could be different according to this findings, more prospective studies should be formed.

P0081 LONG-TERM OUTCOME OF ACUTE ACALCULOUS CHOLECYSTITIS TREATED BY NON-SURGICAL MANAGEMENTS

T.N. Kim, S.B. Kim, J.H. Cho, K.H. Kim, K.O. Kim, S.H. Lee, B.I. Jang
Yeungnam Universitiy College of Medicine, Internal Medicine, Daegu, Korea (Republic of)

Contact E-Mail Address: tnkim@yu.ac.kr

Introduction: Although cholecystectomy is generally recommended in acute acalculous cholecystitis (AAC), non-surgical managements can be considered in patients with high risk of surgery and some recent studies showed favorable outcomes of non-surgical management for AAC. The aim of this study was to analyze the long-term outcome of AAC patients treated by non-surgical managements.

Aims and Methods: We retrospectively analyzed 93 patients diagnosed as AAC between January, 2007 and April, 2014. They were divided into two groups; non-surgical group (n = 43) and surgical group (n = 50). Non-surgical managements included percutaneous transhepatic gallbladder drainage (PTGBD, n = 26) and antibiotics alone (n = 17). Non-surgical group was surveyed for more than 3 years after treatment.

Results: The mean age and the incidence of cerebrovascular accident were significantly higher in non-surgical group than surgical group (70.0 ± 10.8 vs. 65.4 ± 11.1, p = 0.047 and 25.6% vs. 8%, p = 0.026, respectively). No statistical difference regarding the mean hospital stay (9.9 days vs. 8.9 days) and mortality (2.3% vs. 2.0%) was found between two groups, whereas surgical group had a significantly higher incidence of post-treatment complications than non-surgical group (18% vs. 2.3%, p = 0.018). During a mean follow up period of 5.5 years for non-surgical group, AAC was recurred in 4 (9.3%) patients. Of those 4 patients, 3 patients underwent cholecystectomy and one was treated with antibiotics alone, and no recurrence-related death occurred. There was no difference

in recurrence rate between PTGBD and antibiotics only groups (7.7% vs. 11.8%). 2 patients underwent prophylactic cholecystectomy during non-symptomatic period after non-surgical managements.
Conclusion: Recurrence occurred in 9.3% of patients with AAC treated with non-surgical managements and the treatment outcome of non-surgical group was not inferior to that of surgical group. Further studies are needed to clarify role of non-surgical managements in patients with AAC.

Introduction: Cholecystolithiasis and functional gastrointestinal diseases (FGID) are both highly prevalent in the industrialised world. There are over 1.8 million ambulatory visits for symptomatic cholecystolithiasis in the United States. Incorrect assignment of abdominal symptoms may lead to inappropriate cholecystectomies with subsequent lack of benefit. We conducted a systematic review and meta-analysis to determine the prevalence of FGID in patients with uncomplicated cholecystolithiasis.
Aims and Methods: We searched MEDLINE, EMBASE and Web Of Science to identify studies reporting the prevalence of FGID in adults (≥18 years) with uncomplicated cholecystolithiasis. Pooled prevalences and 95% confidence interval (CI) were calculated. Subgroup analyses were performed according to diagnostic criteria used and for dyspepsia and irritable bowel syndrome (IBS) separately.
Results: Of the 1,696 studies evaluated, 11 reported the prevalence of dyspepsia and IBS in a total of 5,069 cholecystolithiasis patients. The pooled prevalence of FGID was 66.8% (95% CI 40% - 89%); 72.7% (95% CI 56% - 87%) for dyspepsia and 42.5% (95% CI 3% - 91%) for IBS. There were no statistically significant differences between diagnostic criteria.
Conclusion: This study finds that 67% of patients with cholecystolithiasis have FGID. In the United States this comprises 1.2 million patients. This is a concern, as these patients are at risk of cholecystectomy that will not benefit them. Extra measures to exclude FGID as a cause of abdominal symptoms, prior to cholecystectomy, is warranted.

Introduction: The Tokyo guideline 2013 indicated emergency cholecystectomy was one of the most important and early treatment options for acute cholecystitis. However, surgical intervention is not necessarily indicated in the patients with advanced ages. Therefore, in this communication, we evaluated percutaneous transhepatic gallbladder aspiration (PTGBA), percutaneous transhepatic gallbladder drainage (PTGBD) and the administration of antibiotics alone as an option for the treatment for acute cholecystitis.
Aims and Methods: From 2010 January to 2015 December, in the period of 6 years, 120 patients with acute cholecystitis were treated at our institution. The data from these patients were retrospectively analyzed.
Results: Of these 120 cases, 84 underwent PTGBA, 28 PTGBD, and 8 were administered antibiotics alone. None of the 120 needed urgent (''early'') cholecystectomy and all patients were discharged without mortality. In only 3 of the 84 patients, cholecystitis was not controlled by PTGBA. PTGBD was performed in these 3 cases.
Long-term follow-up of the patients was conducted in all cases. Of the 120 cases, 111 had gall bladder stones initially, while 9 had none at the time of presentation. Of these 111 patients with gall bladder stones, 67 underwent elective cholecystectomy, while 45 did not. Of the 67 patients who underwent elective cholecystectomy, 2 developed choledocholithiasis. Of the 45 patients who did not undergo elective cholecystectomy, 3 developed choledocholithiasis and 2 developed acute cholecystitis. The incidences of choledocholithiasis and acute cholecystitis did not significantly differ between the 2 groups ($p = 0.19$).
Conclusion: Despite the recommendation in the Tokyo Guideline 2013, emergency cholecystectomy was not needed in any of our patients with acute cholecystitis. Acute cholecystitis can be successfully treated with PTGBA or PTGBD, which are simple procedures with good short- and long-term safety; we highly recommend these procedures for patients with acute cholecystitis, especially in the elderly population.
Disclosure: Nothing to disclose

P0085 PRACTICE PATTERNS FOR THE MANAGEMENT OF CONCOMITANT GALLSTONES AND CHOLEDOCHOLITHIASIS

Y. Abdilla, **J. Gerada**
Mater Dei Hospital, Msida, Malta

Contact E-Mail Address: jugren.gerada@gov.mt
Introduction: Patients with concomitant gallstones and common bile duct (CBD) stones should have endoscopic retrograde cholangiopancreatography (ERCP) followed by cholecystectomy.
Aims and Methods: We studied the success rate of ERCP, and recurrent choledocholithiasis in those who did and did not have cholecystectomy post-ERCP. All patients, diagnosed with CBD stones on imaging between September 2015 and July 2017, and had subsequent ERCP + sphincterotomy, were retrospectively included in this study. Data was collected from medical notes.
Results: 126 patients underwent ERCP for stone extraction. CBD was cannulated in 94%. 20% had normal ERCP. 92 patients (80%) had CBD stones at ERCP. 58 (63%) had complete stone extraction with 1 ERCP (76%), 2 ERCPs (19%), >2 ERCPs (5%). 19 (21%) were lost to follow-up or deemed unfit for repeat ERCPs. 13 (14%) were still undergoing regular ERCPs. 2 (2%) had surgical CBD exploration.
Only 41% (29/71) underwent cholecystectomy post-ERCP. 93% (27/29) remained CBD stone-free at a mean follow-up of 1 year (5 - 23 months). In the 59% (42/71) who did not have cholecystectomy post-ERCP, 95% (40/42) remained CBD stone-free at a mean follow-up of 1 year (1 - 24 months). 5% developed new CBD stones requiring another ERCP.
Conclusion: 95% with choledocholithiasis achieve CBD stone clearance with 1-2 ERCPs. Cholecystectomy post-ERCP was not performed in 60%. Choledocholithiasis-free survival was comparable at 1 year in patients who did and did not have a cholecystectomy post-ERCP. This suggests strong benefits from sphincterotomy alone, however cholecystectomy would still be necessary to prevent cholecystitis, biliary colic, cholangitis or biliary pancreatitis.

P0086 PREVALENCE AND RISK FACTORS OF CHOLELITHIASIS IN CROHN'S DISEASE

I. Sturdik, A. Krajcovicova, Z. Leskova, Y. Jalali, R. Decka, V. Cernotova, J. Toth, T. Koller, M. Huorka, T. Hlavaty
University Hospital Bratislava and Faculty of Medicine Comenius University in Bratislava, 5th Department of Internal Medicine, Sub dept. of Gastroenterology & Hepatology, Bratislava, Slovakia

Contact E-Mail Address: igor.sturdik@gmail.com
Introduction: Cholelithiasis occurs in patients with Crohn's disease more frequently than in a healthy population. The cause of this difference has not been satisfactorily explained, nor its risk factors.
Aims and Methods: The aim of our study was to determine the prevalence of cholelithiasis in CD patients, to compare prevalence with a control group and to analyze the risk factors of cholelithiasis. We performed a monocentric retrospective case-control study. The cohort consisted of all CD patients who underwent abdominal ultrasound from January 2007 to January 2018 at the IBD Center of the 5th Department of Internal Medicine in Bratislava. The control group consisted of patients, who underwent ultrasound at the same department because of dyspepsia and were age and gender matched. Medical records were reviewed and patients demographics, behavior, localisation, duration and number of flare of CD, number and type of bowel resections, number and length of total hospitalization, number of total parenteral nutrition treatments and presence of cholelithiasis and its characterization were noted. An univariate and a multivariate analysis were performed using logistic regression analysis (with cholelithiasis as the dependent variable). Prevalence and odds ratios were calculated with their 95% confidence intervals.
Results: The study cohort consisted of 238 CD patients and 238 controls. The prevalence of cholelithiasis in CD group was 12.6% and 9.2% in control group (RR 1.36, $p = 0.24$). In the univariate analysis, we observed cholelithiasis association with multiple risk factors such as - age, age at CD diagnosis, inflammatory versus aggressive disease behaviour, duration of disease, abdominal resection, number of intestinal resections, length of ileal resection, number of corticosteroid treatments, hospitalizations and total parenteral nutritions. The age (OR 1.077, 95% CI 1.043–1.112, $p < 0.001$) and the number of total parenteral nutritions (OR 1.812, 95% CI 1.131–2.903, $p = 0.013$) were determined as independent risk factors for cholelithiasis in CD patients by multivariate analysis.
Conclusion: The prevalence of cholelithiasis in our CD patient population reached 12.6%, which was not significantly higher than in the control group. We identified the age of patient and the number of parenteral nutritions as the independent risk factors of cholelithiasis in CD patients.

Introduction: Nuclear Protein 1, Transcriptional Regulator gene (NUPR1, p8) was firstly described to be overexpressed in acute pancreatitis and encodes a ubiquitous nuclear and cytoplasmic stress protein. Analysis of insulin sensitivity and glucose tolerance in p8 haplodeficiency and p8-knockout mice revealed counterintuitive results. Thus, we analyzed glycemic control of p8 in mice fed with standard (SD) and high-fat diet (HFD).
Aims and Methods: $p8^{-/-}$ mice and wild type ($p8^{+/+}$) littermates were used to study glucose homeostasis. We determined glucagon (immunohistochemistry) and insulin levels (ELISA) from isolated pancreatic islets and analyzed beta cell mass. In addition, hyperinsulinemic- euglycemic glucose clamp technique, i.p. glucose tolerance test (ipGTT), i.p. insulin tolerance test (ipITT) and metabolic chamber analysis over 72 hours were performed in SD (4% fat) and HFD (55% fat) groups.
Results: $p^{8-/-}$ mice showed no differences in glucagon content but higher levels of insulin in pancreatic islets upon glucose stimulation compared to wildtype littermates. p8 deficiency resulted in elevated beta cell mass but was not associated with increased insulin resistance in ipGTT or ipITT in both SD and HFD groups. Glucose clamp tests also revealed no evidence of association of p8 deficiency with insulin resistance. Metabolic chamber analysis showed equal energy expenditure in $p8^{-/-}$ mice and wildtype animals.
Conclusion: Complete p8 depletion may contribute to glucose metabolism by means of stress-induced insulin production and beta cell mass. Nevertheless, p8 knockout showed no impact on insulin resistance in SD and HFD fed mice.

Introduction: Obestatin, a 23-amino acid peptide encoded by the ghrelin gene, and the GPR39 receptor were reported to be involved in the control of mitogenesis of gastric cancer cell lines. Our data strongly suggest the involvement of the obestatin/GPR39 system in the pathogenesis and/or clinical outcome of human gastric adenocarcinomas and highlight the potential usefulness of GPR39 as a prognostic marker in gastric cancer. Although this system has been described in the rat endocrine pancreas, its exact expression and function in human pancreas has not been assessed yet.
Aims and Methods: The aim of the present study was to determine the expression levels of the obestatin/GPR39 system, both in healthy and diseased human pancreas.
The tissue samples of human healthy pancreas (n = 3), chronic pancreatitis (CP, n = 3) and pancreatic ductal adenocarcinoma (PDAC, n = 3) were obtained from the Biobank of our centre. The expression of obestatin and GPR39 was evaluated by immunohistochemistry and immunofluorescence.
Results: In healthy pancreas, obestatin was exclusively expressed in the ghrelin endocrine cells of the pancreatic islets, whereas GPR39 expression in the pancreatic endocrine cells was much less intense. GPR39 expression was mainly confined to the exocrine pancreas (acinar cells) and to some HSP47 positive cells (stellate cells). In serial sections of the CP samples, GPR39 is expressed in the GFAP positive cells, the stellate cells, localized in the fibrosis area. For the PDAC tissues, an aberrant GPR39 expression was observed in the cancer cells as well as in the stellate cells (alpha-SMA positive cells) of the surrounding fibrotic area. The tumour area is negative for obestatin.
Conclusion: The expression of the obestatin/GPR39 system found in healthy pancreas indicates a potential role of this system in the regulation of the exocrine pancreas, as well as in the regeneration of this organ. Similar to its role in the stomach, GPR39 might be involved in the regulation of enzyme secretion. Obestatin/GPR39 expression in pathological conditions (CP and PDAC) might suggest the implication of this system in the pathogenesis of CP and human pancreatic adenocarcinoma. Similar findings were described by our group in gastric cancer, in which in addition, GPR39 expression was shown to be closely and directly related to proliferation and poor prognosis.
Disclosure: Nothing to disclose

P0089 OBESTATIN PROMOTES MIGRATION AND INVASSION OF ACTIVATED HUMAN PANCREATIC STELLATE CELLS

Introduction: There is evidence that the mature adult pancreas has the ability to regenerate, similar to the liver, although to a lesser extent. Studies in animal models confirmed the plasticity and regeneration of both exocrine and endocrine pancreatic cells. Pancreatic stellate cells (PSC) play a major role in pancreas regeneration after partial pancreatectomy. Obestatin, a peptide derived from preproghrelin, and its receptor GPR39 have been described in the endocrine pancreas. Recent studies showed that exogenous administration of obestatin accelerates the recovery of ischemia/reperfusion-induced or cerulein-induced acute pancreatitis in rats.
Aims and Methods: Based on the previous background, the main objective of the present study was to evaluate the regulatory function of the obestatin/GPR39 system in the human pancreatic stellate cells RLT-PSC.
The immunocytochemical expression of the obestatin/GPR39 system in the activated human pancreatic stellate cells RLT-PSC was evaluated. The effect of the exogenous administration of obestatin on the phosphorylation of key signalling targets of this system (Akt and ERK1/2), proliferation, migration, invasion, epithelial-mesenchymal transition (EMT) and agiogenesis was evaluated.
Results: The obestatin/GPR39 system was expressed in the activated RLT-PSC cells. Obestatin administration (100 nM) activated the targets previously described in the signalling pathway of this system: Akt and ERK1/2 (6.29 ± 1.47, $p = 0.025$ and $0.50 \pm 0.00\%$, $p = 0.002$; respectively). Moreover, obestatin stimulated the proliferation of this cells in an autocrine/paracrine manner ($32.10 \pm 14.69\%$; $p = 0.038$), as well as migration ($16.32 \pm 5.96\%$; $p = 0.018$) and invasion ($86.76 \pm 0.141\%$; $p < 0.001$). This system also regulates characteristic markers of the EMT: E-cadherin (-0.39 ± 0.11, $p = 0.014$), N-cadherin (0.41 ± 0.17, $p = 0.014$), vimentin (6.29 ± 1.47, $p = 0.005$), β-catenin (0.82 ± 0.45, $p = 0.014$); and of the angiogenesis: VEGF (0.59 ± 0.08, $p = 0.009$), expressed as fold of control.
Conclusion: The obestatin/GPR39 system was expressed in the RLT-PSC cells. This system regulated the proliferation, migration and invasion of these cells, as well as the expression of EMT and angiogenesis markers. These data reveal the potential role of this system on the recovery of the injured pancreas via the regulation of the activated pancreatic stellate cells, accordingly to the regenerative and/or protector role previously described for obestatin in the pancreas.

Introduction: The uptake of [^{11}C]methionine ([^{11}C]MET) is associated with pancreatic endocrine and exocrine activity such as insulinogenic index and pancreatic digestive enzyme release. However, studies that examine both, the impact of endocrine and exocrine function, on methionine uptake of the pancreas are rare. Cholecystokinin (CCK), a trigger of pancreas secretion is altered after operations that accelerate gastric emptying, such as gastrectomy. Similarly insulin release is modified due to elevated glucose plasma concentrations and via GLP-1. The purpose of this study was to shed light on the relationship between the secretion of CCK, insulin release and [^{11}C]MET uptake in subjects having undergone pancreaticoduodenectomy (PD).

Aims and Methods: 19 tumor-free survivors after PD (age mean ± SD: 61 ± 8.7 yr; 10 male, 9 female) were given a mixed meal. Plasma CCK, insulin and glucose concentrations were measured before and at 10, 20, 30 and 60 minutes after ingestion. Simultaneously 800 MBq of [^{11}C]MET were administered and the activity (maximum tissue standardized uptake values [SUVmax]) over the pancreas was measured using PET-CT at 15, 30 and 60 minutes after injection. Beta cell function was calculated from basal plasma glucose and insulin concentrations. Area under the curve [AUC] was calculated for insulin, CCK and SUVmax (methionine uptake).
Results: CCK AUC_{30} ($R^2 = 0.26$, $p = < 0.05$), beta cell function ($R^2 = 0.54$, $p < 0.01$) and insulin AUC_{60} ($R^2 = 0.66$, $p < 0.01$) correlated with the SUVmax AUC_{60}. Multivariate analysis revealed CCK, basal beta cell function and postprandial insulin (AUC_{60}) concentrations as significant independent predictors of [^{11}C]methionine uptake ($R^2 = 0.84$, $p < 0.01$, Table 1, Figure 1).
[Table 1. Multiple linear regression on the dependent variable 'methionine SUVmax AUC60' in patients after PD (R2 = 0.84, p < 0.01)]
Conclusion: The association between CCK secretion, beta cell function and postprandial insulin release with pancreatic [^{11}C]MET uptake might suggest the representation of digestive enzyme and insulin metabolism. Further studies are needed to evaluate the relative impact of exocrine and endocrine pancreatic function on the uptake of this tracer.

Variable	*Estimate*	*Standard error*	*p-value*
Intercept	3.33	76.36	0.9658
Betas cell function	1.73	0.57	0.0094
Insulin AUC60 (mU/l x min)	0.07	0.02	0.0014
CCK AUC30 (pmol/l x min)	0.72	0.33	0.0457

[Table 1. Multiple linear regression on the dependent variable 'methionine SUVmax AUC60' in patients after PD (R2 = 0.84, p < 0.01)]

Introduction: Previous research suggests an important role of the CGRP pathway as modulator of innate immune response in mice. The CGRP receptor incorporates 2 important subunits: the receptor activity-modifying protein 1 (RAMP1) and the calcitonin receptor-like receptor (CRLR). It is known, that CGRP can directly influence immune-cells and their capacity of producing inflammatory cytokines. By using a RAMP1 full-body knockout mouse model ($RAMP^{-/-}$) we examined the role and function of the CGRP receptor in the acute phase of caerulein-induced pancreatitis.
Aims and Methods: In order to generate acute pancreatitis we performed hourly injections of caerulein for a period of 8h in our $RAMP1^{-/-}$ and control mice. Analysis was performed at 8h, 24h, 2 days and 7 days post caerulein treatment. To compare the severity and extent of inflammation in $RAMP1^{-/-}$ and wild-type mice, histological analyses including immunohistochemistry were performed. Additionally, cytokine levels were assessed using real-time PCR. For improved characterization serum-levels of LDH and Lipase were measured.
Results: $RAMP1^{-/-}$ mice showed higher ratio between pancreas-weight and body-weight ($p = 0.018$), increased tissue edema ($p = 0.0071$) and higher amount of F4/80 positive cells ($p = 0.0245$) 8h after caerulein injection, as compared to wild-type mice. Furthermore, overall infiltration of immune-cells at 24h was markedly increased in $RAMP1^{-/-}$ mice ($p < 0.0001$) and composed predominantly of MPO positive cells ($p < 0.0001$) without any difference in the number of CD8 and CD4 cells. Cleaved caspase 3 positive cells were markedly increased in $RAMP1^{-/-}$ mice at 24h post caerulein injection ($p = 0.0025$) compared to wild-typ mice. In addition, higher amount of CCL3 and IL-1β in $RAMP1^{-/-}$ mice was observed in the real-time PCR.
Conclusion: Using a murine $RAMP1^{-/-}$ model, this study underlines the essential role of the CGRP receptor as central modulator of the innate immune response in acute pancreatitis. Mice lacking RAMP1 showed increased inflammation and edema particularly in the early phase of acute pancreatitis.

Contact E-Mail Address: egugu0515@yahoo.co.jp
Introduction: Pancreatic circulation failure due to disseminated intravascular coagulation (DIC) is a significant factor in determining the severity of pancreatitis. Pancreatic circulation failure affects walled-off necrosis (WON) caused by pancreatic ischemia/necrosis. A study has shown that patients with severe acute pancreatitis (SAP) administered recombinant human soluble thrombomodulin (rhTM) exhibit significant improvements in coagulation anomalies and inhibited WON development [1]. Perfusion-computed tomography (PCT), an advanced imaging technique for evaluating blood circulation in SAP, can accurately diagnose the development of pancreatic ischemia/necrosis in the early stages of SAP. PCT can also be used to predict the severity of acute pancreatitis [2].
Aims and Methods: This study applies PCT to investigate whether rhTM improved pancreatic blood flow (PBF) in cases of SAP involving pancreatic ischemia/necrosis.
We retrospectively analyzed 27 SAP patients with pancreatic ischemia/necrosis treated from January 2015 to January 2018 at Osaka Saiseikai Nakatsu Hospital. All patient data was gathered from an electronic database. The 27 SAP patients were divided into two groups: SAP patients with DIC treated with rhTM (380 U/kg for 30 minutes, once daily: the rhTM(+)DIC(+) group, 14 patients) and without DIC and not treated with rhTM (DIC(-) group, 13 patients). To determine a diagnosis of pancreatic ischemia, we measured PBF with PCT within 48 hours and set a criterion of 25% or greater reduction of PBF in a region of 1 cm^2 or larger compared to normal pancreatic parenchyma. We assessed the extent of pancreatic ischemia based on the ratio of ischemic pancreatic PBF/normal pancreatic PBF. We calculated the PBF ratio, APACHE II, SOFA, JPN prognostic factor (by the Japanese severity scoring system), and JAAM DIC scores within 48 hours of hospitalization and again on the seventh day of hospitalization (day 7).
Results: The background data for the subjects is as follows: mean age of 62.6 years; male/female ratio: 18/9; cause: 11 alcohol, 5 gallstone, 6 idiopathic, 3 cases of ERCP, 2 other, and 1 fatality. In the Revised Atlanta Criteria, the rhTM(+)DIC(+) group was significantly severe: the rhTM(+)DIC(+) group vs. DIC(-) group (7 severe/6 moderate vs. 1 severe/9 moderate). We found no differences in SOFA scores between the two groups as of the time of hospitalization (i.e., rhTM(+)DIC(+) vs. DIC(-): 3.8 ± 2.1 vs. 2.8 ± 2.4). However, we found significant differences with respect to the prognostic factor (3.5 ± 1.6 vs. 1.8 ± 1.3), mean APACHE II scores (12.5 ± 5.8 vs. 8.2 ± 4.1), and JAAM DIC scores (3.7 ± 1.5 vs. 1.9 ± 1.3) ($p < 0.05$). PBF ratios within 48 hours of hospitalization did not differ between the rhTM(+)DIC(+) and DIC(-) groups: 0.560 ± 0.144 vs. 0.673 ± 0.241. The PBF ratio for rhTM(+)DIC(+) group was significantly higher (0.760 ± 0.218) on day 7 ($p < 0.01$). The PBF ratio for the DIC(-) group without rhTM treatment failed to improve (0.670 ± 0.119) on day 7. The PBF ratio for the rhTM(+)DIC(+) group on day 7 was significantly higher than for the DIC(-) group (0.760 ± 0.218 vs. 0.670 ± 0.119) ($p < 0.05$). WON occurred in 12 cases (44.4%).
Conclusion: Since pancreatic ischemia is defined as a reduction in PBF of 25% or more, we considered ischemia in many of the patients meeting this criteria was reversible. Although the symptoms in the rhTM(+)DIC(+) group were significantly worse, improvements in the PBF ratio were significantly better. Since rhTM improved coagulation anomalies, we considered it may improve PBF ratios. rhTM offers a new therapeutic option in treating pancreatic ischemia.

Introduction: Both alcohol consumption and cigarette smoking have been reported to have harmful effects on the pancreas. These addictions very often go together, therefore careful investigations are crucially needed to understand their independent/synergic effects on the pancreas.
Aims and Methods: To examine the clinical effects of alcohol consumption and/or smoking in patients with acute pancreatitis (AP).
A total of 1435 adult patient were enrolled from 2012 to 2017 with the diagnosis of AP in 28 healthcare centres by the Hungarian Pancreatic Study Group. Specific questionnaires for AP including information on cigarette smoking and alcohol consumption were used, whereas detailed clinical data such as the results of laboratory parameters and imaging, the course and the outcome of AP episodes were collected.
Results: 692 (48.32%) of the patients were non-drinkers and non-smokers (ND-NS). 615 of the patients were drinkers (D) (43.0%). 279 (45.4%) of the drinkers did not smoke (D-NS), whereas 336 (54.6%) of them were smokers (D-S) as well. The age of onset was 61.1y in the ND-NS group, 55.1y in the D-NS and 46.3y in the D-S group. The female/male ratio was 0.6 in the ND-NS group, 3.15 in the D-NS and 5.99 in the D-S group. Drinking alone had no effect on the BMI (ND-NS: 28.2, D-NS: 28.2), but smoking in addition to drinking decreased it (D-S: 25.7). Concerning the parameters on admission the ND-NS, D-NS and D-S groups were as follows: amylase (U/L): 1310 ± 1351, 1009 ± 1194, 737 ± 1237; lipase (U/L): 3233 ± 4911, 2617 ± 3350, 2035 ± 6617; CRP (mg/L): 53 ± 77, 51 ± 72, 63 ± 80; WBC (G/L): 13 ± 5.5, 13.3 ± 6.4, 13.6 ± 5.7. Smoking had synergic effect with drinking on local complications (ND-NS: 34.4%, D-NS: 37.5%, D-S: 44.1%) such as necrosis (8.8%, 11.0%, 11.5%), development of pseudocyst (9.0%, 9.2%, 13.3%) and fluid collection (28.3%, 31.3%, 35.5%). The percentage of moderate AP copied the same pattern (24.9%, 26.8% and 31.9%). We could see no difference in mortality and the rate of severe AP. Drinking and smoking together also elevate the risk for acute recurrent pancreatitis (ARP). 18.9% of the patients had ARP in the ND-NS, 23.5% in the D-NS, whereas 31.9% in the D-S groups.
Conclusion: Drinking and smoking together results in the onset of pancreatitis 15 years earlier, in addition it elevates the risk for recurrence of the disease. Drinking and smoking synergize with each other and increase the rate of local complications.

Introduction: Acute pancreatitis (AP) is a sudden inflammation of the pancreas. The early evaluation and accurate prediction of AP severity is vital, as severe cases require intensive care treatment. It is well established that obesity is a risk factor for AP and increases the incidence of systemic complication, motality. However, the relationship between visceral adiposity and acute pancreatitis has not been fully examined.
Aims and Methods: This study is to explore the predictive significance of visceral adipose tissue (VAT) and visceral adipose tissue /skeletal muscle tissue ratio (VAT/SMT ratio) for the prognosis in AP patients. After 1:2 propensity score matching, a total of 306 patients were enrolled in the analysis from 2010 to 2017. Visceral adipose tissue (VAT), subcutaneous adipose tissue (SAT), and skeletal muscle tissue (SMT) were measured via unenhanced computed tomography (CT). They were calculated by Cox proportional hazards models.
Results: VAT and VAT/SMT ratio were significantly higher in the moderate SAP and SAP groups than those in the MAP group (both p values < 0.001). ICU transfer, AP severity, systemic complications and prognostic scores (Acute Physiology and Chronic Health Evaluation II [APACHE-II] score ≥ 8, Ranson's score ≥ 3, Bedside Index of Severity in Acute Pancreatitis [BISAP] score ≥ 3, the systemic inflammatory response syndrome [SIRS] score ≥ 2) were significantly related to the value of VAT and VAT/SMT ratio in the AP patients. The multivariate adjusted HR for VAT and VAT/SMT ratio in the relationship between body parameters and AP mortality were 1.042 (95% CI, 1.019–1.066) and 7.820 (95% CI, 1.978–30.917), respectively. Compared with other prognostic scores, VAT demonstrated the highest AUC (0.943, 95% CI, 0.909–0.976) among independent predictors.
Conclusion: VAT and VAT/SMT ratio play a prognostic role in AP patients.

P0095 ABDOMINAL ADIPOSITY AND ECTOPIC FAT PHENOTYPES ASSOCIATED WITH THE PRESENCE OF DIABETES AFTER ACUTE PANCREATITIS

R. Singh, A. Cervantes, J.U. Kim, N.N. Nguyen, S. DeSouza, M. Drury, S. Pendharkar, M. Petrov

Introduction: The adverse effects of excess body fat, in particular abdominal adiposity, and ectopic fat deposition during the course of acute pancreatitis (AP) are well established. Emerging studies indicate a high frequency of diabetes after AP, but the role of excess abdominal adiposity in post-pancreatitis setting is not completely understood. Moreover, the associations between abdominal adiposity and ectopic fat phenotypes and pancreatitis-related factors (aetiology, severity) in individuals after AP have never been studied.
Aims and Methods: The aim was to investigate phenotypic differences in distribution of abdominal adipose tissue and ectopic fat between individuals after AP (with and without diabetes) using magnetic resonance imaging (MRI). The secondary aim was to determine pancreatitis-related factors associated with abdominal adiposity and ectopic fat phenotypes. A total of 84 individuals who had been diagnosed prospectively with AP were included in this study. They were recruited after an average time of 28 months since last episode of AP and were categorised into 'diabetes' and 'no diabetes' groups, in line with the American Diabetes Association guidelines.[1] 28 normoglycaemic healthy volunteers were also recruited. Using 3 Tesla (T) MAGNETOM Skyra MRI scanner (SIEMENS, Erlangen, Germany), abdominal adiposity [(visceral fat volume (VFV), subcutaneous fat volume (SFV), visceral-to-subcutaneous fat volume ratio (V/S ratio)], and ectopic fat [liver fat percentage (LF%), pancreatic fat percentage (PF%)] phenotypes were quantified. The differences in abdominal adiposity and ectopic fat phenotypes between the groups were compared using analysis of variance. Linear regression analysis was used to investigate the association between pancreatitis-related factors and the studied phenotypes in unadjusted and adjusted (accounting for age and sex) models.
Results: Of the abdominal adiposity phenotypes, VFV was significantly higher in the diabetes (2715.3 ± 1077.6 cm^3) as compared with no diabetes (1983.2 ± 1092.4 cm^3) and healthy (1126.2 ± 740.4 cm^3) groups ($p < 0.001$). Moreover, V/S ratio was significantly higher in the diabetes (0.97 ± 0.27) as compared with no diabetes (0.68 ± 0.42) and healthy (0.52 ± 0.34) groups ($p = 0.001$). Of the ectopic fat phenotypes, PF% was significantly higher in the diabetes ($10.2 \pm 1.2\%$) as compared with no diabetes (9.2 ± 1.7 %) and healthy (7.9 ± 1.9 %) groups ($p < 0.001$). Other studied phenotypes did not differ significantly between the groups. C-reactive protein levels during hospitalization for AP were associated with significantly increased VFV in unadjusted ($\beta = 3.32$; 95% CI, 1.68, 4.96; $p < 0.001$) and adjusted ($\beta = 2.71$; 95% CI, 1.24, 4.19; $p < 0.001$) models. Biliary aetiology of AP was associated with a significantly increased PF% in adjusted model ($\beta = 0.67$; 95% CI, 0.01, 1.33; $p = 0.047$).
Conclusion: The findings of this study show, for the first time, that individuals after an episode of AP have abnormal adiposity phenotypes, particularly increased visceral fat and pancreatic fat depots. Further, these depots are significantly associated with the presence of diabetes after AP. Levels of C-reactive protein during hospitalisation for AP are significantly associated with VFV whereas biliary aetiology of AP is significantly associated with PF%.

Introduction: Lipolysis of adipocyte triglycerides by pancreatic lipases resulting in the release of free Fatty Acids (FA) seem to be an important factor in the pathogenesis of local and systemic complications in acute pancreatitis (AP). In this setting, several basic and clinical studies suggest that unsaturated FA (UFAs) are associated to a more severe AP, while saturated FA (SFAs) are less toxic. We speculated that differences in dietary fat patterns are associated to different composition of fat storages, and thus to a different frequency of complications and death in AP.
Aims and Methods: Our aim was to investigate whether different patterns of fat intake are associated to worse outcomes in AP. We used data from the Atlantis project, a 23-center prospective nation-wide Spanish database aiming to investigate the determinants of morbidity and mortality in acute pancreatitis. Dietary fat patterns (fat intake, proportion of fats, SFAs, mono and polyunsaturated UFAs) from different regions of Spain were retrieved from the ANIBES (Anthropometry, Intake and Energy Balance in Spain) cross-sectional study using a nationally representative sample of the Spanish population. Outcome variables were: necrotizing pancreatitis (pancreatic gland and/or peripancreatic fat necrosis), persistent organ failure (POF) and mortality. Variables addressing fat intake were divided according to their median value into low and high intake. Univariate (Chi-square) and multivariate (binary logistic regression) analysis were performed. The variables included on the multivariate analysis model were: Charlson comorbidity index >3 (includes also age), alcohol etiology, gender, obesity and recurrent AP; adjusted Odds Ratio (aOR) were calculated.
Results: 1,655 episodes of AP were analyzed. Etiology was biliary in 60%, 54% of the patients were male, AP was associated to necrosis in 17%, to persistent organ failure (POF) in 7% and mortality was 4%. On univariate and multivariate

analysis, a high SFA intake was independently associated to a lower risk of necrosis [15 vs. 19%, aOR 0.746 (0.570–0.978), p = 0.034], a lower risk of POF [5 vs. 9%, aOR 0.550 (0.367–0.822), p = 0.004] and mortality [3 vs. 6%, aOR 0.548 (0.329–0.914), p = 0.021].
Conclusion: Our study suggests that a high saturated fatty acid intake is associated to improved outcomes in acute pancreatitis, resulting in a 50% lower risk of persistent organ failure and mortality.

Introduction: During the past decades, obesity rates have increased sharply. As there is a growing number of cases in which acute pancreatitis (AP) is accompanied by obesity, we found it clinically relevant to investigate how body-mass index (BMI) affects the outcome of the disease.
Aims and Methods: Our aim was to quantify the association between subgroups of BMI and the severity and mortality of AP. A meta-analysis was performed using the Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols. 3 databases (PubMed, EMBASE and Cochrane Library) were searched for articles containing data on BMI, disease severity and mortality rate of AP. English-language studies from inception to 19 June 2017 were checked against our predetermined eligibility criteria. The included articles reported all AP cases with no restriction on the etiology of the disease. In severity analyses we only involved studies that classified AP cases according to the Atlanta Criteria. Odds ratios (OR) and mean differences (MD) were pooled using the random effects model by the DerSimonian-Laird estimation and displayed on forest plots. The meta-analysis was registered in PROSPERO under number: CRD42017077890.
Results: Altogether 19 articles were included in our meta-analysis, containing data on 9,997 patients. Severity: The subgroup analysis shows a direct association between AP severity and BMI. BMI < 18.5 compared to normal BMI (18.5–25) seems to increase the risk of severe AP (OR = 1.89, 95% CI = 0.52–6.87, p = 0.336), however this result is not significant. Patients with a BMI > 25 have an almost 3 times increased risk for a severe AP (OR = 2.87, 95% CI = 1.90–4.35, p < 0.001) in comparison to normal BMI. The mean BMI of patients with severe AP is notably higher than of the non-severe group (MD = 1.79, 95% CI = 0.89–2.70, p < 0.001). Mortality: Death rates of AP patients are the highest in the underweight and obese subgroups. A BMI < 18.5 carries an almost 2-fold increase in risk of mortality (OR = 1.82, 95% CI = 1.32–2.50, p < 0.001) in comparison to normal BMI. However, the chance of mortality is almost equal in the normal BMI and BMI 25–30 subgroups. A BMI > 30 results in a 3 times higher risk of mortality in comparison to a BMI < 30 (OR = 2.89, 95% CI: 1.10–7.36, p = 0.026).
Conclusion: Our new findings confirm that a BMI 25–30 increases the risk of severe AP, but not mortality, while a BMI > 30 increases both the risks of severe AP and mortality. A BMI < 18.5 carries an almost 2 times higher risk of mortality in AP.

P0098 GENERAL AND ADIPOSE TISSUE-SPECIFIC INSULIN RESISTANCE AFTER AN EPISODE OF ACUTE PANCREATITIS

R. Singh, S. Pendharkar, A. Cervantes, J. Cho, V. Miranda-Soberanis, M. Petrov
The University of Auckland, Auckland, New Zealand

Contact E-Mail Address: ruma.singh@auckland.ac.nz
Introduction: Emerging evidence indicates that individuals after an episode of acute pancreatitis (AP) are at an increased risk of developing metabolic derangements, in particular new-onset prediabetes or diabetes after AP.[1] The link between general obesity and insulin resistance (IR) was established decades ago, however the impact of body fat distribution on IR has gained attention only recently and is not completely understood. In the setting of AP, the association between abdominal obesity and IR, and a comprehensive assessment of various IR indices in post-pancreatitis setting, is lacking.
Aims and Methods: The aim of this study was to investigate associations between abdominal obesity and IR (general and adipose tissue-specific) in patients after AP independent of the effect of covariates including diabetes mellitus, and to determine the relative accuracy of several indices of IR in characterising abdominal obesity. Patients were eligible for this cross-sectional study if they were previously admitted with a primary diagnosis of AP, established prospectively. Fasting venous bloods were collected to measure glucose, insulin, free fatty acids, glycerol, adiponectin (AD), omentin (OM), and vaspin(VAS). The IR indices - homeostasis model assessment of IR (HOMA-IR), adipose tissue IR (Adipo-IR), insulin*glycerol (IG) index, HOMA-AD, HOMA-OM, and HOMA-VAS were calculated. Abdominal obesity was defined according to the National Cholesterol Education Program Adult Treatment Panel III (ATP III) guidelines.[2] Modified Poisson regression was conducted, with statistical model adjusting for patient-, metabolic-, and pancreatitis-related risk factors. Areas under the receiver operating characteristic (ROC) curve were calculated to compare the relative accuracy of the studied indices followed by determination of agreement between the two new indices (HOMA-OM, HOMA-VAS) and HOMA-IR.
Results: Of the 92 individuals recruited, 41 had abdominal obesity. The median (interquartile range) time since AP was 24 (7 - 46.5) months. Insulin resistance indices HOMA-IR, IG index, HOMA-OM, and HOMA-VAS were significantly associated with abdominal obesity, both in unadjusted and adjusted models (Table 1). Area under ROC curves for HOMA-IR was 0.698 (95% CI, 0.591, 0.791; p < 0.001), for IG index was 0.695 (95% CI, 0.585, 0.791; p < 0.001), for HOMA-OM was 0.756 (95% CI, 0.648, 0.845; p < 0.001), and for HOMA-VAS was 0.735 (95% CI, 0.625, 0.827; p < 0.001). There was a good agreement between observed HOMA-IR values and values obtained from HOMA-OM (p = 0.733) and HOMA-VAS (p = 0.595).
Conclusion: Individuals with abdominal obesity after AP have a significantly higher IR, independent of diabetes and other covariates. Visceral adipose tissue specific adipokines, omentin and vaspin, hold promise for future clinical investigation of tissue-specific IR.
[Associations between the indices of insulin resistance and abdominal obesity]

Introduction: Acute pancreatitis (AP) is one of the most common diseases in gastroenterology. However, neither the etiology nor the pathophysiology of the disease is fully understood and no specific or effective treatment has been developed. We previously showed that heparanase (Hpa) appears to play an important role in the pathogenesis of AP and that Hpa inhibitors significantly reduced the severity of the AP in an animal model. Aspirin has also been demonstrated to inhibit Hpa activity both *in vivo* and *in vitro*. We hypothesize that a combination of Hpa inhibitor and aspirin can ameliorate AP more efficiently than each drug alone.
Aims and Methods: The current study examines whether combination of Aspirin with PG545 or Roneparstat (SST0001), 2 inhibitors of Hpa, exerts superior pancreato-protective effect in cerulein-induced AP in mice, vs each compound alone.
Heparanase-overexpressing transgenic mice (Hpa-TG) and wild-type (WT) BALB/c mice (n = 7–8) were intraperitoneally injected with either cerulein (50 mg/kg, 5 times, at 1 hour apart) or vehicle, with or without either PG545 (0.4 mg/mouse, kind gift of Dr. Edward Hammond, Zucero Therapeutics, Brisbane, Queensland, Australia), Roneparstat (2 mg/mouse, kind gift of Dr. Alessandro Noseda, Leadiant Biosciences S.A., Mendrisio, Switzerland), Aspirin (250 mg/kg) or combination of both drugs. The animals were sacrificed 24 hours following the induction of pancreatitis. The severity of AP and architectural structure changes were evaluated by serum pancreatic enzyme (amylase and lipase) levels, inflammatory cytokines, pancreatic edema index (determined by organ-to-animal weight ratio), tissue inflammatory response (determined by immune-histopathological analysis) and autophagy response (determined by electron microscopy and immunohistochemistry staining).
Results: Cerulein-induced AP in WT mice was associated with significant rises in the serum levels of amylase (X2.5) and lipase (X4). These increases were characterized by elevated levels of amylase and lipase, enhancement of pancreatic edema index, tissue inflammation, and autophagy response. All types of responses to administration of cerulein were profoundly exaggerated in Hpa-TG mice that over-express heparanase, as was evident by 6- and 8-fold increases in amylase and lipase levels, respectively. Importantly, pretreatment with Aspirin, PG545 or Roneparstat reduced pancreatic inflammatory response, autophagy, and amylase and lipase serum levels in both WT and Hpa-Tg mice. Noteworthy, combination of Aspirin with either PG545 or Roneparstat completely abolished AP at the biochemical, inflammatory and histological levels in both subgroups of animals.
Conclusion: Administration of either Aspirin or Hpa inhibitor exerts protective effect against Cerulein-induced AP. Interestingly, combination of Aspirin and Hpa inhibitors completely abolished AP, providing a rational basis for the treatment of this clinical setting
Disclosure: Nothing to disclose

P0101 CENTRALIZED CARE OF ACUTE PANCREATITIS SIGNIFICANTLY IMPROVES ITS OUTCOMES

Introduction: In this observational study, we investigated whether specialized care improves outcomes of acute pancreatitis (AP).
Aims and Methods: Consecutive patients admitted to 2 university hospitals with AP between 01.01.2016.–31.12.2016. were enrolled in this study (group A: specialized center, group B: general medical care). Data on demographic characteristics, etiology, severity, mortality and quality of care (enteral nutrition and antibiotic use) of AP were extracted from the Hungarian Acute Pancreatitis Registry. Independent sample t-test, Mann-Whitney test, Chi-squared or Fisher test were used for statistical analyses. Costs of care were calculated and compared in the 2 models of care.
Results: There were 355 patients enrolled between 01.01.2016 and 31.12.2016., 195 patients in the specialized center (group A) and 160 patients in the general medical hospital (group B). There was no difference in the mean age (57.02, +/−17.16 vs. 57.31, +/−16.50, p = 0.872) and sex ratio (56% males vs. 57% males, p = 0.837) between group A and B; allowing comparison without selection bias. Group A had lower mortality (n = 2, 1.03% vs. n = 16, 6.25%, p = 0.007), more patients received enteral feeding (n = 179, 91.8%, vs. n = 36, 22.5%, p < 0.001), less patients were treated with antibiotics (n = 85, 43.6% vs. n = 123, 76.9%, p = 0.001) and the median length of hospitalization was shorter (Me 6, IQR 5-9 vs. Me 8, IQR 6-11, p = 0.02). Costs of care were 25%less in group A.
Conclusion: Our data suggests that treatment of AP in specialized centers improves its mortality, the quality of care, the length of hospitalization and reduces the costs of care.

Introduction: In 1998, pancreatic stellate cells (PSCs) were firstly characterized by stelliform cells in pancreas. In healthy pancreas, PSCs are inactive and accompanied by lipid droplets that contain vitamin A. As the response of inflammation of injury, they were awakened from their inactive phenotype into highly proliferative myofibroblast-like cells with extracellular matrix components (EMCs) expressions and α-smooth muscle actin (α-SMA) positive.
In pancreatic ductal adenocarcinoma (PDAC) and chronic pancreatitis (CP), it is the activated PSCs that deposit collagen fibers and contribute to the progression of pancreatic fibrosis. Therefore, the in-depth study of the processes involved in PSCs activation is of critical importance for the development of effective therapeutic approaches for pancreas related diseases. Any agents which can inhibit the activation of PSCs could become potential candidates for treatment strategies in PDAC and CP.
Genistein a kind of isoflavonoid. In many reports, soy production shows potential efficacy to reduce the risk of osteoporosis, cardiovascular disease, and cancer. And genistein also has the antioxidant activity. A recent study showed that genistein can suppress the ROS-induced hypersensitivity.
Many studies have demonstrated that oxidative stress (OS) exists in CP and PDAC proven by reduced sustains antioxidant (AO) capacity and increased levels of products of OS in patients with CP and PDAC.
Genistein has the antioxidant activity, however, whether genistein can affect the activation of PSCs remains unclear until now. Hence, in this study, we aimed to explore the effect of genistein applied to the processes of PSCs activation. Our research can provide more groundwork for genistein related clinical treatment strategies of pancreas disease.
Aims and Methods: Pancreatic stellate cells (PSCs) have a vital role in pancreatic fibrosis accompanied by pancreatic ductal adenocarcinoma (PDAC) and chronic pancreatitis (CP). Any agents which can affect the activation of PSCs could become potential candidates for treatment strategies in PDAC and CP. Our aim was to explore the effect of genistein in the processes of PSCs activation.
Isolated PSCs from C57BL/6 mouse were treated with various dosages of genistein. Effect of genistein on autophagy, senescence and oxidative stress, as well as the activation of PSCs were analyzed by immunocytofluorescent staining, quantitative real time RT-PCR, western blotting, SA-β-galactosidase staining, malondialdehyde and reactive oxygen species (ROS) assay. Chronic pancreatitis animal model was also established to identify the anti-fibrotic effect of genistein by HE, Masson and Red sinus staining.
Results: Expression of α-smooth muscle actin, LC3II and Beclin1 levels were significantly reduced in genistein treatment groups. Meanwhile, compared with the control group, significant differences in the expression of desmin, P62, p-PI3K, p-AKT and p-mTOR levels in genistein treatment groups were found. Moreover, genistein affected the secretion of extracellular matrix components for PSCs. Few SA-β-gal positive cells were found in genistein-treated groups. A significant decrease in ROS positive cells and malondialdehyde levels were observed after exposure to genistein. The HE, Masson and Red sinus staining showed that there was less ECM production in genistein group.
Conclusion: Our finding suggests that genistein inhibits the activation of PSCs by suppressing autophagy through activating the PI3K/AKT/mTOR signaling pathway. Genistein may act as a therapeutic agent in PSC-related pathologies and/or anti-fibrotic approaches.

Introduction: Autoimmune pancreatitis (AIP) is a pancreatic inflammatory process characterized by a strong inflammatory cell infiltration and 2 histopathological distinct subtypes: type 1 and type 2. Diagnosis is often challenging and requires a combination of clinical, laboratory and imaging data. AIP can mimic pancreatic tumors leading to unnecessary resections if not correctly diagnosed. Short and long-term outcomes of AIP have been poorly investigated so far and no big series has been previously reported from Sweden.

Aims and Methods: We aimed to determine clinical presentation together with short and long-term outcomes of AIP in Sweden.
This was a single-center, retrospective, cohort study of patients with histologically confirmed or highly probable diagnosis of AIP according to ICDC criteria. Clinical/radiological characteristics, type of treatment and its outcomes were collected and analyzed. T-test was used for statistical analysis.
Results: 71 patients with AIP (87.3% with type 1), were evaluated at Karolinska University Hospital between 2004 and 2018; 49.2% males, mean age 49.2 years (range 44.7–53.8). Among them, 28.1% were histologically confirmed, 35.2% presented with jaundice, 22.5% with acute pancreatitis, 39.4% had non-specific symptoms such as weight loss or abdominal pain, 40.8% displayed other organ involvement (OOI). Radiologically, 40.5% displayed a focal mass, 36.2% a focal pancreatic enlargement, 27.5% a sausage-like pattern, 27.5% signs of acute pancreatitis, 10.1% of chronic pancreatitis. In total 58 patients (81.6%) underwent treatment comprising different medications: 46 (79%) cortisone, 7 (12.0%) azathioprine, 5 (8.6%) other immunosuppressive drugs. 26 (36.6%) underwent biliary stenting and 12 (16.9%) surgery due to suspicion for pancreatic malignancy. All (100%) of patients treated with cortisone, displayed a clinical response. After a mean follow-up of 46.7 months, 97.1% of patients were alive, 92.6% were in clinical remission, 70% displayed a radiological complete response, 89.6% were treatment-free. None developed pancreas cancer but 1 patient (1.4%) developed mucinous cystic neoplasm (MCN) with high-grade dysplasia and was therefore successfully operated. 59.3% of patients developed pancreatic exocrine insufficiency (PEI) of which 76.4% had a severe form (fecal elastase-1 < 100 μg/g) and 23.8% of patients developed diabetes mellitus (pancreatic endocrine insufficiency) of which 73.3% requiring insulin.
Conclusion: AIP is a challenging disease for diagnosis and treatment. Cortisone treatment is generally successful and provides clinical remission in the large majority of patients ($>90\%$). In the further course of the disease, a considerable number of patients develop PEI (up to 60% of pts) and diabetes (up a quarter of pts). Only a quarter of patients exhibit the characteristic ''sausage-like''pancreas, approximately 40% had a focus mass that can be misdiagnosed as pancreatic malignancy.
Disclosure: Nothing to disclose

P0104 DEFICIENCY OF FAT-SOLUBLE VITAMINS, MINERALS AND TRACE ELEMENTS IN PATIENTS WITH CHRONIC PANCREATITIS OF DIFFERENT ETIOLOGY

M. Vujasinovic[1], P. Maisonneuve[2], A. Hedström[1], R. Valente[1], S.L. Haas[1], J.-M. Löhr[1]

Introduction: Malnutrition with deficiencies of fat-soluble vitamins and trace elements are well-known consequences of maldigestion and poor absorption of nutrients, and have been frequently identified in patients with pancreatic exocrine insufficiency (PEI).
The prevalence of abnormal laboratory nutritional markers in chronic pancreatitis has been investigated in several studies, but most of them were restricted to patients with alcoholic chronic pancreatitis (CP) and had limitations due to the small number of studied patients. We are presenting results of the largest study so far comparing markers of malnutrition in relation to different etiological groups of CP.
Aims and Methods: We performed a retrospective analysis of medical records of patients with CP. Etiology of CP was determined according to M-ANNHEIM classification. The following demographic, clinical and demographic parameters were analyzed: age, gender, smoking (pack years), consumption of alcohol (units per day/years), fecal elastase-1 (FE1), albumin, calcium, magnesium, iron, triglyceride, cholesterol, hemoglobin, vitamin A, vitamin E, vitamin D and zinc.
Results: Altogether, 226 patients were included in the analysis: 131 (58.0%) male and 95 (42.0%) female, mean age 51.8 ± 17.9 years (range 18–89). The different etiologies of CP comprised: autoimmune ($n=69$; 30.5%), alcohol ($n=65$; 28.8%), efferent duct factors ($n=19$; 8.4%), hereditary ($n=26$; 11.5%), smoking ($n=20$; 8.8%) and idiopathic ($n=27$; 12.0%). FE1 was normal (FE1$>$ 200mg/g) in 83 (41.7%) patients. Mild to moderate PEI (FE1: 100–200mg/g was found in 22 (11.1%) of patients and severe PEI (FE1$<$ 100mg/g) in 94 (47.2%) of patients. Prevalence of deficiencies in serum nutritional panel was as follows: vitamin D 51.3%, albumin 34.2%, zinc 26.0%, hemoglobin 15.8%, cholesterol 14.1%, cobalamin 11.0%, iron 10.5%, vitamin A 8.3%, vitamin E 6.9%, magnesium 5.7%, folate 4.4%, triglycerides 1.1% and calcium 0%, with no statistical significant differences between nutritional deficiencies and different etiologies of CP. Factors associated with low zinc values were age >70 years ($p=0.003$) and current smoking status. ($p=0.02$). Factors associated with low vitamin D levels were age >60 years ($p=0.03$), male gender ($p=0.05$), insulin treated diabetes mellitus ($p=0.05$) and severe PEI ($p=0.05$). In patients in whom bone-mineral density was performed, 21 (24.1%) of patients had osteopenia and 9 (10.3%) osteoporosis.
Conclusion: A large number of CP patients exhibits signs of malnutrition with vitamin deficiencies. Deficiencies of fat-soluble vitamins, minerals and trace elements appear not to be related to CP etiology. Noteworthy, more than a third of patients with CP exhibit osteopenia or osteoporosis.
Disclosure: Nothing to disclose

P0105 PREDICTION OF PANCREATIC ATROPHY AFTER STEROID THERAPY USING EQUILIBRIUM CONTRAST CT IMAGING IN AUTOIMMUNE PANCREATITIS

Introduction: Previous reports showed pancreatic atrophy 6 months after the beginning of steroid therapy was associated with diabetes control worsening and incidence of new onset of diabetes in patients with autoimmune pancreatitis (AIP). However, predictor for pancreatic atrophy after steroid therapy at the diagnosis of AIP remains unknown.
Aims and Methods: We aimed to evaluate the role of equilibrium computed tomographic (CT) imaging for the prediction of pancreatic atrophy 6 months after steroid therapy
33 steroid treated AIP patients, who underwent CE-CT examinations before and after steroid therapy, were included in this study during December 2005 to October 2015. CT attenuation (Hounsfield units [HU]) values in noncontrast (NC) and equilibrium phase (EP) images were measured by placing 3 regions of interest (ROIs) from the pancreas swelling at the diagnosis of AIP. The incidence of the pancreatic atrophy after steroid therapy was estimated by the following 3 parameters in CE-CT before steroid therapy: 1) HU values in NC images; 2) HU values in EP images; and 3) subtracted HU values between NC and EP images. The relationship of each HU value with the degree of thickness of pancreatic body ($<$ 10mm, 10–15mm, $<$ 15mm) was also investigated. Pancreatic atrophy 6 months after steroid therapy was defined to be present when the width of the pancreatic body was less than 10 mm.
Results: Pancreatic atrophy was observed in 11 patients and not in 22 patients after the steroid therapy. Pancreatic atrophy was not associated with the thickness of pancreatic body on CE-CT before steroid therapy, other organ involvement, pattern of pancreas swelling (diffuse/focal) and serum IgG4 levels. The HU values in EP and subtracted HU values in AIP with atrophy were significantly higher than those without atrophy (113.2 ± 16.1 vs. 100.0 ± 11.8, $p=0.01$, 70.7 ± 18.0 vs. 57.8 ± 13.9, $p=0.03$). Thickness of pancreatic body after steroid therapy was also associated with HU values in EP and subtracted HU values (less than 10mm: 10–15mm: more than 15mm 113.2 ± 16.1 105.6 ± 9.2: 92.7 ± 10.9, $p=0.002$, 70.7 ± 18.0: 63.6 ± 11.7: 50.4 ± 13.5, $p=0.01$).
Conclusion: Equilibrium contrast CT imaging at the diagnosis of AIP would be a potential predictor for pancreatic atrophy after steroid therapy. The use of other therapies, such as immune-modulating agents, might be recommended for those patients.

Introduction: Fatty pancreas (FP) is an increasingly recognised entity associated with obesity and the metabolic syndrome. It correlates with non-alcoholic fatty liver disease (NAFLD) and progression to cirrhosis. It is hypothesised that a similar process exists resulting in chronic pancreatitis, fibrosis and pancreatic exocrine insufficiency (PEI) with associated malnutrition-related complications; such as vitamin D deficiency and impaired bone metabolism.[1–3] FP as a cause of PEI has not been thoroughly assessed, with published studies largely comprising case reports.[4–5]
Aims and Methods: This study assessed the relationship between FP and PEI, by examining the correlation with impaired bone metabolism. Cases were identified by a search of computed tomography (CT) reports from January 1st, 2010 to June 30th, 2017 at Melbourne Health, using keywords of FP and its synonyms; including pancreatic lipomatosis, fatty replacement or infiltration of the pancreas, lipomatous pseudo-hypertrophy of the pancreas, and pancreatic steatosis.[6] Controls were identified using keywords of normal pancreas. All images were reviewed by a radiologist to confirm CT report diagnoses. Retrospective clinical data was obtained from existing medical records and pathology. Data of interest included features of impaired bone metabolism, namely osteopenia and osteoporosis. Patients without available medical records were excluded. Cases and controls were assessed for baseline characteristics, including gender and age. Outcomes of impaired bone metabolism were assessed as categorical variables and statistical analysis undertaken on identified trends. Chi-square test for independence was used with a statistical significance level of $p < 0.05$; Fisher's exact test was used for small sample sizes with a statistical significance level of $p<0.05$. Sub-analyses were completed to remove confounding variables of age and gender.

Results: 133 cases and 117 controls were identified. There were no statistically significant differences in gender distribution or age between the cohorts. Both groups comprised 59% males. The mean age of cases and controls was seventy-75 years and 76 years respectively [case range 43–99 years; control range 42–94 years; p = 0.15]. There was a statistically significant difference in impaired bone metabolism, present in FP cases and controls in 41.4% and 20.5% respectively [OR 2.73, RR 2.02]. This difference was independent of gender [males OR 3.53, RR 2.65; females OR 2.28, RR 1.63] and age greater than 65 years [total OR 2.83, RR 2.02; males OR 3.44, RR 2.53]; women greater than 65 years demonstrating a positive trend without statistical significance [OR 2.19, RR 1.56].
Conclusion: The study showed a statistically significant relationship between incidental FP and impaired bone metabolism with a RR of 2.02. This was independent of gender and increased age, except with women greater than 65 years of age showing a positive trend but no statistical significance. This suggests that FP is not a benign finding and is associated with PEI. Recognising these patients is of clinical importance, as early detection and treatment of PEI will improve the associated morbidity and mortality.
Disclosure: Nothing to disclose

P0107 METABOLIC BONE DISEASE IN CHRONIC PANCREATITIS; A SINGLE-CENTRE EXPERIENCE

F. Rana, N. Bekkali, R. Charnley, J. Logue, M. Nayar, K. Oppong, J. Leeds
Freeman Hospital, Newcastle, United Kingdom

Contact E-Mail Address: fahdrana@outlook.com

Introduction: Chronic pancreatitis is associated with metabolic bone disease which increases the risk of fragility fractures. The National Institute of Clinical Excellence (NICE) guidance recommends that all patients aged 50 or over should be considered for DEXA scanning if at risk (1). Previous data has shown underutilisation of DEXA scanning in this population despite increased risk of osteoporosis. The aim of this study was to assess compliance with metabolic bone assessment in patients with chronic pancreatitis, assess the prevalence of abnormal DEXA scans and the impact of this assessment on appropriate management.
Aims and Methods: Retrospective analysis of outpatient coding for ''chronic pancreatitis'' was performed over a 2-year period. Patient demographics, aetiology of chronic pancreatitis, prescription of pancreatic enzyme replacement therapy (PERT), vitamin D levels, DEXA scan result, history of fractures and bone protection medications were noted. Univariate and multivariable analysis were performed to explore why DEXA scanning was not performed as well as factors associated with abnormal scans. The impact of DEXA scanning on prescription of bone protection was also assessed.
Results: 134 chronic pancreatitis patients (mean age 57.6 years, 88 males) were included with aetiology recorded as alcohol (n = 68), idiopathic (n = 52), hypertriglyceridaemia (n = 5), autoimmune (n = 4), hereditary (n = 3), anatomical (n = 1) and biliary (n = 1). 102/134 (76.1%) had vitamin D levels tested of which 82/104 (78.8%) were low. 62/134 (46.3%) had been sent for DEXA scanning of which 8 results were unavailable, 19 (30.6%) were normal, 24 (38.7%) showed osteopenia and 11 (17.7%) osteoporosis. 46/62 (74.2%) who had a DEXA scan were on bone protection compared to 30/72 (41/7%) who did not have a DEXA scan (p = 0.002). Lack of DEXA scanning was associated with female sex (adjusted OR 0.22, 95% CI 0.09–0.57, p = 0.0017) and not requiring PERT (adjusted OR 0.44, 0.20–0.95, p = 0.035). Not requiring PERT was also independently associated (protective) with abnormal DEXA scan results (adjusted OR 0.17, 95% CI 0.03–0.98, p = 0.047). 76 patients were prescribed bone protection of which 11 were on bone protection and 10 had a DEXA scan. 21/134 (15.7%) had a previous fracture of which 10 had DEXA scanning. 8/10 were on bone protection compared to 2/11 who had not had a DEXA scan (p = 0.03).
Conclusion: Despite a high prevalence of metabolic bone disease, less than half of chronic pancreatitis patients were assessed. Those not requiring PERT and females were less likely to have a DEXA. Interestingly, DEXA scanning was significantly associated with appropriate prescription of bone protection. Whether a standardised proforma would improve rates of metabolic bone assessments needs to be studied.

Introduction: Although the differential diagnosis between autoimmune pancreatitis (AIP) and pancreatic cancer (PC) is important in clinical settings, it is difficult to distinguish PC and localized type AIP which mimics PC in clinical presentation. However, the difference in imaging study between them has not been fully discussed.
Aims and Methods: The aim of this study was to compare the imaging findings between localized AIP and PC. 81 patients were diagnosed as AIP by International Consensus Diagnostic Criteria (ICDC) from April 2007 to October 2017, and 22 of them who showed the focal enlargement in parenchymal imaging were analyzed retrospectively (Group AIP; definitive 18, probable 4). During the same period, 191 patients were diagnosed as PC after surgical resection, and 44 of them were selected as a control (Group PC) in this study. To minimize the selection bias, the patients in Group PC was extracted by 1: 2 ratio optimal matching, which was adjusted for age, gender, mass location, tumor size using propensity score. Measured outcomes were the findings of contrast enhanced CT, MRCP, and EUS. The statistical evaluations were conducted using Mantel-Haenszel test.
Results: Median ages of Group AIP and PC were 69 (range, 49–80) and 71 (range, 49–82) years old, respectively. The male to female ratios of them were 15: 7 and 28: 16. The mass location of the patients in Group AIP was pancreatic head in 11 and body/tail in 11 while that of the patients in Group PC was pancreatic head in 22 and body/tail in 22. Median tumor sizes of them were 21 (range, 5–40) and 23 (range, 10–23) mm. On CT imaging, the rates of the patients with a low attenuation lesion in arterial phase or apparent capsule like rim were not different between Group AIP and PC (95% vs. 98%; 9% vs. 2%). However, a high attenuation lesion as compared to normal pancreatic parenchyma in equilibrium phase was observed more in the patients of Group PC (27% vs. 55%, p = 0.029). More than 4mm of main pancreatic duct (MPD) dilation was also noticed more in the patients in Group PC (27% vs. 64%, p = 0.008). MRCP was carried out to 19 patients of Group AIP and matched 30 patients of Group PC. Among them, MPD stricture at the lesion was observed in 84% of Group AIP and 80% of Group PC. However, MPD stricture apart from the lesion was also indicated in 53% of Group AIP and 7% of Group PC, which showed a significant difference between them. As for EUS, the significant differences were not present in the findings regarding the boundary or echogenicity of the lesion. However, hyperechoic foci inside the lesion was observed more in the patients of Group AIP (91% vs. 7%, p < 0.007).
Conclusion: While a high attenuation tumor in equilibrium phase or more than 4mm of MPD dilation on CT were observed more frequently in PC, specific findings of AIP were the MPD stricture apart from the lesion on MRCP and presence of hyperechoic foci inside the lesion on EUS.

Introduction: Early diagnosis of chronic pancreatitis (CP) is important in order to stop the disease progression in time. Unfortunately, neither definitions nor biomarkers of early CP are available. It has been reported that acute recurrent pancreatitis (ARP) can lead to CP, therefore, the number of previous attacks or ARP-associated parameters may be suitable for characterizing early CP.
Aims and Methods: The main aim of this study is to identify biomarkers which are significantly different in acute pancreatitis (AP), ARP, and CP. Another aim

is to understand the modifying effect of the number of acute episodes which could be considered as early CP. The Hungarian Pancreatic Study group has built up a prospective register of subjects with AP. In the last 6 years, precise clinical data were collected from 1435 patients. In this study, data on the number of episodes from 1315 patients with high data accuracy were analyzed.
Results: In our cohort, 983 (74.75%), 270 (20.53%), 62 (4.72%) patients had a single episode of AP, ARP, and CP, respectively. In the ARP group, 173 patients (64.07%) had 2 episodes, 43 (15.93%) had 3 episodes, 24 (8.89%) had 4 episodes, and 30 (11.11%) had 5 or more episodes. 13 biomarkers were significantly different in the first attack of AP and CP. The significant difference between AP and CP disappeared after the second episode of AP concerning 8 biomarkers (gender, age, biliary etiology, alcohol consumption, pseudocyst development, gammaGT, amylase, and red blood cell count), as did after the third episode concerning 3 biomarkers (biliary etiology, body mass index, ASAT) as did after the fourth and fifth episodes concerning 2 biomarkers (ALAT and smoking). As an average, the significant differences between AP and CP disappeared from 2.63 attacks. The average number of acute episodes of patients with pre-existing morphological alterations of the pancreas (CP group) was 4.77.
Conclusion: A definition of early CP may be 3 or more previous attacks of AP without chronic morphological alterations in the pancreas.

Introduction: Pancreatic cancer (PC) is a highly aggressive cancer. Gemcitabine (GEM) is a standard chemotherapy of advanced pancreatic cancer, but the efficacy still needs to be improved. Therefore, a more effective therapeutic method needs to be further explored.
Aims and Methods: The purpose of this study is to investigate the effect of hyperthermia on GEM anti-tumor activity and explore its underlying mechanism. In this study, PC cell line SW1990 was treated with hyperthermia at a temperature of 42°C. MTT assay was performed to evaluate cell proliferation, and Annexin V-FITC/PI assay was carried out to confirm the effect of hyperthermia on GEM-induced apoptosis. To further investigate the mechanism of hyperthermia enhancing GEM-induced apoptosis in PC cells, Western blot analysis was performed to detect protein levels of survivin, c-Jun-N-terminal kinase (JNK) and its phosphorylation (p-JNK), and flow cytometry assay was used to detect the generation of reactive oxygen species (ROS).
Results: Mild hyperthermia at 42°C increased effectively the inhibition of GEM on cell proliferation and GEM-induced apoptosis in PC SW1990 cells, and displayed an increased S-phase arrest and downregulated anti-apoptosis protein Bcl-2 expression and upregulated pro-apoptosis protein Bax, cleaved caspase-3 and cleaved caspase-9 expressions. Further, we found that hyperthermia led to a rapid generation of reactive oxygen species (ROS) and substantial activation of c-Jun-N-terminal kinase (JNK). And the introduction of ROS and JNK inhibitors suppressed hyperthermia-induced apoptosis in GEM-treated cells, suggesting that hyperthermia increased GEM cytotoxicity in PC SW1990 cells by inducing apoptosis via ROS/JNK signaling.
Conclusion: Hyperthermia is able to enhance sensitivity of pancreatic cancer SW1990 cells to gemcitabine through ROS/JNK signaling.

Introduction: Pancreatic cancer (PCa) cells have a notorious affinity to nerves. This neural invasion markedly worsens the prognosis of PCa patients. Identifying and targeting the specific molecular mediators of NI may thus have key implications for the future therapy of PCa. In the present study, we analyzed the transcriptome of neuro-invasive genetically induced PCa mouse models and validated the role of an identified mediator in human tissues and cells.
Aims and Methods: Cancer cells from the neuro-invasive Ela1-TGFalpha;p53lox/lox (TPC) mouse model were compared to Ptf1a-Cre;LSL-KrasG12D; p53lox/lox (KPC) cancer cells for difference in their mRNA profile via microarray analyses. The identified mediators were tested for their expression in 7 different human pancreatic cancer cells lines via immunoblotting and QRT-PCR, and in human neural invasion lesions via immunostaining.
Results: TPC cancer cells cells exhibited increased expression for the Fas receptor of the tumor necrosis factor (TNF)/TNF- receptor family, when compared to KPC cancer cells. All the 7 tested human PCa cell lines expressed Fas, yet at varying levels. The Fas protein content of the human PCa cell lines SU86.86 and T3M4 correlated to their *in vitro* neuro-invasive potential. In human PCa tissues, nerve-invading PCa cells exhibited a greater Fas immunoreactivity than cancer cells that were distant to nerves.
Conclusion: Fas may serve as a specific mediator of neural invasion in PCa. Targeting Fas in preclinical studies will further elucidate its actual role for tumor progression.
Disclosure: This abstract has also been submitted for presentation at the 2018 meeting of the European Pancreatic Club

P0112 PANCREATIC CANCER CELLS ENRICH PHOSPHO-PAXILLIN IN THEIR FILOPODIA DURING NEURAL INVASION

X. Wang, S. Teller, H. Friess, G.O. Ceyhan, I.E. Demir
Klinikum rechts der Isar, Technische Universität München, Department of Surgery, München, Germany

Contact E-Mail Address: wangxiaobo7hao@outlook.com
Introduction: Neural invasion (NI) is a leading cause of local recurrence, neuropathic pain sensation in pancreatic ductal adenocarcinoma (PDAC) and is encountered in up to 100% of PDAC cases. The changes that occur in the cytoskeleton of neuro-invasive PDAC cells have, however, never been analyzed.
Aims and Methods: Human PDAC cells and dorsal root ganglia (DRG) neurons isolated from newborn C57BL/6 mouse were suspended in a 3D migration assay and monitored via Apotome-supported digital time-lapse microscopy. The density and length of cancer cell filopodia were quantified with the FiloQuant® software, and the expression of phospho-paxillin was measured and compared between the neuron-facing migration front and control front. Cancer cells were treated with DRG supernatants, and the expression of phospho-paxillin was determined by Western Blotting. Tumor specimens obtained from 18 PDAC patients were immunostained against phospho-paxillin, and the phospho-paxillin content of cancer cells around nerves was compared to cancer cells that were in no contact with nerves.
Results: In the 3D-migration assays, the neuron-facing tumor cells acquired a typical morphological change of their cytoskeleton. In particular, phalloidin stainings shows that cancer cells migrating towards DRG exhibited a more polygonal shape with a consequent increase of their cell volume. The density and length of filopodia were increased, and the filopodia exhibited a specific enrichment of phospho-paxillin in the migration front, when compared to the back front. Accordingly, phospho-paxillin expression was increased in tumor cells around nerves when compared to tumor cells away from nerves in human PDAC tissues. After treatment of PDAC cell with DRG supernatants, the phospho-paxillin expression was prominently enhanced in PDAC cells.
Conclusion: Neuro-invasive PDAC cells exhibit highly characteristic alterations in their cytoskeletal conformation and specifically enrich phospo-paxillin in their filopodia.
Disclosure: This abstract has also been submitted for presentation at the 2018 meeting of the European Pancreatic Club.

P0113 PANCREATIC STELLATE CELLS AUGMENT NEURAL INVASION IN PANCREATIC CANCER

X. Wang, S. Teller, H. Friess, G.O. Ceyhan, I.E. Demir
Klinikum rechts der Isar, Technische Universität München, Department of Surgery, München, Germany

Contact E-Mail Address: wangxiaobo7hao@outlook.com
Introduction: Neural invasion is one of most unfavorable prognostic factors in pancreatic cancer (PCa). Neural invasion in PCa is particularly frequent in desmoplastic tissue areas. Pancreatic stellate cells (PSC) emerged in recent years as the main actor for the generation of pancreatic fibrosis in PCa. Thus, here, we investigated whether pancreatic stellate cells (PSC) can augment neural invasion in PCa.
Aims and Methods: Mouse PSC (mPSC) were isolated from C57BL/6 mouse, KPC (LSL-$Kras^{G12D/+}$; LSL-$Trp53^{flox/flox}$; $p48^{+/Cre}$) and TPAC (Ela-TGFalpha; $p53^{flox/flox}$; $p65^{flox/flox}$; $p48^{+/Cre}$) mice and cultivated under hypoxia, stimulated with TGFbeta, or left untreated as controls. The levels of PSC activation markers was determined by Western Blotting and qRT-PCR. For 3D-migration assays, mouse PCa cells alone or in mixture with mPSCs were placed next to murine dorsal root ganglia (DRG) neurons and observed via digital time-lapse microscopy. Furthermore, different ratios of tumor cell-mPSC co-cultures were confronted with DRG in the 3D-migration assay. Tumor cells were treated with mPSC supernatants and their viability was determined via the MTT assay.
Results: After treatment of mPSCs with recombinant TGFbeta or 12 hrs of hypoxia, the expression of α-SMA and vimentin was increased, both at mRNA level and protein level. In the 3D-migration assays, mPSC exhibited a similar affinity to DRG neurons, which was comparable to the affinity of cancer cells to neurons. Importantly, when cancer cells were mixed together with mPSCs, the migration of the mixture to DRG neurons was prominently increased when compared to their affinity in mono-culture. Here, the tumor cell viability was markedly higher after their treatment with mPSC supernatants.
Conclusion: TGFbeta-activated PSC augment the viability and particularly the neuro-affinity of PCa cells and accelerate their migration to neurons. PSC may be among the key promoters of neural invasion in PCa.

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is one of the most frequent gastrointestinal cancers and the 4th leading cause of cancer-related death. Despite several new developed anti-cancer drugs, the survival rates in advanced stages remain disappointing. Thus, innovative therapeutic approaches are urgently needed.
On molecular levels, oxidative stress (ROS) is important for the development and progression of PDAC. Amongst others, the highly reactive compound methylglyoxal (MGO) is an important source for ROS. MGO is a by-product of glycolysis and mainly detoxified by Glyoxalase-I (Glo-I). Overexpression of Glo-I has been shown in different tumours and linked to multi drug resistance in cancer therapy. So far, the impact of Glo-I in PDAC has not been elucidated. Thus, we analysed the role of Glo-I for proliferation, migration and colony formation in PDAC.
Aims and Methods: Expression of Glo-I was determined in 7 PDAC cell lines (BxPC3, Capan-1, Capan-2, CFPAC, HS776T, MiaPaca-2 and Panc-1) via immunocytochemistry (DAB-staining) by means of Cytospin centrifugation. Analysis of cell proliferation (Wst-assay), migration (scratch assay) and colony formation (clonogenic assay) was performed in all cell lines and correlated to Glo-I expression.
Results: HS776T and MiaPaca-2 cells showed highest expression of Glo-I. Capan-2 and CFPAC revealed low Glo-I staining intensity whereas BxPC3, Capan-1 and Panc-1 indicated average Glo-I expression. Interestingly, HS776T and MiaPaca2 also showed highest rates of proliferation and colony formation but not migration. In contrast, Capan-2 and CFPAC revealed minor proliferation and colony formation but only CFACP indicated high cell migration. Proliferation, migration and colony formation of BxPC3, Capan-1 and Panc-1 was at average levels.
Conclusion: Glo-I is expressed in all examined PDAC cell lines. High expression of Glo-I was positively correlated with proliferation and colony formation but not migration. Ongoing studies analysing the effects of Glo-I-knockdown, -overexpression and pharmacologic inhibition will further elucidate the role of Glo-I for PDAC.

Introduction: A soft texture of pancreatic remnant is one of the most important risk factors recognized for the development of clinical relevant post-operative pancreatic fistula (CR-POPF) after pancreatic resection. Several authors tried to make an objective assessment of pancreatic texture with preoperative scores or with the use of ultrasound elastography; for this latter, controversial results are reported.
Aims and Methods: The aim of the study is to evaluate pancreatic stiffness by shear-wave elastography in patients affected by pancreatic tumor compared to healthy volunteers, and to evaluate its predictive value for CR-POPF. Pancreatic elastography was performed in both groups. Differences in shear-wave elastography (SWE) were then assessed. Pre-operative SWE was compared with a pre-operative risk score for CR-POPF in patients undergoing surgery. A linear regression analysis was performed to evaluate predictive variables associated with CR-POPF.
Results: Ninety subject who underwent pancreatic elastography were consecutively enrolled. No differences were found in SWE (mean and SD, m/s) between healthy volunteers and patients affected by pancreatic neoplasm (1.33 ± 0.31 Vs 1.26 ± 0.30, $p = 0.337$). At multivariate linear regression only male gender was associated with a softer pancreas at SWE (OR 0.74, CI 0.55–0.98, $p = 0.035$). Considering 45 patients suitable for secondary end-point, the presence of a soft pancreas assessed by manual palpation (OR 61.21; CI 2.14->1000; $p = 0.016$) and the increasing of pre-operative risk score (OR 1.72; CI 1.01–2.96; $p = 0.049$) were the only predictors of CR-POPF. SWE seemed to be lower in patients who developed CR-POPF compared to patients who experienced a normal post-operative course (OR 0.01; CI 0.01–1.33; $p = 0.065$).
Conclusion: The pancreatic stiffness of the remnant pancreas of patients with pancreatic neoplasm is the same as healthy controls. A soft pancreas and an increasing pre-operative risk score were associated with CR-POPF. SWE showed a trend in predicting CR-POPF.

Introduction: Core biopsy needles have been developed for endoscopic ultrasound-guided fine-needle biopsy (EUS-FNB). However, the properties of needle gauge on diagnostic outcomes of solid pancreatic lesions remain unknown.
Aims and Methods: This trial compared obtaining rates of histologic cores from solid pancreatic lesions with EUS-FNB using 20- and 25-gauge (G) ProCore biopsy needles. In a prospective randomized multicenter clinical trial, patients with solid pancreatic lesions underwent EUS-FNB with either 20G or 25G ProCore biopsy needles. The obtaining rates of histologic core, overall diagnostic accuracy, and complications were compared between two groups.
Results: In total, 88 patients (48 men, mean age 65.7 years) were enrolled. There were no significant differences between 2 groups in demographic characteristics. The obtaining rate of histologic cores in 20G ProCore needle group (41/45, 91.1%) was significantly higher compared with 25G ProCore needle group (32/43, 74.4%, $p = 0.037$). However, there were no significant differences in overall diagnostic accuracy between 20G (40/45, 88.9%) and 25G (35/43, 81.4%, $p = 0.322$). There were no procedure-related adverse events in both groups.
Conclusion: In total, 88 patients (48 men, mean age 65.7 years) were enrolled. There were no significant differences between 2 groups in demographic characteristics. The obtaining rate of histologic cores in 20G ProCore needle group (41/45, 91.1%) was significantly higher compared with 25G ProCore needle group (32/43, 74.4%, $p = 0.037$). However, there were no significant differences in overall diagnostic accuracy between 20G (40/45, 88.9%) and 25G (35/43, 81.4%, $p = 0.322$). Introduction: Although intraductal papillary mucinous neoplasms of the pancreas (IPMNs) have been recognized as precursor lesions for pancreatic cancer, it has been reported to be associated with pancreatic ductal adenocarcinoma (PDAC) that does not occur from IPMN lesions (concomitant PDAC, C-PDAC). However, the occurrence rate of C-PDAC and clinicopathological features of C-PDAC have not been clarified in comparison to other types of pancreatic adenocarcinoma.
Aims and Methods: This study was performed to elucidate the clinicopathological features of C-PDAC. Of the 438 patients histologically confirmed to have pancreatic invasive adenocarcinoma by using resected specimens, EUS-FNA, or endoscopic biopsy at our center between January 1985 and December 2016, 91 patients with C-PDAC were included in this study and retrospectively analyzed. Accompanying IPMN was diagnosed by using resected specimens in 47 resection cases and by using imaging examinations in 44 non-resection cases. The outcome measurements were defined as (1) the rate of C-PDAC patients among all PDAC patients (C-PDAC + PDAC without IPMN) and (2) the clinicopathological features of C-PDAC (group A, $n = 47$) in comparison to those of PDAC without IPMN (group B, $n = 105$) and those of invasive cancer derived from branch duct IPMN (group C, $n = 27$) in resected cases.
Results: The percentage of C-PDAC was 29% (47/160) in resection cases and 16% (44/278) in non-resection cases. There was no statistical difference in all factors investigated, such as age, sex, history of acute pancreatitis or diabetes mellitus, pathological stage, and survival period after surgical resection, between groups A and B. Between groups A and C, the pathological stages (stage IA, 6% vs. 33%, $p = 0.004$) and survival period after surgery (mean, 1368 vs. 2567 days, $p = 0.044$) were significantly different. As to morphological findings on the accompanying IPMN in groups A and C, there was significant difference in the cyst size (17.1 ± 10.6 mm vs. 44.1 ± 21.0 mm, $p < 0.001$), multifocal

prevalence (60% vs. 15%, $p < 0.001$), existence of mural nodules (11% vs. 63%, $p < 0.001$), and the histological subtype (gastric type, 88% vs, 44%). The cyst size of the largest IPMN lesion was < 20 mm in 66% of the patients in group A, whereas it was ≥ 20 mm in all patients in group C.
Conclusion: PDAC which was not derived from IPMN was accompanied by IPMN apart from the PDAC lesion in 29% of the resection cases and 16% of the non-resection cases. There were no differences in all factors investigated, including the survival period, between PDACs with and without IPMN apart from the PDAC lesion among the resection cases. IPMNs in most cases of concomitant PDAC was multifocal with small lesion sizes, gastric subtype and without mural nodules, unlike the IPMNs in cases with invasive cancer derived from IPMNs.

Introduction: There are many reports that KRAS and p53 were useful in improving the diagnostic yield of endoscopic ultrasound-guided fine needle aspiration biopsy (EUS-FNA) for pancreatic tumors. Nevertheless, KRAS and p53 are often negative if structurally, the tumor is anaplastic or the sample amount is small. On the other hand, Maspin which is serine protease inhibitor, is recently attracted as a new gene marker of pancreatic cancer
Aims and Methods: The aim of this study was to evaluate the usefulness of Maspin staining in histopathological diagnosis using EUS-FNA.
98 patients who were performed both Maspin and p53 staining in specimen obtained by EUS-FNA were enrolled in this study. All patients were diagnosed as the pancreatic adenocarcinoma at Dokkyo medical university hospital using EUS-FNA in the period from April 2015 to December 2017. We evaluated positive rate of Maspin and/or p53, and the relationship between immunohistochemistry and clinical factors (sex, age, location, size, tissue differentiation, rate of metastasis, Maspin positive rate, and tumor biomarker).
Results: The positive rates were 72.4% (71/98) in p53, 98.0% (96/98) in Maspin. There was no statistically significant difference between p53 positive and negative cohorts, but Maspin was positive in all cases of the p53 negative cohort. On the other hand, there was statistically significant difference between Maspin positive cohort and the negative cohort in age (70.5 vs. 53.0, $p = 0.026$) and the revel of SPAN-1 (3569 vs. 5, $p = 0.023$). In addition, p53 was positive in 2 cases where Maspin was negative.
Conclusion: The expression of Maspin was higher than p53 in pancreatic adenocarcinoma. Our study suggested that the immunostaining combined p53 and Maspin would contribute to the improvement of diagnostic yield for pancreatic tumor using EUS-FNA.

Introduction: Although early detection of pancreatic cancer is associated with a better prognosis, it has been extremely difficult to detect. Localized stenosis of the main pancreatic duct (MPD) often indicates early pancreatic cancer, including intraepithelial cancer.
Aims and Methods: The aim of this study was to evaluate the predictive sensitivity of localized MPD stenosis for the detection of pancreatic cancer.
Among 597 patients who underwent intentional endoscopic retrograde pancreatography (ERP) between January 2008 and December 2017 at Sendai City Medical Center, those in whom ERP was performed to evaluate abnormal findings on the MPD were extracted from the prospectively maintained database. Those with multiple MPD stenoses, diffuse MPD dilation, and a mass detectable on other imaging examination, were excluded. Those with other pancreatic diseases, such as intraductal papillary mucinous neoplasm (IPMN), autoimmune pancreatitis (AIP), and definite chronic pancreatitis were also excluded. Finally, 17 patients with a single, localized stenosis in the MPD without a mass (defined as the typical MPD findings for suspicious early pancreatic cancer [TF-EPC]) were included in this study.
Final diagnosis of the etiology causing the MPD stenosis was defined as being (1) malignant or benign by histological diagnosis with a surgically resected specimen when resection was performed, (2) malignant when an obviously malignant tumor appears at the site during follow-up if resection was not performed, or (3) benign when the abnormal findings improved or did not change on imaging examinations (EUS, CT, MRI or ERP) after a 5-year follow-up without resection. If the findings were difficult to define, whether they changed or not, the patients were excluded.
The main outcome measurement was the predictive sensitivity of the TF-EPC for the presence of pancreatic cancer.
Results: Of the 9 patients who underwent surgical resection among the analyzed 17 patients, the final diagnosis of the MPD stenosis was judged as pancreatic cancer in 8 patients and as a non-neoplastic change in 1 patient. In the remaining 8 patients, the MPD stenosis was judged as being non-neoplastic by performing clinical follow-up of >5 years (mean follow-up period, 2186 ± 415 days).
Overall, the final diagnosis of the MPD stenosis with the TF-EPC was pancreatic cancer in 8 patients (47%) and a non-neoplastic change in 9 patients. In other words, the predictive sensitivity of the TF-EPC for presence of pancreatic cancer was 47%. Of the 8 patients with pancreatic cancer, 3 were diagnosed as having intraepithelial adenocarcinoma, whereas the other 5 had invasive ductal adenocarcinoma. The size of the invasive mass was less than 10 mm in all 5 patients with invasive cancer (mean diameter, 7.0 ± 0.9 mm). The sensitivity, specificity, and accuracy of cytology by using pancreatic juice obtained during ERP with cell-block preparation was 100%, 80%, and 88%, respectively.
Conclusion: MPD stenosis with typical findings for suspicious early pancreatic cancer, which was defined as a single, localized stenosis without other pancreatic diseases with no mass detectable on imaging examination, was derived from pancreatic cancer in half of the patients. Such findings were found to be useful for detecting early pancreatic cancer, although histological confirmation using pancreatic juice cytology would be necessary before surgical resection.

Introduction: About 5% of pancreatic ductal adenocarcinoma [PDAC] are inherited, with a deleterious germline mutation detected in $\leq$ 20% of families. Pancreatic screening in high-risk individuals (HRI) is proposed to perform early surgical treatment of malignant lesions, such as pancreatic intraepithelial neoplasia [PanIN] or intraductal papillary mucinous neoplasms [IPMN] with high-grade dysplasia, or even invasive PDAC at an early stage.
Performing surgery in HRI at the optimal time, i.e., neither too early (non-malignant lesions) nor too late (advanced PDAC), remains challenging. The outcomes of pancreatic surgery in HRI have never been properly explored.
Aims and Methods: We aimed to evaluate surgical appropriateness and explore predictive factors in screened HRI who underwent pancreatic surgery. A patient-level meta-analysis was performed on all studies reported since 1999 who included HRI defined by strict criteria and described individual screening, surgical and pathological data of operated HRI.
For each operated HRI, the highest-risk pancreatic abnormality identified at screening was classified into low-risk abnormality [LRA] (cyst with benign features) or high-risk abnormality [HRA] (cyst with worrisome features or high-risk stigmata of malignancy, solid mass and/or sample positive for malignancy). The highest malignant pathological lesion was classified into no/low malignant potential (branch-duct IPMN or PanIN with low-grade dysplasia) or potentially/frankly malignant (branch-duct IPMN or PanIN with high-grade dysplasia, main duct IPMN with low- or high-grade dysplasia or PDAC).
Surgical appropriateness was considered when potentially/frankly malignant lesions were resected. Univariate and multivariate logistic regression models of factors predictive of surgical appropriateness were performed. The variables of the multivariate model were used to establish a score and nomogram allowing the estimation of individual probability of surgical appropriateness.
Results: 13/24 studies were selected, which reported 90 HRI operated on. LRA and HRA were detected in 46.7% and 53.3% of HRI, respectively. Surgical appropriateness was consistent in 38 (42.2%) HRI operated, including 20 HRI (22.2%) with PDAC. Identification of HRA at screening was the only factor associated with surgical appropriateness at multivariate analysis ($p = 0.001$). We proposed the Beaujon score, including the identification of HRA, age $\geq$ 50 and the existence of deleterious germline mutation. The score was used to build a nomogram which predicted individual surgical appropriateness with an area under the curve of 0.81.
Survival data were available for 66 operated HRI. After a median postoperative follow-up of 29 months, 9 HRI died, including 8 who were operated on for invasive PDAC. HRI with invasive PDAC had a significantly lower overall survival (median, 35 months) compared to HRI with other pathological results ($p < 0.0001$).
Conclusion: Overall, 42.2% of HRI underwent appropriate surgery. Surgical appropriateness was higher in HRI with HRA identified at screening. We proposed the Beaujon score to help selecting the best candidates for pancreatic resection. This score requires prospective validation.

Introduction: The poor prognosis after surgical resection of invasive ductal carcinoma of the pancreas (IDCP) is due to the high recurrence rate. IDCP usually recurs in the liver and at local sites, such as the pancreatic bed or adjacent structures. Notably, the survival duration among patients with liver metastasis (LM) is ≤3 years after R0 resection, even when the diameter of the IDCP is < 2 cm (pTS1). We analysed patients with pTS1 IDCP and found that the median number of invading veins within the IDCP area and the percentage of invading veins/total number of veins within the IDCP area were significantly higher in patients with than without LM [1]. However, frequent venous invasion by the carcinoma and cancer cell migration into the bloodstream had already occurred at the time of surgical resection, particularly in patients with LM. Thus, measures should be taken to avoid LM as early as possible. We have attempted to apply the results of venous invasion by the carcinoma to preoperative diagnosis, but vascular invasion could not be detected by conventional imaging. Worrisome imaging features of hepatocellular carcinoma on computed tomography and magnetic resonance imaging were recently shown to correlate with microvascular invasion and recurrence [2]. We analysed the correlations among LM, venous invasion, tumour growth patterns, and endoscopic ultrasonography (EUS) findings in patients with pTS1 IDCP.
Aims and Methods: Of 402 patients with IDCP, 21 (5.2%) had pTS1 tumours. The follow-up period among these 21 patients ranged from 6 months to 25 years. All patients underwent R0 resection. Handling of the surgical specimen and assessment of vascular permeation by the carcinoma were performed as previously described [1, 3]. Clinicopathological factors were assessed according to the Classification of Pancreatic Carcinoma (4th English edition) by the Japan Pancreas Society. The tumour growth pattern of neoplasms infiltrating surrounding tissue (INFa, expanding growth; INFc; diffusely infiltrating pattern; INFb, in between INFa and INFc) was assessed by loupe findings of the maximum cut surface of the IDCP. EUS findings were evaluated with respect to morphology.
Results: The 21 patients comprised 12 men and 9 women aged 51 to 80 years. 5 patients died of LM, and 12 patients remained alive without recurrence. The other 4 patients died of peritonitis carcinomatosa following local recurrence, subarachnoid hemorrhage, primary lung cancer, and old age, respectively. The median number of invading veins in the area of the IDCP was 5 and 2 in patients with and without LM, respectively ($p = 0.0009$), and the percentage of invading veins/total number of veins in IDCP area was 73.2% and 26.0% in patients with and without LM, respectively ($p < 0.0001$). The numbers of INFa/b/c tumours were 0/1/4 and 2/14/0 in patients with and without LM, respectively ($p = 0.0005$). Among 14 patients who underwent EUS, all 4 patients with LM exhibited nodules with a vague periphery and sunburst formation, but 7 of 10 patients without LM showed nodules with a smooth periphery ($p = 0.018$).
Conclusion: Patients with IDCP with a vague periphery as demonstrated by EUS should not only undergo surgical resection but also prepare for LM.
Disclosure: Nothing to disclose

Introduction: EUS-FNA is the first-line technique for sampling pancreatic lesions. It is regarded as safe procedure but many factors influence adequacy and accuracy, among the others presence of the cytopathologist and the real time evaluation and analysis of the specimens.
Aims and Methods: This is a retrospective analysis of patients who underwent EUS-FNA for known pancreatic solid lesions before and after ROSE adoption. All consecutive EUS-FNA procedures for pancreatic lesions performed during the first year of adoption (ROSE1 group) and the following year (ROSE2 group) were compared to those performed during the previous year (pre-ROSE group). EUS was performed using a linear echoendoscope. FNA was performed using fine needles 22 or 25 Gauge diameter. Demographics, lesion location and size, number of needle passes, final diagnosis were recorded. The gold standard for diagnosis was considered histological analysis of surgical specimen, when available, or clinical and radiologic follow up compatible with neoplasia (positive) or absence of deterioration/spontaneous resolution (negative). Specimen were categorized into *diagnostic* if a final diagnosis was reported and *non diagnostic* in case of no sufficient cells or when atypia was not further classified. Adequacy (samples providing sufficient material for evaluation), diagnostic yield (rate at which a diagnosis is made), diagnostic accuracy (correspondence between cases for which a diagnosis was rendered and the gold standard) were evaluated. Aim of the study was to compare the adequacy, diagnostic yield and accuracy of EUS-FNA for solid pancreatic lesions before and after introduction of ROSE.
Results: 94 pancreatic lesions in 92 patients were enrolled (26, 30 and 38 in pre-ROSE, ROSE1 and ROSE2 groups respectively). Adequacy rate was 96.2%, 93.3% and 100% in pre-ROSE, ROSE1 and ROSE2 groups, respectively ($p = NS$). Diagnostic yield was 76.9 %, 86.7%, 92.1% and accuracy 65.4%, 76.7% and 86.8% in pre-ROSE, ROSE1 and ROSE2 groups, respectively, with significant difference between pre-ROSE and ROSE2 groups ($p < 0.5$).
Conclusion: The routine use of ROSE during EUS-FNA for solid pancreatic lesions is associated with an improvement in terms of diagnostic yield and accuracy, but it does not seem to improve the adequacy of FNA. Lack of difference during the first year of adoption of ROSE was probably due to the learning curve of the multidisciplinary team.

P0124 WATER-POCKET ENDOSCOPIC SUBMUCOSAL DISSECTION FOR SUPERFICIAL GASTRIC NEOPLASMS: A PROSPECTIVE STUDY

H. Harada, R. Nakahara, D. Murakami, S. Suehiro, T. Nagasaka, T. Ujihara, R. Sagami, Y. Katsuyama, K. Hayasaka, Y. Amano
New Tokyo Hospital, Gastroenterology, Chiba, Japan

Contact E-Mail Address: nerimaendo@hotmail.co.jp
Introduction: It is essential to obtain a clear view during the endoscopic submucosal dissection (ESD) to precisely dissect the appropriate submucosal layer. Some advantages of underwater techniques for gastric ESD have been reported in comparison with gas insufflation method [1, 2]. We have developed a new ESD method with the creation of a local water-pocket that provides a clear view in the dissection field. Therefore, we aimed to investigate the feasibility and safety of water-pocket ESD (WP-ESD) for superficial gastric neoplasms.
Aims and Methods: We prospectively recruited 50 patients with gastric neoplasms (early gastric cancer or gastric adenoma) between April 2017 and December 2017. Among them, 48 patients were treated with WP-ESD technique. The patients with WP-ESD were compared with 48 patients treated with standard ESD (S-ESD) who were selected by propensity score matching. The primary outcome was the ESD procedure time.
The rationale of the WP-ESD technique is that ESD procedure is carried out underneath the target lesion via a locally created water pool in the submucosal layer. First, to create a submucosal pocket, an initial incision is made approximately 2 cm proximal to the lesion. Second, the tip of the attached transparent ST hood is inserted into a small hole followed by injection of saline solution, and dissection of the submucosal layer is initiated in the water pool.
The study protocol was approved by the ethics committee of New Tokyo Hospital (IRB No. NTH 0112) and was registered in the University Hospital Medical Network Clinical Trials Registry (UMIN: 000030266).
Results: Total procedure time was significantly shorter in the WP-ESD group than in the S-ESD group (median [IQR], 27.5 [19–45] min vs. 41 [29.8–69] min; $p < 0.001$). Similarly, the dissection speed was significantly greater in the WP-ESD group than in the S-ESD group (median [IQR], 22.5 [16.8–35.3] mm^2/min vs. 17.3 [12.7–22.1] mm^2/min; $p < 0.001$). The rates of complete en bloc resection in the WP-ESD group and the S-ESD group were 97.9% and 95.8%, respectively ($p > 0.99$). The volume of saline solution used in the WP-ESD group was 205 ml (median). There were no perforations in either group.
Conclusion: WP-ESD was associated with a shorter procedure time than S-ESD. WP-ESD may provide an alternative method for resection of superficial gastric neoplasms.
Disclosure: Nothing to disclose

P0125 CLINICAL VALUES OF DENTAL FLOSS TRACTION ASSISTANCE IN ENDOSCOPIC FULL-THICKNESS RESECTION FOR SUBMUCOSAL TUMORS ORIGINATING FROM THE MUSCULARIS PROPRIA LAYER IN THE GASTRIC FUNDUS

Q. Shi, Y.-S. Zhong, P.-H. Zhou
Endoscopy Center, Zhongshan Hospital of Fudan University, Shanghai, 200032, China, Endoscopy Center, Shanghai, China

Contact E-Mail Address: shiqiangqy@126.com
Introduction: With the development and maturation of endoscopic resection, endoscopic full-thickness resection (EFTR) derived from endoscopic submucosal dissection (ESD) is gradually accepted and promoted to treat submucosal tumors (SMTs) originating from muscularis propria (MP) lays. However, there are some difficulties when EFTR is applied in the treatment of muscularis propria lesions in gastric fundus. This study intends to explore whether EFTR can be more simple, safe and effective with the traction assistance of dental floss.
Aims and Methods: From January to December in 2016, the clinical data of patients (trial group) with lesions from MP in gastric fundus undergoing EFTR with traction assistance of dental floss at Zhongshan Hospital, Fudan University were reviewed retrospectively. Control group was matched with trial group according to tumor size by 1 to 1 from January to December in 2015. The differences in tumor resection time, patient hospitalization time and complication rate were evaluated. EFTR with dental floss traction was performed as follows: During the stripping process, after removing the endoscope, an clip was tied on the tip of the dental floss, while the shorter side of the floss was cut to prevent it from affecting the field of view. The longer side of the floss was attached to the endoscope body side and was guided by an assistant.The endoscope was then reinserted, and the tumor was fastened by the clip. When the assistant pulled the dental floss, the tumor edge became clearly exposed. The tumor was then peeled away under direct visualization.
Results: There was no significant difference in the average age of the 2 groups with 24 cases respectively (58.7 ± 11.8 y vs. $56.6 + 7.9$ y, $t = 0.663$, $p = 0.511$). The statistic difference occurred when operative time was compared in 2 groups ($10.8 + 2.8$ min vs. 19.0 ± 4.7 min, $t = 7.298$, $p < 0.05$). There was no statistically significant difference in postoperative hospital stay time ($3.2 + 0.5$ d vs. $3.2 + 0.5$ d, $t = 0.291$, $p = 0.772$). In the trial group, there were 19 cases of gastrointestinal stromal tumors (both Group1) and 5 cases of leiomyoma. The control group had the same result. 2 groups of patients did not have postoperative delayed bleeding, or perforation and other complications.
Conclusion: First, dental floss traction could help expose the tumor boundaries, so that the operation field was clearer to simplify the operation process and significantly reduce the procedure time. Second, in the course of surgery, EFTR-assisted dental floss traction could better reveal the blood vessels or find bleeding blood vessels for prevention and early treatment of bleeding. Third, when the tumor was completely resected, dental floss could also prevent the tumors from falling into the abdominal cavity and help to remove the excised tumors.

Introduction: Serious complications due to perforation restrict the development of duodenal endoscopic treatment. The key stage for remediation is the successful endoscopic closure to prevent peritonitis and the need for surgical intervention. This report presents a new simple method for the closure of large iatrogenic duodenal perforations with purse-string sutures using the novel endoloops and repositionable clips through a single-channel endoscope.
Aims and Methods: A total of 23 patients with iatrogenic duodenal perforations ≥ 1cm were retrospectively studied who were respectively treated by purse-string sutures using the novel LeCamp™ endoloops and the SureClip™ repositionable hemostasis clips with the single-channel endoscope at 4 institutes.
Results: The median maximum diameter of iatrogenic duodenal perforations was 1.65 cm (range 1.0–3.0 cm). Complete endoscopic closure of all 23 perforations was achieved. No patient had severe complications such as peritonitis. The wounds were healed and no obvious duodenal stricture was observed in all cases after 3 months.
Conclusion: Purse-string sutures using the novel endoloops and the repositionable endoclips through single-channel endoscope were feasible, effective and easy methods for the closure of large duodenal iatrogenic perforations.

P0127 TO ASSESS THE ANAESTHETIC REQUIREMENTS AND MODIFICATIONS REQUIRED IN PER ORAL ENDOSCOPIC MYOTOMY (POEM) FOR SAFE PROCEDURE AND PREVENTION OF COMPLICATIONS. A RETROSPECTIVE ANALYSIS OF PROTOCOL FOR ANESTHESIA IN POEM DEVISED AT OUR CENTRE. A STUDY OF 175 CASES

P.N. Desai[1], M. Kabrawala[2], A. Jha[3]

[2]*Surat Institute of Digestive Sciences, Gastroenterolgy, Surat, India*
[3]*Surat Institute Of Digestive Sciences, Anesthesia, Surat, India*

Contact E-Mail Address: drp_desai@hotmail.com
Introduction: To assess modifications in anaesthesia practices for POEM.
Aims and Methods: To assess the anaesthetic requirements and modifications required in Per Oral Endoscopic Myotomy for safe procedure and prevention of complications.
Preoperative Measures: Clear liquids and lukewarm water 24 hours before. Thorough pre anesthesia work up.
Induction of anaesthesia and intraoperative management: POEM procedures were carried out under general anaesthesia with endotracheal intubation and positive pressure ventilation to reduce the risk of capno mediastinum. One assistant is kept ready for Selliks manoeuvre and suctioning of the oral cavity if patient aspirates the fluid in the esophagus. Anaesthesia in all the patients was induced by rapid sequence method (to prevent aspiration of esophageal content). Sedation and induction was achieved by (Inj. Glycopyrrolate 0.2 mg; Midazolam 0.02 mg/kg; Propofol-1-2mg/kg; Fentanyl 100mcg; Succinylcholine 1–2 mg/kg). Atracurium (0.5 mg/kg) was used as neuromuscular block and maintenance done by N_2O+O_2+Sevoflurane (0.5–2 minimum alveolar concentration). As and when required intravenous infusion of nitro-glycerine and selective beta-blocker was used. Mechanical ventilation with pressure control mode was taken as choice method. Intraoperative screening including NIBP, ECG, and PULSE OXIMETRY & $ETCO_2$ was used. $ETCO_2$ was kept between 35–45 mm Hg by adjusting Respiratory Rate & Minute ventilation. Peak Airway pressure was observed as potential indicator for elevated intra abdominal pressure. It was tried to maintain below 35cm of H_2O by allowing low flow of CO_2 and frequent suctioning of excess CO_2 from stomach by EGD scope. Periodic assessment by palpation of upper abdomen, thorax and neck area was done to rule out capno peritoneum, capno thorax and surgical emphysema.
The tidal volume is kept low and ventilator rate is kept high to eliminate ET CO_2.
Results: Observations:
Total number of patients: **175**
Number of patients with fluid in oral cavity: **24 (13.7%)**

Number of patients who aspirated during induction of anaesthesia: 3 (1.7%). They were not required to be ventilated more than normal, but antibiotics and intensive medical support were needed in these cases.
Patients with significant rise in blood pressure intra operatively: 36 (20.5%). CO_2 flow at very low pressures was a key to avoiding this.
Patients developing high airway pressures: **16 (9.1%)**. Usually airway pressures are kept in between 20–30 cms of H2O. Airway pressures more than 40 cms of H_2O had capno thorax. They were hyperventilated and the airway pressure controlled.
Patients with symptomatic capno peritoneum/capno thorax: **3 (1.7%).** 2 needed needle decompression and 1 intercostal drain.
Patients with insignificant capno peritoneum: **108 (61.7%).** Noted on gastrografin study after 24 hours. No management needed.
Patients with post-operative pain: **140 (80%).** Controlled with tramadol and paracetamol.
Conclusion: For induction of anaesthesia in POEM, initial ventilation before intubation should not be used.
We have to be prepared for managing aspiration.
Aggressive blood pressure monitoring and maintenance is a must. Nitro glycerine and beta blockers are very useful for this.
Low tidal volume and high ventilatory rate are essential to eliminate ET CO_2.
Keen observation of ET CO_2 and persistent clinical assessment is mandatory to detect surgical emphysema and capno thorax and peritoneum. Manage these immediately.
Analgesics are required post operatively in majority.

P0128 SAFETY OF PROPOFOL-BASED SEDATION WITHOUT ENDOTRACHEAL INTUBATION DURING ENDOSCOPIC SUBMUCOSAL DISSECTION IN THE ESOPHAGUS AND STOMACH

S.E.M. Van de Ven[1], L. Leliveld[2], M. Klimek[2], T.R.H. Hilkemeijer[2], M.J. Bruno[1], A.D. Koch[1]

Introduction: Endoscopic submucosal dissection (ESD) in the upper gastrointestinal tract is mostly performed in patients under general anesthesia with endotracheal intubation, especially when the estimated procedure time is likely to exceed two hours [1]. The reasons for using general anesthesia are continuous airway protection, less respiratory problems or interruptions during the procedure and therefore lower complication rates [2]. However, general anesthesia leads to longer post-procedural hospital stay [3]. Anesthetic complication rates for general anesthesia reported in the literature are up to 18.9% [2]. Analgo-sedation using propofol is favorable due to its appropriate sedation level, short half-life and rapid recovery period [4]. We hypothesized that ESD can be safely performed with analgo-sedation using propofol and remifentanil without endotracheal intubation instead of general anesthesia. The aim of this study is to report on the endoscopic and anesthetic complication rates of ESD with propofol sedation.
Aims and Methods: Retrospective cohort study of patients who underwent esophageal or gastric ESD in a tertiary referral center in the Netherlands between October 2013 and February 2018. All patients were sedated by intravenous administration of propofol until the required level of sedation was achieved according to the Ramsey Sedation Scale (score 4 to 5). Remifentanil infusion was started until the required level of analgesia was achieved. Vital signs were continuously monitored during the procedure in the endoscopy room. Primary endpoints were the rates of intra-procedural endoscopy and anesthesia related complications, secondary endpoints were 30-days post-procedural complication rates and the endotracheal intubation conversion rates.
Results: We included 86 patients with a median age of 70 years (range 24–91). 34 ESDs were carried out in the esophagus, 51 in the stomach and 1 in the duodenal bulb. Median lesion size was 25 mm (range 8–120). Median procedure time was 100 minutes (range 15–510). En bloc resection was performed in 77 patients (89.5%), piecemeal resection in 1 patient (1.2%). In 7 patients (8.1%), the procedure was discontinued and no histology was obtained due to muscular invasion ($n = 5$) or bleeding ($n = 2$). In 1 patient (1.2%), ESD was converted to endoscopic mucosal resection due to bleeding. Early cancer was found in 72/79 patients (91.1%). In 2 patients (2.3%), an intra-procedural endoscopic complication occurred; both bleeding. In 14 patients (16.3%), a post-procedural complication occurred; 5 bleeding (5.8%), 6 retrosternal pain (7.0%), 2 dysphagia (2.3%), 1 stomach pain (1.2%). In 2 patients (2.3%) an intra-procedural anesthetic complication occurred; 1 coughing and in 1 patient hypotension and desaturation ($SpO2 < 90$) occurred. Due to hypotension, desaturation and extended duration of the procedure (>5 hours), this patient was converted to endotracheal intubation. In 2 patients (2.3%), a minor post-operative anesthetic complication occurred; 1 nausea and 1 atrial fibrillation. 42 patients (48.8%) were discharged the same day. 38 patients (44.2%) were discharged the following day (29 logistical reasons, 9 medical reasons). In 6 patients, hospital stay was >2 days. Longer hospital stay was not related to anesthesia and no patients were readmitted for anesthesia-related complications.
Conclusion: Propofol-based analgo-sedation without endotracheal intubation is safe for ESD procedures in the esophagus and stomach with low complication rates and short hospital stay.
Disclosure: Nothing to disclose

Introduction: Endoscopic submucosal dissection (ESD) is a standard treatment for early stage esophageal neoplasia. However, because the residual mucosa after ESD retains a high potential for development of metachronous neoplasia, recurrence sometimes develops proximal to a previous ESD scar. Such lesions are predictably difficult to treat with ESD due to severe submucosal fibrosis.
Aims and Methods: In the absence of prior reports, we evaluated the clinical outcomes of esophageal neoplasia located proximal to a previous ESD scar. This was a retrospective observational study in a single institution. Between May 2004 and March 2016, 549 consecutive patients with 927 esophageal lesions were treated with ESD. The initial or largest lesion was the target in patients with multiple lesions. The primary treatment outcomes were resectability and adverse events of esophageal neoplasia located proximal to a previous ESD scar (recurrent group). These patients were compared with cases of primary esophageal ESD (primary group). Secondary outcomes were factors predictive of esophageal perforation. Perforation was defined as a visible hole in the esophageal wall, exposing the mediastinal space. Multivariate logistic regression and the generalized estimating equation were used for statistical analysis, and inverse probability of treatment weighting (IPTW) with propensity scores was used to reduce selection bias between the groups.
Results: A total of 545 primary cases and 29 recurrent cases were evaluated. Age, antithrombotic use, macroscopic appearance, lesion size, clinical invasion depth, and treatment device significantly differed between the groups. En bloc and complete (R0) resection rates in the recurrent group were lower than those in the primary group (79.3% vs. 98.3%, $p < 0.01$ and 75.9% vs. 93.4%, $p < 0.01$). Perforations occurred more frequently in the recurrent group than in the primary group (10.3% vs. 2.0%, $p = 0.03$). However, these could be treated with endoscopic closure and conservative management. Rates of delayed bleeding and stricture were similar between the groups. A lesion located proximal to a previous esophageal ESD scar was an independent predictive factor for perforation, following adjustment for lesion size and circumference using multivariate logistic regression analysis (odds ratio (OR) = 10.37, 95% confidence interval (CI): 2.15–49.94, $p = 0.004$). IPTW methods showed similar results (OR = 6.78, 95% CI: 1.40–32.98, $p = 0.018$). Limitations of this study were the small sample size and data from a single center.
Conclusion: ESD for esophageal neoplasia located proximal to a previous ESD scar was difficult to completely resect and increased the likelihood of perforation. Large centers with surgeons specialized in treating the esophagus may be recommended for ESD of such lesions.

P0130 USEFULNESS OF DEMARCATION OF EARLY GASTRIC CANCERS AFTER *HELICOBACTER PYLORI* ERADICATION BY MAGNIFYING ENDOSCOPY WITH NARROW-BAND IMAGING

Y. Akazawa[1], H. Ueyama[1], T. Yao[2], A. Ikeda[1], N. Yatagai[1], H. Komori[1], K. Izumi[1], K. Matsumoto[1], K. Ueda[1], K. Matsumoto[1], M. Hojo[1], A. Nagahara[1]

[2]*Juntendo University School of Medicine, Human Pathology, Tokyo, Japan*

Contact E-Mail Address: yakazawa@juntendo.ac.jp
Introduction: Early gastric cancer after *Helicobacter pylori* (*Hp*) eradication is difficult to demarcate. Previous studies have reported that gastric cancers after *Hp* eradication show unclear demarcation in 41.7–44% of these lesions [1,2]. However, the capacity of magnifying endoscopy with narrow-band imaging (M-NBI) to demarcate early gastric cancer after *Hp* eradication has not been evaluated enough. The magnifying endoscopy simple diagnostic algorithm for early gastric cancer (MESDA-G) is a new uniform diagnostic system for gastric cancer by means of M-NBI in Japan [3].
Aims and Methods: In this study, we compared the usefulness of M-NBI using MESDA-G for demarcation of early gastric cancer between the *Hp*-eradicated

group and the *Hp*-infected group. Among 492 cases of early gastric cancer who underwent endoscopic resection in our hospital between April 2013 and February 2018, the following lesions were excluded: special type gastric carcinoma (gastric adenocarcinoma of the fundic gland type [n = 27], gastric adenocarcinoma with enteroblastic differentiation [n = 4], and gastric carcinoma with lymphoid stroma [n = 2]), remnant gastric carcinoma (n = 6), *Hp*-uninfected gastric carcinoma [n = 20], lesions in which M-NBI has not been performed [n = 2], and lesions without details of *Hp* eradication (190). The remaining lesions were classified into of the *Hp*-eradicated group (n = 92) and the *Hp*-infected group (n = 149). Moreover, all cases of the 2 groups were classified into 3 histological subgroups according to Lauren classification; pure intestinal-type/pure diffuse-type/mixed-type. We compared the clinicopathological factors (age, sex, tumor location, tumor size, macroscopic type, invasion depth, lymphatic invasion, venous invasion, horizontal margin, vertical margin, non-neoplastic epithelium, adenocarcinoma with low-grade atypia) and endoscopic findings (the range of mucosal atrophy, demarcation line, microvascular pattern, microsurface pattern).

Results: The *Hp*-eradicated group was subclassified into 81 cases of pure intestinal-type and 11 cases of mixed-type. There was no case of pure diffuse-type in *Hp*-eradicated group. The *Hp*-infected group was subclassified into 131/5/12 cases of pure intestinal-type/pure diffuse-type/mixed type. In comparison between pure intestinal-type of the 2 groups, significantly smaller tumor size (12.5 ± 8.8 mm vs. 16.4 ± 11.4 mm, $p < 0.05$), more depressed lesion (elevated/flat/depressed = 15/3/63 vs. 60/2/69, $p < 0.01$), milder mucosal atrophy (C-1, 2/C-3, O-1/O-2, 3 = 11/30/40 vs. 8/30/93, $p < 0.01$), higher non-neoplastic epithelium covering rate (25/81, 30.9% vs. 19/131, 14.5%, $p < 0.01$) were observed in *Hp*-eradicated group than in the *Hp*-infected group. Although DL (+) cases were significantly less in *Hp*-eradicated group than in the *Hp*-infected group, DL was detected in most cases in both groups (76/81, 93.8% vs. 130/131, 99.2%%, $p < 0.05$). Furthermore, DL was detected in all cases of mixed-type in both groups. Whereas, there were small number of DL (+) cases in pure diffuse-type in the *Hp*-infected group (2/5, 40%).

Conclusion: M-NBI with MESDA-G can identify the DL in most patients with pure intestinal-type and mixed-type of early gastric cancer after *Hp* eradication.

Introduction: Few studies have classified risk factors according to the onset time of bleeding after endoscopic submucosal dissection (post-ESD bleeding).

Aims and Methods: We studied 1767 consecutive lesions in patients who underwent ESD for early gastric cancer from December 2006 through June 2016. Patients who had a remnant stomach or a reconstructed gastric tube were excluded. Post-ESD bleeding was classified into acute bleeding (0 to 5 days after ESD) and delayed bleeding (6 or more days after ESD), and the risk factors for each type of bleeding were compared.

Results: Post-ESD bleeding occurred in 150 (8.5%) of 1767 lesions. Bleeding was acute in 129 lesions (7.3%) and delayed in 21 (1.2%). Acute post-ESD bleeding was frequently associated with lesions located in the distal stomach, expanded indications or non-indicated lesions, a specimen diameter of ≥40 mm, and antithrombotic therapy. Delayed post-ESD bleeding was often associated with lesions located in the proximal stomach, hemodialysis, and antithrombotic therapy. Among 334 lesions in patients who received antithrombotic therapy, post-ESD bleeding occurred in 47 lesions (14.1%). Independent risk factors for post-ESD bleeding were a specimen diameter of ≥40 mm and treatment with 2 or more antithrombotic agents.

Conclusion: Acute post-ESD bleeding and delayed post-ESD bleeding were associated with different clinical characteristics. Antithrombotic therapy is a risk factor for post-ESD bleeding in both the acute and delayed phases.

P0132 EFFICACY OF ORAL MIXTURE OF HYDROCORTISONE SODIUM SUCCINATE AND ALUMINUM PHOSPHATE GEL FOR THE PREVENTION OF RESTENOSIS AFTER ENDOSCOPIC BALLOON DILATION(EBD) FOR BENIGN ESOPHAGEAL STRICTURE

Y. Huang[1], X. Yan[1], D. Nie[1]

[1]*Peking University Third hospital, Beijing, China*

Contact E-Mail Address: 13911765322@163.com

Introduction: The medical management of benign esophageal strictures consists of lifelong antireflux measures and periodic mechanical esophageal dilation. Repeat EBD is usually required over long period to resolve the stricture, which makes quality of life in the patients drastically decreased. We explore an innovative strategy with oral mixture of hydrocortisone sodium succinate and Aluminum phosphate gel for prevention of the restenosis after EBD and evaluate the efficacy of this mixture in single center of Beijing, China.

Aims and Methods: 32 patients who were diagnosed with benign esophageal strictures were included in this study. They were divided into 2 groups chronologically: 12 patients underwent EBD with no preventative treatment for restenosis (EBD alone group) were in control group and 20 patients received oral mixture of hydrocortisone sodium succinate and aluminum phosphate gel for restenosis (OHA group) were in treatment group. Patients in OHA group started with mixture of hydrocortisone sodium succinate 50mg and aluminum phosphate gel 20g, qid for 2weeks and continued with a gradually tapering OHA dose on the second day post-EBD. Patients in EBD alone group were treated by conventional method. Esophagogastroduodenoscopy (EGD) was performed on demand whenever patients complained of dysphagia. Among those cases, EBD was performed again when patients experienced persistent dysphagia. If the patient had no complaint of dysphagia, EGD was performed 8 weeks after EBD to evaluate any possible stricture. The primary end point in this study was the restenosis rate after EBD. The secondary end point was the number of EBD sessions required to resolve the stricture. A stricture was defined as a difficulty in swallowing solids or an inability to pass an EGD (9.2mm diameter endoscope).

Results: No significant differences were seen among the 3 groups in terms of demographic parameters including age, sex, etiology, stricture location, diameter of the narrowest segment. The restenosis rates of OHA group, EBD alone group were 25.0% (5 of 20 patients), 66.7% (8 of 12 patients), respectively (95% confidence interval, $p = 0.025$). The EBD sessions were less in the OHA group than EBD alone group (median 1, interquartile ranged from 1 to 1.8 vs. median 2, interquartile ranged from 1 to 2.5; $p > 0.05$).

Conclusion: Short period, oral mixture of hydrocortisone sodium succinate and aluminum phosphate gel showed promising results for the prevention of restenosis after EBD for benign esophageal stricture.

P0133 NARROW BAND IMAGING CHARACTERISTICS OF POLYPOID GASTRIC LESIONS: A SINGLE-CENTER PROSPECTIVE STUDY

G. Esposito, S. Angeletti, M. Cazzato, G. Galli, L. Conti, E. Lahner, E. Di Giulio, B. Annibale

Sapienza University of Rome, Sant'Andrea University Hospital, Department of Medical-surgical Sciences and Translational Medicine, Rome, Italy

Contact E-Mail Address: gle.esposito@gmail.com

Introduction: Gastric polypoid lesions (GPL) are possible endoscopic findings detected during gastroscopies but the histological nature is difficult to determine by white light endoscopy. Hyperplastic polyps (HP), type-1 gastric carcinoids (T1-GC) and adenomas are the most frequent GPL in the stomach and need different management. Narrow-band imaging (NBI) has been associated with high accuracy for the identification of gastric malignant lesions. Few studies tried to assess whether GPL display specific NBI characteristics permitting to endoscopically identify a specific histological type[1,2,3]

Aims and Methods: We aimed to investigate endoscopic NBI appearances of GPL. 40 pts (F 55%; median age 63 (36–85) yrs) presenting at least 1 GPL between March 2016 and March 2018 were prospectively investigated. Gastroscopies were performed by 2 experienced endoscopists. GPL images were recorded during gastroscopies and GPL were removed for histological examinations. Both endoscopists independently reviewed digital images in a blinded manner and registered endoscopic NBI appearances on a specific check-list previously elaborated[4]. 5 variables were taken into consideration: the mucosal and vascular pattern, vascular thickness and density as well as the presence of 'light-blue crest'. Endoscopists could further indicate other features and disagreement was resolved by discussion. GPL were then categorized in 3 different groups (HP, adenomas and T1-GC) using the histological exam as gold standard. Differences of NBI features between groups were analyzed by Fisher's exact test

Results: Overall, 52 GPL were included (29 (55.8%) HP; 18 (34.6%) T1-GC; 5 (9.6%) adenomas). The median size was 7 mm (range 2–35). Agreement between endoscopists was 92.3%. As shown in Table 1, HP had regular circular mucosal pattern in 82.8% while regular tubule-villous pattern was observed in 17.2%. Only one (3.4%) presented light blue crest, while vascular pattern, thickness and density were normal for all HP but one (3.4%) which presented thin vessels. T1-GC presented regular circular mucosal pattern in 94.4% (one presented irregular mucosal pattern), absence of light blue crest in 94.4%, regular vascular pattern in 83.3%, normal vascular thickness in 94.4% and regular vascular density in 83.3% (11.1% presented low density and 5.6% variable vascular density). Both endoscopists observed the presence of a central erosion in 14 (77.8%) T1-GC and 6 (33.3%) had a clear demarcation line in the central part. Adenomas had a

Abstract No: P0133

NBI features	Hyperplastic polyps n = 29 (55.8%)	Adenomas n = 5 (9.6%)	Type-1 gastric carcinoids n = 18 (34.6%)
Mucosal pattern Regular circular Regular tubulo-villous Irregular	24 (82.8%)* 5 (17.2%) 0	1 (20%) 4 (80%)# 0	17 (94.4%)° 0 1 (5.6%)
Light blue crest Present Absent	1 (3.4%) 28 (96.6%)	0 5 (100%)	1 (5.6%) 17 (94.4%)
Vascular pattern Regular Irregular	29 (100%) 0	5 (100%) 0	15 (83.3%) 3 (16.7%)
Vascular thickness Normal or thick Thin or ultrathin	28 (96.6%) 1 (3.4%)	5 (100%) 0	17 (94.4%) 1 (5.6%)
Vascular density High Low Variable	29 (100%) 0 0	5 (100%) 0 0	15 (83.3%) 2 (11.1%) 1 (5.6%)
Other features Central erosion Central erosion + demarcation line	1 (3.4%) 0	0 0	8 (44.4%)^ 6 (33.3%)^

tubule-villous mucosal pattern in 80% ($p = 0.01$ versus other lesions); light blue-crest and regular vascular pattern, thickness and density were absent in all of them. The presence of a regular circular mucosal pattern was more frequently observed in HP and T1-GC compared to adenomas ($p < 0.001$). The presence of a central erosion with or without demarcation line was more frequently observed in T1-GC ($p < 0.001$ vs. HP).

*[Table1. *$p < 0.012$ versus adenoma; °$p = 0.003$ versus adenoma; # versus HP and T1-GC $p = 0.01$; ^ versus HP $p < 0.001$]*

Conclusion: The NBI analysis of the mucosal pattern seems to be effective to endoscopically discriminate between adenomas and HP while the main characteristic of T1-GC is the presence of a central erosion sometimes with a clear demarcation line. Accordingly, NBI could be an important tool to endoscopically distinguish the histological nature of GPL.

Introduction: Endoscopic submucosal dissection (ESD) for gastric neoplasms was accepted as a standard treatment even in elderly patients. However, it is difficult to compare directly the clinical outcomes between elderly patients and non-elderly patients because background characteristics are different. Therefore, this study aimed to compare the clinical outcomes between elderly and non-elderly by propensity score matching analysis.

Aims and Methods: Early gastric neoplasms treated by ESD between January 2015 and March 2018 at out hospital were retrospectively reviewed. Elderly patients were defined as those aged 75 years old or more. ESD in elderly (ESD-E, n = 58) and ESD in non-elderly (ESD-N, n = 58) were compared. Multivariate analyses and propensity score matching were used to compensate for the differences in age, gender, ASA-score, underlying disease, Anti-thrombotic agent use, tumor size, tumor location, tumor shape, presence of ulcer, differentiation and operator level, which included factors previously reported to affect the outcomes of ESD. Primary outcome was procedure time. Secondary outcomes were the rates of en-block/complete resection and the rates of complications (aspiration pneumonia/perforation/post-procedure bleeding).

Results: Propensity score matching analysis created 38 matched pairs. Adjusted comparisons between 2 groups showed similar treatment outcomes (median procedure time: 61.5min vs. 77.5min; $p = 0.342$; en-block resection rate: 100% in both groups; complete resection rate: 86.8% vs. 97.4%, $p = 0.200$. However, the rates of complications were higher in ESD-E than those in ESD-N, but not significant. (Aspiration pneumonia: 10.5% vs. 7.9%, $p = 1$, Perforation: 5.3% vs. 0%, $p = 0.493$, post-procedure bleeding: 2.6% vs. 0%, $p = 1$).

Conclusion: ESD for gastric neoplasms in elderly patients achieved favorable outcomes as well as ESD in non-elderly patients. However, we should take care of complications in ESD for elderly patients.

Contact E-Mail Address: bcm.bruno@gmail.com

Introduction: Upper gastrointestinal bleeding (UGIB) from malignancy is a clinical emergency associated with high rebleeding and mortality rates (1). Endoscopic treatment with argon plasma coagulation has been shown to provide adequate initial hemostasis but with no impact on rebleeding or mortality rates (2). **Tc-325** (Hemospray™) has been recently introduced into the endoscopic arsenal for the treatment of UGIB.

Aims and Methods: The aim of this study was to compare the efficacy of Hemospray versus optimal clinical treatment in the management of UGIB from malignant lesions. Primary outcomes were 30-day rebleeding and 30-day mortality rates.

A randomized prospective study comparing patients treated with Hemospray versus a control group (optimal clinical treatment). Inclusion criteria were patients with evidence of UGIB from primary or metastatic neoplasia in the last 48 hours. Exclusion criteria included hemoglobinemia drop without evidence of bleeding, bleeding of non-tumor origin, pregnancy and patients under 18 years. To guarantee a study power of 0.8 with 0.05 alpha, a sample size of 100 patients was calculated.

Results: From August 2016 to May 2017, 36 patients (22 males and 14 females, $p = 0.494$) were randomized (Hemostatic Powder = 18; Control group = 18). The mean age was 56.7 years (range: 32–86). Mean hemoglobin at admission was 7.6 (4.3–14.3; $p = 0.183$). ECOG performance status scale was similar between groups ($p = 0.555$). Site of bleeding was: esophagus 6, stomach 20, duodenum 10 ($p = 0.489$). At endoscopy, active bleeding was observed in 13 patients of Hemospray group and 10 patients of the control group ($p = 0.489$). Successful initial hemostasis with Hemospray was achieved in all cases. Additional therapy such as radiotherapy ($p = 1.00$), surgery ($p = 1.00$) or angiography embolization ($p = 0.486$) was similar in both groups. There was no statistical difference in rebleeding rates at 30 days (hemospray 61.4% vs. control 38.9%, $p = 0.502$); nor in 30-day mortality rate (Hemospray 27.8% vs. control 22.2%, $p = 1.00$). Length of hospital stay after bleeding was also similar (Hemospray 16.9 days vs control 13.6 days, $p = 0.149$). There were no complications related to the method.

Conclusion: In this preliminary analysis, treatment with hemostatic powder demonstrated high initial hemostasis rate. However, there was no relevant impact on 30-day rebleeding or 30-day mortality rates. It is still necessary to include more patients to confirm the results.

Introduction: Duodenal adenomas consist of sporadic and familial adenomatous polyposis (FAP) associated adenomas. Endoscopic mucosal resection (EMR) is the recognised technique when considering endoscopic removal of these lesions, but outcomes from large studies are lacking. Leeds Teaching Hospitals (LTHT) is a large tertiary centre that has a local catchment area of more than 800,000 people, and to our knowledge this is the largest UK cohort assessing duodenal EMR outcomes.

Aims and Methods: Retrospective data collection was performed of all patients who underwent duodenal EMR over a 17-year period at LTHT. We collected data on patient demographics, lesion characteristics and outcomes including significant complications, recurrence and surgery-free survival. Procedures were performed by a single advanced therapeutic endoscopist or an endoscopy fellow under supervision.

Results: A total of 98 patients underwent EMR (sporadic n = 23, FAP n = 75). Median adenoma size was 12.5 mm (IQR 9.0–30.0 mm), with 46.9% removed en-bloc. Standard EMR was performed in 87 procedures, and pull-within snare technique in the remaining 11 procedures. Final lesion histology was TA/TVA with LGD (n = 80), TA/TVA with HGD (n = 12), intra-mucosal cancer (n = 3) and in 3 cases data was missing. Patients with FAP were significantly younger with a median age of 49 years ($p < 0.001$).

The overall complication rate was 12.4%. 1 (1.0%) patient had an intra-procedural bleed which could not be managed endoscopically, delayed bleeding occurred in 6 cases (6.2%) and perforation occurred in 5 cases (5.2%), 3 (3.1%) of which could not be managed endoscopically. Following univariate analysis, "pull-within snare" technique ($p = 0.03$), piecemeal resection ($p = 0.002$), and increasing polyp size ($p = 0.003$) were significantly associated with complications. Adenoma recurrence at first follow up was 25.0%.

Surgery was required in 6 patients (6.2%) within 24-months of their EMR, 4 (4.1%) cases for adenomas > 30 mm, 2 (2%) cases for 10–29 mm and no cases for adenomas < 10 mm.

Conclusion: This is the largest cohort in the UK pertaining to duodenal EMR outcomes, with success, recurrence and complications similar to other world-leading endoscopy centres. Adverse outcomes are associated with increasing lesion size, piecemeal resection and EMR technique.

Introduction: Esophageal band ligation (EBL) for esophageal varices has significantly less rebleeding rates and complications, and needs a lower number of sessions to achieve eradication of the varices than sclerotherapy yet has a higher recurrence rate This is because EBL does not obliterate the deeper varices or perforating veins, whereas the chemical effect of sclerotherapy does Scleroligation (combined sclerotherapy and band ligation) has been used successfully for management of esophageal varices and has been recently evaluated in management of gastroesophageal varices.

Aims and Methods: We aimed to determine therapeutic efficacy and safety of endoscopic scleroligation and endoscopic band-ligation of esophageal varices

A literature search was conducted in the following medical electronic databases: PubMed, CENTRAL, SCOPUS and Web of Science on the 23rd of December 2017 using the following strategy: scleroligation OR (sclerotherapy AND plus AND ligation) AND (Esophageal varices OR varices). 8 randomized controlled trials from 1996 to 2017 were included in the meta-analysis after tight full text screening. The included studies were analyzed by using RevMan 4.2 software to assess the efficacy and safety of Endoscopic Scleroligation (ESL) versus Endoscopic Band ligation (EBL) in management of Varices.

Results: Of 97 citations discovered by initial search, 8 parallel RCTs were finally included in this meta-analysis. We found that there were significantly less bands used in ESL than in EBL ($Chi^2 = 46.80$; 95% CI: −3.13 to −1.30; $df = 6$ ($p < 0000.1$); $I^2 = 87\%$). Compared to EBL, the overall number of sessions to variceal obliteration in ESL was significantly lower [$Chi^2 = 571.90$; 95% CI: −0.54 to 1.12, $I^2 = 99\%$; $p < 0.00001$]. ESL required fewer weeks of treatment than EBL, further confirming its positive therapeutic effect. Variceal recurrence following ESL was significantly lower than with EBL [$Chi^2 = 17.35$; 95% CI: 0.97 to 1.09, $I^2 = 54\%$; $p < 0.03$]. Both procedures had the same adverse effects with no significant difference regarding frequency.

Conclusion: Endoscopic Scleroligation (ESL) shows high efficacy and safety in management of varices with a low incidence of recurrence.

P0138 CAP-ASSISTED REMOVAL OF IMPACTED ESOPHAGEAL FOOD BOLUS: "THE EASY WAY"

M. Wahba, A. Farag, A. El Mazny, W. Aref, O. Ashoush
Cairo University, Internal Medicine, Cairo, Egypt

Contact E-Mail Address: dr.mahmoudwahba@gmail.com

Introduction: The commonest foreign body impacted in the esophagus in adults is a food bolus [1]. The European Society of Gastrointestinal Endoscopy issued clinical guidelines to deal with this problem in 2016 [2]. It recommends either pushing technique or retrieval methods using one of several accessories. However, pushing technique could be associated with adverse events. Also, during retrieval, with the conventional methods, the food bolus tends to fragment into small pieces making extraction both time and effort consuming. Cap-assisted endoscopic extraction of food bolus is an easier method. In this method, a cap is fixed to the tip of the scope and the bolus is removed by applying suction. However, data comparing it to other methods is scarce.

Aims and Methods: We aimed to compare two methods for extraction of an impacted esophageal food bolus; the cap-assisted suction method and the conventional methods. We retrospectively reviewed data from 253 patients who underwent endoscopy for food bolus extraction in the period between 2014 and 2017. We compared the two groups for the rate of en bloc removal, total procedure time, and procedure-related complications.

Results: 253 patients had endoscopy for food bolus extraction. In 76 patients (30%) the push-technique was used. 177 patients (70%) had one of the retrieval methods. The cap-assisted method was used in 84 patients while 93 patients had retrieval with the conventional methods. The application of cap-assisted technique achieved a higher rate of en bloc removal 82.1% compared to 11.8% with the conventional method ($p < 0.001$), a shorter procedure time (6.7 ± 3.2 minutes versus 15.3 ± 4.6 minutes, $p < 0.0001$), and less adverse events (0/84 versus 5/93, $p = 0.01$).

Conclusion: Cap-assisted removal of impacted esophageal food bolus is associated with more en block removal, shorter procedure duration, and less adverse effects compared to conventional methods. We encourage including this method in the options to remove an impacted esophageal food bolus.

Introduction: Currently, ablation of confirmed low-grade dysplasia (LGD), high-grade dysplasia (HGD) and residual Barrett's esophagus (BE) after endoscopic mucosa resection (EMR) of early carcinoma is recommended [i-iv]. Radiofrequency ablation is the best study method, but is not readily available in Russia. Moreover, the prevalence of BE and dysplasia is rather low, which may compromise the outcome of other more operator dependent techniques, like Hybrid-APC.

Aims and Methods: The aim of the present study was to evaluate the efficacy and safety of Hybrid APC eradication therapy for BE in a low prevalence setting after a former onsite training. All procedures were performed by a single operator (SK) after a formal onsite training on 3 different occasions by a very experienced endoscopist (HM). Hybrid APC probe was used for marking of the neo-Z-line, then consecutive lifting the Barrett's mucosa with 0.9% saline solution injected by the high-pressure water jet system (ERBEJET 2) and mucosa ablation (PULSED APC, Effect 2, 60 Watt). After that the ablation area was mechanically cleaned with a transparent cap on the tip of the endoscope for further detailed inspection. Detected remained BE was retreated with a second APC application with the lower power (40 Watt). High dose PPI treatment (esomeprazole 80 mg/day) was used after procedures for strong acid suppression that provided an environment for development squamous mucosa on the site of ablation[i]. After complete eradication of BE (histologically and endoscopically confirmed), a control endoscopy was performed at 3 months, 6 months and annually thereafter for taking 4-quadrant biopsies from the whole area of the former BE segment including biopsies of Neo-Z-line. All histological findings were confirmed by an experienced gastrointestinal pathologist.

Results: In our tertiary referral center, we have 120 BE patients registered between July 2014 to September 2017. Of these, 11 patients were diagnosed with LGD and HGD (5 male, 6 female) and were treated with Hybrid APC and included in this long-term follow-up study. At enrollment, the mean age was 46 years (range 25–63). The mean length of Barrett's esophagus was C1 M2. Five EMRs of visible lesions before ablation were performed. In total 18 Hybrid APC sessions have been successfully performed with curative intent. Complete macroscopic and microscopic BE ablation was achieved in all patients after a mean of 1.6 (range 1–3) treatment sessions. No perforations or uncontrollable bleeding occurred. Stricture formation was observed in 1 patient 3 months after Hybrid APC, which was combined with EMR in the same session. This stricture was managed by 1 session of balloon dilatation. The patients were followed for a mean of 2.5 years (range 10–46 months) after complete eradication of BE with a mean number of follow-up endoscopies of 3.0 (range 1–4). Recurrence of intestinal metaplasia was not seen in any patient. Generally, we took 64 biopsy samples, 8 (12.5%) of them contained sufficient subepithelial lamina propria. Buried intestinal metaplasia was not found in any of these biopsies.

Conclusion: We showed that Hybrid APC is a safe and effective method for treatment of dysplastic BE with dysplasia in a tertiary referral center in a country with low prevalence of BE and BE dysplasia. 3-year follow up didn't reveal any recurrence of BE mucosa, buried metaplasia or any major complications. Because Hybrid APC is highly operator dependent our data underscore the importance of a proper training and adherence to a standardized treatment protocol to provide good long term outcomes.

Introduction: According to the current guidelines of the European Society of Gastrointestinal Endoscopy (ESGE), the endoscopic resection is the treatment of choice of gastric superficial neoplastic lesions. The most current criteria for the curative treatment include 1 piece (en bloc) resection of mucosal or submucosal membrane ≤500 μm with free lateral and vertical margins and lack of the limfoangioinvasion. In the case of non-curative endoscopic resection, surgical treatment is required. However, the follow-up for patients who did not receive radical surgery was not extensively investigated.

Aims and Methods: We aimed to investigate follow-up of patients with early gastric cancer (EGC) after non-curative endoscopic submucosal dissection (ESD).

The retrospective analysis of prospective assessed database of ESD procedure for EGC, from 2008 to 2018 in Department of Gastroenterology of Pomeranian Medical University Hospital in Szczecin was performed. The follow-up examinations were as follows: endoscopy 3, 12 and 36 months after ESD and CT 24 to 36 months after ESD.

Results: The 81 ESD procedures were performed for 80 EGC patients (M 50, mean age 68.31 +/- 1.71), the en bloc resection rate was n = 73, (91.3%) and curative resection rate (R0) was n = 54, (67.5%). Non-R0 resection was due to: submucosal invasion n = 16, (20.0%), including n = 8, (10.0%) [SM2(+)] and n = 8, (10.0%) [SM3(+)], positive lateral margin n = 9, (11.3%) [LM(+)], including piecemeal resection [PM], positive vertical margin n = 1, (1.3%) [VM(+)]. The median follow-up was 29 months, range 7 - 122.

In the non-R0 group (n = 26; 32.5%; mean age 71.03 +/- 2.08) initially n = 5 patients underwent surgical treatment, n = 17 patients were followed-up without surgery because of lack of consent, poor general condition or comorbidities and n = 4 were lost to follow-up.

In the follow-up group only 1 patient after PM had recurrence of cancer in the +3 months gastroscopy and was sent to surgery. In the initially surgical group, n = 5, (100%) were negative for cancer in the resected specimen. Overall survival was n = 17, (65.4%) patients and cause-specific survival was n = 22, (100%): n = 5, (19.2%) patients died (n = 4 due to comorbidities, n = 1 due to postoperative complications). In the whole non-R0 group only 1 patient (1/22, 4.5%) had recurrence of cancer and was successfully treated with surgery.

Conclusion: Our results confirmed that in group of patients with advanced age or comorbidities who underwent non-curative ESD for EGC, only close observation may be an acceptable option without radical surgical procedure. Further research is required to set up more exact criteria to enrol the follow-up group.

Introduction: Patients with head and neck cancers have an increased risk for developing an esophageal squamous cell carcinoma (ESCC). Small, superficial, lesions are difficult to detect using only white light endoscopy. To improve detection chromoendoscopy is recommended. The aim of this study was to compare the narrow band imaging (NBI) endoscopy and Lugol chromoendoscopy in the early diagnosis of high-grade dysplasia and esophageal cancer in patients with head and neck cancers.

Aims and Methods: In a randomized trial, patients ≥ 1 year after curative treatment of head and neck cancers were randomly assigned in 2:1 ratio to NBI or Lugol chromoendoscopy. Following white light endoscopy the entire length of the esophagus was examined using 1 of the selected chromoendoscopic method. The primary outcome measure was positive predictive value of finding a lesion requiring biopsy with each method. The secondary endpoints were: number of biopsies/per patient, examination time, endoscopy tolerance (according to visual analogue scale) and characteristics of patients diagnosed with high-grade dysplasia or invasive cancer.

Results: Of the 294 patients included in the study 204 were assigned to NBI group and 90 to the Lugol chromoendoscopy group. In total, 3 ESCC and 2 high-grade dysplasia were detected.The positive predictive value of NBI and Lugol chromoendoscopy were 7.69% (95% CI, 0.94%–25.1%) and 8.11% (95% CI, 1.70%–21.9%), respectively (p = 1).The NBI was significantly superior to Lugol chromoendoscopy in: number of biopsies needed/per patient (26/204 vs. 37/90,

p = 0.003), mean examination time (3.50 min. vs. 5.15 min., p < 0.001) and mean endoscopy tolerance (25mm vs. 36.5 mm, p < 0.002). In all patients diagnosed with high-grade dysplasia or invasive cancer successful endoscopic mucosal resection or endoscopic submucosal dissection were performed.
Conclusion: Diagnostic performance of NBI and Lugol chromoendoscopy seems to be equal but NBI is superior to Lugol chromoendoscopy in terms of number of biopsies/per patient, examination time and procedure tolerance. These results indicate that NBI should be taken into account as a standard examination method for early diagnosis of high-grade dysplasia and esophageal cancer in patients with head and neck cancers and thus replacing cumbersome Lugol staining.

Contact E-Mail Address: hsmanner@gmx.de
Introduction: In contrast to POEM for achalasia, there is only limited data available on the new technique of gastric poem (G-POEM). The question arises whether G-POEM may be a helpful tool for the treatment of gastric emptying disorders (GED) going along with pylorospasm.
Aims and Methods: Patients with clinically, endoscopically and scintigraphically confirmed diagnosis of gastric emptying disorder with pylorospasm and who had undergone repeated endoscopic treatment sessions, e.g. by balloon dilation and/or BoTox injection with short-term relief, were treated by G-POEM. ESD knives with integrated injection function were used (Flush knife, Fujifilm; Dual Knife J, Olympus; Hybrid Knife, Erbe). All procedures were carried out under general anaesthesia using CO^2 insufflation and periinterventional application of i.v. antibiotics. Technical and clinical success, adverse events (AE), as well as the need of repeated endoscopic therapy were evaluated.
Results: From 11/2016 to 04/2018, a total of 9 patients were treated by G-POEM (7 female, 2 male; HSK Wiesbaden n = 7; Frankfurt Höchst n = 2). Pylorospasm was caused by vagal nerve injury after fundoplication surgery (n = 4), thoracal surgery (n = 1), esophageal resection (n = 3), and in 1 case by multiple sclerosis. Mucosal incisions were made at the 5–6 o'clock (n = 8) or the 7 o'clock position (n = 1). Technical success was 100% (complete pyloric incision with collapse of the muscle ring). AE that were judged to be minor complications occured in 3/9 pt (33%; shivering without fever (n = 1), abdominal pain and nausea (n = 1), mucosal ulcerations next to the submucosal tunnel on the next day (n = 1). 6/9 pt underwent at least 1FU examination (mean FU 5.5 ± 4 mo.; range 3–12). Symptom relief was found in 6/6 pt (100%) after 3 months. 2/6 pt (33%) reported symptom deterioration thereafter. 1 patient was referred to gastric pace maker implantation, the other patient underwent endoscopic balloon dilation and BoTox injection with symptom relief thereafter.
Conclusion: G-POEM was shown to be effective and safe in the short term with 100% rates of technical and clinical success. However, relapse of symptoms may occur in the mid term requiring additional treatment strategies.

P0143 RISK FACTORS OF METACHRONOUS GASTRIC NEOPLASM BEYOND 5 YEARS AFTER ENDOSCOPIC RESECTION FOR EARLY GASTRIC CANCER

E. Lee, S.G. Kim, J.L. Kim, J. Kim, H. Chung, H.C. Jung
Seoul National University Hospital, Seoul, Korea (Republic of)

Contact E-Mail Address: rfsquid@naver.com
Introduction: Endoscopic resection has been standard treatment for selected patients with early gastric cancer (EGC) and the risk factors of metachronous gastric cancer after endoscopic resection discovered throughout previous studies. However, the risk factors over a long period of time has not yet been well demonstrated. To develop an optimal endoscopic surveillance strategy, it is necessary to elucidate the risk factors associated with metachronous tumor development in long-term follow-up.
Aims and Methods: This study aimed to clarify the risk factors of metachronous gastric neoplasm beyond 5 years after endoscopic resection for EGC.
We performed a retrospective analysis of the patients who underwent endoscopic resection for EGC from Jan 2005 to May 2012 in Seoul National University Hospital.
Results: Among 1280 patients with EGC, 663 patients were followed-up for over 5 years, in whom metachronous gastric neoplasm developed in 65 patients beyond 5 years after endoscopic resection for EGC. In multivariate analysis, male (odds ratio, OR 3.242; 95% confidence interval, CI 1.367–7.689; p = 0.008), elevated gross type (OR 5.240; 95% CI 1.872–14.668; p = 0.002), mixed Lauren classification (OR 5.240; 95% CI 2.535–92.054; p = 0.003), intestinal metaplasia (OR 1.456; 95% CI 1.065–1.990; p = 0.019), tumor-positive lateral margin (OR 3.322; 95% CI 1.092–10.104; p = 0.034), synchronous adenoma (OR 2.832; 95% CI 1.261–6.364; p = 0.012) were positive predictive factors for metachronous gastric neoplasm.
Conclusion: Metachronous gastric neoplasm had developed in 9.8% of patients beyond 5 years after endoscopic resection for EGC. Male sex, elevated gross type, mixed Lauren classification, intestinal metaplasia, tumor-positive lateral margin, synchronous adenoma were significantly associated with metachronous tumor development in long-term follow-up.

Introduction: Duodenal cancer is one of the extracolonic malignancies which causes death in patients with familial adenomatous polyposis (FAP). However, the visualization of the ampulla of Vater is not always sufficient with standard esophagogastroduodenoscopy (EGD) because of a limited field of view. Full-spectrum endoscopy (FUSE) provides a wider 245-degree field of view with images on the front and left side of the tip of the endoscope. The aim of this prospective study was to evaluate the improvement of visualization of the ampulla of Vater in FAP using FUSE compared to standard EGD.
Aims and Methods: This study included patients with FAP followed-up in our hospital. We excluded individuals with a history of upper gastorointestinal surgery. EGD was performed using FUSE by qualified endoscopists of the Japanese Gastroenterological Endoscopy Society and visibility of the ampulla of Vater was evaluated. All examinations were video-recorded and 2 videos of the duodenum were edited in each patient, 1 of the FUSE group (forward-viewing and left-side viewing) and 1 of the conventional group (forward-viewing alone). 3 qualified endoscopists at an outside institution then reviewed the videos and compared the visibility of the ampulla of Vater between the 2 groups. The visibility of the ampulla of Vater was classified according to Woo et al., as follows: Type 1, the whole area of the papilla; Type 2, the upper part of the papilla including the orifice; Type 3, the upper part of the papilla excluding the orifice; Type 4, the lower part of the papilla including the orifice; or Type 5, no visualization of the papilla. The primary endpoint was the proportion of Type 1 in off-line review of the videos, and the secondary endpoint was that of Type 1 in on-site diagnosis.
Results: 49 FAP patients were enrolled in this study between July 2016 and December 2017. Patients characteristics were as follows: median age of 37 years (range 19–61) and male/female ratio of 38/11. The average observation time of the duodenum was 114 ± 47.9 seconds. Visibility of the ampulla of Vater was determined as follows: for off-line review, reviewers A,B,C for the FUSE group (Type 1/ Type 2-4/ Type 5 = 49, 49,49/ 0, 1, 0/ 0, 0, 0) vs. the conventional group (Type 1/ 2-4/ 5 = 4, 8, 7/ 31, 26, 27/ 14, 15, 15) and for on-site diagnosis, the FUSE group (Type 1/ 2-4/ 5 = 49/ 0/ 0) vs. the conventional group (Type 1/ 2-4/ 5 = 16/ 19/ 14). The visualization of the ampulla of Vater was significantly better in the FUSE group in both on-site diagnosis and off-line review (p < 0.001). Intraclass correlation coefficients were 1.0 (FUSE group) and 0.85 (conventional group).
Conclusion: FUSE EGD is recommended for screening and surveillance endoscopy for patients with FAP.
Disclosure: Nothing to disclose

P0145 ENDOSCOPIC SCORING SYSTEM FOR PREDICTING THE ANASTOMOTIC COMPLICATIONS AFTER ESOPHAGECTOMY: A PROSPECTIVE COHORT STUDY

Introduction: The postoperative complications relative to gastric conduit reconstruction are still common issues after esophagectomy. We previously reported early diagnosis of ischemic reaction provided the suitable postoperative management and therapeutic intervention to prevent leakage, strictures and necrosis (1). An endoscopic examination is a rapid and highly sensitive procedure to evaluate the gastrointestinal organ. Thus, the novel endoscopic scoring system which enables to predict anastomotic complications after esophagectomy is required.
Aims and Methods: The purpose of this study is the safety and efficacy of an endoscopic evaluation of the anastomotic region in the acute period after esophagectomy.
The patients, who have malignant or end-stage benign esophageal disease, were enrolled. The patients undergo an esophagectomy with reconstruction with a gastric pull-up and a cervical esophagogastrostomy. Anastomotic complications were defined as leakage, strictures, and necrosis.
Endoscopic examinations were performed on the postoperative days (POD) 1, 8, and 15. The investigators prospectively assess the probability of anastomotic complications based on the novel endoscopic scoring system as the following.

Score 1: normal mucosa or erosion, score 2: less than 67% circumferential ischemic mucosa or ulcer formation, score 3: more than 67% circumferential ischemic mucosa or ulcer, or full-circumferential ischemic mucosa or ulcer formation with lesion length less than 20mm, score 4: full-circumferential ischemic mucosa or ulcer formation with lesion length more than 20mm. The highest score was adapted in each patient.
The primary outcome measure was the predicting rate of the anastomotic complications using the scoring system within 2 months after esophagectomy.
Clinical Trials.gov Registry, ID:NCT02937389.
Results: From 2015 April to 2018 April, 49 patients were enrolled in this study. 47 patients underwent esophagectmy to esophageal cancer. 2 patients underwent esophagectomy to benign strictures due to corrosive esophagitis and achalasia. 16 patients (33.3%) developed anastomotic complications after esophagectomy. Anastomotic leakage occurred in 4 patients. A stricture occurred in 13 patients. 1 patient had gastric conduit necrosis.
All patients safely underwent endoscopic examinations without any complications. The incidence rates of each patients score 1, 2, 3, and 4 were 47.9%, 20.8%, 16.7%, and 14.6%. In 72.9% of patients, the maximum value of the endoscopic classification is scored at 1 POD. The incidence rates of anastomotic complications for maximum score 1, 2, 3, and 4 were 4.4%, 20.0%, 75.0%, and 100%, respectively ($p < 0.01$).
Next, the patients with a maximum score 3 or 4 were defined as the high-risk groups of anastomotic complications. The patients with maximum score 1 or 2 was defined as the low-risk groups of anastomotic complications. The sensitivity and the specificity of predicting anastomotic complications in high-risk groups were 62.5% and 100% at 1POD. The sensitivity and the specificity of predicting anastomotic complications in high-risk groups were 81.3% and 93.8% at 8POD. The patients in high risk groups of anastomotic complications had a significantly longer postoperative hospital stay than patients in low-risk groups ($p = 0.02$).
Conclusion: Endoscopic examinations after esophagectomy were safely performed. The application of the endoscopic classification to mucosal ischemia after esophagectomy resulted in suboptimal accuracy to predict the anastomotic complications.
Disclosure: Nothing to disclose

Introduction: Conventional surgery requires full-thickness suture in order to ensure the safety from leakage. Full-thickness suture has shown to be more effective than superficial suture, but full-thickness suture has been controversial in endoluminal surgery because it can cause external organs damage or bleeding. Partial-thickness suture has been attempted to ensure the stability, but its effectiveness has been questioned after events of suture tear. The aim of our study was to compare the strength between partial-thickness suture and full-thickness suture to provide information in choosing the adequate suture method.
Aims and Methods: We designed our study in 2 steps. We compared the full thickness suture strength depending on the suture site, and measure the suture strength that needed for the suture to be cut off or to be torn from the sample and their change as the suture width varies. Samples were prepared by cutting the pig stomach into 5 cm diameter circle. Then a loop with a nylon 3-0 suture on the sample was made endoscopically. We defined the depth of the loop as the suture thickness and the distance of the loop as the suture width. The suture thickness was measured and categorized into 2 groups, full-thickness or partial-thickness. The width was measured on the surface of the sample, in the range of 0.6 to 2.2mm, and categorized into 3 groups, narrow, medium and wide. Each sample was placed in the manufactured bite, tightly fastened and the loop was pulled by the tension tester. The maximum suture strength was the force recorded at the tension tester when the loop was detached from the sample.
Results: With the same suture width (1.4cm) and using full-thickness suture method, the antrum had the highest strength considering the thickness of the wall, and the fundus had shown to have the highest elasticity. The mean strength of the partial-thickness suture and the full-thickness suture were 20.18 ± 6.12N ($n = 11$) and 27.79 ± 7.29N ($n = 12$), respectively ($p = 0.0135$), and the strength of the partial-thickness suture was 73% of that of full-thickness suture. As the suture width increased and deepened, the strength of the suture increased with both methods ($p = 0.001$). On average, the width of the partial-thickness suture should be 5 mm longer than the width of the full-thickness suture to reach the same strength as the full-thickness suture.
Conclusion: Partial-thickness suture may be considered as an option for safety in an operative environment if feasible. Because the difference of the intensity between 2 suture methods, it is necessary to consider widening the width when performing the partial-thickness suture to have similar strength. Further studies on endoscopic suture method in gastrointestinal tract are needed.

P0147 AND WHEN NBI DOESN'T SHOW GASTRIC INTESTINAL METAPLASIA: DO WE STILL NEED TO SEPARATE BIOPSY SAMPLES INTO DIFFERENT VIALS?

R. Castro[1], G. Esposito[2], M. Dinis-Ribeiro[1], P. Pimentel Nunes[1]

Introduction: For the correct staging and classification of chronic atrophic gastritis and gastric intestinal metaplasia (GIM) it is necessary to perform ≥ 4 biopsies (2 from the atrum/incisure and 2 from the body) with the biopsy samples being placed in different vials according to the current recommendations. Virtual Chromoendoscopy with Narrow-Band-Imaging (NBI) assists the diagnosis and vigilance of GIM.
Aims and Methods: We aimed to evaluate if, in the absence of a typical endoscopic pattern of GIM with NBI, biopsy samples can be placed in the same vial without implications in the diagnosis and follow-up of the patient.
Multicentre prospective study of a consecutive series of patient with indication to perform an upper endoscopy with biopsies of both antrum/incisure and body. In every patients, upper endoscopy was performed with NBI. Patients with gastric lesions and/or suggestive areas of GIM were excluded. Patients included were submitted to ≥ 4 biopsies (2 from the antrum/incisure and 2 from the body) with the samples being placed in the same vial for histologic assessment ($n = 182$). Finally, histologic staging systems OLGA and OLGIM were calculated.
Results: OLGA/OLGIM calculation was possible for every patients as it was possible to distinguish samples from antrum/incisure from those of gastric body. In total, 178 (97.8%) presented OLGIM 0 and only 4 (2.2%) presented OLGIM I. 149 (81.9%) presented OLGA 0, 23 (12.6%) presented OLGA I and 10 (5.5%) presented OLGA II. The placement of biopsy samples in the same vial had no implications in the diagnosis and follow-up in none of the patients since no one was diagnosed with severe gastric atrophy/intestinal metaplasia (negative predictive value of 100%).
Conclusion: In the absence of a typical endoscopic pattern of GIM with NBI, biopsy samples can be placed in the same vial if it is desired to determine the presence of *Helicobacter pylori* or even to abstain from biopsies if this is not the case. This change in clinical practice can have a significant financial impact on endoscopy costs.

Introduction: *Helicobacter pylori* (HP) eradication is a critical therapeutic approach to reduce gastric cancer mortality. In Japan, 1.5 million people annually undergo HP eradication; meanwhile, it has been revealed that despite successful eradication, the risk of gastric cancer persists for patients who already show progressed mucosal atrophy and intestinal metaplasia[1]. Post-eradication patients demonstrate a negative reaction for the majority of noninvasive HP infection tests. As a consequence esophagogastroduodenoscopy (EGD) represents the only examination that enables distinction between HP uninfected patients at extremely low risk for gastric cancer and patients who have a history of HP eradication therapy. With the present study we planned to create a novel computer aided endoscopic diagnosis (CAED) system for HP eradication history using linked color imaging (LCI) and deep learning (DL). LCI is a new image-enhanced endoscopy (IEE) that enhances slight differences in mucosal color, while DL is a type of machine learning technology that imitates neural network in the brain.
Aims and Methods: The aim of this prospective study was to create a CAED system to distinguish between HP uninfected people and patients who have history of HP eradication therapy, using LCI and DL. In this study, we included patients who underwent EGD and were tested for serum HP antibodies (HPab) or urea breath test (UBT) at our medical clinic. Patients with active HP infection, in the absence of eradication history, were excluded from the study. As a gold standard for HP infection status, we used HPab titer for uninfected subjects (< 3 U/ml, $n = 148$), and UBT value for eradicated patients ($< 2.5\%$, $n = 81$). Patients underwent HP eradication out at our hospital. In total, 229 subjects were enrolled in this study. In order to evaluate the diagnostic accuracy of the CAED system patients were subdivided in 2 groups: a training group ($n = 189$, HP uninfected $= 128$, eradicated $= 61$); and a test group ($n = 40$, HP uninfected $= 20$, eradicated $= 20$). Comparing the output data from the test group with the actual data on HP infection status allowed us to assess the accuracy of the CAED system. During the course of the EGD an endoscopist took 3 LCI pictures of the lesser curvature, greater curvature, and antrum of the stomach using EG-L580NW (Fujifilm Co., Japan). The LCI images were subsequently augmented by rotation and right-left flip. We generated 2,508 training images and 480 testing images. An original DL model was designed, which has 18 deep convolutional layers for the CAED system. R (version 3.3.2.) was used for statistical analyses.

Results: Area under the curve (AUC) of the receiver operating characteristics (ROC) for the lesser curvature, greater curvature, and antrum were 0.95 (95% CI 0.914–0.981), 0.93 (95%CI 0.882–0.969), and 0.89 (95%CI 0.843–0.944), respectively.
Conclusion: Patients with an HP infection are easy to diagnose without using EGD because noninvasive infection reaction is positive. In contrast, EGD is the only examination capable of distinguishing between HP uninfected patients with low gastric cancer risk and patients with a history of eradication. The CAED system demonstrated excellent accuracy in distinguishing between the 2 groups using LCI. Our next goal is to apply our findings to clinical practice.
Disclosure: Nothing to disclose

Introduction: Inflammatory pancreatic fluid collections are common complications of both acute and chronic pancreatitis. They may be drained endoscopically (ED), percutaneously (PD) or surgically (SD) with diverse efficiacy. Several retrospective and case control studies but only a limited number of randomized trials compared the outcomes of these treatment modalities.
Aims and Methods: A meta-analysis was performed using the preferred reporting items for systematic review and meta-analysis protocol. A comprehensive literature search was conducted until November 2017 to identify studies comparing at least 2 of the treatment options regarding mortality, clinical success, recurrence, complications and length of hospitalisation (LoH). Initially, 1248 and 2539 articles were identified in Embase and PubMed, respectively, but only 25 studies were suitable for the meta-analysis. The meta-analysis is registered at PROSPERO under CRD42018079200.
Results: ED provided a higher rate of clinical success (OR = 4.10; 95%CI 1.76, 9.54; p = 0.001) and lower postoperative LoH (weighted mean difference (WMD) = −21.23; 95% CI −37.09, −5.37; p = 0.009) compared to PD based on 6 studies (including 650 and 166 patients, respectively). The postoperative LoH (WMD = −4.42; 95% CI −6.05, −2.80; $p < 0.001$) was shorter after ED than after SD based on 14 studies (including 789 and 750 patients, respectively). The recurrence and complication rates were higher (OR = 10.30; 95% CI 2.78, 38.18; $p < 0.001$ and OR = 3.29 95% CI 1.39, 7.77; p = 0.007, respectively), while the clinical success rate was lower (OR = 0.12; 95% CI 0.07, 0.21, $p < 0.001$) in PD compared to SD based on 11 studies (including 8404 and 7161 patients, respectively).
Conclusion: ED and SD are equally effective in the treatment of inflammatory pancreatic fluid collections, but ED is associated with shorter LoH. PD has lower success rate compared to the other modalities.

P0150 COMPARISON BETWEEN ENDOSCOPIC SUBMUCOSAL DISSECTION AND SUBMUCOSAL TUNNELING ENDOSCOPIC RESECTION FOR ESOPHAGEAL SUBMUCOSAL TUMORS ORIGINATING FROM THE MUSCULARIS PROPRIA LAYER

J. Zhu[1], Q. Li[1], T. Chen[1], P. Zhou[1]
[1]*Zhongshan Hospital, Fudan University, Endoscopy Center, Shanghai, China*

Contact E-Mail Address: zjysjtu@yahoo.com
Introduction: Endoscopic submucosal dissection (ESD) or submucosal tunneling endoscopic resection (STER) is widely acknowledged as an important treatment option for esophageal submucosal tumor from the muscularis propria layer. However, the clinical outcomes of ESD or STER for esophageal submucosal tumor have not been completely evaluated.
Aims and Methods: The aim of this study is to compare the 2 different treatments. We retrospectively collected the data of 876 patients who had undergone ESD or STER for esophageal submucosal tumors from January 2011 to September 2015 in the Endoscopy Center of Zhongshan Hospital. Gender, age, tumor size, depth and shape, procedure time, complications, postoperative length of stay, and follow-up were compared between ESD and STER groups.
Results: 424 patients received ESD, while 452 patients received STER. There was no significant differences in age, gender, tumor size, depth and shape, en bloc resection rate, complications, postoperative hospital stay ($p > 0.05$). The patients receiving STER had apparently a longer procedure time due to closing the tunnel entrance (ESD vs STER, 23.2 ± 16.5 min vs. 44.0 ± 25.8 min, $p < 0.001$). No recurrence and death was occurred in the STER and ESD groups during a mean follow-up of 50.0 and 51.8 months, respectively.
Conclusion: Both ESD and STER would likely be effective and safe alternatives for resecting SMTs ≤ 10mm. Accounting for safety and preventing perforation, we are inclined to STER for SMTs > 10mm. Additionally, the choice between the 2 procedures will also depend on the depth and shape of submucosal tumors.

P0151 THE CLINICAL IMPACT OF CLOSURE OF THE MUCOSAL DEFECT AFTER DUODENAL ESD

Y. Ochiai, M. Kato, Y. Kiguchi, T. Akimoto, A. Nakayama, T. Maehata, N. Yahagi
Keio University School of Medicine, Division of Research and Development for Minimally Invasive Treatment, Cancer Center, Tokyo, Japan

Contact E-Mail Address: yochiai.a7@keio.jp
Introduction: Delayed complications (bleeding or perforation) are major concerns of duodenal ESD. Recently, we conducted a retrospective study including about 170 cases of duodenal ESD and found both perforation and bleeding was much lower than those reported by previous reported (presented at DDW 2018). We have routinely closed the post-ESD mucosal defect as far as possible, and we hypothesized the discrepancy of the outcomes between ours and previous studies was come from the difference in the proportion of complete closure of post ESD mucosal defect.
Aims and Methods: The aim of this study was to assess the efficacy of prophylactic closure of mucosal defect after duodenal ESD. This is a retrospective study from a university hospital. We collected the outcomes of duodenal ESD in 169 patients with duodenal epithelial neoplasia (174 lesions) treated by ESD at our department between July 2010 and June 2017. Study subjects were divided into 3 subgroups according to the degree of closure of post-ESD mucosal defect; complete group, incomplete group, and not attempted group. The proportion of delayed complications (including delayed bleeding and delayed perforation), the maximum serum level of C-reactive protein (CRP), and the total hospital stay were compared among these subgroups. Moreover, a multivariate logistic regression model to find risk factors for delayed complications.
Results: The proportion of delayed complications of patients in complete group, incomplete group, and not attempted group were 1.7%, 25%, and 15.6%, respectively. The difference between complete group and the others was significant ($p < 0.01$). Maximum serum CRP level was much lower in complete group (1.51 ± 2.18 vs. 6.28 ± 10.0mg/dl. $p < 0.01$) and hospital stay was significantly shorter in complete group than in incomplete/none group (median [range] 4 [4–13] vs. 7 [3–58] days, $p < 0.01$). Multivariate analysis revealed complete closure was an only independent predictor to reduce delayed complications and it revealed about 95% significant decrease of delayed complications.
Conclusion: The present study revealed that complete closure of the mucosal defect after duodenal ESD significantly decreased delayed complications and improved other outcomes such as inflammatory reaction or duration of hospital stay.

Introduction: Familial adenomatous polyposis (FAP) is an inherited autosomal-dominant disease characterized by the development of neoplasms in both upper and lower gastrointestinal tract. With the implementation of prophylactic colectomy, the incidence of colorectal cancer has declined and extracolonic manifestations have become more relevant.
In what gastric lesions are concerned, FAP patients are known to have an increased risk for gastric dysplasia, although it is unclear if these lesions confer an increased risk of gastric cancer.
Aims and Methods: The aim of our study was to characterize gastric dysplastic lesions in patients with FAP. We enrolled 144 patients with germline mutation in the APC gene from 63 FAP families and we retrospectively reviewed 366 Upper Gastrointestinal Endoscopies (UGE) performed during regular surveillance at the Familial Cancer Clinic.
Statistic tests: Chi-square, Fisher's Exact Test, Student T test, Mann-Whitney U test, Cox Regression Model
Results: From the 144 patients included in the study, 94 (Men: 49/Women: 45, mean age 48.3 ± 14,8 years) underwent UGE at least once during a median follow up period of 12.7 ± 8.9 years.
81.9% of patients had classical FAP and 18.1% presented the attenuated phenotype. 14.9% of patients did not have family history of FAP and only 6.4% had family history of gastric cancer.
Gastric dysplastic lesions were detected in 16 patients (17%): 37 endoscopically visible lesions (Paris classification: 0-Ip: 10, 0-IIa: 26, 0-IIa+IIc: 1) and 1 case of dysplasia in random biopsies. Regarding their location, the majority of dysplastic lesions were at the antrum (70.3%) and 18.9% were found within fundic gland polyps (FGP)
Mean age was significantly higher in patients with gastric dysplastic lesions compared with those without dysplasia (59.3 ± 15.7 vs. 46.0 ± 13.7 years, p = 0.001).

Histopathologic findings revealed 28 lesions with low-grade dysplasia (LGD), 8 with high-grade dysplasia (HGD) and 2 adenocarcinomas, both diagnosed in the first UGE performed.
In regard to the evolution of dysplasia, 7 patients maintained LGD in the subsequent EGDs; only one patient had progression from LGD to HGD, in a 1 year period. This case involved multifocal dysplasia of the antrum and the patient underwent subtotal gastrectomy.
The majority (70.3%) of gastric dysplastic lesions were treated endoscopically (endoscopic mucosal resection: 16; polypectomy: 9; endoscopic submucosal dissection: 1) and surgery was conducted in 2 cases.
Gastric dysplasia was positively associated with the presence of gastric polyps and flat lesions ($p = 0.014$ and $p < 0{,}001$, respectively) and with atrophic gastritis and/or intestinal metaplasia ($p = 0.001$). Gastric dysplasia was not associated with FAP phenotype, *Helicobacter pylori* infection or the presence/number of FGP.
Conclusion: Despite the high prevalence of gastric dysplasia in FAP patients, its course is indolent. This may allow endoscopic surveillance and validate a conservative treatment strategy in the majority of cases.
Disclosure: Nothing to disclose

Introduction: The endoscopic approach of esophageal perforations poses a therapeutic challenge. Recently, a predictive score has been proposed to predict the chance of successful endoscopic stenting in benign esophageal leaks. This score consists of 4 clinical variables that proved to be effective in discriminating the probability of success, especially when the probability of success is $\geq 70\%$ or $\leq 50\%$, with lower discriminatory power in case of intermediate probabilities (50–70%).
Aims and Methods: We aimed to evaluate the applicability of the clinical score in a cohort of patients with anastomotic leaks managed with fully /partially covered self-expanding metal esophageal stents.
Multicenter retrospective cohort study including patients submitted to endoscopic stenting due to anastomotic leak. Demographic data, score variables (etiology, leak size and location and C-reactive protein), clinical success, and need for additional therapies were assessed. The score and consequent probability of success of the therapy ($\leq 50\%$, 50–70%, $\geq 70\%$) were calculated and its agreement with clinical success was assessed.
Results: 39 patients included; 59% men, mean age 65 ± 10.7 years old, submitted to esophageal stenting after cancer surgery - esophagectomy ($n = 10$), gastrectomy ($n = 26$) - and bariatric surgery ($n = 3$), with an average of 2 stents /patient. Clinical success achieved in 59% of patients, with mean resolution time of 67.91 ± 41 days.
Application of the score:
Predicted probability of success $\geq 70\%$ ($n = 11$): Clinical success in 8/11 (72.8%); Clinical failure in 3/11: combination therapy with stenting, OTSC and fibrin glue-1; death -2.
Predicted probability of success 50–70% ($n = 17$): Clinical success in 11/17 (64.7%); Clinical failure in 6 /17: surgery-1; therapy with OTSC and fibrin glue-1; death-4.
Predicted probability of success $\leq 50\%$ ($n = 11$): Clinical success in 4/11 (36.4%); Clinical failure in 7/11: combined therapy with stenting and endosponge-1; surgery-4; death-2.
Conclusion: The application of this predictive model proves to be useful in clinical practice, favoring management with endoscopic stenting in patients with probability of success $\geq 50\%$. It is cautious to consider other therapeutic options in patients with a lower probability of success.

Introduction: Implementation of colorectal cancer (CRC) screening programs and the improvement of endoscopic techniques increases the endoscopic resection of polyps with early invasive CRC (pT1 Nx M0). The risk of lymph-node metastasis often leads to additional surgery, but despite guidelines, correct management remains unclear
Aims and Methods: Aim of this study was to assess factors affecting the decision-making process in endoscopically resected pT1-CRCs in an academic centre.
We retrospectively reviewed patients undergoing endoscopic resection of pT1 CRC from 2006 to 2016. Clinical, endoscopic, surgical treatment and follow up data were collected and analysed. Such lesions were categorized according to endoscopic/histological risk-factors in low- and high-risk groups. In detail, low-medium grade of differentiation, no lymphovascular invasion, no tumour budding, Haggit 1–3 and Kikuchi sm1, and en bloc resection was considered as low-risk pT1-CRC. Comorbidities were classified according to Charlson index (CCI). Surgical referral for each group was computed, and dissociation from current European CRC screening guidelines recorded. Multivariate analysis for factors affecting the post-endoscopic surgery referral was performed.
Results: 72 patients with endoscopically resected pT1-CRC were included. Overall, 20 (27.7%) and 52 (72.3%) were classified as low- and high-risk, respectively. In the low-risk group, 11 (55%) were referred to surgery, representing an over-treatment as compared with current guidelines. In the high-risk group, a non-surgical endoscopic surveillance was performed in 20 (38.5%) cases, representing a potential under-treatment). After median follow up of 30 (6–130) months, no patients developed tumour recurrence. At multivariate analysis, age (OR 1.21, 95% CI 1.02–1.42; $p = 0.02$) and comorbidities (CCI) (OR 1.67, 95% CI 1.12–3.14; $p = 0.04$) were independent predictors for subsequent surgery.
Conclusion: A substantial rate of inappropriate post-endoscopic treatment of pT1-CRC was observed, when compared with current guidelines. This was apparently related with an over-estimation of patient-related factors rather than endoscopically or histological-related factors.

Introduction: Patients with ulcerative colitis (UC) are at high risk for the development of colorectal neoplasia: colitis-associated cancer or dysplasia. We recently performed a randomized controlled trial comparing targeted vs. random biopsy and demonstrated that targeted biopsies were almost comparable to random biopsies in terms of the neoplasia detection rate when performed by specialists; however, the appropriate site for targeted biopsy is still unclear. Therefor suggestive endoscopic findings of neoplastic lesions for targeted biopsy are necessary for the further effective surveillance colonoscopy.
Aims and Methods: We aimed to elucidate key endoscopic findings suggestive of neoplastic lesions for targeted biopsy in UC. We created 769 stereomicroscopic pictures (509 neoplastic, 260 non-neoplastic) mimicking magnifying colonoscopic images from surgically resected specimens stained with undiluted Carrazzi's hematoxylin solution, including areas of 25 lesions in 15 preoperatively diagnosed patients with UC-associated neoplasia. Surgical procedures were performed between April 2016 and October 2017 at a single referral center (Department of Surgical Oncology, the University of Tokyo, Japan). Two gastrointestinal (GI) surgeons/endoscopists, who were blinded to the pathological diagnosis, independently assessed the images and classified them according to Kudo's pit pattern and surface morphology, such as pine-cone/villi patterns. GI pathologists independently made pathological findings. The correlation between stereomicroscopic and pathological findings (neoplastic vs. non-neoplastic) for each image was investigated. The interobserver agreement was assessed using *kappa* statistics.
Results: Kudo's neoplastic pit patterns (type III-V) were significantly correlated with the presence of neoplasia (sensitivity 77.4%, specificity 89.5%, positive

predictive value 92.8%), with a substantial concordance rate (*kappa* value 0.677). A hundred regions presented with pine-cone/villi patterns, which showed high specificity (96.8%) and positive predictive value (92.0%) for neoplasia, although sensitivity was low (21.4%). Concordance rate was also substantial (*kappa* value 0.625). A revision of the endoscopic findings of flat dysplasia with non-neoplastic pit patterns (9 lesions in 6 patients) revealed that 7 of 9 lesions had a reddish area with a demarcation line in each neoplastic lesion.
Conclusion: Targeted biopsies in surveillance colonoscopy for patients with UC must focus on lesions showing pine-cone/villi patterns in addition to Kudo's neoplastic pit patterns such as type III, IV or V. For some flat neoplastic lesions with non-neoplastic pit patterns such as type I or II, a reddish area with a demarcation line may be one of the effective clues for targeted biopsy.

Introduction: In the last decade, colonoscopy has proven to be the most efficient screening tool for colorectal cancer (CCR). It still carries many limitations, and the application of certain quality indicators can improve its performance. A minimum withdrawal time (WT) of 6 minutes is recommended and adenoma detection rate (ADR) increases with WT. ADR is a reliable index of careful inspection of the mucosa, and is inversely correlated to the development of interval cancers. Goal of our work: to evaluate the impact of active monitoring of WT known by the endoscopist on quality of colonoscopy, measured by the ADR.
Aims and Methods: Withdrawal time and adenoma detection rate are the quality indicators measured in our department. 8 gastroenterologists from the Bellevue Medical Center department of endoscopy have prospectively performed 373 colonoscopies over a period of 15 months, from February 2016 to April 2017. Quality indicators were measured in the first phase (Phase I) without the operator's knowledge (n = 252 colonoscopies) and in the second phase (Phase II) with the operator being aware of the monitoring (n = 121 colonoscopies). Other quality indicators (bowel preparation, cecal intubation) were also measured in the 2 phases.
Results: The study gathered 373 colonoscopies (206 men and 167 women), of which 252 in phase I and 121 in phase II. The mean Boston Bowel Preparation Scale was 7.71/9 with a slight improvement between the 2 phases: 7.696 in phase I vs. 7.74 in phase II. The mean cecal intubation rate was 96.1% without significant difference between the 2 phases. The mean WT was 9.21 ± 6.38 minutes [2–53], with improvement from 9.16 to 9.62 minutes between phases I and II (p = 0.539). The adjusted WT, after substracting polypectomy time, rises from 7.47 to 8.18 minutes (p = 0.141). There was no difference in ADR between the two phases: 26.7% (H: 29.1%, F: 24.1%) vs. 25.6% (H: 22.9%, F: 29.4%) (p = 0.815, IC 95% [0.5866; 1.6874]). However ADR seemed to be affected by WT in both phases: OR 23.41, p < 0.001 and OR 5.899, p = 0.015 in phases I and II respectively, with a tendency towards improvement of ADR in phase II.
Conclusion: Colonoscopy with an active monitoring system known to the endoscopist shows an improvement in WT, and seems to sharpen the inspection of the mucosa, demonstrated by the tendency to improvement in ADR and quality of bowel preparation. The implementation of a mandatory monitoring system with measurement of ADR and WT for each endoscopist could contribute in improving ADR and the overall quality of colonoscopy.
Disclosure: Nothing to disclose

P0157 LOWER GASTROINTESTINAL SYMPTOMS AND SYMPTOM-BASED TRIAGING SYSTEMS ARE POOR PREDICTORS OF CLINICAL SIGNIFICANT DISEASE ON COLONOSCOPY

M.S. Ismail, O. Aoko, J. Omorogbe, S. Sihag, A. O'Connor, B. Ryan, N. Breslin, D. McNamara
Tallaght Hospital, Gastroenterology, Dublin, Ireland

Contact E-Mail Address: ismailsy@tcd.ie
Introduction: Previous studies have shown lower gastrointestinal symptoms alone are a poor marker of clinically significant disease (CSD) on colonoscopy. At-risk triaging systems, such as the NICE guidelines, are recommended to help clinicians stratify patient referrals in order to prioritise those with potential CSD, in particular colorectal cancer (CRC) and inflammatory bowel disease (IBD) for early investigation.
Aims and Methods: We aimed to determine the prevalence of CSD and the diagnostic yield of symptoms in an Irish cohort and to determine the impact of applying at risk triaging protocols on patient selection and outcome.
Retrospective cohort study of sequential patients who underwent a colonoscopy for investigation of lower gastrointestinal symptoms as the primary indication over a 2-year period at our institution. Patients were identified from an endoscopy database, those with known IBD, previous CRC, a hereditary cancer syndrome or had a colonoscopy within the last 5 years, or without a clear indication were excluded. Basic demographics, symptoms, colonoscopy findings and subsequent histology were documented. CSD was defined as colorectal cancer, high-risk adenoma or inflammatory bowel disease including microscopic colitis. CSD rates were analysed by symptom and by NICE criteria, positive or negative. Odds ratios (OR) and p values were determined as appropriate and one-way anova used to compare groups.
Results: 1116 patients were identified, 493 (44%) males, mean age 54.3 (16–91), in all 287 (25%) were excluded. Colonoscopy indications were; chronic diarrhoea n = 188 (22%), PR bleeding n = 148 (18%), symptomatic anaemia n = 212 (26%), abdominal pain n = 108 (13%), alternating diarrhoea and constipation n = 79 (10%), chronic constipation n = 57 (7%), weight loss n = 37 (4%).
Overall prevalence of CSD was low 17%, (n = 141); colorectal cancer 20 (2.4%), high-risk adenoma 40 (5%), inflammation 75 (9%) [IBD 66 (8%), microscopic colitis 9 (1%)]. As expected, PR bleeding was positively associated with a diagnosis of CRC, OR 2.87 (95% CI 1.08 - 7.61) and HRA, OR 2.31 (95% CI 1.10-4.83), while chronic diarrhoea was associated with IBD, OR 2.5 (95% CI 1.50–4.20). The diagnostic yield of PR bleeding 18% (n = 27), and chronic diarrhoea 17% (n = 32), for CSD, were significantly higher than for other symptoms, symptomatic anaemia 11%, (n = 23), alternating diarrhoea and constipation 11% (n = 9), chronic constipation 7% (n = 4), weight loss 5% (n = 2) and abdominal pain 5% (n = 6), p = 0.016. In all 439 (53%) patients were NICE criteria (+) ive for CRC and 381 (46%) for IBD, 671 (81%) were positive for either criteria, while 217 (19%) fitted neither. Positive NICE criteria improved diagnostic yield for CRC and IBD, but overall detection rates remained low; 3% versus 0.9%, OR 7.7 (95% CI 1.77 to 33.56, p = 0.0064) for CRC and 9% versus 2.8% (OR 3.5, 95% CI [1.99–6.17] p < 0.0001) for IBD. The diagnostic yield for CSD overall for NICE positive patients was 18%, similar to the unselected cohort.
Conclusion: The prevalence of CSD in symptomatic patients is low (17%) and application of symptom-based triaging systems did not improve diagnostic yield. Our data suggests the routine addition of biomarkers into diagnostic algorithms for patients presenting with lower GI symptoms may be beneficial and warrants further investigation.

P0158 WARFARIN OR DIRECT ORAL ANTICOAGULANT; WHICH IS RISKY FOR POST-POLYPECTOMY BLEEDING?

Y. Shimodate, M. Mizuno, M. Miyake, R. Takezawa, A. Doi, N. Nishimura, H. Mouri, K. Matsueda, H. Yamamoto
Kurashiki Central Hospital, Gastroenterology and Hepatology, Kurashiki, Japan

Contact E-Mail Address: ys13544@kchnet.or.jp
Introduction: Patients who undergo endoscopic resection of colorectal polyps under medication with anticoagulants, warfarin and direct oral anticoagulant (DOAC) for theirs cardiovascular/neurovascular conditions are increasing.
Aims and Methods: In this study, we investigated which has higher risk for post-polypectomy bleeding.

Abstract No: P0158

		Univariate Odds ratio	p-value	Multivariate Odds ratio	p-value
Anticoagulant agents	DOAC	ref			
	Warfarin	2.4 (0.76–9.73)	0.17		
Heparin bridging	No	ref		ref	
	Yes	3.0 (1.15–8.87)	0.02	3.1 (1.14–8.28)	0.03
NSAIDs/Corticosteroid	No	ref		ref	
	Yes	5.0 (1.26–17.3)	0.01	8.6 (2.27–32.7)	0.002
Number of removed polyps	<3	ref		ref	
	≥3	2.7 (1.08–7.22)	0.03	2.9 (1.18–7.34)	0.02

286 patients receiving anticoagulant therapy underwent hot-snare polypectomy of colonic polyps at Kurashiki Central hospital between January 2012 and December 2017. 6 patients under treatment for concurrent gastrointestinal bleeding were excluded. In total, medical records of 280 patients (705 colorectal polyps) were retrospectively reviewed. DOAC (rivaroxaban, apixaban, edoxaban or dabigatran) was used in 83 patients and warfarin in 197 patients. Anticoagulants were discontinued according to the guideline of Japan Gastroenterological Endoscopy Society in 2012 when the cessation of anticoagulants was required. Delayed bleeding was defined as hematochezia requiring emergent colonoscopy within 4 weeks after polypectomy. Analyzed factors were; anticoagulants, antiplatelet agents, heparin bridging, comorbidities (diabetes mellitus, hypertension, hemodialysis, hyperlipidemia, liver cirrhosis), age, sex, number of removed polyps, and maximal size of polyps in each patient.

Results: Delayed bleeding occurred in 25 (8.9%) patients, who were all completely managed with endoscopic hemostasis. The incidence rate of post-polypectomy bleeding was 10.7% in patients with warfarin and 4.8% with DOAC; the difference did not reach statistical significance ($p = 0.17$). Patients with warfarin had more chance of heparin bridging than those with DOAC (62.4% vs. 14.5%). In 145 patients without heparin bridging, the bleeding rates were similar between the patients with warfarin (4.1% (3/74) and those with DOAC 5.6% (4/71). Multivariate analysis identified heparin bridging (odds ratio = 3.1; 95% confidential interval (CI), 1.1–8.3), non-steroidal anti-inflammatory drug or corticosteroid user (odds ratio = 8.6; 95% CI, 2.3–32.7), and resection of more than 3 polyps (odds ratio = 2.9; 95% CI, 1.2–7.3) as significant and independent risk factors associated with post-polypectomy bleeding. Thromboembolism occurred in 1 patient (0.4%) with heparin bridging. *[Risk factors associated with post-polypectomy bleeding]*

Conclusion: Warfarin and DOAC had similar risk for post-polypectomy bleeding, and heparin bridging was associated with an increased risk of post-polypectomy bleeding. Given that heparin bridging was more frequently performed in patients with warfarin, DOAC may be preferable in terms of post-polypectomy bleeding.

Introduction: High-quality colon cleansing is associated with improved lesion detection during colonoscopy (1-3). The cleansing efficacy and safety of NER1006, a novel 1L polyethylene glycol (PEG)-based bowel preparation, was evaluated in 3 randomised phase 3 trials DAYB[4], MORA[5], and NOCT[6].

Aims and Methods: For each trial, this post hoc analysis compared the level of high-quality segmental cleansing attained by NER1006 versus its comparator: Sodium Picosulfate + Mg Citrate (SPMC; DAYB), 2L PEG + Ascorbate (2LPEG; MORA) and Oral Sulfate Solution (OSS; NOCT). Dosing regimens varied by trial. All trials had treatment-blinded central reader-assessed cleansing scores and similar recruitment criteria. Alternative primary endpoints were overall and right colon cleansing using the validated Harefield Cleansing Scale (HCS)[7]. The number and share of high-quality segments (HCS score 3-4) attained by NER1006 versus its comparator were analysed in 3 primary analysis populations: The full analysis set (FAS; all randomised patients), the modified FAS (mFAS; FAS excluding any patient who failed lab screening after randomisation and who also did not take their study treatment), and the Per-protocol set (PP; FAS with fulfilled entry criteria, who took ≥75% of both study preparation doses, had data for at least 1 of the primary endpoints, and no major protocol deviations).

Results: A total of 1,985 patients were included in this analysis (Table 1). In each of the 3 primary analysis populations (FAS, mFAS, PP), day before dosing with NER1006 attained significantly more high-quality segments than with SPMC (16.9% vs. 10.4%; $p < 0.001$, 17.4% vs. 10.7%; $p < 0.001$, 18.4% vs. 10.7%; $p < 0.001$). Overnight split dosing with NER1006 showed more high-quality segments than with 2LPEG (46.1% vs. 29.0%; $p < 0.001$, 47.5% vs. 30.2%; $p < 0.001$, 48.7% vs. 32.5%; $p < 0.001$). Morning only dosing with NER1006 AM/AM also achieved more high-quality segments than overnight split dosing with 2LPEG PM/AM (46.8% vs. 29.0%; $p < 0.001$, 48.1% vs. 30.2%; $p < 0.001$, 50.6% vs. 32.5%; $p < 0.001$). Finally, overnight split dosing with NER1006 PM/AM delivered more high-quality segments than with OSS (40.1% vs. 36.2%; $p = 0.013$, 45.0% vs. 40.2%; $p = 0.005$, 48.8% vs. 44.0%; $p = 0.011$). No serious adverse events were reported in the entire population in this post hoc pooled analysis.

[Table 1. Colon segments with Harefield Cleansing Scale score 3-4 (high-quality), per treatment, in three central reader-assessed phase 3 trials]

Conclusion: NER1006 delivered more colon segments with high-quality cleansing scores than SP+MC, 2LPEG+Asc, or OSS. NER1006 is the first bowel preparation to demonstrate a superior high-quality colon segment cleansing efficacy versus these 3 current alternatives through adequately powered randomized controlled trials. The encouraging high cleansing efficacy of NER1006 AM/AM may help patients reduce their total bowel preparation time.

Disclosure: AR: NER1006 phase 3 trial investigator. No other conflicts of interest. BA: Employee of Norgine, PU: NER1006 phase 3 trial investigator. No other conflicts of interest. SS: NER1006 phase 3 trial investigator. No other conflicts of interest.

Introduction: Colorectal cancer is the second most commonly diagnosed cancer in Ireland. (1) Incomplete polypectomy is common among Endoscopists.(2) NCCS (National Colon Cancer Screening) colonoscopies are offered to bowel cancer screening patients after a positive Faecal Immunochemical Testing (FIT). These anecdotally have larger polyps.The goal of polypectomy is to achieve an R0 margin meaning that the margin is free from abnormal tissue.

Aims and Methods: To determine whether there is an association of R0 resection margin with Endoscopist, histopathologist, size, location and technique of polypectomy in an NCCS cohort. It was a retrospective observational study on NCCS colonoscopies between October 2013 and June 2017. All these procedures were conducted in a single centre at Louth county hospital (LCH). SPSS software was used for statistical analysis. Statistical significance was set a priori at $p < 0.05$.

Results: In this ongoing study a total 542 colonoscopies were performed with no polyps in 19%. Here we present a subanalysis of 186 colonoscopies on which 707 polyps were identified. The average age was 66 years (SD 2.8) with 190 (27%) females. The polyp distribution was 255 (36%), 85(12%) and 365 (52%) in right, transverse and left colon respectively. Most of the polyps were less than 5 mm (59%) with 11.5% more than a cm in size. 152 (27%) had an R0 margin histologically, and 30 (5%) had involvement of the margin. In 373 (67%) polyps pathologist were unable to assess the margin and (3%) polyps were not retrieved. Polypectomy technique in the form of hot snare had a direct relation with R0

FAS, Full Analysis Set. mFAS, modified Full Analysis Set (FAS excluding patients who failed lab screening after randomisation and who also failed to take their study treatment). Per-Protocol (FAS with fulfilled entry criteria, who took ≥75% of both study preparation doses, had data for at least one of the primary endpoints, and no major protocol deviations).

margin ($p<0.003$) with an inverse relation of Endoscopic mucosal resection (EMR, $p<0.004$). Accessibility of margins also had a linear relation with the size of the polyp, resection technique, statistically significant difference between hot snare and biopsy to cold biopsy and snare ($p<0.02$) and the reporting pathologist. Achieving an R0 margin was not statistically significant with endoscopist (our experienced endoscopist on average do more than 300 colonoscopies per year), size and location of the polyp.

Conclusion: Only 25% of the polyps retrieved achieved an R0 margin while in 71% cases pathologist were unable to assess the margin. A multidisciplinary approach has to be developed between the endoscopist and pathologist for achieving R0 margin. Polypectomy requires significant focused training and experience to maximize success. In future, this could be included as a key performance indicator for polypectomy.We also recommend more studies on margin analysis.

Introduction: Endoscopic resection of colorectal polyps has been shown to reduce colorectal cancer related death1. For sessile colorectal polyps, endoscopic mucosal resection (EMR) is an established method for the removal2. However, recurrence after EMR is a major limitation. Piecemeal resection and intraprocedural bleeding are reported to be risk factors of recurrence after EMR3,4. Underwater EMR (UEMR) was proposed as an alternative method for removal of colorectal polyps5. There is no large-scale dataset directly comparing the efficacy and safety of UEMR with conventional EMR in resecting average sized lesions.

Aims and Methods: The aim of our study is to compare efficacy and safety of UEMR with conventional EMR in average sized colorectal sessile polyps using a large retrospective cohort with propensity score matched design.

A retrospective observational study was conducted on all adult patients referred to us for endoscopic resection of sessile colorectal polyps between August 2012 and November 2017. During this period, conventional EMR was performed until August 2015, when UEMR was introduced to our hospital, and UEMR was performed for all lesions after August 2015. Follow-up of the patients was by a clinic visit around 7–14 days after the procedure to monitor adverse events. Surveillance colonoscopy was scheduled according to MSTF guidelines. The outcome measurements included en bloc resection rate, procedure time, bleeding, and muscle layer injury. We match and compensate the baseline differences in both groups in a 1:1 ratio by calculating propensity scores using a multivariable regression model.

Results: 462 lesions in 407 consecutive patients were treated. In the first study period between August 2012 and August 2015, all of the 256 lesions in 224 patients were resected by conventional EMR. In the second study period between August 2015 and November 2017, all of the 206 lesions in 183 patients were resected by underwater EMR.

The propensity score matching created 170 matched pairs (totally 340 patients). The mean age is 64 years old. The mean tumor size is 14.6mm, 73% of the resected lesions are less than 20mm. 28% of the lesions has been biopsied or resected before.

There is no difference between the en bloc resection rate of UEMR (89%) and conventional EMR (87%). The mean resection time in UEMR group (8mins) is significantly shorter than conventional EMR (10mins).

The risk of intraprocedural bleeding is lower in UEMR (4.1% versus 18.2%) while the risk of delayed bleeding is low in both groups (0.6%–1.2%). The risk of muscle layer injury is also low in both groups (1.2%).

Conclusion: Our study is the largest study comparing UEMR with conventional EMR. We confirmed that UEMR could be an alternative to conventional EMR in resecting sessile colorectal polyps. It has similar en bloc resection rate, shorter procedure time, and causes less intraprocedural bleeding than conventional EMR. The risk of muscle layer injury is similar to conventional EMR and cannot be ignored. Further investigations are required to compare the long-term outcome between both procedures.

Introduction: Adenoma detection rate (ADR) is a key indicator of colonoscopy quality. Previous studies have shown that performance feedback can improve ADR, but these were mostly based in the West and lack examination of factors associated with response.

Aims and Methods: The aim of this study is to compare individual ADR before and after implementation of scorecard, and determine patient and procedure factors associated with response in a multi-centre study in Singapore.

We documented patient factors (age, gender), procedure factors (bowel preparation, withdrawal time, indication) and histology findings for all colonoscopies performed in March 2014-August 2017 at Gastroenterology and Surgical units of 2 hospitals. After 1 year of baseline data collection, endoscopists were informed of colonoscopy quality tracking at unit briefings. After an adjustment period, we issued 6-monthly scorecards confidentially (intervention). They reported individual withdrawal time (WT), completion rate, complication rate, polyp/adenoma detection rate, average Boston Bowel Preparation Score (BBPS), adenoma count per colonoscopy (APC), as well as unit averages and percentiles. Endoscopists with >25 scopes in each 6-monthly period were included in analysis. Regression models were used to derive patient age, sex and indication adjusted ADR, proximal ADR, APC and largest polyp size in all complete colonoscopies with at least fair bowel preparation (BBPS>4). A benchmark for overall ADR of 25% was adopted. Those below this benchmark at baseline but showed significant increase in ADR after intervention were identified as responders. t test and chi-square test were used to compare patient and procedure factors between responders and non-responders.

Results: 33 endoscopists who performed 21760 scopes met the inclusion criteria. Overall adjusted baseline ADR was 27.3%($\pm$1.3%) and increased to 31.8%($\pm$0.9%) after intervention ($p<0.01$). At baseline, 12 endoscopists had ADR$<$ 25%. Their ADR increased from 17.0%($\pm$2.0%) to 27.3%($\pm$1.3%) after intervention ($p<0.01$), with highest ADR in the 6 months immediately after intervention. APC, proximal ADR, proportion of cases with largest polyp<5mm also increased after intervention (0.25 to 0.50, 8.8% to 16.3%, 14.7% to 22.8% respectively, all $p>0.01$). 6 responders and 6 non-responders were identified. Responders had higher mean patient age (60.0 vs. 56.9 years, $p<0.01$), performed more scopes with BBPS$\geq$5 (94.9% vs. 92.0%, $p<0.01$) and more screening scopes (33.4% vs. 25.3%, $p<0.01$) than non-responders. Non-responders had shorter WT, but this difference was not significant after intervention (8.35min vs. 8.39min, $p=0.83$).

Conclusion: Quality scorecards were successful in improving ADR in a multi-centre study in Asia. Response to feedback is multi-factorial. Increased WT alone without improving other modifiable factors may not result in improved ADR after feedback.

P0163 USEFULNESS OF JNET CLASSIFICATION WITH DUAL-FOCUS MAGNIFICATION FOR DIAGNOSIS OF COLORECTAL TUMORS: SINGLE CENTER RETROSPECTIVE STUDY

Y. Koyama[1], M. Fukuzawa[1], M. Suguro[1], T. Matsumoto[1], K. Uchida[1], A. Madarame[1], T. Morise[1], H. Yamaguchi[1], Y. Aoki[1], A. Sugimoto[1], Y. Yamauchi[1], S. Kono[1], T. Kawai[2], T. Itoi[1]

Introduction: Narrow-band imaging (NBI) magnifying endoscopy has been reported to be useful for qualitative and quantitative diagnosis of colorectal lesions. Recently, Japan NBI Expert Team (JNET) classification was advocated which is the first universal narrow-band imaging magnifying endoscopic classification of colorectal tumors. However, magnifying endoscopy requires high experience and skill. On the other hand, dual-focus NBI with electronic zoom (DF-NBI) can easily provide almost the same image of optical zoom magnifying images only by button push.

Aims and Methods: The aim of study is to clarify the usefulness of JNET classification with DF-NBI for colorectal tumors. We analyzed consecutive 290 colorectal lesions, which were diagnosed by JNET classification with DF-NBI observation before endoscopic treatment or surgery between April 2017 and

March 2018. The instrument used in this study was a dual focus endoscope (CF-HQ290L/I; Olympus Medical Systems). The resected lesions were pathologically diagnosed in accordance with the criteria of the World Health Organization. Using these cases, we examined the relationship between each type of the JNET classification with DF-NBI and histopathologic findings. We calculated sensitivity, specificity, positive and negative predictive value (PPV and NPV), and accuracy for each category of the classification.
The JNET classification; the colorectal NBI magnifying classification consists of 4 types that are classified based on vessel pattern and surface pattern. The characteristics of Type 1 are invisible vessel pattern and having regular dark or white spots as surface pattern. The characteristics of Type 2A are regular vessel pattern, such as regular caliber or distribution, and regular surface pattern. The characteristics of Type 2B are irregular vessel pattern, such as variable caliber, irregular distribution, and irregular or obscure surface pattern. The characteristics of Type 3 are loose vessel areas or interruption of thick vessels and amorphous surface pattern. Indicators of types; Type 1 as hyperplastic polyp (HP) or sessile serrated polyp (SSP), Type 2A as low-grade dysplasia (LGD), Type 2B as high-grade dysplasia (HGD) or superficial submucosal invasive cancer (SM-s), and Type 3 as deep submucosal invasive cancer (SM-d).
Results: I. Final diagnosis: 38 Type 1 (26 HPs, 8 SSPs and 4 LGD), 229 Type 2A (8 HPs, 216 LGD, 4 HGD and 1 SM-d), 8 Type 2B (2 LGD, 5 HGD and 1 SM-s), and 2 Type 3 (2 SM-d).
II. Diagnostic ability: The respective sensitivities, specificities, PPV, NPV, and accuracies were as follows: Type 1, 81.0%, 98.3%, 89.5%, 96.7%, and 95.7%; Type 2A, 95.2%, 80.4%, 96.1%, 77.1%, and 92.8%; Type 2B, 60.0%, 99.3%, 75.0%, 98.5%, and 97.8%; and Type 3, 66.7%, 100%, 100%, 99.3%, and 99.6%.
Conclusion: Our results suggest that JNET classification with DF-NBI is not only convenience but also have sufficient diagnostic ability. However, the sensitivities of JNET Type 2B and Type 3 were lower than that of Type 1 and Type 2A. Therefore, JNET Type 2B and Type 3 need to be examined by increasing the number of cases. Further investigation comparing DF-NBI and conventional magnifying NBI is needed in the near future.

P0164 EFFECTIVENESS OF SUBMUCOSAL EPINEPHRINE INJECTION FOR LARGE COLON POLYP EMR

T. Ikeya, A. Takasu, K. Nakamura, T. Okamoto, K. Fukuda
St. Luke's International Hospital, Gastroenterology, Tokyo, Japan

Contact E-Mail Address: takaike@luke.ac.jp
Introduction: Currently, the use of endoscopic submucosal dissection is more widespread than Endoscopic Mucosal Resection (EMR) as a treatment for large colon polyps in Japan. However, the effectiveness and simplicity of EMR has never changed and it is still a key treatment for type 0-Ip and 0-Isp polyps. Although the intra-procedural bleeding rate is not high, reaching hemostasis once bleeding occurs requires time. A detachable snare, often used for type 0-Ip polyps, is effective in reducing intra-procedural bleeding. For short pedicle or large 0-Isp polyps, an effective prevention for intra-procedural bleeding after large colon EMR is desired. A 1:20000 epinephrine submucosal injection has been used for colonic diverticular bleeding, and is effective and safe for even massive diverticular bleeding.
Aims and Methods: The aim of this study was to reveal the risk factor of intra-procedural bleeding and to evaluate the effectiveness of submucosal 1:20000 epinephrine injection in large colon polyp EMR.
Between January 2015 and February 2018, patients with 0-Is, 0-Isp, or 0-Ip polyps over 2 cm treated by EMR or polypectomy were enrolled. Age, sex, polyp size, location, Paris classification,use of anti-thrombotic agents, intra-procedural bleeding, post polypectomy bleeding were evaluated retrospectively. Intra-procedural bleeding was defined as spurting bleeding or arterial pumping occurring during the procedure. Bleeding within 14 days after the procedure was defined as post-polypectomy bleeding.
Results: A total of 117 patients of over 2cm colon polyp were treated by EMR or polypectomy.
1:20000 epinephrine submucosal injection was used in 11 patients. Mean size of polyp was 22mm ± 3mm (range: 20–40mm), over 25mm polyp were 20% 24/117). Pathological diagnosis of polyp was adenoma, 46 (39%): mucosal cancer, 41 (35%): submucosal cancer, 7 (6%): others, 21 (18%). Paris classification was 0-Is, 6 (5%): 0-Isp, 33 (28%): 0-Ip, 60 (51%): 0-IIcnt;) were treated by polypectomy with detachable snare, 86 cases (73%) were treated by EMR, 15 cases (12%) were treated by EMR with detachable snare. Only 3 (3%) post polypectomy bleeding occurred in EMR cases.
Intra-procedural bleeding was occurred in 10 cases. Despite no intra-procedural bleeding occuring in the sub mucosal epinephrine injection group, there was no significant different compared conventional serum saline injection with epinephrine injection ($p = 0.286$). Detachable snare was effective to prevent intra-procedural bleeding ($p = 0.047$).Polyp size over 25mm was a risk factor of intra-procedural bleeding ($p = 0.015$).
Conclusion: 1:20000 epinephrine injection should be performed for over 25mm colon polyp to prevent intra-procedural bleeding after EMR without detachable snare.
[Comparison non-bleeding group with intra-procedural bleeding]

Introduction: The main aim of this study was to conduct a meta-analysis on the effect of clipping on DPB following endoscopic mucosal resection (EMR) of colorectal lesions ≥ 20 mm.
Aims and Methods: The main aim of this study was to conduct a meta-analysis on the effect of clipping on DPB following endoscopic mucosal resection (EMR) of colorectal lesions ≥ 20 mm. We performed a search of PubMed and the Cochrane library for studies comparing the effect of clipping vs. no clipping on DPB following endoscopic resection. The Cochran Q test and I^2 were used to test for heterogeneity. Pooling was conducted using a random-effects model.
Results: 13 studies with a total of 7794 polyps were included. Overall, when lesions of all sizes and types of endoscopic resection (conventional polypectomy, EMR or endoscopic submucosal dissection [ESD]) were included, DPB was observed less frequently with clipping (1.3%) as compared to no clipping (2.7%) (pooled OR 0.50, 95% CI: 0.25–0.91, $p = 0.02$). In the subgroup analyses, clipping was also associated with a decrease in the rate of DPB after (1) resection of lesions ≥20 mm (pooled OR: 0.33; 95% CI: 0.18–0.62; $p < 0.001$) and for lesions ≥20 mm removed by EMR (pooled OR 0.24, 95% CI: 0.12–0.50, $p < 0.001$).
Conclusion: Prophylactic clipping may reduce DPB following EMR of large colorectal lesions. Future trials are needed to further identify risk factors and stratify high risk cases in order to implement a cost-effective preventive strategy.

Introduction: We investigated the outcome of a second colonoscopy after preparation-associated failure of the first colonoscopy and determine the proper timing of a second colonoscopy.
Aims and Methods: Patients who failed in their first colonoscopy due to poor bowel preparation were randomly allocated to 2 groups: next day repeated colonoscopy with sodium phosphate (NaP) 45mL group (Next day group) vs after 7 days repeated colonoscopy with polyethylene glycol (PEG) 4L (After 7 days group). Age, sex, past medical history, current medication, bowel habit, reason for colonoscopy were compared between the 2 groups. The quality of bowel preparation was assessed using Ottawa scale. Bowel preparation scale, colonoscopic findings and polyp detection rate were compared between the 2 groups.
Results: A total of 101 patients with unacceptable colonic preparation were enrolled. 51 patients were included in Next day group and 50 patients in After 7 days group. Next day group showed the better quality of bowel preparation than After 7 days group (4.75 ± 2.45 vs. 5.52 ± 2.24, $p = 0.003$). There was no

Abstract No: P0164

	Non-Bleeding group (n = 107)	Intra-procedural group (n = 10)	P-value
Anti-thrombotic agents, n(%)	11 (10%)	2 (20%)	0.34
Location (C/A/T/D/S/R)	7/22/6/6/53/13	1/3/2/1/3/0	*
0-Is/0-Isp/0-Ip/0-IIa/others	5/30/56/15/1	1/3/4/2/0	*
EMR without detachable snare, n(%)	76 (71%)	10 (10%)	0.047
Epinephrine injection, n(%)	11 (10%)	0 (0%)	0.286
Polyp size over 25mm, n(%)	19 (17%)	5 (50%)	0.015

significant difference in age, sex, current medication, reason for colonoscopy, colonoscopic findings and polyp detection rate between the 2 groups. Constipation and past history of abdominal surgery was found to be predictive of a failed repeated preparation (Odd ratio = 1.54, 95% CI (1.14–2.07), p = 0.004).
Conclusion: Second colonoscopy on next day with NaP 45 mL was more effective than after 7 days with PEG 4L in colonic preparation failure.
Constipation and past history of abdominal surgery were significant risk factors of repeated preparation failure.

Introduction: Successful bowel cleansing is required for effective colonoscopy. Polyethylene glycol (PEG)-based bowel preparations are widely used for this, despite many still requiring high fluid volume intake. To enhance the patient experience, the phase 2 study OPT[1] assessed the clinical proof of concept of NER1006, a novel 1L PEG-based bowel preparation, versus standard 2L PEG + ascorbate (2LPEG). Here we report the cumulative segmental cleansing score versus total fluid intake for NER1006 and the Control.
Aims and Methods: The OPT study had 2 parts and evaluated 5 different low volume PEGs vs the control. This post-hoc analysis assessed the lead phase 3 candidate, NER1006, from Part 2 of the study vs the Control. Treatment-blinded colonoscopists assessed the bowel cleansing quality using the Harefield Cleansing Scale (HCS). For each patient, the sum of observed segmental cleansing scores (0–4) for each of the 5 segments (cumulative maximum total = 20), and the total fluid volume intake (i.e. preparation volume + mandatory additional clear fluid volume + voluntary ad libitum clear fluid volume) were assessed. The number and share of patients who attained high-quality cleansing (segmental HCS scores 3 or 4) in all segments (cumulative HCS score of 15 or higher) were calculated.
Results: 60 patients underwent screening colonoscopy (Table 1). They were either 40 to 70 years old with a known personal or familial risk of contracting colorectal cancer, or 55 to 70 years old. 30 patients per group had their bowels prepared with overnight split dosing regimens of either NER1006 or 2L PEG. Among patients on NER1006, 29/30 (97%) achieved cumulative segmental scores of 15 or higher versus 11/30 (37%) on the 2L PEG. Beyond the total required minimum of 2L, total fluid volume intake seemed independent of the cleansing quality. 2L PEG showed larger cleansing variability. At an average of 3004 ± 718 mL (SD) for the NER1006 group the total fluid volume intake was significantly lower than for the 2LPEG group (3667 ± 530 mL; p < 0.001). Half of the patients (15/30) taking NER1006 chose to drink under 3L in total but still achieved a very high level of cleansing.

	NER1006		2LPEG	
Sample Size, n	30		30	
Dose intake start time	5–6pm	7–8am	5–6pm	7–8am
Preparation	500	500	1000	1000
Required additional fluid	500	500	500	500
Required fluid Total	2000		3000	
Total fluid volume intake ml, mean [SD]	3004 [718]		3667 [530]	
P-value	[p < 0.001]			
Patients with a cumulative segmental HCS score ≥15, n (%)	29/30 (96.7)		11/30 (36.7)	

[Table 1. Split dosing regimens, mean total volume intake and cumulative HCS scores]

Conclusion: Overnight split dosing with NER1006 can achieve a clinically useful bowel cleansing with a low total volume intake. NER1006 achieved its cleansing success mostly at the high quality level and at a significantly lower total fluid intake than standard 2L PEG + ascorbate.

Disclosure: Lucy Clayton and Bharat Amlani, employees of Norgine Ltd. Cesare Hassan was an investigator in the DAYB study and received honoraria from Norgine Ltd or investigator advisory board attendance.

P0168 ENDOSCOPIC FEATURE OF DEPRESSED TYPE COLORECTAL NEOPLASMS IN MAGNIFYING ENDOSCOPY AND ENDOCYTOSCOPY-

S. Kudo, K. Mochizuki, Y. Mori, K. Mochida, Y. Kouyama, T. Sakurai, K. Ichimasa, S. Matsudaira, H. Nakamura, Y. Yagawa, N. Toyoshima, M. Misawa, N. Ogata, T. Kudo, T. Hisayuki, T. Hayashi, K. Wakamura, N. Sawada, T. Baba, E. Hidaka, F. Ishida

Introduction: Colorectal cancers are generally recognized to develop from polyps. This adenoma-carcinoma sequence theory has been in the mainstream of development of colorectal cancers. However, recently the existence of many depressed-type cancers has been revealed, which are considered to emerge directly from normal epithelium, not through the adenomatous stage. This theory is called de novo pathway.
Now, it is possible to presume the histology of colorectal lesions using magnifying endoscopy (pit pattern classification) and endocytoscopy (EC classification). We can observe not only the structural atypia but also the cellular atypia *in vivo*.
Aims and Methods: The aim is to clarify the endoscopic characteristics of depressed-type colorectal neoplasms, demonstrating the validity of pit pattern and EC classification.
A total of 30021 colorectal neoplasms excluding advanced cancers were resected endoscopically or surgically in our unit from April 2001 to May 2017. Of these, 22958 lesions were low-grade dysplasia, 5913 were high-grade dysplasia and 1150 were submucosally invasive (T1) carcinomas. According to the developmental morphology classification, they were divided into 3 types: depressed, flat and protruded-type. We investigated the rate of T1 carcinomas and the characteristics of depressed-type neoplasms concerning pit pattern and EC classification.
Results: The rate of T1 carcinomas in depressed-type lesions reached to 62.1%, meanwhile that in flat-type and protruded-type lesions was 3.4% and 2.9%, respectively. Within less than 5mm in diameter, that was 10.4%, 0% and 0%, respectively. Most of the flat-type (91.9%) and protruded-type (94.3%) lesions showed type IIIL or IV pit pattern corresponding to adenomas, whereas 91.7% of the depressed-type lesions were characterized by type IIIS, VI or VN pit patterns corresponding to carcinomas. As for endocytoscopy, most of the flat- and protruded-type lesions showed EC2 corresponding to adenomas. In contrast, the depressed-type lesions were observed as EC3a (39.0%) and EC3b (53.5%) corresponding to invasive carcinomas.
Conclusion: This study revealed the diagnostic characteristics of depressed-type lesions. They show typically typeIIIS,VI or VN pit patterns in magnifying endoscopy and type EC3a or EC3b in endocytoscopy. These lesions tend to invade the submucosal layer even when they are small. I-t is important to diagnose colorectal neoplasms according to their morphology.

Introduction: One of the main benefits associated with CR-ESD is to achieve an oncological curative resection in tumours with superficial submucosal invasive carcinoma (SSIC) and no other risk factors for lymph node metastasis. However, ESD has a higher complication rate than EMR. In addition, at least theoretically, the oncological outcomes for non-invasive CR lesions (Vienna classification ≤ 4) removed by EMR should not be worse than those achieved with ESD.

Aims and Methods: To assess the prevalence of SSIC on colorectal lesions removed by ESD, and to evaluate the complication rate for these procedures. We recorded prospectively, in an intention-to-treat basis, the lesions selected for ESD and performed by members of the ESD interest group (a division of the SEED Endoscopic Resection Working Group) of the Spanish Society of Digestive Endoscopy (SEED). Delayed bleeding, immediate and delayed perforation were defined as complications.

Results: We prospectively included 393 lesions in 392 consecutive patients with CR neoplasms scheduled for ESD from January 2016 to January 2018 in 15 centres. Case volume was over 40 ESDs in 4 hospitals. Median size of the tumours was 35 mm (range 5 - 20). Median duration of the procedures was 104 min (range: 10 - 375). The duration of the procedures was significantly correlated with size ($R^2 = 0.17$; $p < 0.0001$). The morphology of the polyps was 64 LST-G homogeneous type (16%), 120 LST-G mixed type (31%), 127 LST-NG FE type (32%), 31 LST-NG PD type (8%) and other morphologies for the remaining (13%). The location of the tumours was as follows: rectum n = 111 (28.2%); sigmoid n = 37 (9.4%); descending colon n = 28 (7.1%); splenic flexure n = 9 (2.3%); transverse colon n = 38 (9.7%); hepatic flexure n = 33 (8.4%); ascending colon n = 75 (19.1%) and cecum n = 62 (15.8%). 25 cases had received previous endoscopic treatment (6.3%). The *en bloc* resection rate was 80.4% (n = 316). There were 17 (4.3%) aborted procedures. Most of them as a result of technical difficulty although in 2 cases an intraprocedural perforation occurred (only 1 of them requiring surgery). The R0 resection rate was 72%. The final pathological report showed: Vienna 1; n = 14 (4%); Vienna 2; n = 2 (1%); Vienna 3; n = 196 (50%); Vienna 4; n = 130 (33%) and Vienna 5; n = 16 (4%). 1 of the lesions was a neuroendocrine tumor (1%) and the pathology for another 17 (4%) are pending. Regarding the Vienna 5 cases, a curative resection (R0, SSIC, G1/G2, ly -, v-) was achieved in 8 tumours (2%). Deep submucosal invasion was observed in 5 cases (1.3%). Additionally, 2 cases showed G3 (0.7%) and the invasion depth could not be assessed in another 1 case (0.2%). Regarding complications, a delayed bleeding occurred in 19 patients (5%). There were 54 intraprocedural perforations (13.7%), 8 delayed perforations (2%) and 1 case developed both (0.2%). Surgery was needed in 10 cases: 8 perforations (2%) and 2 hemorrhages (0.7%).

Conclusion: The frequency of SSIC without risk factors for lymph node metastasis is low (2%) in our Western multicentre ESD series. Most of the procedures were performed for lesions not capable to develop metastatic disease. 1 every 2 ESDs was performed for mucosal low-grade neoplasms. The complication rate was 21%. The clinical benefit of ESD, in terms of avoiding surgery, might be controversial when only the pathological results are considered.

Introduction: Inadequate bowel cleansing is a major burden for endoscopy units. Although, a low fiber diet (LFD) is usually recommended before colonoscopy, there is no evidence regarding the number of days required to achieve a proper bowel cleansing.

Aims and Methods: The purpose of the study was to assess the quality of bowel cleansing comparing a 3-day LFD-based regimen with 1-day LFD-based regimen. Consecutive patients scheduled for outpatient colonoscopy in a tertiary care Hospital were included between December 2017 and February 2018. Patients with past poor bowel preparation and not willing to participate in the study were excluded. Patients were randomized to: 1-day LFD (Group 1) or 3-day LFD (Group 2). All patients received 2-L split-dose polyethylene-glycol (PEG) plus ascorbic acid before colonoscopy. A structure LFD was designed by an endocrinologist. Compliance was assessed using a validated questionnaire and a personal food intake record. Cleansing was considered to be adequate if the Boston Bowel Preparation Scale (BBPS) scored ≥ 2 points at each colonic segment. The analysis was carried out by intention-to-treat (ITT) and *per*-protocol (PP). A superiority analysis was performed to demonstrate that colon cleansing after a 3-day LFD regimen was superior to 1-day LFD with a margin of 10%. Assuming a type I error of 5%, a power of 80% and considering a dropout rate of 15%, a total of 202 participants *per* group were required.

Results: 287 patients (60 ± 14.5 years, 51% males) were included from December 2017 to February 2018, 143 in group 1 and 144 in group 2. No differences were found between the 2 groups with respect to demographic variables, comorbidity, received treatments, change in bowel habits, indication for colonoscopy, compliance with the diet or cleansing solution and polyp/adenoma detection rates. Cleansing quality (BBPS scale ≥ 2 points at each colonic segment) was not significantly different between groups in ITT analysis (82.6% vs. 88.2%, $p = 0.17$; Odds Ratio (OR) 1.6, 95% confidence interval (CI) [0.81–3.08]) or in PP analysis (83.8% vs. 90.4%, $p = 0.10$; OR 1.8, 95% CI [0.88–3.79)]. However, there was a significant difference in favour of the 3-day LFD either in ITT analysis (86.7% vs. 93.8%; $p = 0.04$) or PP analysis (86.8% vs. 94.1%; $p = 0.04$) in the quality of the left colon.

Conclusion: Preliminary analysis suggests that the number of days following a LFD before colonoscopy does not significantly affect the total quality of bowel cleansing but the 3-day LFD regimen may improve cleansing quality in the left colon. (NCT03247452)

P0171 PERIOPERATIVE HEPARIN BRIDGING FOR ENDOSCOPIC RESECTION OF THE COLORECTAL TUMOR FOR PATIENTS RECEIVING ANTICOAGULATION RESULTED IN A HIGHER INCIDENCE OF BLEEDING COMPLICATION THAN OTHER HIGH-RISK ENDOSCOPIC PROCEDURES

D. Yoshimura, T. Ochiai, T. Chaen, S. Fukuda, K. Nakano, Y. Kitagawa, K. Ichida

Contact E-Mail Address: yoshimura1972@gmail.com

Introduction: In the ESGE and Japanese guidelines, perioperative heparin bridging is recommended for high thrombotic risk patients who are receiving anticoagulation and require high-risk endoscopic procedures.

Aims and Methods: We retrospectively investigated clinical outcomes of patients with atrial fibrillation who had been applied perioperative bridging anticoagulation by intravenous unfractionated heparin for high-risk endoscopic procedures from April 2006 to June 2015. The heparin bridging method was as follows. (1) Warfarin was discontinued 5 days before the procedure and intravenous unfractionated heparin was started with 5000 unit bolus followed by 500 unit per kilogram of body weight per day continuous intravenous injection. (2) Activated partial thromboplastin time (APTT) was evaluated to adjust the dose of heparin to raise APTT 45 to 70 seconds. (3) Heparin was discontinued 4–6 hours before the endoscopic procedure and resumed from the next morning. (4) Warfarin was also resumed along with heparin with a loading dose of 5mg for 3 days followed by a preoperative dose of the patient. (5) Heparin was discontinued when INR reached 1.6 or higher. The primary outcomes were arterial thromboembolic events within 30 days of the endoscopic procedures, and postoperative bleeding events that needed endoscopic hemostasis or blood transfusion.

Results: During the study period, 76 cases received high-risk endoscopic procedures. Among them, 2 cases refused heparin bridging, thus we assessed 74 (19 females) cases with a mean age of 73.8 years old in the study. The endoscopic procedures were colorectal EMR or ESD (29 cases), gastric ESD (23 cases), endoscopic sphincterotomy (15 cases), esophageal ESD (5 cases), and duodenal EMR (2 cases). There was no arterial thromboembolic event within 30 days of the procedures, however, 19 cases (25.7%) experienced postoperative bleeding complications. The bleeding incidence was very high with colorectal EMR/ESD, 15 out of 29 cases (51.7%). It was significantly higher than any of other high-risk procedures. Between the bleeding group and non-bleeding group, there was no significant difference in the maximum size of the colorectal tumor resected, numbers of the tumor resected, type of the procedures (EMR vs ESD), and concomitant use of low dose aspirin. Accordingly, we could not find any risk factors for postoperative bleeding of colorectal EMR/ESD.

Conclusion: Our study indicated that warfarin interruption and perioperative intravenous heparin bridging warranted the very low risk of arterial thromboembolism for patients with atrial fibrillation with high-risk endoscopic procedures. On the other hand, the incidence of postoperative bleeding was high, especially with colorectal EMR/ESD. Perioperative heparin bridging should be applied only for high thrombotic risk patients provided with a sufficient information of postoperative bleeding.

Introduction: High-quality bowel cleansing facilitates effective colonoscopy[1–3]. Split dosing is the preferred treatment regimen. A waiting time of 7 or more hours to the start of colonoscopy after dose 2 may reduce the chances of cleansing success, so treatments with sustained high efficacy would be valuable[4]. Afternoon procedures may also reduce the colonoscopy yield[5]. NER1006 is a novel 1L polyethylene glycol (PEG)-based bowel preparation. It was evaluated in the 2 phase 3, randomized, treatment-blinded assessor trials MORA[6] and NOCT[7]. This post hoc analysis assessed the duration of the cleansing efficacy after the second dose, of NER1006 evening/morning dosing versus 2L PEG + ascorbate (2LPEG) or oral sulfate solution (OSS).

Aims and Methods: Patients aged 18–85 years were randomized to receive a split-dosing regimen of either evening/morning (PM/AM) NER1006, or 2LPEG or OSS. Overnight split dosing started at ~6:00 pm (±2 h) with dose 2 at ~6:00 am (±2 h). The percentage of patients with overall bowel cleansing success (Harefield Cleansing Scale grades A and B) was analysed by duration between the end of the second dose of the bowel prep plus mandatory fluids and the start of colonoscopy (1-h intervals: ≤3, >3-4, >4-5, >5-6, >6-7, or >7 h). Data were analysed in the modified full analysis set 2 (mFAS2) population, which comprised all patients who received at least 1 dose of study drug and who had documented primary colonoscopy data from a central reader. Patients included in the analysis of variance (ANOVA) between time intervals and colon cleansing success also needed calculable time intervals after dose 2.

Results: Data from 1037 patients were included in the analysis (Table 1). In time intervals from up to 3 h to over 7 h after dose 2, successful bowel cleansing was attained in at least 88% (7 out of 8) patients with NER1006 PM/AM dosing regimen. At >7 hours NER1006 PM/AM attained at least 89.3% HCS cleansing success whereas this level of cleansing efficacy was not attained by either 2LPEG or by OSS which both showed reduced success rates after 7 hours (81.3% and 77.4%, respectively). The ANOVA revealed a significant decline in efficacy over time for OSS ($p=0.033$). No such differences were observed for NER1006 PM/AM ($p=0.32$; MORA, $p=0.36$; NOCT) or 2LPEG ($p=0.15$).

Conclusion: Split dosing with NER1006 evening/morning dosing can, in a reproducible fashion, deliver overall cleansing success in 7 out of 8 patients even after 7 or more hours post dose 2. This sustained efficacy may become particularly useful for afternoon or delayed colonoscopies.

Introduction: Colonoscopic screening with indigo carmine chromoendoscopy (ICC) in Lynch Syndrome (LS) patients improves adenoma detection rate and is widely used nowadays. Nevertheless, it is a time- and-money-consuming technique which requires a dedicated training. Narrow band imaging (NBI) is a well-known virtual chromoendoscopy technique that highlights superficial mucosal vessels and improves contrast for adenomas. We conducted a prospective multicenter study in a back-to-back fashion to compare 3rd generation NBI to ICC for detecting colonic adenomas in LS patients.

Aims and Methods: 138 patients underwent a double colonoscopy, first with NBI, followed by ICC, in a back-to-back fashion. All polyps detected in either pass were removed for histopathological analysis. The primary outcome measure was the number of patients with at least 1 adenoma after NBI compared with the number of patients with at least 1 adenoma after NBI and ICC. Proportions were compared with the paired exact test (McNemar's test). Continuous variables were compared with the Wilcoxon signed-rank test.

Results: All of the 138 patients were proven MMR mutation carriers (MLH1 = 33%, MSH2 = 47%, MSH6 = 15%, PMS2 = 4%, EPCAM = 1%). Mean age (SD) was 40.5 (14.7) years, 64 (46.4%) were male. The median time for an NBI procedure was 8 minutes (interquartile range [IQR] 6-11) compared to 13 minutes (IQR 8-17) for ICC. At least 1 adenoma was detected during the initial NBI pass in 36 (26.1%) of 138 patients. ICC detected additional adenomas in 35 (25.4%) of 138 patients. 56 patients (40.6%) had at least 1 adenoma detected after both NBI and ICC; this represents an increase of 55.6% of the adenoma detection rate (ADR) ($p<0.0001$). The total number of adenomas increased from 53 after NBI pass to 101 after ICC pass with a mean number of adenomas detected per patient of 0.4 (0.7) after NBI pass vs 0.7 (1.2) after both NBI and ICC passes ($p<0.0001$). The ADR for flat adenomas was 15.2% after NBI vs 31.9% after ICC ($p<0.0001$). The ADR increased for right sides adenomas (14.5% after NBI vs 23.2% after ICC, $p=0.0005$) as well as for diminutive adenomas ≤5mm (21.7% after NBI vs 37.7% after ICC, $p<0.0001$). Detection of both sessile adenomas (13.0% NBI vs 15.9% ICC, $p=0.125$) and adenomas > 5mm (8.0% NBI vs 10.9% ICC, $p=0.125$) did not differ significantly between the 2 techniques. After adding white light detected adenomas, the total ADR of the study was 43.5%.

Conclusion: Colonoscopy with indigo carmine chromoendoscopy detects significantly more adenomas than 3rd generation NBI in LS patients, whereas sessile and > 5mm adenomas are equally detected. Although less time consuming, NBI colonoscopy cannot be recommended to replace indigo carming chromoendoscopy in LS patients.

Introduction: Computer-aided diagnosis (CAD) for colonoscopy is drawing attention as an attractive tool to identify neoplastic polyps requiring resection from non-neoplastic polyps that can be left *in situ* [1]. However, its role has not been established because of the lack of high-quality clinical trials.
Aims and Methods: We aimed to clarify the efficacy of "real-time" use of CAD with endocytoscopes (520-fold ultra-magnifying endoscopes [2]) with a single arm, open-label, prospective trial. This trial included 821 patients undergoing colonoscopy with use of CAD in a tertiary university hospital between June and December 2017. CAD predicted pathology (neoplastic or non-neoplastic) of the detected diminutive polyps (≤5 mm) based on real-time outputs. CAD performance was evaluated, with the actual pathology of the resected specimen as the gold standard. The CAD system had been trained with 61925 endocytoscopic images acquired from a total of 5 university hospitals and cancer center hospitals in advance. Primary endpoint was the assessment of whether CAD demonstrated a ≥90% negative predictive value (NPV) for identifying diminutive, rectosigmoid adenomas, which is the threshold required to perform the "diagnose-and-leave" strategy for non-neoplastic polyps. Secondary outcome measures included the diagnostic accuracy in the whole colon.
Results: Overall, 466 diminutive polyps (including 250 in the rectosigmoid colon) from 325 patients were assessed by CAD using both the narrow-band imaging (NBI) mode and the methylene blue-stained mode. CAD was able to analyze 98.1% (457/466) of the polyps. Intention-to-treat analysis, in which non-analyzable polyps were treated as misdiagnosed ones, revealed mean NPVs for CAD regarding diminutive, rectosigmoid adenomas of 95.2% (95% confidence interval, 90.3–98.0) with the NBI mode and 93.7% (88.3–97.1) with the stained mode. For the total diminutive polyps, CAD demonstrated accuracy of 91.6% (88.7–94.0) with the NBI mode and 90.3% (87.3–92.9) with the stained mode.
Conclusion: Real-time use of CAD offered the performance that allowed the "diagnose-and-leave" strategy for diminutive, rectosigmoid non-neoplastic polyps. (This trial is registered with UMIN Clinical Trial Registry, No. UMIN000027360)

Introduction: In treatment goal of ulcerative colitis (UC), the incremental benefit of achieving histological healing beyond that of endoscopic mucosal healing has been suggested; persistent histological inflammation increases the risk of exacerbation and dysplasia. However, it is extremely difficult for conventional endoscopy to distinguish histological active/healing.
Aims and Methods: The aims of this study were to develop and evaluate a computer-aided diagnosis (CAD) system to predict the presence of histological activity using endocytoscopy (520-fold ultra-magnifying endoscope).
We retrospectively collected 9095 endocytoscopy images from 107 patients with UC. Among them, 4562 images from 57 patients were used for machine learning. The other 4533 images from 50 patients were used to validate CAD. Endocytoscopy images and biopsy samples of each patient were collected from 6 colorectal segments: cecum, ascending colon, transverse colon, descending colon, sigmoid colon, and rectum. All endocytoscopy images were tagged according to the Geboes index. The outcome measure was the diagnostic ability of CAD to differentiate histological active/healing based on patients. The secondary outcome measures were the diagnostic ability of CAD based on all segments of all patients.
Results: CAD provided diagnosis outputs for 100% (4533/4533) of the validation images with a diagnosis time of 0.2 s/image. The diagnostic sensitivity, specificity, and accuracy of CAD were as follows; 83% (95% confidence interval, 64%–94%), 95% (76%–100%), and 88% (76%–96%) in the patient-based analysis, 77% (64%–87%), 97% (94%–99%), and 93% (89%–96%) in the segment-based analysis.
Conclusion: Our CAD system allows fully automated identification of persist histological inflammation associated with UC.
Disclosure: Nothing to disclose

P0176 WHAT IS THE COST OF ENDOSCOPIC SUBMUCOSAL DISSECTION IN FRANCE? A PROSPECTIVE MEDICO-ECONOMIC STUDY

Introduction: There is no economic assessment existing in Europe today about submucosal dissection.
As yet, the CCAM (Health Insurance System) has not delivered a listing of price quotation concerning this new medical procedure. It is an expensive technique in terms of time and material. The primary aim of this study is to assess the costs and benefits of endoscopic submucosal dissection. The secondary aims of the study are to assess the part of sterile medical devices (SMD) in the overall cost of the procedure, to determine predictive factors for a positive cost/benefit balance and to do a medico-economic comparative with surgery for superficial colonic neoplasms.
Aims and Methods: A monocentric prospective study including all hospitalized ESD patients was conducted from January 2015 to December 2017. The global cost of hospital stays was measured by summing up the actual cost of SMD used for ESD using a bottom-up approach (micro-costing) and the hospitalization day cost was extrapolated from the results of the National Cost Study for these patients. The revenue is based on DRGs (Diagnosis Related Goups).
The difference between the overall cost and the revenue provide the medico-economic study with core information. We have selected in the same center patients who had surgery from 2009 to 2017 for superficial colonic tumors with anatomopathology data. Univariate comparisons employ the Fisher exact test for qualitative variables and the Wilcoxon rank test for quantitative variables. All the statistical tests carried out provided significant values for $p < 0.05$.
Results: We had 193 patients having ESD in 2015-2016-2017. 80% of the lesions were colorectal lesions and 20% oesogastric. The average age was 68.8 years. The average duration of the procedure was 133 minutes. The rate of monobloc resections was 93%, with 78% R0 and 71.4% curative. 20 perforations (10.4%) were to be deplored. The rate of hemorrhages was 6.7%. The hospitalization day cost €463.18 with an average length of 3.6 days. The medical devices cost €970.77 the procedure cost € 1,604.96 which gave a global cost of €3,464 subtracted from a €2,727 gain. Consequently, we had a negative budgetary balance of €- 737 per patient with a global extracharge of €142,232 for the 193 patients. The medical devices represented 60.4% of the procedure cost. We identified only 1 predictive factor for a positive budgetary balance which was a severity level of DRG higher than 1 (OR 49.21; IC95% 11.3–214.25; $p < 0.0001$). We compared colonic surgery and ESD for superficial lesions in the same center/hospital. 69 patients were in surgery and 71 in ESD. There is no significant difference between the 2 groups in terms of age, localization, anatomopathology or ASA score. The size of lesions was twice higher in ESD than in surgery (50 mm vs. 25 mm; $p < 0.0001$). The average length of hospitalization was superior in surgery (11 days vs. 2 days in ESD; $p < 0.0001$). Morbidity at 30 days was not significantly superior in surgery (28 vs. 14% in ESD; 0.061). At country level, the cost of surgery was 5 times higher if we consider revenue related to the stay (€8,960 vs. €1,770; $p < 0.0001$). But at the hospital scale, the budgetary balance was positive for surgery patients €+542 whereas it was negative €-1,300 in the dissection group.
Conclusion: As of today, the ESD benefit/deficit balance is negative in 80% of cases.
This overcharge is due to a lack of act ranking. Specific dissection equipment accounts for the largest share of expenditures. It is clearly less morbid and expensive than classic surgery
Disclosure: Nothing to disclose

Introduction: Endocytoscopy (EC) enables *in vivo* observation of nuclei at about 500-fold magnification during gastrointestinal endoscopy. We have developed a system using artificial intelligence that provide a predictive pathological diagnosis for colorectal lesion in real time based on EC image during examination [1]. Our computer aided diagnosis (CAD) system for EC (EC-CAD) analyzes 312 image features of EC obtained as a result of texture analysis. We used a support vector machine to help classify these many features and output 4 predictive

pathological diagnoses (non-neoplastic, adenoma, SSA/P, invasive cancer). The high diagnostic ability of EC-CAD to distinguish between adenoma and invasive cancer has already revealed in previous report [2]. As a next step, we conducted a prospective study to evaluate the real-time use of the current system.
Aims and Methods: The primary endpoint of this study was to verify the positive predictive value (PPV) in distinguishing invasive cancer from other lesions was 90% or higher when EC-CAD was applied for examination. This prospective study was conducted at Showa University Northern Yokohama Hospital from June 2017 to December 2017. In this study, we used the software constructed based on EC images obtained by staining cell nuclei with 1.0% methylene blue. At the start of the study, we used software that let the system learn 16800 images. During the study period, we made an update 3 times (the number of learning images for the system: 1st 18966 images, 2nd 32265 images, 3rd 36586). The subjects were colorectal lesions of 20mm or more in diameter which histological evaluation was performed after EC observation. Regarding the diagnostic results given by the EC-CAD, since a plurality of endoscopic images were acquired from one lesion, the majority decision method adopting the most frequent diagnosis results was used as a final diagnosis of the system. As a sub analysis, the endoscopists were divided into experts and trainee based on the difference in experience, and it was examined whether procedure time and diagnostic accuracy using EC-CAD were affected by the expertise.
Results: A total of 106 colorectal lesions (4 non-neoplasms, 34 adenomas, 68 invasive cancers (10 T1 cancers, 58 T2-T4 cancers)) from 99 patients were included. 77% (6434/8313) of the acquired EC images were able to be diagnosed by EC-CAD. Regarding the diagnostic performance of EC-CAD to distinguish invasive cancers from other lesions, sensitivity, specificity, accuracy, PPV and negative predictive value (NPV) were 93%, 97%, 94%, 98% and 88%, respectively. Considering experts and trainees separately, the sensitivity, specificity, accuracy, PPV, NPV were 93% vs. 93%, 97% vs. 100%, 94% vs. 94%, 98% vs. 100% and 89% vs. 67%, respectively. The time taken for EC image acquisition was 5.6 seconds on average. There was no significant difference in image acquisition time between experts (5.5 sec) and trainees (6.3 sec).
Conclusion: This study suggested that EC-CAD will provide a reliable diagnosis with PPV 90% or higher in distinguishing invasive cancer from other lesions, regardless of the experience of endoscopists.

Introduction: Colonoscopy has emerged as the main diagnostic and therapeutic tool in the detection of colonic adenomas. Training future endoscopists is essential to meet future demands.
Aims and Methods: Studies have shown somewhat conflicting results regarding the influence of trainee-participation on adenoma detection rates (ADR), mostly showing positive or indifferent effects of trainee participation. A previous prospective study by our group showed no adverse effect of trainee participation on ADR. However, this study did not include first-year trainees or subsequent surveillance exams. The aim of the current investigation was to see, whether the inclusion of first year trainees magnifies the noted difference and whether trainee participation affects ADRs or the timing of subsequent surveillance exams.
A retrospective analysis of average-risk screening colonoscopies over a 3-year interval was performed. Patients with poor preparation were excluded. The final analysis included 4922 screening colonoscopies between the years 2004–2006, as well as 2184 subsequent surveillance exams. Data were collected from pathologic and endoscopic electronic data bases. The primary outcome was the ADR at colonoscopies with and without trainee participation.
Results: Trainees participated in 1131 (23%) screening exams and in 232 (11%) surveillance exams. ADR did not significantly differ ($p = 0.19$) for screening exams with trainee participation (19.5%) or those without (21.4%). ADRs were generally higher at surveillance exams, both with (22.4%) and without (27.5%) trainee participation. The noted difference of ADRs at surveillance colonoscopies with or without trainee participation did not reach statistical significance ($p = 0.1$). Multivariate analysis showed no influence of first year fellow participation on the outcome. When surveillance recommendations differed from guidelines, shorter surveillance intervals were given more frequently if trainees participated during the initial screening procedure ($p = 0.0001$).
Limitations: Single-center, retrospective study.
Conclusions: ADR did not significantly differ at screening or surveillance colonoscopies with or without trainee participation. There was a trend towards higher ADR at surveillance exams in both groups. The inclusion of first year trainees had no adverse effect on the outcome. However, trainee participation may result in shortened surveillance recommendations after initial screening exams.

Introduction: The development of a real-time robust detection system for colorectal neoplasms will significantly reduce the risk of missed lesions during colonoscopy. However, gaps in colonoscopy skills among endoscopists, primarily due to experience, have been identified, and solutions are critically needed.
Aims and Methods: To overcome this experience gap, we aimed to develop an artificial intelligence (AI) system that automatically detects early signs of colorectal cancer during colonoscopy.
Patients with and without colonic polyps and those with colorectal cancer were included. A training data set of colonoscopic still and video images consisting of 5,000 images of 2,116 early-staged colorectal cancers or precursor lesions and 134,983 images of noncancerous tissue were provided. Using this training set, Deep Learning algorithms were provided to learn the colonoscopic features of the disease. The diagnostic accuracies and area under the receiver-operating characteristic curve of this algorithm as well as the processing speed of this AI system were measured by using validation set of 4,840 images (705 images with 752 lesions and 4135 images without lesions) from consecutive patients with and without early-staged colorectal cancers or precursor lesions.
Results: The sensitivity and specificity of the system were 97.3% (95% confidence interval [CI] = 95.9%–98.3%) and 99.0% (95% CI = 98.6%–99.2%), respectively, and the area under the curve was 0.975 (95% CI = 0.964–0.986) in the validation set. The sensitivities were 98.0% (95% CI = 96.6%–98.8%) in the polypoid subgroup and 93.7% (95% CI = 87.6%–96.9%) in the nonpolypoid subgroup. A supplementary human observational study demonstrated that the AI system had a superior diagnostic yield as endoscopists, including experienced, fellows, and beginners (Figure 1). The system analyzed all 4,840 images in 106.0 s (average, 21.9 ms/image), whereas endoscopists required median 725.2 s (IQR = 655–914) to analyzed the 309 images. In addition, this system achieved in real-time detecting and displaying results of each video frame within 33 milliseconds (30 frames per second).
Conclusion: We have developed a real-time endoscopic image diagnosis support system using deep learning technology that automatically detects early signs of colorectal cancer during colonoscopy. This AI system can alert endoscopists in real time to avoid missing abnormalities such as polyps during colonoscopy, improving the early detection of this disease.
[Table 1. Diagnostic performance of AI system for detecting and displaying early stage colorectal early-staged cancers and precursor lesions]
Disclosure: Nothing to disclose

Abstract No: P0179

	Sensitivity* (n) (95% CIs)	Specificity** (n) (95% CIs)	
		Without lesions	With lesions
All lesions (752 lesions)	97.3% (732/752) (95.9–98.3)	99.0% (4092/4135) (98.6–99.2)	90.2% (636/705) (87.8–92.2)
Polypoid lesions (641 lesions)	98.0% (628/641) (96.6–98.8)	99.0% (4092/4135) (98.6–99.2)	89.1% (529/594) (86.3–91.3)
Flat and depressed lesions (111 lesions)	93.7% (104/111) (87.6–96.9)	99.0% (4092/4135) (98.6–99.2)	96.4% (107/111) (91.1–98.6)

*Sensitivity was defined as AI correctly detected lesion number/number of all lesions; **Specificity was defined as AI negative image number/ true lesion negative image number (images without lesions); Correct answer was defined when AI detect and display loci of lesion by flag.

P0180 GRADING OF DYSPLASIA FOR DIAGNOSING COLORECTAL ADENOMAS USING ENDOCYTOSCOPY (EC)

Introduction: Recent opinions have expressed that if an endoscopic diagnosis of adenomas can be made with high accuracy, then the omission of a pathological diagnosis following endoscopic resection is acceptable. Currently, there is no clear consensus regarding whether endoscopic treatment is required for all adenomas. Colonoscopy-based grading of dysplasia can be clinically effective for diagnosing adenomas, if such a diagnosis of adenomas, particularly of low-grade adenomas, can be made with high accuracy.
Aims and Methods: In this study, we focused on the existence of mixed-pit pattern type I lesions in slit-like lumens, which is an endocytoscopy (EC) finding characteristic of adenomas, and investigated pathological findings that were correlated with this observation. We retrospectively examined 700 lesions among the neoplastic lesions that could be observed by EC between May 2005 and May 2017 and that were classified as EC2 according to the EC classification system and could be pathologically examined via endoscopic resection. Lesions characterized by mixed-pit pattern type I in slit-like lumens were classified as EC2 normal pit (NP) sign (+), while those characterized by slit-like lumens only were classified as EC2 NP sign (−). We investigated the final pathological diagnosis results. In addition, we investigated the concordance rate of surveillance interval recommendation in EC diagnosis and pathological diagnosis based on USA guideline, and also examined the location, diameter, and morphological type of NP (+) lesions to elucidate their clinical traits. In order to evaluate the concordance rate of EC 2 NP sign, 3 experts (T.K., Y.M. and M.M) and 3 trainees (T.W.,T.K and K.M) reviewed digitally recorded EC images of the lesions.
Results: A total of 466 lesions were classified as EC2 NP sign (+). Of these, low-grade adenomas accounted for 450 lesions and advanced lesions (high-grade dysplasia, tubulovillous adenoma, invasive cancer) accounted for 16. NP sign (+) as an indicator of low-grade adenomas had a sensitivity of 85.4%, specificity of 90.8%, positive predictive value of 96.6%, negative predictive value of 67.1%, accuracy of 86.7%, and positive likelihood ratio of 9.23. It was 95.5% that the concordance rate of surveillance interval recommendation based on USA Guideline compared with EC and pathological diagnosis. Furthermore, an examination of the EC2 NP (+) rate by location, diameter, and morphological type of the lesions revealed that 75.7% were located in the proximal colon ($p < 0.001$), 81.4% of the lesions were ≤10 mm in diameter ($p < 0.001$). Further, 79.8% were of the flat/depressed type ($p < 0.001$). The interobserver agreement for the EC2 diagnosis using EC2 NP sign among the 3 experts were 0.82, 0.90, and 0.94 and among the 3 trainees were 0.84 (T.K., Y.M.), 0.78 (T.K.-M.M.), and 0.82 (Y.M.-M.M.), respectively. The intraobserver agreement of the 3 experts were 0.84 (T.W.-T.K.), 0.86 (T.W.-K.M.) and 0.98 (T.K.-K.M.), and the 3 trainees were 0.80, 0.80 and 0.86, respectively.
Conclusion: These results suggest that when using EC for diagnosing colorectal neoplastic lesions, NP sign is a good indicator of low-grade adenomas with the EC2 classification. It was suggested that EC diagnosis could make the Resect and Discard strategy practicable regardless of polyp size. Furthermore, the NP (+) rate tended to be high in lesions located in the proximal colon, that were ≤10 mm in diameter, and that were of the flat/depressed type.

P0181 DEVELOPMENT OF A MODIFIED SMSA SCORING SYSTEM WITH IMPROVED ACCURACY IN THE PREDICTION OF COMPLICATIONS OF ENDOSCOPIC MUCOSAL RESECTION IN THE COLON

J.P. Rodrigues, R. Pinho, M. Sousa, J.C. Silva, C. Gomes, T. Freitas, J. Carvalho
Centro Hospitalar Vila Nova De Gaia/Espinho, Gastroenterology, Porto, Portugal

Contact E-Mail Address: jaimepereirarodrigues@gmail.com
Introduction: The SMSA (*size, morphology, site, access*) scoring system allows stratification of the complexity of endoscopic mucosal resections (EMR). However, the influence of other lesion characteristics in EMR outcomes is widely recognized.
Aims and Methods: The aim of this study was to develop a modified SMSA scoring system with complementary lesion characteristics and determine its accuracy in the prediction of complications of EMR. Consecutive colorectal, non-pedunculated lesions, ≥20mm, referred to EMR between January 2015 and December 2016 were included. Lesions with previous resection attempts were excluded. The relation between SMSA and total complication rate (intra-procedure and post-EMR bleeding, intestinal perforation and post-polypectomy syndrome) was evaluated. Additional predictive characteristics of complications were determined and their incorporation into the SMSA evaluated.
Results: A total of 225 lesions were selected, mean size 29.5 ± 13.0 mm, most of type 0-IIa (37.3%) or 0-Is (28.0%) of the Paris Classification, with granular surface (72.9%). Technical success of EMR was 94.2% (n = 212), with *piecemeal* (68.9%) or *en bloc* (31.1%) resection, and was related to the SMSA ($p < 0.001$). Total complication rate was 22.6%: intra-procedure bleeding = 15.1%; post-EMR bleeding = 6.1%; intestinal perforation = 0.9%; post-polypectomy syndrome = 0.9%. The area under the ROC curve of the SMSA for prediction of complications was 0.70 (95%CI 0.61–0.79, $p < 0.001$). On multivariate analysis, lesion component 0-IIb or 0-IIc (OR = 2.4, 95%CI 1.1–6.5, $p = 0.041$) and non-granular/mixed surface type (OR = 2.6, 95%CI 1.2–5.9, $p = 0.020$) were associated with complications independently of the SMSA. The incorporation of the 2 characteristics into the SMSA (component 0-IIb/IIc = 2 points, non-granular/mixed surface = 3 points) had a significantly increased association with the total complication rate (area under the ROC curve = 0.79), by a difference of 0.087; $p = 0.032$ (*DeLong et al. method*).
Conclusion: The incorporation of the Paris Classification (component 0-IIb or IIc) and lesion surface type (granular or non-granular) into the SMSA scoring system increased its accuracy in the prediction of complications of EMR.

Contact E-Mail Address: ivanakaj@seznam.cz
Introduction: ADR (adenoma detection rate) is generally accepted quality indicator. For possible gaming with ADR other indicators are needed. MAP (mean adenoma per colonoscopy) reflects the quality of examination of entire colon and is considered to be the most objective quality indicator.
Aims and Methods: The aim of our study was to compare MAP with ADR and PDR (polyp detection rate) of all colonoscopists in our department. We retrospectively assessed the quality indicators of all colonoscopies performed in non-university hospital Frydek-Mistek from January 2013 to December 2017. We counted ADR, PDR and MAP for all colonoscopies in patients over 50 years of age excluding therapeutic, IBD, management of complications and sigmoideoscopies (screening, surveillance, diagnostic) and separately only for screening colonoscopies. Correlations between MAP/ADR and MAP/PDR were performed using Pearson's correlation coeficient, $p < 0.05$ was considered significant.
Results: The group for statistics comprised 6925 patients (3620 men, 3305 women, mean age 66.2 years). There were positive correlations between ADR and PDR both for all and for screening colonoscopies ($p = 0.044$, $p = 0.025$) wchich was also proven in previous studies. There were positive correlations between MAP and ADR for all and screening colonoscopies ($p = 0.009$, $p < 0.005$) but not for MAP and PDR ($p = 0.176$, $p = 0.055$), see the table.

Endoscopist	PDR screening	ADR screening	MAP screening	PDR all	ADR all	MAP all
1	64.7	41.3	0.727	60.7	39.1	0.641
2	82.9	49.3	0.876	79.2	47.0	0.833
3	55.3	40.0	0.770	55.2	37.7	0.610
4	65.6	49.3	0.916	58.2	41.7	0.719
5	66.9	48.3	1.029	61.3	45.0	0.827
6	83.7	57.0	1.209	77.1	48.6	0.906

Conclusion: In our study there were significant positive correlations between MAP and ADR but not between MAP and PDR for both all and screening colonoscopies. Considering MAP to be the most objective quality indicator, the quality of colonoscopy is better reflected by ADR than PDR.
[ADR, PDR and MAP of all and screening colonoscopies]

P0183 CORRELATION BETWEEN ADR OF SCREENING AND ALL COLONOSCOPIES - IS IT POSSIBLE TO CALCULATE ADR FOR ALL COLONOSCOPIES IN PRACTICE?

I. Mikoviny Kajzrlikova[1], P. Vitek[2], J. Chalupa[1], J. Kuchar[1], J. Platos[1], P Reha[1], P. Klvana jr[1]
[1]*Hospital Frydek-Mistek, Beskydy Gastrocentre, Internal Department, Frydek-Mistek, Czech Republic*
[2]*Hospital Frydek-Mistek, Univerzity of Ostrava, Beskydy Gastrocentre, Internal Department, Frydek-Mistek, Czech Republic*

Contact E-Mail Address: ivanakaj@seznam.cz
Introduction: ADR (adenoma detection rate) is generally accepted quality indicator and is calculated from screening colonoscopies in patients over 50 years of age. For possible gaming with ADR for screening colonoscopies, monitorig of ADR for all colonoscopies is discussed nowadays.
Aims and Methods: The aim of our study was to compare ADR for colonoscopies from various indications and to find correlation between ADR of screening and all examinations. We retrospectively assessed the quality indicators of all

colonoscopies performed in non-university hospital Frydek-Mistek from January 2013 to December 2017. We counted ADR for all colonoscopies in patients over 50 years of age excluding therapeutic, IBD, management of complications and sigmoideoscopies (screening, surveillance, diagnostic) and separately only for screening colonoscopies. Correlation analysis was performed using Pearson's correlation coeficient, multiple chi square test was used to compare patients' age and one way ANOVA was used to compare proportion of men and women among endoscopists, $p<0.05$ was considered significant.
Results: In study period, 10472 colonoscopies and sigmoideoscopies were done in total. The group for statistics comprised 6925 patients over 50 years of age (3620 men, 3305 women, mean age 66.2 years). Among six endoscopists, there were differenciens in proportion of men and women ($p=0.048$) and age of patients ($p=0.002$). This should be taken into consideration when comparing various endoscopists but it does not affect the correlation analysis of ADR from all and screening colonoscopies. ADR for screenig and surveillance were higher than for diagnostic colonoscopies in all endoscopists, ADR for all colonoscopies were lower than for screening but sufficiently over 25 %, see the table. There was positive correlation between ADR of screening and all colonoscopies ($r=0.906$, $p<0.005$).

Endoscopist	N all	ADR all	N screening	ADR screening	N surveillance	ADR surveillance	N diagnostic	ADR diagnostic
1	1467	39.1	567	41.3	380	45.3	520	32.1
2	419	47.0	146	49.3	186	52.7	87	31.0
3	815	37.7	170	40.0	226	48.7	419	30.3
4	1394	41.7	430	49.3	379	44.6	585	39.4
5	2406	45.0	700	48.3	589	52.8	1117	38.9
6	424	48.6	86	57.0	115	47.0	223	46.2

Conclusion: Calculation of ADR for all colonoscopies was possible in our department and there was positive correlation with ADR for screening colonoscopies. Because of inclusion of diagnostic examinations, ADR for all colonoscopies was lower than for screening but still over recommended values.
[ADR for screening surveillance, diagnostic colonoscopies and all together]

P0185 RATIO OF RIGHT-SIDED TO LEFT-SIDED DYSPLASTIC COLONIC POLYPS IS A VALID KEY PERFORMANCE INDICATOR

M. Madalinski[1]
[1]*The Pennine Acute Hospitals-NHS Foundation Trust, Manchester, United Kingdom*

Contact E-Mail Address: m.h.madalinski@pro.onet.pl
Introduction: Quality improvement in performance of colonoscopy, with special attention to the detection of proximally located precursors, have the potential to prevent postcolonoscopy colorectal cancer [1].
Aims and Methods: A prospective analysis of consecutive diagnostic or surveillance colonoscopies for various indications performed from 2013 - 2017 by an endoscopist with high lesion detection rate. The primary outcome was a detection of dysplastic polyp (DP); secondary outcome - a detection of non-dysplastic polyps (nDP) but with inflammatory and postinflammatory polyps exclusion. Findings from colonoscopies were evaluated with regard to number, size, distribution, prevalence, and incidence of polyps with and without dysplasia. Differences in numbers of the polyps were calculated using between subject and within subject ANOVA and Pearson's $\chi 2$-test. For the multivariate analysis, a logistic regression test was used. All statistical analyses were performed using SPS STATISTICS 24 and a p-value of less than 0.05 was considered statistically significant.
Results: A total of 3811 colonoscopies were analysed. Adenomas detection rate was 26.03% (regardless of the patients' age and an indication for colonoscopy). The crude caecal intubation rate was 93.55%. After exclusion of patients with hemicolectomy, 1480 patients were included in the study; their mean age: 64.43 ± 12.92 years. In those 1480, 65.54% ($n=970$) of patients with average age at 66.89 ± 11.69, had at least one polyp with dysplasia; 623 individuals had only DP and 347 had DP and nDP. The remaining 34.46% ($n=510$) of patients had only nDP.
There were 499 patients with DP located only in the right colon (RC) (caecum, ascending and transverse colon), 273 patients only in the left colon (LC) (descending, sigmoid and rectum) and 198 patients in both sides of the colon.
Although, there was no difference in the proportion between patients with DP $\geq$ 1 cm in the right and the LC (2.4% vs. 2.2%, $p=0.48$), respectively, but significant differences were noted ($p<0.001$) when patients with smaller than 1 cm DP were compared ($\chi 2=117.52$; 18.3% vs. 10.3%) or regardless their size in both colonic parts (10.3% vs. 6.2%) - in group of patients in age $\geq$ 50 ($\chi 2=112.59$ $p<0.001$) or in all patients regardless their age ($\chi 2=94.39$ $p<0.001$).
In total, 3892 polyps were removed: 1549 from the RC and 2343 from the LC (39.80% vs. 60.20%). 1254 DP were located in the RC and 678 DP in the LC (64.9% vs. 35.1%); 295 nDP and 1665 nDP were found respectively in the RC and the LC (15.05% vs. 84.95%). The proportion of DP amount was significantly greater on the right colon when compared with the left colon ($M=0{,}85$; $SD=1.33$ vs. $M=0.46$; $SD=0.91$) ($F=25.86$ $p<0.001$). The same rule was even noticeable when DP in more proximal colon (caecum, ascending colon) were compared with more distal colon (sigmoid, rectum) ($F=9.67$ $p<0.01$). This correlation disappears when we compare polyps in the right and the left colon without differentiation between polyps; then ratio of polyps (nDP and DP) in the right colon to polyps in the left colon becomes < 1 ($F=39.82$ $p<0.001$).
Conclusion: Right-sided colon polyps more likely to have dysplasia compared with left-sided polyps. Therefore, missing a polyp in the right colon is likely more significant than missing one in the left colon and guidelines should focus attention on the proximal colon and provide feedback to endoscopists regarding their proximal adenoma detection rates.
Ratio of dysplastic polyps located in the right colon to dysplastic polyps in the left colon is a valid key performance indicator.
Disclosure: Nothing to disclose

P0186 LAPAROSCOPY ENDOSCOPY COOPERATIVE SURGERY (LECS) TO OVERCOME THE LIMITATIONS OF ENDOSCOPIC RESECTION FOR COLORECTAL TUMORS

Y. Tamegai[1], Y. Fukunaga[2], A. Chino[1], S. Saito[1], N. Hiki[2], T. Muto[2]
[1]*Cancer Institute Hospital, Dept. of Endoscopy, Tokyo, Japan*
[2]*Cancer Institute Hospital, Gastroenterological Surgery, Tokyo, Japan*

Contact E-Mail Address: yoshiro.tamegai@jfcr.or.jp
Introduction: We established a new procedure, laparoscopy endoscopy cooperative surgery (LECS) procedure to overcome the limitations of endoscopic resection (ER) for colorectal tumors. This procedure involves local full-thickness resection using a combination of laparoscopy assisted colectomy (LAC) and endoscopic submucosal dissection (ESD), which is quite different from the conventional method. In this report, we clarify the feasibility of performing a safe full-thickness resection with an adequate surgical margin by LECS with ESD.
Aims and Methods: The aim of this study is to clarify the feasibility of performing a safe full-thickness resection with an adequate surgical margin by LECS with ESD. We performed full-thickness resection for 17 colorectal tumors in 17 patients (male: female 10:7; mean age, 66.5 years) by LECS. The clinicopathological outcomes of these 17 cases and the feasibility of full-thickness resection were evaluated retrospectively.
The indications for LECS in patients with colorectal tumors were as follows: 1) intra-mucosal carcinoma (Tis) and adenoma with high-grade atypia (Vienna Classification, Category 3, 4) accompanied by wide and severe fibrosis in the submucosal layer (tumor recurrence after endoscopic or surgical resection), 2) intra-mucosal carcinoma (Tis) and adenoma with high-grade atypia involving the diverticulum or appendix, and 3) involving intraluminal or intramural growth-type submucosal tumors.
Results: We successfully performed full-thickness resection using LECS in 17 cases (Tis cancer [n = 6], adenoma [n = 9], schwannoma [n = 1], and gastro-intestinal stromal tumor [GIST] [n = 1]. The average tumor diameter was 22.4mm (range, 8–41mm). LECS was successfully performed in 17 all cases without conversion to open surgery; the R0 rate was 100%. The indications for LECS were as follows: involvement of the mucosa of the appendix (n = 6), tumor accompanied by severe fibrosis (n = 5), involvement of a diverticulum (n = 3), submucosal tumor (n = 2), and poor endoscopic operability (n = 1). We experienced no complications (*e.g.*, leakage or anastomotic stricture), and the median hospital stay was 6.4 (range, 4 to 12) days. All 17 patients who were followed for $\geq$3 months (average, 30.8 months; range, 3–72 months) showed no residual or local recurrence. Thus, the use of the ESD technique in LECS, can achieve a safe oncological margin in cases involving colorectal tumors. Furthermore, a high complete resection rate, with an adequate surgical margin and a lower local recurrence rate can be expected.
Conclusion: We developed a LECS procedure to overcome the limitations of colorectal ESD, and completed the full-thickness resection of tumors that were considered to have a high risk of perforation. LECS was a safe, feasible, minimally-invasive procedure that achieved the full-thickness resection of colorectal tumors and which showed excellent clinical outcomes.

Introduction: Colorectal cancer (CRC) is one of the most common causes of cancer-related death worldwide, colorectal endoscopic submucosal dissection (ESD) has spread rapidly as an effective treatment strategy for early-stage CRC. However, there is major concern about bleeding as a complication of this procedure. While some reports have been published on the management of delayed bleeding after colorectal ESD, there is no consensus on the optimal treatment protocol for which situations we should perform emergency colonoscopy for delayed bleeding after ESD. The criteria of judgement for emergency

colonoscopy remains unclear. In this study, we attempted to extract the risk factors for delayed bleeding after colorectal ESD and to evaluate whether emergency colonoscopy is really needed. The aim of this study is to investigate the feasibility and safety of this "watch and wait strategy" of delayed bleeding.
Aims and Methods: The data of 454 consecutive patients who underwent ESD at Omori Red Cross Hospital between April 2012 and February 2018 were reviewed in this study. The watch and wait strategy is a protocol of delayed bleeding after colorectal ESD: We assess these following conditions after delayed bleeding; shock index≥1, and/or moderate amount of hematochezia more than 5 times. If these conditions are not satisfied, we carefully observed the clinical courses without emergency colonoscopy. All subjects were divided into 2 groups (bleeding group and no-bleeding group) to investigate the potential risk factors for delayed bleeding and assessed the necessitation of emergency colonoscopy based on watch and wait strategy. We investigated the age, sex, comorbidities, antithrombotic agents, location, macroscopic appearance, lesion size, sample size, fibrosis, hemostatic forceps use, prophylactic clip closure, peak blood pressure, nicardipine use, en-bloc resection rate, pathology, and operation time.
Results: We excluded 15 neoplasms from the analysis, with the final analysis performed on the remaining 439 lesions. All subjects were divided into 2 groups: bleeding group (27 neoplasms), and no-bleeding group (377 neoplasms). In bleeding group, there are no cases which require emergency colonoscopy for hemostasis after delayed bleeding under this "watch and wait strategy". The location of rectum, and lesion size ≥40mm were identified by multivariate analysis as being significantly and independently associated with bleeding after ESD (OR: 5.547, and 3.967, 95% CI = 1.456 - 21.130, and 1.003 - 15.696, respectively; $p \leq 0.05$ for all).
Conclusion: Our results suggest that the location of rectum, and lesion size ≥40mm are an independent factors of delayed bleeding after colorectal ESD, but there were no cases which require emergency colonoscopy, blood transfusion, or serious condition caused by delayed bleeding under our "watch and wait strategy".

Introduction: Colonoscopy and endoscopic eradication of neoplastic lesions are effective for the reduction of colorectal cancer incidence. However, 26% of colorectal diminutive neoplasms were reported to be missed in one colonoscopy (1). To reduce the number of missed cases, we developed a prototype computer-aided detection (CADe) system for colonoscopy (2).
Aims and Methods: The aim of this study was to evaluate the performance of the developed CADe system for colorectal polyps by using recorded video data. To develop the CADe system, we collected 84 full high-definition colonoscopy videos from study participants who underwent total colonoscopy from April 2015 to October 2015 at Showa University Northern Yokohama Hospital. Each colonoscopy video recorded from cecal intubation to withdrawal of the scope across the anus. Therefore, these videos included polyp-positive and polyp-negative frames. Regarding the machine learning process, 2 expert endoscopists annotated all the frames regarding the presence or absence of a polyp. These videos included 166 polyps. The video data of 105 polyps were randomly selected, and 80-min polyp-negative videos were used for machine learning. If the system detects a polyp in the frame, it outputs an alert. To evaluate the performance of the system, we extracted 61 polyp-positive videos and 20-min polyp-negative videos from the study materials as validation sample. The percentage of correctly detected polyps and false-positive detection rate for the negative frames were calculated using the validation sample. Correct detection by the system was defined as a system output of an alert for more than half the length of each polyp-positive video.
Results: The system correctly detected 92% (56/61) of the polyps. Regarding morphological assessment, 92% (36/39) of flat lesions and 91% (20/22) of protruded lesions were correctly detected. With regard to the negative videos, the false-positive detection rate was 59% (19,680/33,088 frames).
Conclusion: The results showed that artificial intelligence has the potential of automated detection of colorectal lesions. Further machine learning is required to reduce false-positive detections. We have already begun to use the system in real-time practice to collect more learning materials.
Disclosure: Nothing to disclose

Introduction: Total colonoscopy is commonly used for screening examinations in many countries. However, specialized skill training is required until one can handle a colonoscope freely and diagnose an abnormal region accurately. One of the reasons that it takes a long period to acquire such skills is the difficulty in recognizing anatomical locations during colonoscopy. Recently, various computer-aided diagnosis (CAD) systems with deep convolutional neural networks (CNN) have achieved remarkable performance in many medical fields including the diagnosis of colorectal diseases. A CNN system that can recognize anatomical locations during colonoscopy may assist undertrained practitioners efficiently.
Aims and Methods: We constructed a CAD system with CNN based on GoogLeNet architecture to categorize colonoscopic images according to anatomical locations. 7 anatomical categories were used; terminal ileum, cecum, ascending colon to transverse colon, descending colon to sigmoid colon, rectum, anus and indistinguishable image. We retrospectively obtained images that were taken during total colonoscopy performed from January, 2017, to November, 2017, at single center in Japan. We used 9995 images of 409 cases for training the CNN system, and independent 5121 images of 118 cases for validating its performance. For each validation process of an image, the CNN system provided a probability score ranging from 0 to 100%, which indicates the probability for which category an image would belong to. We drew receiver operating characteristic (ROC) curve and calculated the area under the curves (AUCs) by each category.
Results: In the validation process, the CNN system correctly recognized 66.6% of images (3410/5121). The rates of correct recognition by each anatomical category were 69% (145/209) for terminal ileum, 50% (211/423) for cecum, 51% (891/1742) for ascending to transverse colon, 90%(1872/2081) for descending to sigmoid colon, 23% (109/467) for rectum, and 91%(182/199) for anus, respectively. The specificity for each category were 99.3% for terminal ileum, 98.2% for cecum, 93.8% for ascending to transverse colon, 60.9% for descending to sigmoid colon, 98.1% for rectum, and 97.8% for anus. The calculated AUCs by the ROC curves were more than 0.8 for each anatomical category; 0.979 for terminal ileum, 0.940 for cecum, 0.875 for ascending to transverse colon, 0.846 for descending to sigmoid colon, 0.835 for rectum, and 0.992 for anus. The CNN system provided 507 images with a probability score of more than 99% that showed 91.7% accuracy in total.
Conclusion: We constructed the new CNN system with clinically relevant performance for recognizing anatomical locations of colonoscopic images, which may reduce the burden and time of acquiring the colonoscopic technique for beginners.

Introduction: Endoscopic submucosal dissection (ESD) has enabled en-bloc resection of an early-stage gastrointestinal tumor, which has many advantages of histological assessment, irrespective of the lesion's size. Although the use of ESD for colorectal tumors has been studied, a definite indication for ESD among them is controversial.
Aims and Methods: The present study aimed to assess the validity of colorectal ESD. We analyzed clinicopathological findings for 376 early-stage colorectal sessile polypoid and superficial tumors greater than 20mm resected endoscopically or surgically (296 low/high-grade intraepithelial neoplasias and 80 submucosal invasive carcinomas) after observation by magnification chromoendoscopy. They were classified into 3 subtypes according to their morphology: 25 cases of sessile polypoid-type, 329 cases of laterally spreading tumor (LST) and 22 cases of the depressed-type. Moreover, LSTs are divided into 193 cases of granular types (LST-G) with aggregates of even or uneven nodules on the surface and 136 cases of non-granular types (LST-NG) with a smooth surface. Submucosal invasive carcinomas were classified into 23 minute (SM-minute Ca) and 57 deep cases (SM-deep Ca; over 1mm from the muscularis mucosae to the deepest of invasion).
Results: All 22 depressed-types were SM-deep Ca cases. The rates of SM-deep Ca cases in LSTs were significantly lower than those in the polypoid and depressed-types, respectively (LST 22 cases, 7% vs polypoid 15 cases, 60%; $p < 0.01$, LST vs depressed 100%; $p < 0.01$). In 338 cases with a type non VN pit pattern, the rates of intraepithelial neoplasias and SM-minute Ca cases were 94%, while all 38 lesions with a type VN pit pattern were SM-deep Ca cases. There was significant

relationship between histology and pit pattern ($p<0.01$). According to LSTs, all 182 LST-Gs with a non VN pit pattern were intraepithelial neoplasias and SM-minute Ca cases. In 22 SM-deep Ca cases of LSTs, all 11 LST-Gs showed a type VN pit pattern, while only 2 cases in 11 LST-NGs showed a type VN pit pattern. There was significant relationship between subtypes and pit pattern in submucosal deep invasion of LSTs ($p<0.01$).

Conclusion: We suggest that the treatment for early-stage colorectal tumors greater than 20mm should be determined on the basis of the morphology and pit pattern by magnification colonoscopy. It is necessary to consider surgical resection for most of depressed and sessile polypoid-types because of the high rates of submucosal deep invasion. According to LSTs, LST-Gs with a type non VN pit pattern are possible to allow of endoscopic piecemeal mucosal resection because of absence of SM-deep Ca cases, while LST-NGs should be considered a definite indication for ESD and it is necessary to obtain en-bloc specimens for precise histological assessment, because a few SM-deep Ca cases with a type non VN pit pattern cannot be correctly diagnosed despite of using magnification endoscopy.

Introduction: Endoscopic submucosal dissection (ESD) evolved as a method for en bloc resection of large early-stage gastrointestinal tumours for accurate histopathological evaluation in Japan. Colorectal endoscopic submucosal dissection (ESD) can be technically difficult for various reasons, such as submucosal fibrosis. A thin muscular layer can lead to increased perforation rates and longer procedure times. Novel strategies, such as the submucosal pocket creation method, have been reported to overcome these difficulties. Additionally, we recently introduced a new technique, submucosal pocket creation using a traction device (TD). This device is designed to be fixed with clips on the free edges of a mucosal overlay to deflect the diseased mucosa away from the dissection plane during submucosal dissection. When colorectal ESDs are initially performed, we use this technique to facilitate a safe and efficient procedure.

Aims and Methods: We aimed to evaluate the utility of submucosal pocket creation using the TD during colorectal ESD as required by trainee endoscopists. At the Cancer Institute Hospital of Japanese Foundation for Cancer Research from January to March 2018, we retrospectively investigated outcomes of 82 colorectal ESDs performed by 2 groups of endoscopists (A and B). Group A comprised 5 endoscopists with less than 50 cases of colorectal ESD experience and group B comprised 5 endoscopists with more than 500 cases of ESD experience.

Results: There were few practical differences in terms of therapeutic outcomes between the 2 groups. In contrast, the rate of using the TD in group A was significantly higher than that in group B. The details are presented in the table.

	Group A (n = 63)	Group B (n = 19)
Rate of using the TD (%)	41.2 (26/ 63)	21.1 (4/ 19)
Size of specimen (mm)	33 (15–70)	35 (25–70)
Rate of en bloc resection (%)	100 (63/ 63)	100 (19/ 19)
Median time of the procedure (min)	51.0 (18–165)	40.0 (5–190)
Perforation (%)	1.6 (1/63)	0 (0/ 19)
Clinically significant bleeding (%)	1.6 (1/63)	0 (0/ 19)

Conclusion: The technique of submucosal pocket creation using TD for colorectal ESD enabled trainees to perform colorectal ESD effectively and safely even in the initial period when they were under the supervision of ESD experts.

Introduction: Endocytoscopy (EC) is a next-generation endoscopy that allows diagnostic imaging at 520× magnification. In the EC classifications, lesions diagnosed as EC3a vary extensively from adenoma to SM-m, including some lesions that are unsuitable for endoscopic treatment. Therefore, to improve the accuracy of assessing the depth of invasion based on the EC classification, we investigated the presence or absence of 2 factors; high degree of nuclear enlargement (HNE) and multilayered nuclei (MNs), that are indicators of SM-m.

Aims and Methods: Between May 2005 and March 2018, we retrospectively examined 721 lesions diagnosed as EC2 or EC3, according to the EC classification. We subclassified EC 3a into 2 grades (low grade and high grade) and defined low grade as not recognizing both HNE and MNs, and high grade as for any of the 2 factors. We examined the diagnostic accuracy of SM-m based on this EC3a subclassification. In addition, we compared the diagnostic ability of EC for SM-m with that of other modalities; narrow-band imaging (NBI) and pit pattern.

Results: The sensitivity, specificity, positive predictive value, negative predictive value, accuracy, and positive likelihood ratio for the diagnostic accuracy of the EC3a subclassification were 90.4%, 91.5%, 81.0%, 96.0%, 91.2%, and 10.7 ($p<0.001$). Diagnostic performance for predicting SM-m or worse among EC, NBI and pit pattern is as follows: The sensitivity, specificity, positive predictive value, negative predictive value, and accuracy about EC were 96.8%, 92.4%, 96.6%, 92.8%, 95.4% respectively. On the other hand, Those of NBI were 98.6%, 52.2%, 83.7%, 93.9%, and 84.6%, and pit pattern were 96.1%, 83.3%, 93.4%, 89.7%, 92.4%, respectively.

Conclusion: From the EC findings, the presence of HNE, and MNs are important risk factors for SM-m or worse outcomes. Furthermore, the EC3a subclassification taking account of these findings could be effective for the diagnosis of SM-m or worse.

P0193 EARLY-STAGE COLORECTAL PROTRUDED TUMOR WITH DEPRESSION MAY ORIGINATE FROM "DE NOVO" CANCER

H. Miyazaki, K. Kuroda, M. Fujii, D. Shirasaka, K. Tsuda, H. Kaku, S. Tanaka, K. Nagao, A. Hiemori, Y. Asada

Introduction: It is widely accepted that the majority of colorectal cancers develop through polypoid growth. However, recent studies have shown that depressed tumors also contribute to the development of colorectal cancers. According to careful observation during colonoscopy, a protruded tumor with depressed morphology at the top of the lesion is sometimes detected and it is difficult to diagnose and treat it precisely. The present study aimed to evaluate the importance of early-stage colorectal protruded tumors with depression.

Aims and Methods: We analyzed clinicopathological findings for 2108 early-stage colorectal protruded sessile tumors excluding pedunculated types, resected endoscopically or surgically (2013 low/high-grade intraepithelial neoplasias and 95 submucosal invasive carcinomas) after observation by magnification chromoendoscopy. They were classified into 2 subtypes according to depression at the top of a lesion: 14 cases with depression and 2094 cases without depression.

Results: All 14 protruded tumors with depression were submucosal invasive carcinoma (SM-Ca) cases, and the rates of SM-Ca cases in them were significantly higher than those in protruded tumors without depression (81/2094, 4%; $p<0.01$). In SM-Ca cases, the tumors with depression (11.3 ± 2.9mm in diameter) were significantly smaller than those without depression (18.8 ± 9.2mm; $p<0.01$). According to adenomatous glands in the tumors, all 14 SM-Ca tumors with depression had no adenomatous glands, and the rates of cases containing adenomatous glands in them was significant lower than those in tumors without depression (44/81, 54%; $p<0.01$). According to the bases of SM-Cas, all 14 tumors with depression showed a type I pit pattern surrounding depression, which suggests that the bases are covered with normal mucosa. On the other hand, all 81 tumors without depression showed type III, IV or V pit patterns, which suggests that the bases are composed of neoplastic glands. There was significant relationship between the presence of depression and histology of the bases of protruded SM-Cas ($p<0.01$).

Conclusion: Our findings suggest that the treatment for early-stage colorectal protruded sessile tumors should be determined on the basis of the detection of depressed morphology and pit pattern diagnosis by magnification colonoscopy. It is necessary to consider surgical resection for the protruded tumors with depression, because they are all submucosal invasive carcinoma cases. Also, they may originate from what we call de novo cancers, depressed-type tumors, because all their cases are submucosal invasive carcinomas regardless of their small size and have no adenomatous glands and moreover their bases are covered with normal mucosa. Therefore, we should always pay attention to protruded tumors with depression during colonoscopy.

Introduction: Cold forceps polypectomy (CFP) is often used to remove diminutive colorectal polyps. It does not induce thermal damage to tissue, and therefore has few complications such as postoperative bleeding and perforation. Other advantages are that it can be implemented using routine biopsy techniques, and the resected tissue can be recovered easily and reliably after resection. In addition, jumbo biopsy forceps are considered superior to standard forceps for removing colorectal polyps. The observation to check the margin of resected regions using narrow band imaging (NBI)-enhanced endoscopy can also improve complete resection rate. However, in such cases, we sometimes experience local recurrence cases, the issue of features of them have not been clarified in detail.
Aims and Methods: In this study, we examined the clinicopathological features of locally recurrent lesions after jumbo forceps biopsy assisted by NBI endoscopy for patients with diminutive polyps. This multicentre, prospective, single-arm observational study was conducted at 11 institutes of the National Hospital Organization in Japan between January 2015 and September 2016. Patients aged 20–75 years with diminutive polyps ≤5 mm were enrolled. A total of 503 patients were prospectively assessed, and 1015 polyps were resected. In addition, a total of 955 lesions were resected in the 471 patients who were followed up 1 year after CFP to examine the polypectomy sites for local recurrence (follow-up rate; 94.1%). We analysed the local recurrence rate, clinicopathological characteristics of primary polyps and local recurrent polyps, as well as resection rates and adverse events.
Results: Local recurrence occurred in 20 (2.1%) cases of the 955 lesions subjected to 1-year follow-up. The patients consisted of 14 (70%) men and 6 (40%) women with a median age of 67.5 years. The primary polyp morphologies were: 0-Is lesions in 17 (85%) cases, 0-IIa lesions in 2 (10%), and a 0-Isp lesion in 1 (5%) case. The mean size of the primary polyps was 3.9 ± 0.9 mm. The number of resected primary polyps in the right and left colon were 12 (60%) and 8 (40%) cases, respectively. The histological diagnoses of the primary resected polyps were adenomas in all cases. The complete resection rate was 100% (20/20). The rate of one-bite polypectomy was 55% (11/20). Immediate bleeding occurred in 1 (5%) case; delayed bleeding and perforation were not observed. The mean size of local recurrent polyps was 1.5 ± 0.6 mm and all were less than 3 mm in size. Re-CFP successfully managed local recurrent polyps in all cases, and the rate of one-bite polypectomy for local recurrent polyps was 95% (19/20). No adverse events occurred in any of the cases. The histological diagnoses of local recurrent polyps were adenomas in all cases.
Conclusion: The local recurrence rate after CFP using jumbo biopsy forceps assisted by NBI endoscopy for diminutive polyps was acceptable (2.1%). Even if local recurrence occurred, the size would be small and it could be treated using re-CFP.

Introduction: Endoscopic submucosal dissection (ESD) is one of the most useful methods for treating early colorectal neoplasms, and an insulation-tipped knife, hook knife, flush knife, or dual knife is conventionally used to perform ESD. However, because these devices are used without fixation to the target tissue, there is the potential risk of adverse events due to an unexpected incision or perforation. To reduce the risk of adverse events associated with a conventional knife when performing ESD, we used a scissors-type stag beetle (SB) knife Jr, which maintains an adequate dissection layer and prevents unexpected muscular layer injury. We previously reported that performing colorectal ESD with the SB knife Jr is easy, safe, and technically efficient. However, there is a need for more long-term clinical data to establish the full advantages of colorectal ESD with the SB knife Jr, with respect to favorable survival rates and very low recurrence rates.
Aims and Methods: The aim was to evaluate the long-term outcomes of ESD performed with the SB knife Jr for early colorectal neoplasms. ESD was performed for 163 lesions in 151 patients (male:female ratio = 78:73; mean age = 69 years) between October 2010 and March 2015. Data for 137 lesions in 126 patients (84.1%) who were confirmed dead or had follow-up for more than 3 years were identified and analyzed. The en bloc resection rate, complete resection rate, curative resection rate, resected tumor size, procedural time, complications, and long-term outcomes, including local and distant recurrence rates, and survival rates (3/5-year overall survival [OS] and 3/5-year disease-specific survival [DSS]) were evaluated. The survival rates were analyzed for the entire study cohort, and the local and distant recurrence rates were analyzed for the cohort that underwent curative resection or those who were observationally managed with non-curative resection.
Results: The patients' mean age was 68 ± 10 years, and the male:female ratio was 67:59. On histopathology, the prevalence rate for tubular adenoma was 29.9% (41/137), with Tis in 46.7% (64/137), T1a in 10.2% (14/137), and T1b in 13.1% (18/137). The mean resected tumor size was 32.5 ± 16.5 mm, and the median procedure time was 80 (range, 15 - 420) min. The en bloc resection rate, complete resection rate, and curative resection rate were 97.8% (134/137), 94.2% (129/137), and 83.9% (115/137), respectively. No perforations occurred during the procedure. The delayed bleeding rate was 3.6% (5/137); rectal stricture occurred in one patient (0.7%) and was treated conservatively.
For long-term outcomes, the local recurrence rate was 1.6% (2/123), and no distant recurrence was observed in the recurrence analysis cohort. On survival analysis (median follow-up period: 52.8 [range, 5.5–89.3] months), the 3/5-year OS and DSS rates were 94.2%/92.1% and 99.0%/99.0%, respectively. 1 patient (0.7%, 1/137) died of colorectal cancer, and 9 (6.6%, 9/137) died of other diseases.
Conclusion: ESD provides good long-term outcomes for patients with early colorectal neoplasms. Even though the local recurrence rate is very low, patients should be monitored after ESD.
Disclosure: Nothing to disclose

P0196 MUCOSAL FLATTENING-ASSISTED COLONOSCOPY (FAC) FOR IMPROVING ADENOMA DETECTION RATE: A SYSTEMATIC REVIEW WITH PAIRWISE AND NETWORK META-ANALYSIS

M. Clelia[1], L. Frazzoni[2], L. Fuccio[2], P. Bhandari[3], S. Thayalasekaran[4], C. Hassan[5], R. Marmo[6]

Introduction: The adenoma detection rate (ADR) has emerged as the most important quality measure in colonoscopy, as it predicts the risk of interval cancer after colonoscopy. Improving ADR is the central focus of the current quality movement in colonoscopy. The fold flattening devices could ameliorate the ADR.
Aims and Methods: The aim of the study was to compare the efficacy of mucosal flattening assisted colonoscopy vs standard colonoscopy to improve the adenoma detection rate in patients undergoing colonoscopy. Secondary outcomes evaluated were intubation rate, time of endoscopy, number of polyps found, number of advanced adenomas, number of cancer, safety of procedures. We searched, from inception to April 7 2018. Search terms included "adenoma detection rate AND improving colonoscopy"; "Adenoma detection rate AND (Endo Cuff OR Endo Vision OR Endo Rings)"; "adenoma detection rate AND improving device". All references from the reviewed articles were searched for any other articles that may have been missed. Randomized Clinical Trials (RCT) comparing flattening assisted colonoscopy to standard colonoscopy, for any indication, were included in the analysis. Data were analyzed by Intention To Treat and Per Protocol. Pooling methods was initially pairwise; potential effect modifiers were evaluated and than network meta analysis, was conducted by STATA software using the mvmeta command; relative ranking was evaluated by surface under the cumulative ranking curves (SUCRA) routine.
Results: Starting from 138 abstracts initially evaluated, a total of 10 articles were included. The ADR of a total of 6407 patients (Endocuff 2986, EndoRing 354 and Standard 3067) were evaluated. Overall, using Endocuff, ADR improved with an OR of 1.36 (c.l.95% 1.12 to 1.60) p = 0.001. A significant Heterogeneity was present: Overall I-square 60.0% p = 0.01. Sub grouping studies in 3 level of ADR in the SC, (< = 25%; >25% and <=40%, >40%) the OR between the 2 treatment arms are significantly different.In the studies with higher ADR no difference was present between Endocuff and SC: OR 1.07 (c.l95% 0.85 to 1.34) p = 0.184, in lower ADR, OR = 1.85 (c.l95% 1.35 to 2.53) p = 0.000; intermediate ADR, OR = 1.43 (c.l.95% 1.13 to1.77) p = 0.014. These results are similar for both PP and ITT analysis. In the network meta analysis ADR Log odd ratio comparing SC vs Endocuff was 0.29 [c.l.95%.11 to.47] p = 0.001; Log odd ratio standard colonoscopy vs Endo Ring was -0.018 [c.l.95% -.42 to.38] p = 0.929. Endocuff vs EndoRing in direct (log OR = −0.33 [c.l.95% -.88 to.22] p = 0.24 and Indirect comparison (log OR = −0.29 [c.l.95% -.98 to.41] p = 0.42 provide not significant difference probably due a beta error (Figure). Testing for inconsistency was not signicant: $chi^2(2) = 0.01$; Prob > $chi^2 = 0.9966$. Endocuff device reach the higher (SUCRA) percentage of effectiveness: 92.3 and the higher probability to be the best 84.8%. The probability to be the first or second best was 99.9%
Conclusion: Endocuff devices improve ADR overall by 1.33 - 1.34 both on per protocol and by intention to treat analysis. The improvement was not significant

when the ADR was greater than 40% using standard colonoscopy. Endocuff was clinically and statistically relevant when ADR with standard colonoscopy is lower than 25%. (O.R. 1.87 ITT analysis). About Endoring no definitive conclusion could be drawn due to the scarce literature available, although the preliminary analysis did not shown an advantage when was compared to standard colonoscopy. Direct and indirect comparison between Endoring vs Endocuff did not provide definitive conclusions
Disclosure: Nothing to disclose

P0197 FORWARD-VIEWING ENDOSCOPE FOR ERCP IN PATIENTS WITH BILLROTH II GASTRECTOMY: A SYSTEMATIC REVIEW AND META-ANALYSIS

T.Y. Park[1], C.S. Bang[2], Y.J. Yang[2], S.P. Shin[2], K.T. Suk[2], G.H. Baik[2], D.J. Kim[2]

Contact E-Mail Address: ptymd@hotmail.com
Introduction: The forward-viewing endoscope has been increasingly used to perform endoscopic retrograde cholangiopancreatography (ERCP) in patients who underwent Billroth II gastrectomy.
Aims and Methods: This study intended to assess efficacy and safety of the forward-viewing endoscope for ERCP in Billroth II gastrectomy patients compared with conventional side-viewing endoscope using a systematic review and meta-analysis. A systematic review was conducted for studies that evaluated the outcomes of ERCP for patients with Billroth II gastrectomy. Random-effect model meta-analyses with subgroup analyses were conducted. The methodological quality of the included publications was evaluated using the risk of bias assessment tool for non-randomized studies. The publication bias was assessed.
Results: In total, 25 studies (1 randomized, 18 retrospective, 1 prospective, and 5 case series studies) with 2446 patients (499 forward-viewing and 1947 side-viewing endoscopes) were analyzed. The pooled afferent loop intubation rate was higher with the forward-viewing endoscope (90.3%, 95% confidence interval (CI):85.6–93.6% vs. 86.8%, 95% CI:82.8–89.9%). The pooled selective cannulation rate was higher with the side-viewing endoscope (92.3%, 95% CI:88.0–95.2% vs. 91.1%, 95% CI:87.2–93.9%). The pooled bowel perforation rate was higher with the side-viewing endoscope (3.6%, 95% CI:2.3–5.7% vs. 3.0%, 95% CI:1.7–5.3%). The pooled pancreatitis rate was higher with the forward-viewing endoscope (5.4%, 95% CI:3.6–8.0% vs. 2.5%, 95% CI:2.3–5.7%). The pooled bleeding rate was higher with the forward-viewing endoscope (3.0%, 95% CI:1.6–5.5% vs. 2.0%, 95% CI:1.4–3.0%). The heterogeneity among the studies was not significant. The publication bias was minimal.
Conclusion: This meta-analysis indicates that the forward-viewing endoscope is as safe and effective as conventional side-viewing endoscope for ERCP in patients with Billroth II gastrectomy.
Disclosure: Nothing to disclose

P0198 LIVER HYDATID CYST - WHEN DO WE NEED BILIARY STENTING IN MANAGEMENT PROTOCOL. A STUDY OF 56 CASES FROM A TERTIARY REFERRAL CENTRE IN INDIA

P.N. Desai[1], D. Mangukiya[2], K. Bhatt[2]
[1]*Surat Institute Of Digestive Sciences, Endoscopy, Surat, India*
[2]*Surat Institute Of Digestive Sciences, Surat, India*

Contact E-Mail Address: drp_desai@hotmail.com
Introduction: Hydatidosis, a zoonotic infection, is due to the larval stage of the tapeworm Echinococcus (E.). The outmost layer of a cyst, the ectocyst or pericyst, is formed by compressed and fibrotic host tissue and may become calcified, whereas inner layers are of parasitic origin and act as a germinal centre. A cyst may or may not contain daughter cyst(s). Secondary echinococcosis can develop in the same or other organs. Most patients will have a single organ involvement in primary echinococcosis. In adults the liver represents the prevalent site (50–70%) and lungs are the second commonest site (10–30%). Rupture into the biliary tree is the commonest complication (up to 25% of cases) and can be associated with biliary obstruction by daughter cysts.
Aims and Methods: We aimed to identify the subset of patients suffering from liver hydatid cysts who will require ERCP with biliary stenting in the management protocol.
We analyzed our data in tertiary care urban centre from October 2010 to March 2017 for liver cysts. Total 56 patients were identified with liver cysts that were operated, out of which 43 had liver hydatid cyst. Who were operated for the same. As a part of protocol all our patients underwent Cystectomy - *non-radical* alternative. It comprises cyst de-roofing and cyst content evacuation without removal of the pericyst, plus or minus omentoplasty and whenever required they were subjected to ERC (Endoscopic retrograde cholangiography) and stenting of biliary system. We have opted for surgery after routine protocol of Albendazole pre operatively except the patients who presented with cholangitis due to cyst internal rupture. None of the patients in our series was of type CE 1 (WHO Classification).
Results: Out of 43 patients we found biliary communication (on imaging, preoperatively) in 18 patients, out of which we required ERC in 11 (25.6%) patients postoperatively. 2 patients were presented with cholangitis and jaundice preoperatively so they were subjected to ERC preoperatively. Total 9 patients had demonstrable biliary communication on table (20.9% of total). A factor which was found significant in our series was distance from hilum. ERC group patient had average distance of 1.66 cm vs. 4.35 cm in non-ERC group. Size of cyst (10.79cm vs. 9cm), Serum alkaline phosphatise level (103.88 vs. 62.13, normal range up to 80), and Bilirubin levels (1.54 vs. 0.75) were statistically insignificant. ERC group patient had average hospital stay of 9.22 vs. 3.2 days for non ERC group. 1 patient had combined liver spleen hydatid cyst. We have 1 mortality in our series (elderly patient presented to us with severe cholangitis and sepsis with internal rupture of cyst) he was operated upon after ERC but did not survive due to multiorgan failure. None of the patients had recurrence in our present series, in average follow up of 3 months to 7 yrs. 1 patient had fluid collection which was treated with percutaneous drainage.
Conclusion: Cystectomy - a non radical alternative of hydatid disease is practical and feasible approach.
ERC is needed in patents with biliary communication and patients with cholangitis due to rupture in the biliary tree.
Majority should be subjected to ERC post operatively when we identify bile in the cyst.
Preoperative ERC only of patients with cholangitis.
Cyst which is near to hilum has more chances of biliary communication rather than large peripheral cysts.
However larger studies are needed to reciprocate the same findings. Morbidities are higher in internal rupture cases.
Disclosure: Nothing to disclose

P0199 COMPARISON OF DEXMEDETOMIDINE WITH MIDAZOLAM VERSUS MIDAZOLAM ALONE FOR SEDATION DURING ERCP: A PROSPECTIVE OBSERVATIONAL STUDY

K. Yamakita[1], Y. Kitano[1], K. Takahashi[1], H. Iwamoto[1], T. Ota[1]
[1]*Asahikawa Medical University, Asahikawa, Japan*

Contact E-Mail Address: keisuke_yamakita@yahoo.co.jp
Introduction: Dexmedetomidine (DEX) is a highly selective α2-adrenoceptor agonist that elicits sedative and analgesic effects in humans. Recently, DEX has been used for endoscopic sedation. However, the usefulness and safety of DEX for sedation during endoscopic procedure has not been fully evaluated.
Aims and Methods: The aim of this study was to compare the efficacy and safety of standard sedation using midazolam (midazolam group) with combination sedation using DEX and midazolam (midazolam+DEXgroup). A prospective, observational study was conducted in 89 patients who underwent ERCP. Written informed concents were obtained from all patients before enrollment. Satisfaction score among patients were evaluated with Visual Analogue Scale. Body motion during sedation (1–5; 5 represents discontinuance of procedure), vital signs and the recovery time were assessed.
Results: 46 patients were administrated with midazolam alone (midazolam group) and 43 patients were administrated with DEX and midazolam (midazolam+DEX group). The baseline characteristics and procedure time were similar between the 2 groups. Body motion was significantly lower in midazolam+DEX group than in midazolam group (1.50 vs. 2.58, $p<0.0001$), Satisfaction score, recovery time, respiratory depression, hypotension and bradycardia were not significantly different between the 2 groups.
Conclusion: The present study suggests that a combination of DEX and midazolam is as safe as midazolam alone for sedation during ERCP. This combination provides less body motion than midazolam alone without extending recovery time.

P0200 UTILITY OF ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY FOR THE MANAGEMENT OF SYMPTOMATIC PANCREAS DIVISUM IN CHILDREN: EXPERIENCE FROM A SINGLE CENTER IN CHINA

G.-X. Cui, J. Yang, W. Lu, L. Lu, X. Zhang
Hangzhou First People's Hospital, Gastroenterology and Hepatology, Hangzhou, China

Contact E-Mail Address: 18258855475@163.com
Introduction: Pancreas divisum (PD) is the most common congenital anomaly of the pancreas. Most PD individuals are asymptomatic, but a few may present symptoms in the form of recurrent acute pancreatitis (RAP), chronic pancreatitis (CP) or pancreatic-type pain. Currently, most PD-related studies published in the literature have been limited to adults. Clinical data in pediatric PD are relatively insufficient. However, it is important to early diagnose and timely treat symptomatic PD, especially in children for the better clinical outcomes.

Aims and Methods: To estimate the safety and efficacy of endoscopic retrograde cholangiopancreatography (ERCP) for the treatment of symptomatic PD in children. We retrospectively analyzed patients of symptomatic PD(s-PD) who were younger than 18 years old from January 2011 to December 2017 in our institute. The s-PD included PD with RAP (RAP group) and PD with CP (CP group). All children were treated with ERCP as a main therapy. During an ERCP, minor endoscopic sphincterotomy combined with dorsal duct stenting(Mi-ESCS) was performed for complete PD (CPD) patients, and Bi-papilla ESCS (Bi-ESCS) was performed for incomplete PD (IPD) patients. ERCP-related data, complications, clinical outcomes, and follow-up data were collected and analyzed. Long-term follow up was carried out to observe occurrence of developing CP in RAP group, children's recovery, as well as their weight, growth and intelligence.
Results: A total of 312 pediatric ERCPs were performed for 157 children during this period. Of which 34 were PD cases, among which 30 were s-PD. The endoscopic detection rate of PD was 21.7%. Of the 30 s-PD patients, 19 were PD with RAP, among which 17 were CPD and 2 were IPD. The other 11 were PD with CP, among which CPD and IPD were 7 and 4 respectively. A total of 84 therapeutic ERCPs were performed, among which 44 were for RAP group and 40 for CP group. The success rate of cannulating the minor papilla was 97.6% (82/84). The total response rate to endotherapy was 93.3%, with that of 100% (19/19) in RAP group and 81.8% (9/11) in CP group. The 2 patients with no response to endotherapy in CP group underwent surgery. The mean interval of changing pancreatic dorsal duct stent is 3 months (from 2 to 6 months). The mean number of changing dorsal duct stent was 2.3 in RAP group and 3.6 in CP group. ERCP-related complications were mild with a rate of 7.1% (6/84), all of which were managed conservatively. During follow up from 3 to 84 months (mean 38.1 months), all patients had pain relief. In RAP group, 2 patients developed CP with a rate of 10.5%, others showed no more dilation of dorsal ducts. In CP group, all patients had pain relief with few onset of acute pancreatitis, however, they demanded multiple repeated changing dorsal stents with no obvious improvement in pancreatic duct. In both groups, children presented normal in weight, growth and intelligence.
Conclusion: The techniques of Mi-ESCS and Bi-ESCS with ERCP are safe and effective methods to manage s-PD in pediatric patients. It seems very important for such children to undergo endoscopic interventions as early as possible in order to avoid developing CP. Children of PD with CP may present asymptomatic with long term ERCP therapy.
Disclosure: Nothing to disclose

P0201 PANCREATIC DUCT PERFORATION DURING GUIDEWIRE CANNULATION IN THERAPEUTIC BILIARY ERCP

J. Garcia-Cano[1], L. Taberna-Arana[2]
[1]*Hospital Virgen de la Luz, Gastroenterology, Cuenca, Spain*
[2]*Health District, Family Practice, Cuenca, Spain*

Contact E-Mail Address: jegarca59@gmail.com
Introduction: Guidewire (GW) cannulation of the common bile duct (CBD) in ERCP is becoming increasingly widespread. Inadvertent GW passage into the main pancreatic duct (MPD) is relatively common. As a consequence, sometimes involuntary perforation of the MPD occurs.
Aims and Methods: We aimed to evaluate the rate of MPD perforation after unintentional GW access to the pancreas in a series of ERCPs intended for CBD cannulation.
A prospective study was conducted. Endoscopist-controlled GW cannulation was performed in order to gain the CBD. Several marketed types of 0.025" straight tip GWs were used. GWs were loaded into a 4.4 Fr distal tip sphincterotome. When the GW first entered the MPD a small amount of cotrast was injected to verify its correct position. If the GW was stuck in some pancreatic sidebranch or perforation occurred 2 gentle attempts were made to place the GW correctly in the MPD. If this was unsuccessful, the GW was withdrawn from the pancreas. When posible, pancreatic stenting was performed always, as recommended [1]. A straight plastic pancreatic stent, 5 F and 4 cm, without internal flaps was always inserted when the GW was properly positioned along the MPD. Spontaneous expulsion was expected due to lack of internal flaps. Prophylactic NSAIDs were administered to all patients
Results: 174 patients with naïve papilla needing ERCP biliary drainage were included. Inadvertent GW cannulation of the pancreas ocurred in 73 (42.5%) patients. In 55/73 (75.34%) the GW was properly placed along the MPD. MPD perforation was observed in 12/73 (16.4%). In 9 out of these 12 patients the GW could be reinserted to a proper position wihin the MPD. 6 out of these 12 patients had a visible pancreatic contrast leakage. Finally in total, pancreatic stents could be inserted in 64/73 (87.6%) patients having GW cannulation of the pancreas. Post-ERCP pancreatitis rate was 1/64 (1.56 %) in the group of successful pancreatic stenting and 1/9 (11%) in the group in which the GW did not enter properly the MPD and stenting was not posible ($p<0.05$). Both pancreatitis were mild in severity. Pancreatitis was not observed in patients with MPD leakage in whom a pancreatic stent could be placed later on.
Conclusion: In this study a 16.4% rate of MPD perforation was seen after unintentional GW passage into the pancreas. If pancreatic stenting is posible, stents appear to revert damage caused by inadvertent GW perforation. Future improvements to reduce this perforation rate could include comparison between angled vs straight tip GWs and development of GWs with enhanced tip flexibility.
Disclosure: Nothing to disclose

[5]*HCFMRP-USP Dept. of Surgery and Anatomy, São Paulo, Brazil*

Contact E-Mail Address: amy.tyberg@gmail.com
Introduction: Endoscopic ultrasound guided biliary drainage (EUS-PD) is an efficacious, safe option for patients with pancreatic duct obstruction who fail conventional endoscopic retrograde cholangiopancreatography (ERCP). The procedure involves accessing the pancreatic duct using EUS, creating a fistulous tract, and deploying a decompressing stent across the tract. It is a technically challenging procedure, requiring advanced skills in EUS and ERCP. The aim of this study was to define the learning curve for EUS-PD.
Aims and Methods: Consecutive patients undergoing EUS-PD by a single operator with training in therapeutic endosonography, were included from a dedicated registry from May 2003 to September 2017. Demographics, procedure info, adverse events, and follow-up data were collected. Non-linear regression and CUSUM analyses was conducted for the learning curve. Technical success was defined as successful stent placement. Clinical success was defined as resolution of procedural indication.
Results: 55 patients were included (54%M, mean age 58 years). The majority of patients had benign disease (n = 51, 91%): chronic pancreatitis n = 26, anastomotic stricture n = 16, divisum n = 6. The remaining 5 patients had malignant obstruction. 25 patients (44%) had altered anatomy. Technical success was achieved in 47 patients (84%). Stent placement was transluminal in 43 patients (92%) and transpapillary in 4 (9%), antegrade in 36 patients (77%) and retrograde in 11 (23%). All stents were plastic except 1 which was metal. Clinical success was achieved 46/47 (98%) patients who achieved technical success. Adverse events were seen in 13 patients (6 of whom did not achieve technical success) and included bleeding requiring embolization (n = 5), bleeding treated with clips peri-procedurally (n = 1), pancreatitis (n = 5), and a pancreatic fluid collection drained via EUS (n = 2). Median procedure time was 80 mins (range 49–159 mins). CUSUM chart shows 80 minute procedure time was achieved at the 27th procedure indicating efficiency. Apart from 2 outliers, procedure durations further reduced with consequent procedures from 40th onwards reaching a plateau which could be the plateau indicating mastery (nonlinear regression $p<0.0001$)
Conclusion: Endoscopists experienced in EUS-PD are expected to achieve a reduction in procedure time over successive cases, with efficiency reached at 80 minutes and a learning rate of 27 cases. Continued improvement is demonstrated with additional experience, with plateau indicating mastery suggested at the 40th case. EUS-PD is probably one of the hardest therapeutic endosonographic procedure to learn and master.

[2]*Weill Cornell Medical College, New York, United States*
[3]*Methodist Dallas Medical Center, Dallas, United States*

Contact E-Mail Address: amy.tyberg@gmail.com
Introduction: Endoscopic ultrasound-guided gallbladder drainage (EUS-GLB) is an efficacious, safe option for patients with cholecystitis who cannot undergo cholecystectomy. The procedure involves accessing the gallbladder using EUS, creating a fistulous tract, and deploying a stent across the tract. It is a technically challenging procedure, requiring skills in EUS, fluoroscopy, and stent deployment. The aim of this study was to define the learning curve for EUS-GLB.
Aims and Methods: Consecutive patients undergoing EUS-GLB by a single operator were included from a prospective registry from January 2012 to July 2017. Demographics, procedure info, post-procedure follow-up data, and adverse events were collected. Non-linear regression and CUSUM analyses was conducted for the learning curve. Clinical success was defined as resolution of cholecystitis post-procedure.
Results: 48 patients were included (58%M, mean age 76 years). 20 patients (42%) had malignant cholecystitis, the remainder had benign disease. Technical success was 100%. Most patients had lumen-apposing metal stents (LAMS) (15mm, n = 29, 60%; 10mm, n = 8, 17%), 25 of which were cautery-enhanced. The remaining patients had FCSEMS (n = 9, 19%) or plastic stents alone (n = 2, 4%). 1 patient required bridging stents placement. The majority of stents were transduodenal (n = 28, 58%), the remaining transgastric (n = 15, 31%) or transjejunal (n = 4, 8%), and 1 patient had 2 stents placed from transgastric and

transduodenal position during the same procedure. Clinical success was achieved in 36 (86%) of patients. Of the remaining 12, 7 were lost to follow-up and 5 had persistent cholecystitis. 9 patients (19%) had adverse events including bleeding (n = 4), liver abscesses (n = 2), and hypotension post procedure. 2 patients passed away post-procedure due to respiratory failure and peritonitis secondary to ruptured gallbladder wall. 6 patients required re-intervention for stent occlusion with repeat endoscopy or surgical cholecystectomy. The median procedure time was 41 minutes (range 16–121 mins). CUSUM chart shows 41 minute procedure was achieved at the 19th procedure hence indicating efficiency. Procedure durations further reduced with the last 10 procedures being 20 minutes or under (nonlinear regression $p < 0.0001$) indicating continued improvement with experience. This also may be due to the introduction of cautery-enhanced LAMS.
Conclusion: Endoscopists experienced in EUS-GLB are expected to achieve a reduction in procedure time over successive cases, with efficiency reached at 41 minutes and a learning rate of 19 cases. Continued improvement is demonstrated with additional experience and the introduction of cautery-enhanced LAMS.

Introduction: Endoscopic Retrograde Cholangio-Pancreatography (ERCP) is a well-established endoscopic procedure for treatment or palliation of a great variety of hepatobiliary and pancreatic diseases, routinely performed using X-ray fluoroscopy. Due to extended fluoroscopy times and increased number of images, patient radiation doses can be high, especially in complex cases. A new digital single-operator cholangioscopy (D-SOC) system (SpyGlass Digital System, Boston Scientific), allows direct visualization of the ducts, targeted biopsies, visual wire manipulation and difficult stone lithotripsy in a radiation-free manner. We investigated whether the SpyGlass platform used adjunctively to ERCP may actually reduce patient radiation exposure.
Aims and Methods: We retrospectively analyzed a prospective database of consecutive patients undergoing D-SOC following failure of ERCP either for difficult-to-treat biliary stones or indeterminate strictures. The overall patient radiation exposure outcomes in terms of Kerma Area Product (KAP), Fluoroscopy time (T) and the total number of films (F) were compared to a historical cohort of patients with difficult stones or indeterminate strictures exclusively managed by conventional ERCP before the era of D-SOC. All procedures were performed by a single, experienced operator
Results: Between 2016 and 2017, a total of 17 patients (10 males, 64 median years old) underwent successful D-SOC management of difficult biliary stones (n = 12) or indeterminate strictures (n = 5). The historical cohort comprised 20 patients (11 males, median 67 years,) with difficult-to-treat stones (n = 12) or indeterminate strictures (n = 8) who were successfully managed by repeat conventional ERCP between 2012 and 2015.
The median KAP, T and F in patients undergoing D-SOC were 11.8 $Gycm^2$, 4.2 min and 1.6 films respectively, compared with 17 $Gycm^2$, 5.8 min, and 2.6 films respectively in the historical ERCP cohort. Statistically significant differences ($p < 0.05$) were found for KAP and T.
Conclusion: Adjunct use of the new SpyGlass cholangioscopy platform appears to significantly reduce radiation exposure in patients with difficult stones or indeterminate strictures in whom conventional ERCP has failed.

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is the first-line procedure to iatrogenic biliary leaks approach. In patients who have undergone biliary stenting, the timing and optimal method (ERCP or esophagogastroduodenoscopy) of stent removal is controversial.
Aims and Methods: With the present study we aimed to evaluate ERCP efficacy in the treatment of biliary leaks and identify patients in whom repetition of ERCP may be unnecessary. We conducted a retrospective, unicentric analysis of all patients that underwent ERCP with sphincterotomy and biliary stent placement between 2008 and 2017 due to iatrogenic biliary leaks. All patients were submitted to reevaluation ERCP with removal of the stent(s). Factors associated with the *outcome*, resolution of the biliary leak and absence of another pathology in reevaluation ERCP, were identified.
Results: A total of 43 patients were included, 62.8% (n = 27) female, mean age 58.2 ± 17.2 years. The most common etiology of biliary leaks was laparoscopic cholecystectomy (56.8%) and the most common location the cystic duct stump (53.5%). Technical success was 93.3%, with resolution of the biliary leak in 92.9% of those. On multivariate analysis, elective iatrogenic procedure (OR = 209.1, 95% CI 2.18–2050.8), normal total bilirubin (OR = 138.9, 95% CI 1.19–1627.2), ERCP performed in ≤7 days (OR = 32.9, 95% CI 1.08–1004.8) and removal of the stent in ≤12 weeks (OR = 40.7, 95% CI 1.11–1634.9) were independently associated with resolution of the biliary leak and absence of another pathology ($p < 0.05$; $r^2 = 0.71$). The area under the ROC curve of these criteria for *outcome* prediction was 0.93 ($p < 0.001$). When ≥3 criteria were present (42.9% of patients), the model presented specificity of 100%, sensitivity of 58.1%, positive predictive value of 100% and negative predictive value of 45.8% in *outcome* prediction.
Conclusion: We identified criteria that allow selection of 43% of patients in whom repetition of ERCP after treatment of biliary leaks may be unnecessary. These patients can have their biliary stents removed by esophagogastroduodenoscopy, increasing safety and efficiency of healthcare resources utilization.

Contact E-Mail Address: dr25027@gk2.so-net.ne.jp
Introduction: The rates of post endoscopic sphincterotomy (EST) bleeding range from 0.3 to 2.0% [1]. Although several studies reported that continuous antithrombotic therapy (ATT) was a risk factor for postoperative bleeding after endoscopic treatment, patients with a higher risk of thrombosis require continuous ATT to prevent thromboembolic events. C.-K. HUI, et al. reported that there was no significant difference in post-EST bleeding between patients who continued to take aspirin until the day of EST and patients who had their aspirin discontinued for 1 week before EST [2].
Aims and Methods: We retrospectively investigated the safety and feasibility of EST with continuous ATT. ERCPs were performed 1933 times from July 2012 to December 2017 at New Tokyo Hospital. Among them, 645 patients were performed with EST. The patients undergoing EST were categorized according to ATT. The bleeding rates were calculated and compared in each group.
Results: The overall rate of postoperative bleeding after EST was 3.9% (25/645). The patients were divided into the following 2 groups: no ATT (n = 365) and ATT (n = 280). ATT included discontinuous ATT (n = 68), continuous ATT (n = 212) subgroups. Furthermore, continuous ATT included continuous antiplatelet therapy (APT, n = 166), continuous anticoagulant therapy (ACT, n = 28), and continuous combination therapy (continuous CT [continuous APT + continuous ACT], n = 18) subgroups. The bleeding rate with ATT (6.1%) was significantly higher than that without ATT (2.2%) (p = 0.013). The bleeding rate with continuous ATT (6.2%) was similar to that with discontinuous ATT (7.4%) (p = 0.570). The bleeding rates were 6.0% in continuous APT, 7.1% in continuous ACT, and 0% in continuous CT. Transcatheter arterial embolization was required for one patient in no ATT group because of severe bleeding.
Conclusion: ATT was associated with post-EST bleeding. However, the bleeding rate with continuous ATT was not statistically different from that with discontinuous ATT. Therefore, continuous ATT administration may be acceptable for EST, although patients should be carefully monitored for possible bleeding.

Introduction: In endoscopic retrograde cholangiopancreatography (ERCP), the risk of adverse events during precut is increased when the terminal bile duct (tBD) is not dilated. Some studies suggest that the major papilla morphology, particularly its width is determined by the prominence of the supra- and intra-duodenal portion of the tBD.
Aims and Methods: The study aim was to assess if the terminal bile duct diameter can be determined by inspecting the major papilla morphology/width during duodenoscopy.
Between July 2017 and January 2018, in 3 hospitals, all consecutive patients with naïve papilla referred for ERCP were eligible for enrollment. The transverse diameter (tD) of the papilla was measured using a comparative measurement technique (biopsy forceps) and a novel software (validity and reliability tested). The papilla morphology was classified into 1 of 4 groups: non-proeminent, proeminent, bulging, distorted. The tBD's diameter was measured in the distal 1 cm (cholangiogram acquired in supine/prone) in a workstation, by an independent researcher. Main outcome was evaluated using a Pearson correlation.
Results: 137 patients were included; 57 males (41.61%), median age of 78 years (26–99). The median tD of the papilla was 6 mm (IQR = 3 mm) and the median tBD's diameter was 8.07 mm (IQR = 4.87 mm). Half (50%) of the papillas were non-proeminent (tBD median = 7.66mm; IQR = 4.473), 32.08% proeminent (tBD median = 8.05mm; IQR = 4.869), 12.26% bulging (tBD median = 8.978mm; IQR = 5.814) and 5.66% distorted (tBD median = 7.533 mm; IQR = 0.832); p[C2 = 2.237)] >0.6923. The correlation between tD and tBD diameters was 0.0245.
Conclusion: Despite what is suggested in the literature, the morphology and the width of the major papilla do not have any association with the diameter of the tBD, and consequently these 2 dimensions should not be taken into account when deciding for a cannulation technique.

P0208 FEASIBILITY OF A NEW SHORT-TYPE DOUBLE-BALLOON ENDOSCOPE WITH ADVANCED FORCE TRANSMISSION AND ADAPTIVE BENDING FOR PANCREATICOBILIARY INTERVENTION IN PATIENTS WITH SURGICALLY ALTERED ANATOMY: A PROPENSITY-MATCHED ANALYSIS

A. Yamada[1], H. Kogure[1], Y. Nakai[1], N. Takahara[1], S. Mizuno[1], M. Tada[1], K. Koike[1]
[1]*The University of Tokyo, Gastroenterology, Tokyo, Japan*

Contact E-Mail Address: yamada-a@umin.ac.jp
Introduction: Recently, short-type double-balloon endoscopes (DBEs) for pancreaticobiliary interventions in patients with surgically altered anatomy have become available in many institutions. However, we previously demonstrated in a multicenter study that endoscopic retrograde cholangiopancreatography (ERCP) using a conventional short-type DBE is a lengthy procedure, requiring approximately 22 minutes to reach the target site and 56 minutes to complete ERCP-related interventions.[1] A new short-type DBE has been developed with a major focus on facilitating scope insertion to the target site for pancreaticobiliary interventions in patients with surgically altered anatomy.
Aims and Methods: We investigated the feasibility of this new short-type DBE by comparing it with a conventional DBE. Data from 885 ERCP procedures using balloon endoscopy were analyzed. We used propensity score matching to adjust for differences between patients who underwent ERCP procedures using the new short-type DBE versus the conventional short-type DBE. The outcomes of interest were the success rate of reaching the target site, the success rate of the pancreaticobiliary intervention, the insertion time required to reach the target site, the overall procedure time, the success rate of cannulation of the papilla of Vater, the time to cannulation of the papilla of Vater, and adverse events during or after the ERCP procedure.
Results: A total of 163 pairs of patients were selected on the basis of propensity score matching. The success rate of reaching the target site was 100% in both the new DBE group and the conventional DBE group (p = 1.0). The new DBE group had a significantly shorter insertion time required to reach the target site than the conventional DBE group (10 min vs. 14 min, p < 0.01). The success rate of the pancreaticobiliary interventions in the new DBE group was as high as that in the conventional DBE group (92% vs. 89% p = 0.35). The overall procedure time decreased from 62 min in the conventional DBE group to 55 min in the new DBE group (p = 0.26). Apart from choledochojejunostomy and pancreaticojejunostomy cases, the success rate of cannulation of the papilla of Vater in the new DBE group was higher than that in the conventional DBE group (96% vs. 87%, p = 0.10). No significant difference in the rate of adverse events was observed between the 2 groups.
Conclusion: A new short-type DBE allows faster insertion to the target site for pancreaticobiliary intervention in patients with surgically altered anatomy.

P0209 POSITIVE CORRELATION BETWEEN PANCREATIC PARENCHYMAL VOLUME AND PEP

H. Maruyama, M. Shiba, Y. Ishikawa-Kakiya, K. Otani, S. Hosomi, Y. Nagami, F. Tanaka, K. Taira, N. Kamata, H. Yamagami, T. Tanigawa, T. Watanabe, Y. Fujiwara

Contact E-Mail Address: hiromaruyama99@gmail.com
Introduction: Post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP) remains the most common and serious adverse event associated with ERCP. PEP after initial ERCP was reported to have an incidence ranging from 10% to 15% in various studies, and the mortality rate was 0.11%. PEP is considered a high-priority adverse event.
Recently, preventative measures for PEP such as high-dose rectal diclofenac and pancreatic stent placement have been proposed as useful approaches. However, they may not be appropriate for all patients, given the risks involved. Therefore, in order to use these preventive methods more effectively, it is necessary to be able to easily stratify patients into the high- and low-risk groups for PEP.
The three major causes of PEP are patient-related factors, operator-related factors, and technique-related factors. It is difficult to predict the incidence of PEP because there are many potential factors in each category. We considered the importance of predicting PEP based on pre-ERCP findings because it may be possible to increase the safety of the endoscopic procedure.
In a previous study, the degree of pancreatic exocrine function showed a significant positive correlation (p < 0.001) when determined using the ^{13}C-labeled Breath Test and acinar cell area ratio. However, the risk associated with pancreatic parenchymal volume has never been examined as a risk factor for PEP. We hypothesized that a large pancreatic parenchymal volume would increase the risk of PEP. The parenchymal volume of the pancreas was quantified using the volume analyzer SYNAPSE VINCENT® (Fujifilm Medical Co, Tokyo, Japan) in pre-ERCP images and used to evaluate whether it could be a risk factor for PEP.
Aims and Methods: The aim of this study was to investigate the risk factors for PEP by quantification of pancreatic parenchymal volume using pre-ERCP images. Overall, 800 patients were recruited from April 2012 to February 2015 for this study. There were 240 patients who satisfied the inclusion criteria. Measurement of pancreatic parenchymal volume was achieved using the volume analyzer SYNAPSE VINCENT® in all cases and was used to evaluate the risk factors for PEP.
Results: According to the criteria established by the consensus guidelines (Cotton classification), 23 patients (9.6%) were classified as having mild disease, 4 (1.7%) as having moderate disease, and 5 (2.1%) as having severe disease. Multivariate model analysis adjusted for age, female sex, pancreatic duct guidewire cannulation, precut sphincterotomy, and pancreatic injection showed that a large pancreatic parenchymal volume was a significant risk factor for PEP (odds ratio 1.12, 95% confidence interval 1.07–1.17; p < 0.01). In addition, a larger pancreatic parenchymal volume was significantly associated with a higher incidence of PEP (p < 0.001).
Conclusion: A large pancreatic parenchymal volume was identified as a risk factor for PEP. The results of this study suggest that pre-ERCP images might be useful for predicting PEP. Additional caution should be required for patients with larger pancreatic parenchymal volumes to prevent PEP.

Introduction: The continuous monitoring of quality indicators in gastrointestinal endoscopy became an essential requirement nowadays. Most of these data cannot be extracted from the currently used free-text reports, therefore a

web-based data collecting system, the Hungarian ERCP Registry was developed. Here we present the first multicentre data from the registry.
Aims and Methods: Data collection started in January 2017 at University of Pécs, and a further 4 centres (Szeged, Debrecen, Budapest and Szombathely) started to use the registry from a later date.
Results: 1117 ERCPs of 884 patients were recorded in the database until March 2018 in the 5 participating centres. 30-day follow up data was collected to detect all procedure related late complications, this data is available in 73.5% of the procedures. Native papilla (NP) was detected in 698 ERCPs (62.5% of all procedures), the success rate of biliary cannulation was 90.5% in these patients. Post-ERCP pancreatitis (PEP) developed in 22 cases (3.2% of procedures with NP), clinically significant bleeding was reported in 14 patients (2.0% of cases with NP). Cholangitis was observed in 18 cases (1.6% of all procedures), and perforation occurred in 16 cases (1.4%). Indomethacin suppository was used in 43.8% of the cases, while prophylactic pancreas stent was applied in 9.5% of the procedures to prevent PEP. The data of the participating centres are shown below. Center/ERCP number/30d F/U (%)/ERCP in NP (%)/Success in NP (%)/Complication rate (%): PEP/Bleed/Cholang. /Perf.: Pécs/692/75.1/62.6/89.6/3.2/1.4/0.7/1.9; Szeged/207/67.6/66.2/94.2/4.4/2.9/3.9/1.0; Budapest/151/69.5/55.6/89.3/1.2/1.2/3.3/0; Debrecen/35/85.7/57.1/100/0/10.0/0/0; Szombathely/32/81.3/75.0/83.3/4.2/4.2/0/3.1
Conclusion: These are the first prospectively collected multicentre key performance indicators from the Hungarian ERCP Registry. This web-based registry is a suitable tool to detect the quality of patient care and also can be used for clinical research. Further centres are encouraged and welcome to join this project.

Introduction: A forward-viewing endoscope is used for endoscopic retrograde cholangiopancreatography (ERCP) in patients with surgically altered anatomy such as Billroth II type or Roux-en Y type reconstruction. Difficulty in procedures with the forward-viewing endoscope may increase the incidence of post-ERCP pancreatitis (PEP). However, there have been few studies directly comparing the incidence of PEP between the forward-viewing and side-viewing endoscopes.
Aims and Methods: We conducted a prospective analysis to compare the incidence of PEP in ERCP with the forward-viewing endoscope with that of the side-viewing endoscope and evaluated the forward-viewing endoscope as a risk factor for PEP. Between May 2015 and May 2016, 2078 patients who underwent ERCP at 5 high-volume hospitals in Japan were enrolled (SOSUI study). We excluded patients with acute pancreatitis, biliary-enteric anastomosis, failure to reach the papilla, altered anatomy other than Billroth II or Roux-en Y reconstruction, and special approach like transgastrostomy. A total of 1877 patients were analysed, including 1814 patients with normal anatomy who underwent ERCP with the side-viewing endoscope and 63 patients with altered anatomy who underwent ERCP with the forward-viewing endoscope. In the present study, the diagnosis of PEP requires the presence of at least 2 of the following criteria: i) abdominal pain persistent for more than 24 hours, ii) elevation in serum amylase to 3 times or greater than the upper limit of normal the following day after ERCP (12 - 20 hours after ERCP), and iii) characteristic findings of acute pancreatitis on computed tomography.
Results: 103 out of 1877 (5.5%) patients developed PEP. The rates of PEP were 5.1% (96/1814) and 11.1% (7/63) for the side-viewing and forward-viewing endoscope groups, respectively. Univariate analysis revealed that the factors significantly correlated to PEP development were the following: use of the forward-viewing endoscope, female sex, naïve papilla,more than 10 trials for selective cannulation, pancreatic duct injection and precut sphincterotomy.
Multivariate analysis identified use of the forward-viewing endoscope as an independent risk factor for PEP (OR 2.78; 95% CI 1.08–6.27), as well as female sex (OR 2.30; 95% CI 1.51–3.53), naïve papilla (OR 3.81; 95% CI 2.14–7.22) and pancreatic duct injection (OR 2.48; 95% CI 1.60–3.89).
Conclusion: Use of the forward-viewing endoscope in ERCP is a risk factor for PEP. The reason for this may be that mechanical injury to the papilla or pancreatic duct can be increased by difficult and prolonged procedures due to the limitations derived from endoscope characteristics and the absence of dedicated devices. When ERCP is performed with the forward-viewing endoscope, some means to prevent PEP and careful observation after ERCP should be considered. In addition, it is desirable that devices dedicated to ERCP with the forward-viewing endoscope should be developed.

Contact E-Mail Address: jotillfernandes@gmail.com
Introduction: ERCP is the first choice for the removal of biliary and pancreatic stones. In difficult stones, advanced therapeutic techniques, such as electrohydraulic lithotripsy (EHL) and laser lithotripsy (LL) have been proposed. Recently, the availability of single-operator cholangiopancreatoscopy (SOCP) turned these techniques more accessible and easier to perform.
Aims and Methods: We sought to evaluate the clinical efficacy and safety of SOCP guided-lithotripsy using EHL or LL in patients with complex biliary and pancreatic stones.
A prospective study was carried out in 3 hospitals, comprising 30 consecutive patients with complicated biliary and pancreatic stones treated with SpyGlass DS (Boston Scientific, Marlborough, United States) guided-lithotripsy using EHL or Holmium LL. We analyzed the complete cleaning of the ducts, the incidence of adverse events, the impact of the number of stones and its location on clinical success, and the performance of the 2 lithotripsy modalities.
Results: 22 patients (73.3%) had common bile duct/common hepatic duct stones, 2 patients (6.7%) had a single cystic stump stone, 4 patients (13.3%) had pancreatic calculi and 2 patients (6.7%) had intrahepatic stones. 28 patients (93.3%) were successfully treated in one procedure and the remaining 2 patients (6.7%) required additional sessions to obtain cleaning of the ducts. 22 patients were treated with LL and 8 patients with EHL; 2 of the EHL-treated patients required more than 1 probe in the first ERCP; 1 of these patients was submitted to a subsequent ERCP in which LL was opted in, with success. The median duration of each session was 62 minutes (30–110). Complications were mild in 6 patients (20%) and included fever (n = 4), pain (n = 1) and mild pancreatitis (n = 1).
Conclusion: SOCP guided-lithotripsy using EHL or LL in patients with difficult biliary and pancreatic stones is very effective and is associated with transient and mild complications. There is a clear need for comparative studies between EHL and LL.

Introduction: Selective biliary duct cannulation is an essential prerequisite for biliary ERCP. Some authors suggest that the difficulty of biliary cannulation and the use of rescue techniques (rT) can be conditioned, among other factors, by the papillary morphology.
Aims and Methods: We intend to evaluate if the duration of biliary cannulation, the existence of a difficult cannulation and the use of rT are influenced by the papillary morphology.
This was a multicenter (3) prospective cohort study, including consecutive patients referred for ERCP with naïve papilla between August 2017 and January 2018, performed by experienced endoscopists (> 4000 CPREs). The papillae were classified into 4 types: non-prominent, prominent, bulging and distorted (Leés classification). The transverse, longitudinal papilla diameters and the diameter of the distal bile duct were measured. Primary outcomes: duration of biliary cannulation (tbc), difficult cannulation and rT. The influence of papilla type/dimensions on outcomes was assessed by multiple linear and logistic regressions.
Results: We included 106 patients, 43 men (40.57%), median age = 79 years (26–96). The main indication: suspected obstruction of the biliary tract in 83.02%. The success rate of biliary cannulation was 100%; 29.24% of the cannulations were considered difficult. Rescue access techniques were used in 28.3% of the non-prominent papillae, 41.18% of the prominent ones, 30.77% of the bulging

and 16.67% of the distorted ones. In patients with non-prominent papillae (50%), tbc = 3.35 mins (iqr = 6.84); in the prominent papillae (32%), tbc = 5.08 mins (iqr = 8.53); in the bulging papillae (12.26%), the tbc = 2.25 mins (iqr = 5.66); in the distorted (5.66%), tbc = 2,025 mins (iqr = 7.51). In the multivariate analyzes the papilla type/dimensions did not show to be a predictor of the 3 outcomes evaluated.
Conclusion: Contrary to what is stated in the literature, the type and dimensions of the papilla do not correlate with the difficulty of cannulation nor condition the techniques used.

P0214 THERAPEUTIC ENDOSCOPIC RETROGRADE CHOLANGIOGRAPHY IN PATIENTS WITH ALTERED GASTROINTESTINAL ANATOMY

R Koyama, Y Sato, T Tamura, Y Koizumi, T Imamura
Toranomon Hospital, Dept. of Gastroenterology, Tokyo, Japan

Contact E-Mail Address: rikako@pm.highway.ne.jp
Introduction: Endoscopic retrograde cholangiography (ERC) is an endoscopic procedure that is globally used for the treatment of biliary disease. However, ERC in patients with surgically altered gastrointestinal (GI) anatomy remains a challenging procedure due to the difficulty of reaching the target site. Consequently, percutaneous interventions or open surgery have been selected in these patients in spite of being more invasive procedures. Today the progression of techniques and devices like a Double-balloon endoscope (DBE) enables us to perform ERC on these patients. The aim of this study is to evaluate the utility and safety of therapeutic ERC in patients with surgically altered GI anatomy (except for Billroth-I reconstruction).
Aims and Methods: A total of 2314 consecutive ERCP procedures were performed at Toranomon Hospital during a 5- year period (2012 to 2016). 105 ERC procedures for biliary disease on 67 separate patients with altered GI anatomy were included in this study. We retrospectively investigated: (1) the success rate of reaching the target site; (2) the success rate of cholangiography; (3) the therapeutic success rate (the success rate of ERC-related interventions); (4) the occurrence of adverse events.
Results: The mean age was 69.7 years, ranging from 37 to 87 years; 43 were male and 24 were female. The most common reconstruction technique was Roux-en-Y reconstruction, which was performed in 54 cases, followed by biliojejunal anastomosis in 48 cases, Billroth-II reconstruction in 12 cases, and bilioduodenal anastomosis in 5 cases. Bile duct stone 59% (n = 62), benign bile duct stenosis 19% (n = 20), pancreatic cancer 9.5% (n = 10), hepatocellular carcinoma 3.8% (n = 4), bile duct cancer 2.9% (n = 3) were major indications. Bile duct stone extraction was performed in 46.7% (n = 49), plastic stent and self-expanding metal stent (SEMS) was positioned for biliary drainage in 42.9% (n = 45) and 1.9% (n = 2), respectively. The results of the above investigations were: (1) 92.4% (97/105), (2) 97.9% (95/97), (3) 83.8% (88/105). Adverse events occurred in 9 cases (8.6%) with perforation 3.8% (n = 4), pancreatitis 1.9% (n = 2), aspiration pneumonia 1.9% (n = 2), and cholangitis 1% (n = 1). They were successfully treated conservatively in all patients with the exception of 1 in whom a perforation developed, requiring emergency surgery. Procedure-related mortality did not occur.
Conclusion: ERC in patients with surgically altered GI anatomy remains a challenging procedure. But today, the number of the successful therapeutic ERCs is increasing in these patients by using DBE or PCF. Successful therapeutic ERC was achieved in 83.8%, a relatively high figure and the rate of adverse events were relatively low in this study. Therapeutic ERC should be performed positively for biliary disease, even if it's a case of altered GI anatomy.
Disclosure: Nothing to disclose

Introduction: Several studies have compared Endoscopic Ultrasonography (EUS) fine needle aspiration (FNA) to biopsy (FNB) needles, but none has proven the superiority of 1 needle over the other.
Aims and Methods: As studies were either underpowered or confined to 1 geographical region, we performed an investigator-initiated global randomized controlled trial, to compare the performance of a novel 20G FNB to a 25G FNA needle. 13 EUS-centers from 5 continents randomized consecutive patients with a solid lesion for FNB (ProCore) or FNA (EchoTip Ultra). Primary endpoint was diagnostic accuracy for malignancy and for the Bethesda classification (non-diagnostic, benign, atypical, malignant). Secondary, technical success, safety, and sample quality were assessed. Multivariable and supplementary analysis were performed to adjust for confounders.
Results: 608 patients were allocated to FNA (n = 306) or FNB (n = 302), encompassing 312 pancreatic lesions (51%), 147 lymph nodes (24%), and 149 other lesions (25%). Technical success rate was 100% for FNA and 99% for FNB (p = 0.043), without differences in adverse events. FNB outperformed FNA in terms of histological yield (77% vs. 44%, p < 0.001), accuracy for malignancy (87% vs. 78%, p = 0.002) and Bethesda classification (82% vs. 72%, p = 0.002). This was robust to correction for indication, lesion size, number of passes, and an on-site pathologist (OR 3.53, 95% CI 1.51–8.26, p = 0.004), and did not differ between centers (p = 0.836).
Conclusion: The 20G FNB needle outperforms the 25G FNA needle in terms of histological yield and diagnostic accuracy. This diagnostic benefit was irrespective of lesion type and consistent amongst participating centers, supporting general applicability of our findings.
Disclosure: This investigator-initiated study was supported by means of an unrestricted grant from Cook Medical

P0216 CHOLANGITIS AFTER ENDOSCOPIC ULTRASOUND IN PATIENTS WITH BILIARY STRICTURES AND ASSOCIATED RISK FACTORS

K Ikezawa[1,2], M Shigekawa[1], T Tamura[1], K Sato[1], M Urabe[1], H Sueyoshi[1], T Yamai[1], T Suda[1], T Kegasawa[1], T Yoshioka[1], R Sakamori[1], T Tatsumi[1], T Takehara[1]

Introduction: Endoscopic ultrasound (EUS) and EUS-guided fine needle aspiration (FNA) have emerged as an efficient diagnostic tool for pancreatobiliary diseases and have been considered to be a safe modality because of low risk of complications such as bleeding, perforation and pancreatitis. However, the risk of cholangitis after EUS/EUS-FNA in patients with biliary strictures has not

been fully examined. In this study, we examined the rate and the risk factors of cholangitis after EUS/EUS-FNA in these patients.
Aims and Methods: We retrospectively reviewed the data of 138 inpatients with biliary strictures who underwent EUS/EUS-FNA at our institution between April 2012 and September 2017. We excluded 8 patients with percutaneous biliary drainage, 5 patients with difficulty in reaching duodenum and 1 patient who underwent EUS/EUS-FNA and ERCP at the same day. Cholangitis and its severity were diagnosed based on Tokyo Guidelines 2013.
Results: 125 patients (147 cases in total) were included; 59.2% were male; median age was 71. 92 patients (73.6%) were malignant (49 patients, pancreatic cancer; 13 patients, distal cholangiocarcinoma; 18 patients, hilar cholangiocarcinoma; 2 patients, intrahepatic cholangiocarcinoma: 3 patients, gallbladder cancer; 7 patients, the others) and 33 patients were benign (13 patients, IgG4-related disease; 1 patient, primary sclerosing cholangitis; 2 patients, tumor-forming pancreatitis; 17 patients, the others). The location of biliary strictures was 106 cases in distal (72.1%), 30 in hilar (20.4%), 4 in intrahepatic (2.7%) and 7 in spreading (4.8%). Endoscopic biliary stenting (EBS) had been already performed before EUS/EUS-FNA in 86 cases (58.5%). Median time from EBS to EUS/EUS-FNA was 21 days (range; 1–125 days). EUS-FNA was performed in 57 cases (38.8%). Cholangitis was observed in 4.1% (6/147). The severity was mild in 2, moderate in 3 and severe in 1 case. The patient who suffered from severe cholangitis underwent urgent endoscopic nasal biliary drainage at the day of EUS. The incidence of cholangitis in the cases with EBS was significantly higher than those without EBS (7.0% (6/86) vs. 0% (0/61), $p = 0.042$). Other statistically significant risk factors of cholangitis were gamma-GTP levels ($> 1.5 \times$ upper limit of normal (ULN) (7.2%, 6/83) vs. $< 1.5 \times$ ULN (0%, 0/64), $p = 0.030$) and ALP levels ($> 1.5 \times$ ULN (10.7%, 6/56) vs. $< 1.5 \times$ ULN (0%, 0/91), $p = 0.003$). Age, gender, malignant/benign disease, the location of biliary strictures, endoscopic sphincterotomy, examination time, examination with/without EUS-FNA, WBC, CRP, AST and ALT were not significant risk factors. In the cases with higher ALP levels, cholangitis occurred in 16.7% of the cases with EBS (6/36), while no cholangitis occurred in the cases without EBS (0/20).
Conclusion: The rate of cholangitis after EUS/EUS-FNA was 4.1% in the cases with biliary strictures. The use of prophylactic antibiotics might be beneficial in these cases, especially the cases with EBS and biliary enzyme elevation.

P0217 EFFICACY AND SAFETY OF ENDOSCOPIC RADIOFREQUENCY ABLATION FOR METASTATIC PANCREATIC RENAL CELL CARCINOMA: A MONOCENTRIC EXPERIENCE

M Giovannini[1], B Chanez[2], J Walz[2], J.P Ratone[2], G Pignot[2], F Caillol[1], J Thomassin[2], C Pesenti[1], S Brunelle[2], N Salem[2], S Dermeche[2], **E Bories**[2], G Gravis[2]
[1]*Paoli-Calmettes, Dept. of Endoscopy, Marseille, France*
[2]*Paoli-Calmettes, Marseille, France*

Contact E-Mail Address: erwan.bories@outlook.fr
Introduction: Glandular metastasis (GM) from metastatic renal cell carcinoma (mRCC) are rare but associated with good prognosis and pancreas metastasis (PM) is the more frequent site. The management of PM only, is surgery or tyrosine kinase inhibitor (TKI). Endoscopic radiofrequency ablation (ERFA) is a very innovative approach to control metastasis and have never been reported to treat PM from mRCC.
Aims and Methods: We report a monocentric, prospective analysis for local control and toxicity of patients (pts) treated by ERFA for progressive PM from mRCC. ERFA was performed under general anesthesia, with a linear EUS scope and a 19 G RFA needle; time of ablation was short (30sec –1 mn), 1 or 2 shots were needed to ablate a 2 cm lesion.
Results: 6 pts from Paoli Calmettes Institute (France) were recruited between May 2017 and January 2018. Median age was 72y (69–73), 4/6 female, ECOG 0 (100%). The median time from diagnosis to PM was 14 years (9.98–22.18), median number of PM was 2 (1–3), 5/6 was documented by histology and all were classified as progressive before ERFA. PM localizations was: head in 40%, body 40%, tail 20% and average size was 19.6 mm. 80% of pts (4/6) had other mRCC spread, 4/6 received systemic treatment and 2 of them were on therapy at ERFA time (1 TKI, 1 Nivolumab). 2 pts had ERFA as the only treatment for oligometastatic RCC. Median number of ERFA sessions was 2 (1–3). With a median follow up of 6.6 months (0.5–9.3), 5/6 pts had local control (with 2 CR). 1 patient treated by TKI during procedure, developed a paraduodenal abscess 2 months after ERFA and was drained endoscopically. Pancreatitis or diabetes were not reported and no toxicity was observed for pt treated with nivolumab.
Conclusion: ERFA is feasible and displays an excellent local control for PM without any major side effect. However TKI should be stop before the procedure to avoid complications. ERFA could be a valuable option, less morbid than pancreas resection for progressive PM.
Disclosure: Nothing to disclose

P0218 GRANULOMATOUS LYMPHADENITIS - TO REACH A DEFINITIVE DIAGNOSIS IN INDIAN POPULATION. A PROTOCOL-BASED STUDY

P.N Desai[1], M Kabrawala[2], C Patel[1]
[1]*Surat Institute Of Digestive Sciences, Endoscopy, Surat, India*
[2]*Surat Institute of Digestive Sciences, Gastroenterolgy, Surat, India*

Contact E-Mail Address: drp_desai@hotmail.com
Introduction: In India mediastinal and abdominal lymphadenopathy is widely seen. In cases where EUS-guided FNA reveals granulomatous disease, to identify the real cause we devised a specific protocol.
Aims and Methods: Retrospective analysis of last 1 year data of EU FNA and FNB with a specified protocol to reach a final diagnosis in granulomatous lymphadenitis in India.
Protocol: from September 2016 to October 2017. 6 passes for each node sampling with a 22 G Aquire needle. 2 passes - cytology, 2 passes- Core biopsy for histopathology and Immunohistochemistry, 2 passes- Core biopsy in saline for Gene Xpert and SOS AFB Culture. If granuloma found on cytology -subjected to Gene Xpert and AFB Culture. If malignant on cytology- excluded. Only with granulomas on smear - caseating or non caseating were included.
Results: No of cases of lymphadenopathy that underwent EUS-guided FNA in a period of 1 year from October 2016 to October 2017 - 38 Granulomatous lymphadenitis on FNA cytology found - 26 (68.4%) Cases which had other diagnosis than granulomas - 12 (31.6%) Gene Xpert was done in 24 /26 cases - 92.3% TB culture was done in 21/26 cases - 80.7% Positive either for gene Xpert or TB culture or both - 12/26 - 46.1% Out of 12 positives: Gene Xpert positive - 7 /11 (63.6). Xpert was not done in one case Culture positive - 7 /10 (70%). Culture was not done in 2 cases Xpert negative but positive on culture - 4 cases (33.3%) TB CULTURE - correlated with presence of caseation in smears &/or biopsies caseous necrosis - identified in 7/12 positive cases (58.3%) Cases positive on Xpert or culture and showed non caseating granuloma on cytology & histology - 5 (41.6%) Granulomatous lymphadenitis which were negative on culture & Xpert were evaluated clinically - 14 Raised ACE levels- 1 (7.1%) - Diagnosed as sarcoidosis Empirical ATT & were followed up for response - 13 (92.8 %) Responded to ATT - 13 (100%).
Conclusion: In our region (India and the Asian nations) - Granulomatous Lymphadenitis is major cause lymphadenopathy. Of the positive granulomatous nodes - a definitive diagnosis of tuberculosis was obtained in around half the cases only with all expensive tests. But of the remaining cases, almost 93% responded to Anti Tubercular Treatment when followed up clinically. Only 1 case of all the granulomatous cases turned out to be sarcoidosis. Therefore, if we see granuloma on smear of any lymph node during FNA, giving a trial of ATT sounds prudent. However further studies are warranted to confirm this. Clinical setting will impact our diagnosis. Should look for non-responders to ATT and do ACE levels to rule out sarcoidosis. Of course a culture and sensitivity should be done all cases that we can rule any drug resistance.
Disclosure: Nothing to disclose

P0219 WHICH APPROACH IS BETTER FOR PANCREATIC NECROSECTOMY - COMPARING DATA IN A TERTIARY REFERRAL CENTRE IN INDIA

P.N Desai[1], M Kabrawala[2], **C Patel**[3], K Bhatt[1], D Mangukiya[3]

Introduction: Minimal access techniques have gained popularity for the management of necrotizing pancreatitis, but only few studies compared open necrosectomy with a less invasive treatment.
Aims and Methods: We aimed to evaluate the outcomes of minimally invasive treatment including endoscopic methods for necrotizing pancreatitis in comparison with open necrosectomy in our own data.
Our data were compared in 3 groups - Surgery, Minimal Access Surgery and EUS Guided Drainage for management of walled of necrosis.
Total Number of patients with acute pancreatitis between October 2010 to March 2017: **1860,** Number of patients with necrotizing pancreatitis: **572 (30.7%),** Number of patients with Walled of Necrosis: **266 (46.5%),** Procedures Offered: **Open surgery, Endoscopic transgastric approach & Minimal access Necrosectomy (MAN)** - Including (Retroperitoneal Videoscopic Approach, Laparoscopic approach, Transgastric approach, Laparoscopic transabdominal, Hybrid- open surgery + retroperitoneal approach).
Number of Sessions in Open Surgery: 1 in 44 of 48 (91.7%), Repeat Sessions in Open Surgery: 4 of 48 (8.3%), Number of Sessions in MAN: 56 of 56 (100%), Number of sessions in Endoscopy: Average 4. Average time for first session was 25 min with plastic stents, 15 minutes with metal stents. Average time for the second session and third was 20 min, Outcome and data in all 3 groups compared. Follow up –6 years to 3 months. All the patients tolerated the procedures well,
Bleeding: 3 patients in endoscopy & Open surgery each and 1 in MAN. Endoscopic procedures were abandoned and patients were subjected to laparoscopic transabdominal surgery, all 4 patients were angioembolized from the bleeding vessel of which 1 patient died.
Wound infections - 42 vs 8 in open and MAN
Intestinal fistulae 4 vs 1 in open and MAN (Controlled retroperitoneal fistula treated without ileostomy); 4 were treated with Laparotomy and ileostomy.
Pulmonary complications were 24, 6 and 2 in open, MAN & Endoscopy

Average length of ICU stay in MAN group was 3.57 vs 8.14 days in case of open vs 2.04 days in Endoscopy.
The average length of hospital stay after ICU - 11.33 vs 12.7 vs 11.8 days in open vs MAN vs endoscopy respectively.
Mortality - (0.6%) in Endoscopy vs 3 (5.35%) in MAN vs 12 (25%) in open
Incisional hernia - 8 vs 3 patient in open vs MAN.
Average time of doing intervention in Endoscopy was 45th day (32 - 75days), while MAN was 34th day (24 to 50 days) and Open was 33rd (18 to 40 days) day of illness.
Results: Endoscopic necrosectomy - 162, Trans gastric surgery - 18, Laparoscopic surgery - 10, Retroperitoneal minimal access surgery - 20, Retroperitoneal Videoscopic + laparoscopic/open - 8, Conventional open surgery - 48
Conclusion: Later the necrosectomy better the outcome. No statistical difference in clearance of the necrosis when all groups were compared head to head.
Endoscopic necrosectomy with plastic or SEMS (LAMS Excluded) - technically feasible in upto 50% necrosis- should be preferred whenever possible.
More necrosis - minimally access necrosectomy - better technique compared to open & endoscopy not possible.
Open surgical techniques - More risk of fistula formation than minimal access group and least with endoscopic group.
More bleed in conventional open and transgastric approach.
Endoscopic approach - limitation- Not useful in early days.
Pulmonary complications are more in the open.
ICU stay - more in open and minimal access group.
More mortality in open and MAN groups.
Mortality in endoscopy group - 1. Due to serious septic complications. Salvage open lavage done but succumbed.

P0220 ROLE OF ENDOSCOPIC ULTRASOUND-GUIDED FINE NEEDLE ASPIRATION OF PORTAL VEIN THROMBUS IN THE DIAGNOSIS AND STAGING OF HEPATOCELLULAR CARCINOMA

A Altonbary, H Hakim, D Eskandere, M Hamed
Mansoura University, Gastroenterology and Hepatology, Mansoura, Egypt

Contact E-Mail Address: a.tonbary@gmail.com
Introduction: Portal vein thrombosis (PVT) is being increasingly diagnosed. Presence of neoplastic thrombus serves as an important determinant of tumor staging, as well as prognosis, and influences treatment selection. In some cases, it may be the initial sign of an undetected HCC. Therefore, accurate differentiation of bland from neoplastic thrombus is crucial for patient treatment.
Aims and Methods: This is a prospective study that included 11 cirrhotic patients with PVT which don't fulfill the criteria of malignancy by imaging techniques; either with or without hepatic mass or undergone local treatment following a diagnosis of HCC and develop PVT during their follow-up. Under EUS guidance, the main, left and right portal veins were identified and a 22-gauge EUS-FNA needle was advanced from the duodenum into the portal vein, 1–2 passes through portal vein thrombus were taken. The puncture site was monitored under EUS for complications. To assess the ease, safety, and efficacy of EUS-FNA in characterizing the nature of the PVT which don't fulfill the criteria of malignancy via imaging techniques.
Results: Out of 11 patients; 7 patients (64%) were males. 6/11 were cirrhotic without liver masses, 4/11 HCC and 1/11 developed PVT during follow-up after TACE for HCC. EUS-FNA was done using 22G needle from main portal vein in 9 patients and from right portal vein in 2 patients. Pathological examination was malignant in 1 patient with HCC and non-enhancing PVT by CT abdomen. No complications were reported in any case.
Conclusion: EUS-FNA is an effective and safe method in characterizing the nature of PVT which don't fulfill the criteria of malignancy via imaging techniques. We believe that EUS-FNA should be utilized more frequently in the diagnosis and staging of HCC.

P0221 EVALUATION OF THE ROLE OF ENDOSCOPIC ULTRASOUND-GUIDED GASTRIC BOTULINUM TOXIN INJECTIONS IN THE TREATMENT OF OBESITY

A Altonbary[1], M Bahgat[1], S Sief[1], M Ragab[1], M Abd El-Ghany[2], A Gameel[1], H Hakim[1]

Introduction: Obesity is an important public health concern. In rats, botulinum toxin A (BTA) injected subserosally into the antrum resulted in significant decreases in caloric intake and body weight. Subsequent open-label human studies have reported conflicting results, finding little or no body weight loss after gastric BTA injection. We hypothesized that EUS guidance would help to assure injection of BTA in the gastric muscularis propria and subserosal layers.
Aims and Methods: To assess the safety, feasibility and efficacy of EUS-guided gastric Botulinum toxin A injections in obese subjects to reduce body weight. This is a pilot study that included 16 subjects with obesity (BMI > 30). Under EUS guidance, BTA injections (100U) were made with 25G needle. A ring of 5 injections were made into the antral muscularis propria; 2–3 cm proximal to the pylorus. During a 16 weeks follow-up period, subjects were weighed and completed the Gastrointestinal Symptom Rating Scale (GSRS) 2 weeks before and weekly after injection. Nutrient drink tests 1 week before and at 4 and 16 weeks after injection. No behavioral or dietary interventions were offered to study subjects.
Results: Out of 16 subjects; 15 subjects (93.7%) were females. Mean age was 34.5 years (21–43) and mean BMI was 41.5 (33–50). In a follow-up period of 16 weeks, weight loss ranged from 7 to 25 kg. Nutrient drink tests decreased from a baseline value 1200 cc (600–1800) to 420 cc (240–600) at 4 weeks. Mild elevation of the GSRS score was found in 2 subjects who reported diarrhea at 1–4 week in 1 subject and at 5–7 week in another 1. No vomiting, abdominal pain or any complications were detected in any subject.
Conclusion: EUS-guided botulinum toxin injection is an effective method for weight reduction which can be performed safely with minimal adverse events. However, further studies are still warranted.

Introduction: The primary aim was to evaluate the safety and feasibility of EUS-TTNB of PCLs. The secondary aim was to assess the potential incremental diagnostic yield of TTNB of mucinous cysts.
Aims and Methods: The primary aim was to evaluate the safety and feasibility of EUS-TTNB of PCLs. The secondary aim was to assess the potential incremental diagnostic yield of TTNB of mucinous cysts. Prospective multicenter study of consecutive patients undergoing EUS fine-needle aspiration (FNA) and TTNB for PCLs $\geq$ 15 mm in size between June 2016 to November 2017. Technical success by FNA or TTNB was defined as successful tissue acquisition of a specimen adequate for cytohistopathological evaluation. Cyst fluid CEA was used to initially categorize cysts as nonmucinous (CEA < 192ng/mL) or mucinous (CEA $\geq$192ng/mL). A cyst was determined to be mucinous on cytology or histology by the presence of mucinous pancreatic cystic epithelium.
Results: A total of 49 patients (mean age 64.4 ± 15.2 years; 51% women) were included in the interim analysis. Mean PCL size was 36.2 mm, range 15–200 mm. Technical success was significantly higher with TTNB (77.6%) compared to EUS-FNA (36.7%) ($p<0.001$) for PCL sampling. For cysts with insufficient amount of fluid for CEA ($n=14$) or CEA < 192 ng/mL ($n=24$), the cumulative incremental diagnostic yield of a mucinous cyst was significantly higher with EUS-TTNB (44.7%) compared to EUS-FNA (2.6%) ($p<0.001$). In all, there were 2 cases of self-limited intracystic bleeding (4.1%) that did not require additional interventions. There was 1 case (2%) of mild acute pancreatitis reported 48 hours after the procedure.
Conclusion: This interim analysis of our multicenter prospective study suggests that EUS-TTNB is safe and effective for the evaluation of PCLs. EUS-TTNB represents an additional tissue acquisition method that may help increase the diagnostic yield of pancreatic mucinous cysts during EUS.
Disclosure: Nothing to disclose

P0223 PROSPECTIVE MULTICENTER STUDY OF EUS-GUIDED THROUGH-THE-NEEDLE BIOPSY FOR SOLID LESIONS: AN INTERIM ANALYSIS

Introduction: EUS-FNA is standard practice for tissue acquisition of solid lesions adjacent to the gastrointestinal tract. An EUS-guided through-the-needle microforceps is a novel tissue acquisition device.
Aims and Methods: The aim of our study was to evaluate the safety and feasibility of EUS through-the-needle biopsy (TTNB) of solid lesions using the microforceps. Prospective multicenter study of consecutive patients undergoing EUS fine-needle aspiration (FNA) and TTNB of solid lesions $\geq$ 15 mm in size between June 2016 to November 2017. Demographics, size, location and final diagnosis were recorded. Technical success by FNA or TTNB was defined as successful tissue acquisition of a specimen adequate for cytohistopathological evaluation.

Results: A total of 45 patients (mean age 64.2 ± 15.3 years; 60% men) were included in the interim analysis. Mean lesion size was 44.1 mm, range 18–222 mm. The following sites were sampled: pancreas (n = 25; 55.6%), gastric/duodenal subepithelial lesion (n = 12; 26.7%), lymph nodes (n = 6; 13.3%), retroperitoneum (n = 1; 2.2%) and liver (n = 1; 2.2%). Technical success (adequate cellularity for cytohistopathological analysis) was similar between FNA (n = 42; 93.3%) and TTNB (n = 39; 86.7%) (p = .48). Diagnostic yield with FNA was 83.3% compared to 89.7% with TTNB (p = 0.5). There were no intra-procedural or post-procedural adverse events reported with FNA and TTNB.
Conclusion: This interim analysis of our multicenter prospective study suggests that EUS-TTNB is a safe and feasible technique for tissue acquisition of solid lesions. The diagnostic yield with TTNB was similar to that of FNA. EUS-TTNB represents a novel tissue acquisition method for the evaluation of solid lesions adjacent to the GI tract.

Introduction: Various gastrointestinal societies have released guidelines on the evaluation of asymptomatic PCs. These guidelines differ on several aspects, which creates a conundrum for clinicians.
Aims and Methods: An electronic survey distributed to members of the American Society for Gastrointestinal Endoscopy (ASGE). Main outcomes included practice setting (academic vs. community), preferences for evaluation, management, and surveillance strategies for PCs. An electronic survey distributed to members of the American Society for Gastrointestinal Endoscopy (ASGE). Main outcomes included practice setting (academic vs. community), preferences for evaluation, management, and surveillance strategies for PCs.
Results: 172 subjects completed the study (52% academic-based endoscopists). 86 (50%) and 138 (80%) of the participants responded that they would recommend EUS surveillance of incidental PCs measuring less than 2 cm and 3 cm, respectively. Nearly half of the endosonographers (42.5% community and 44% academic; p = 1.0) would routinely perform FNA on PCs without any high-risk features. More academic-based endoscopists (57% academic vs. 32% community; p = 0.001) would continue incidental PC surveillance indefinitely.
Conclusion: There is significant variability in the approach of incidental PCs among clinicians, with practice patterns often diverging from the various GI societal guideline recommendations. Most survey respondents would routinely recommend EUS-FNA and indefinite surveillance for incidental PCs without high-risk features. The indiscriminate use of EUS-FNA and indefinite surveillance of all incidental PCs is not cost-effective, exposes the patient to unnecessary testing, and can further perpetuate diagnostic uncertainty. Well-designed studies are needed to improve our diagnostic and risk stratification accuracy in order to formulate a consensus on the management of these incidental PCs.

Introduction: Despite evidence suggesting a role of chronic pancreatitis (CP) in pancreatic carcinogenesis, its relationship with invasive intraductal papillary mucinous neoplasm (invasive IPMN) and pancreatic cancer (PC) in concomitant with IPMN (PC with IPMN) remains unclear. Endoscopic ultrasonography frequently reveals evidence of CP (EUS-CP findings) in the background pancreatic parenchyma of patients with IPMNs.
Aims and Methods: We investigated whether EUS-CP findings were associated with a higher incidence of invasive IPMN or PC with IPMN. This study included 104 patients who underwent preoperative EUS and surgical resection for IPMN (N = 86: IPMA N = 62, Invasive IPMN N = 24) and PC with IPMN (N = 18) between January 2010 and August 2016. The association of EUS-CP findings (total number of EUS-CP findings; 0 vs. ≥1) with invasive IPMN or PC with IPMN was examined. The association of EUS-CP findings with pathological changes of the background pancreatic parenchyma (atrophy/inflammation) was also examined.
Results: EUS-CP findings were significantly more frequently observed in Invasive IPMN (for Invasive IPMN vs IPMA: multivariable odds ratio [OR] = 2.8, 95 % confidence interval [CI] = 1.08–7.72, p = 0.03), but not in PC with IPMN (for PC with IPMN vs. other IPMNs: OR = 0.4, 95 % CI = 0.09–1.29, p = 0.12). In addition, EUS-CP findings were also associated with higher-grade pancreatic atrophy and inflammation (EUS-CP findings absent vs. present: 13.1%(8/61) vs. 25.6%(11/43), p = 0.13, 8.2%(5/61) vs. 25.6%(11/43), p = 0.02, respectively).
Conclusion: Detection of EUS-CP findings in the background pancreatic parenchyma was associated with a higher prevalence of invasive IPMN, but not with PC with IPMN.

Contact E-Mail Address: amy.tyberg@gmail.com
Introduction: EUS-directed transgastric endoscopic retrograde cholangiopancreatography (EDGE) is a minimally invasive option for ampullary access or head of pancreas access in patients with roux-en-y anatomy. The procedure involves creating a fistulous tract between the remnant stomach or jejunum and the bypassed stomach with deployment of a lumenapposing metal stent (LAMS), followed by advancement of an endoscope through the LAMS to perform an ERCP or EUS. It is a technically challenging procedure, requiring skills in EUS, fluoroscopy, and LAMS deployment. The aim of this study was to determine the learning curve for EDGE.
Aims and Methods: Consecutive patients undergoing EDGE by a single operator were included from a prospective registry from Aug 2014 to Oct 2017. Demographics, procedure info, post-procedure follow-up data, and adverse events were collected. Nonlinear regression and CUSUM analyses was conducted for the learning curve. Technical success was defined as successful creation of fistulous tract. Clinical success was defined as successful EUS or ERCP via the LAMS.
Results: 19 patients were included (21%M, mean age 58.7 years). Indication included symptomatic biliary stricture (n = 6, 32%), choledocholithiasis (n = 5, 26%), pancreatitis (n = 3, 16%). Technical success was 100%. All patients had a 15mm LAMS placed, 3 (16%) had cautery-LAMS. Clinical success was achieved in 18/19 (95%) patients. 14 patients had an ERCP, 1 patient had an EUS, and 3 patients had both. 5 patients had the EUS or ERCP performed during the same session as fistula creation; the remaining 14 were separated by 2–3 weeks. 13 patients had their LAMS removed and fistula closed. 1 patient had bleeding requiring EGD with clipping post-procedure; 3 patients required a bridging stent, 1 for tamponade and 2 for misdeployment. No other adverse events were noted. Median procedure time was 54.5 mins (range 31 - 88 mins). CUSUM chart shows 54 minute procedure time was achieved at the 9th procedure hence indicating efficiency. Apart from 2 outliers, the procedure duration further reduced with consequent procedures with the last 3 being under 40 minutes indicating at that after 25–35 procedures a plateau may be reached indicating mastery (nonlinear regression p < 0.0001)
Conclusion: Endoscopists experienced in EDGE are expected to achieve a reduction in procedure time over successive cases, with efficiency reached at 54.5 minutes and a learning rate of 9 cases. After 25–35 procedures, a plateau may be reached indicating mastery

[2]*Kitasato University Hospital, Sagamihara, Japan*

Contact E-Mail Address: m-kida@kitasato-u.ac.jp
Introduction: Endoscopic ultrasonography-guided fine-needle aspiration (EUS-FNA) has become a indispensable examination in the clinical fields. Furthermore, therapeutic EUS such as pseudocyst drainage, EUS-biliary drainage, and EUS-pancreatic duct drainage, etc. have become popular year by year. Generally, it is important to learn EUS-anatomy by books and DVDs at first. And it has been believed that the learning of EUS-FNA takes a long time and a certain number of case experiences are essential, in order to become a good endosonographer. On the other hand, clinical cases are not enough for training young endosonographers and hands-on training with models are able to reduce the number of performing clinical EUS-FNA on training programs. Therefore, we have developed newly designed model for training EUS-FNA and therapeutic EUS-FNA procedure and investigated its usefulness and limitations.
Aims and Methods: We have made a model for EUS-FNA with Olympus Co. and pseudocyst model by non-rupture-balloon (Sumitomo Bakelight Co., Tokyo) which is 8cm in diameter. This balloon is filled with lubricant, and these models are puts into water tank. We have tried this model at Kitasato hands-on training workshop with 16 attendees who have experienced 100 to 700 diagnostic EUS examinations and 0 to 50 EUS-FNA procedures. We have investigated whether all attendees can complete EUS-FNA of the pancreas and pseudocyst drainage or not, and how long it takes to complete the procedure. Furtheremore, we have checked their impression of this model. We have employed UCT-260 (Olympus Co., Tokyo), 19G EUS-FNA needles and 7Fr plastic stent as a drainage tube.
Results: All attendees have found the pancreas which is located behind the stomach and performed EUS-FNA in the target of the pancreas. Concerning about pseudocyst model, attendees firstly have to look for a good position for pseudocyst drainage. Secondly, attendee punctures the balloon with 19G needle and put a 0.035 inch guidewire in pseudocyst model. Thirdly, attendee pushes a dilator into the pseudocyst model and finally puts a 7 Fr drainage tube in the model. All attendees completed pseudocyst dranage with 6.5 minutes in average. No balloons have not ruptured during these procedures and all kept the balloon size, in spite of some leakage. According to their impression, resistance of puncture and putting in a stent is less, compared with clinical cases, however it is very useful to understand EUS-guided pseudocyst drainage and EUS-FNA.
Conclusion: We concluded that newly designed pseudocyst model is useful to train the beginner, in order to understand the procedure. Furthermore, using this model, we can do hands-on training everywhere and there is no necessity of animal laboratory because of dry model.
Disclosure: Nothing to disclose

P0229 THE FEASIBILITY AND EFFICACY OF ENDOSCOPIC ULTRASOUND-GUIDED LIVER BIOPSY USING A CORE NEEDLE FOR HEPATIC SOLID MASSES

H.K Chon[1], T.H Kim[2]

Introduction: Evaluate feasibility and efficacy of EUS-guided fine-needle biopsy (FNB) using a core needle for hepatic solid masses (HSMs). Also, assess the factors that influence diagnostic accuracy of EUS-FNB for HSMs.
Aims and Methods: A retrospective analysis of patients who underwent EUS-FNB for the pathological diagnosis of HSMs between January 2013 and July 2017 was conducted. The procedure was performed with core needles of different calibers. The variable evaluated were mass size, route of puncture, needle type, and number of needle passes.
Results: During study period, 58 patients (23 female; mean age, 68.0 ± 11.5 years [range, 42–86]) underwent EUS-FNB for pathologic evaluation of HSMs with a mean size of 21.4 ± 9.2 mm. EUS-FNB with 20G (n = 14), 22G (n = 29) or 25G core needle (n = 15) was performed (right lobe: n = 16, left lobe: n = 39, caudate lobe: n = 3). The median number of needle passes was 2.6 ± 0.8 (range, 1–5). The diagnostic accuracy were 89.7%, but both specimen adequacy for histology and available immunohistochemistry stain was 91.4%. The sensitivity and specificity of EUS-FNB were 89.7 and 100%, respectively. Additional information regarding cytology results increased sensitivity, and diagnostic accuracy of 93.1%, respectively. There was 1 bleeding complication, but well-controlled with endoscopic hemostasis. The median score of the procedure related pain using visual analog scale (VAS) was 1.76 ± 0.68 and 50 patients (86.2%) had a pain score of less than 2. No variable were independently associated a correct final diagnosis according to the multivariate analysis.
Conclusion: EUS-FNB with core biopsy needle is a safe and highly accurate diagnostic option for assessing HSMs. There was no variable factors associated with diagnostic accuracy.
Disclosure: Nothing to disclose

P0230 A MULTI-CRITERION, FULLY AUTOMATED, HIGH-PERFORMANCE, RAPID TOOL ASSESSING THE MUCOSAL VISUALIZATION QUALITY OF STILL IMAGES IN SMALL BOWEL CAPSULE ENDOSCOPY

S Oumrani[1], A Histace[2], E Abou Ali[1], O Pietri[1], A Becq[1], G Houist[1], I Nion Larmurier[1], M Camus[3], C Florent[1], X Dray[3]

[3]*University paris 6, Saint Antoine Hospital, Paris, France*

Contact E-Mail Address: sarra.oumrani@gmail.com
Introduction: Capsule endoscopy (CE) is the preferred method for small bowel (SB) exploration. Its diagnostic yield can be reduced by poor mucosa visualization secondary to the presence of residues, bile, bubbles in the digestive luminal, or due to insufficient or excessive brightness. An electronic evaluation, image by image, is likely to be more efficient and reproducible than human evaluation of full length videos. The main objective of this study was to evaluate diagnostic performances of 3 computerized parameters, isolated and then combined, to assess quality of SB mucosa visualization for 3rd generation CE still images: (a) red/green ratio pixels of the image (1); (b) an index reflecting the abundance of the bubbles based on a gray-scale co-occurrence matrix (GLCM) (2); (c) an index reflecting the image's brightness.
Aims and Methods: 600 still images were randomly extracted from 30 full and normal SB-CE. 3 experimented CE readers evaluated these images according to an assessment grid with 5 items and 10 points, based on the quantitative scale by Brotz et al (3): mucosa visibility (2 points), brightness of the picture (2 points), bubbles abundance (2 points), bile and chime abundance (2 points), liquids and residues abundance (2 points). An image was judged to be of good visual quality when the mean score was $\geq$ 7/10. These images were analyzed electronically according to the 3 pre-cited parameters (ratio of red/green pixels, abundance of bubbles, brightness). A random forests methodology was used for machine learning and testing. Performances of the electronic analysis, using the expert's analysis as reference, were compared for each of the 3 electronic parameters individually and then combined.
Results: Combination of the 3 parameters on the computerized analysis of the 600 images compared to the experts' evaluation achieved the highest diagnostic performances, to discriminate between adequately and inadequately cleansed still frames. Sensitivity was of 90.01% (95% CI [84.12–95.88]) and specificity 87.73% (95% CI [81.63–94.37]), positive and negative predictive values were respectively of 81.10% (95% CI [73.31–88.69]) and of 93.70% (95% CI [88.94–98.46]). The mean time required to electronically analyze a still image using the 3 criteria test method was 34 ± 2 milliseconds using the MATLAB©software. An extrapolation on 50,000 images suggests a 28 minutes analysis of a full-length CE video.
Conclusion: We propose a novel, efficient, perfectly reproducible, automatic and rapid multi-criterion electronic score to determine the level of cleanliness of SB-CE still frames. This tool will be able to serve in clinical practice (to determine if the quality of preparation of SB-CE is acceptable) and research (testing different modalities of bowel preparation). A European patent is pending.

Introduction: Capsule endoscopy (CE) has become a standard non-invasive tool for small bowel (SB) examination. However, with an average number of 50,000 SB still frames per CE video, lesions can be missed and CE reading remains a time-consuming activity. Therefore, the development of computer-aided algorithms for lesions' detection has become an active research area in CE. Gastrointestinal angiodysplasias (AGD) are the most common SB vascular lesions with an inherent risk of bleeding. This study aimed to develop a computer-assisted diagnosis (CAD) tool for SB-AGD detection in CE.
Aims and Methods: A French national database (CAD-CAP) was created: 4166 deidentified third-generation SB-CE videos (Pillcam® SB3 system, Medtronic) were collected from 13 centers; 6013 pathological still frames were extracted from 1354 SB-CE with at least 1 pathological findings; 20,000 normal (control) still frames were extracted from 200 normal SB-CE videos. 600 still images with typical AGD were selected from the database by expert readers. 600 normal still frames were randomly extracted as controls. The 600 selected AGD were annotated on each individual pathological frame, as ground truth reference. 2 sets of 600 SB-CE still frames (300 normal frames and 300 frames with AGD per set) were created. Different learning-based algorithms were tested including color-based approaches and deep feature extraction. The first set of still frames was used for the machine learning process and the second set for the validation process.
Results: Among the tested algorithms, the 1 with the best diagnostic performance characteristics used a semantic segmentation images approach associated with an artificial convolutional neural network (CNN) for deep feature extraction (figure 1 from left to right: original image, annotated image, CNN approach, CNN approach on original image). This algorithm reached a 100% sensitivity, a 96% specificity, a 96% positive predictive value, and a 100% negative predictive value for AGD detection. Reproducibility was perfect (Kappa = 1.0).
Conclusion: This study shows that a computed algorithm based on a CNN has very good reproducibility, diagnostic sensitivity (100%), and specificity (96%), for detection of AGD on still frames. This study opens the way to automated SB-CE reading softwares, and calls for prospective evaluations of CNN at the video level. The CAD-CAP project is founded by the French National Society of Gastroenterology (SNFGE), and endorsed by the French Society of Digestive Endoscopy (SFED).

Introduction: Capsule Endoscopy (CE) is preferred method for small bowel (SB) exploration. With a mean number of 50,000 SB frames per video, SBCE reading is time-consuming and tedious (30 to 40 minutes per video). We describe herein a large, multicentric, public database named CAD-CAP (Computer-Assisted Diagnosis for CAPsule Endoscopy, CAD-CAP). This database aims to serve the development of CAD tools, from the initial steps (machine learning) to the last preclinical steps (assessment and comparison of performances).
Aims and Methods: 13 endoscopy French centres were involved, together with a research group specialized in signal treatment and analysis in medicine. All available Pillcam® SB3 (Medtronic) SB-CE videos were retrospectively selected from these centres and deidentified. Any pathological frame selected from the initial reading was extracted and included in the database. Manuel annotation was performed by premed students trained and supervised by an expert reader. All annotated lesions were then read again by a panel of 3 expert readers Any inadequate annotation was revised. Lesions were then classified both by type and clinical pertinence. An automated extraction process was also developped to create a dataset of normal, control images from normal, complete, SB-CE videos. For any extracted still frame (with or without a lesion), a short video sequence was also captured (9 secondes long, with 25 frames upstream and downstream of the index frame).
Results: 4,166 SB-CE were included. 1,127 videos (27%) containing at least 1 pathological frame were selected. 6,103 pathological frames (with their short video sequences) were extracted and annotated: 691 frames with fresh blood, 2946 frames with vascular lesions, 1676 frames with inflammatory lesions, and 790 frames with miscellanous lesions (including tumors and polyps). 20,000 normal frames (controls, with their short video sequences) were extracted from 206 SB-CE normal videos. CAD-CAP has already been used for the development of an automated angiodysplasia detection tool, with sensitivity of 100% and specificity of 96% (1). International challenges between research groups specialized in signal treatment and analysis in medicine have been organized, using the CAD-CAP database (2,3).
Conclusion: The CAD-CAP database is an innovative tool, serving the developement of artificial intelligence for SB-CE reading. Requests from academic research groups to use CAD-CAP will be made possible on www.sfed.org in September 2018.

Introduction: Video Capsule Endoscopy (VCE) is commonly used for evaluation of small bowel in patients with iron deficiency anemia. Patients undergoing VCE are typically instructed to end the recording after 8 hours. Due to limited recording time the presence of delayed gastrointestinal transit often leads to incomplete examination. The influence of Diabetes Mellitus (DM) on VCE is controversial - 1 study found prolonged gastric transition time and increased VCE failure rate in DM, while others didn't demonstrate correlation between the 2.
Aims and Methods: The aim of the study was to evaluate the influence of DM, with or without end-organ damage, on gastric and small bowel transit times, and on VCE examination completion rate.
In single center, retrospective study we investigated the records of patients who underwent VCE (PillCam, Given Imaging,Israel) for evaluation of iron deficiency during the period of 2010–2017. Only outpatient examinations were included. Patients with history of gastric/colonic/small bowel surgery, Parkinson's disease, Crohn's disease, chronic laxative use and active non-prostate malignancy were excluded. Demographic and VCE examination related data were collected. VCE was considered complete if the capsule reached cecum within the examination allotted time. DM-variables of interest included duration of the disease, use of insulin, presence of end-organ damage, average and peak HgA1c within the past 3 months prior to the VCE.
Results: A total of 254 patients met the inclusion criteria. 47% had type 2 DM. Patients with diabetic neuropathy had significantly prolonged small bowel transition time (SBTT) compared both to non-DM patients (5.24+/−1.18 VS 4.38+/−1.34 hours, p = 0.02) and to patients with DM without end-organ damage (5.24+/−1.18 VS 4.08+/−1.48 hours, p = 0.005). Likewise, patients treated with insulin had significantly prolonged SBTT compared to DM patients without insulin treatment (5.32+/- 1.19 VS 4.23+/−1.59, p = 0.007). Retinopathy and

nephropathy alone did not significantly influence SBTT. No correlation was found between average and peak HgA1c levels and SBTT.
Gastric transit time (GTT) was similar between the DM and non-DM cohorts (0.54 +/−0.67 hours VS 0.6 +/−0.82 hours, p = 0.55), and no correlation was found between GTT and either the presence of end-organ damage, HgA1c levels within 3 months from VCE, peak Hga1c or the duration of the disease.
VCE completion rate was significantly lower in DM patients with neuropathy compared to to those without end organ damage (87.5% VS 98%, p = 0.03). There was a trend towards lower VCE completion rate in patients treated with insulin or with multiple effected end-organs, however it didn't reach statistical significance. VCE completion rate was similar between non-DM patient and DM patients without end-organ damage (94% VS 98%, p = 0.11).
Conclusion: SBTT is significantly prolonged in DM patients with neuropathy or insulin treatment, and might lead to lower VCE completion rate in those patients. An *a priori* longer VCE recording time should be considered for patients with these conditions. For DM patients without end-organ damage or insulin treatment, bowel transition times and VCE completion rates are similar to those without DM, thus examination time adjustments are not needed.

P0234 VIDEOCAPSULE ENDOSCOPY IN UNEXPLAINED IRON DEFICIENCY ANEMIA: A RETROSPECTIVE COHORT STUDY

A Contaldo, G Losurdo, F Albano, A Iannone, E Ierardi, M Principi, A Di Leo
University of Bari, Emergency and Organ Transplantation, Bari, Italy

Contact E-Mail Address: contaldoantonella@gmail.com
Introduction: Iron deficiency anemia (IDA) may affect 1–2% of all adults. After conventional endoscopy, the cause of IDA remains unknown in up to 40% of patients. Video-capsule endoscopy (VCE) represents the cornerstone of investigation for unexplained IDA in subjects with strong suspicion of obscure bleeding. We aimed to investigate the prevalence of VCE-detected small bowel injury and associated risk factors in a cohort of inpatients with IDA and obscure small-bowel bleeding.
Aims and Methods: We included inpatients with IDA (hemoglobin levels < 12.0 g/dl in women and < 13.0 g/dl in men), showing obscure bleeding demonstrated by fecal occult blood test (FOBT) and negative upper endoscopy and colonoscopy. Cirrhosis and inherited polyposis syndromes were exclusion criteria. A complete medical history and laboratory tests were collected. All subjects received VCE (PillCam SB2/SB3) and Lewis score was calculated. Comparison between continuous variables was performed by unpaired t-test and between categorical variables by Fisher's exact test. Variables with statistical significance at univariate analysis were evaluated by a multivariate binomial or linear regression analysis. The risk was expressed with Odd Ratio (OR) and 95% confidence intervals (CI).
Results: 109 (female/male ratio 53/56, aging 63.4 ± 18.9 years) were recruited according to exclusion and inclusion criteria. All patients had hemoglobin levels < 10 g/dl and a strong suspicion of obscure bleeding. 80 (73.4%) presented 1 or more small bowel lesions at VCE (11 petechiae, 13.7%; 29 erosions, 36.2%; 7 hemorrhagic areas, 8.75%; 3 denuded areas, 3.75%; 5 strictures, 6.25%; 15 neoplasms, 18.75% and 25 angiodysplasiae, 31.25%; 14 patients had multiple lesions, 18.75%).
52 patients (65%) showed a mild Lewis score (<135), 25 (31.2%) had a moderate score (135 to 790), and only 3 (3.8%) showed a score >790. The mean Lewis score in patients with lesions was 193 ± 198. We did not find a significant correlation between hemoglobin levels and severity of damage: Pearson's r = 0.10, p = 0.41.
When compared to patients without small bowel injury, subjects with lesions had a longer small bowel transit time (6.2 ± 2.9 versus 5.2 ± 2.1 hours), had used non steroidal anti-inflammatory drugs for at least 2 weeks (17.5% versus 0%, p = 0.01) and used more frequently oral anticoagulants (20% versus 6.9%, p = 0.10) at univariate analysis. None of the factors statistically significant in univariate analysis was associated with the presence of small bowel injuries at multivariate analysis (table 1).
Age (b = 1.05, 95% CI 0.76–0.98, p = 0.10), small bowel transit time (b = 1.26 95% CI 1.05–1.86, p = 0.09), and PPI use (b = 5.81 95% CI 4.54–7.45, p = 0.09) showed a favorable trend, correlating directly with the severity of the lesion at univariate analysis. In the multivariate analysis, only the use of PPI correlate with the severity of the lesion (b = 4.56 95% CI 4.12–5.77, p < 0.001).

	OR (95% confidence interval)	P value (univariate)	OR (95% confidence interval)	P value (multivariate)
Small bowel transit time	0.88 (0.76–0.98)	0.049	0.86 (0.72–1.03)	0.09
NSAIDs assumption for at least 2 weeks	12.86 (0.74–223.1)	0.01	2.15 (0.44–10.50)	0.34
Oral anticoagulants	3.38 (0.73–15.70)	0.10	2.50 (0.46–4.56)	0.36

[Table 1. Estimation of risk, expressed as odd ratio (OR), for presence of lesions detected at VCE, both in univariate and multivariate analysis (binom]

Conclusion: VCE can reveal a source of obscure bleeding in unexplained IDA in up to 73.4% of subjects. Old age is the main risk factor for small bowel lesions. In about the 26.6% the cause of anemia could be not linked to gastro-intestinal bleeding despite a positive FOBT.

Introduction: Capsule endoscopes are designed for screening a long tube organ such as the small intestine or colon. Though they are non-invasive, they have various drawbacks compared to conventional endoscopes, such as inadequate observation in the esophagus and stomach, an unacceptable amount of preparation solution for colon screening and a long examination time.
Aims and Methods: Our aim was to realize an entire gastrointestinal (GI) tract examination with high accuracy, easy preparation and a short examination time. Our system was composed of a current colon capsule endoscope (CCE: PillCAM colon2, Covidien, USA), a length of carbon thread attached to the CCE and a 7.5 Fr. catheter with a tilting function at the tip (Smart touch: Biosense Webster, USA). At first a 0.04mm carbon thread was inserted into the nose and taken out through the mouth using a magnet. After the AFR function was turned on, a CCE was attached to the thread and swallowed. After confirming the CCE's position in the stomach, the catheter was inserted into the stomach along the thread. The examiner used the catheter to control the volume of air in the stomach or to flash water through it if the stomach needed cleansing. After observing all parts of the stomach, the CCE was navigated into the duodenum. The capsule was detached from the tip of the catheter by pulling on the thread. After the detachment, the catheter was used for injecting a large volume (over 2 liters) of preparation solution into the small bowel quickly to accelerate the CCE's movement and cleanse the colon easily. To evaluate this method, 15 volunteers were enrolled in a pilot study.
Results: 1) We could observe all the parts of the stomach easily and manipulation of the catheter was the same as a current endoscope. Image quality was not inferior to conventional gastroscopy. 2) The preparation solution was injected into the duodenum through the catheter at a speed of 10cm/sec, which meant that we could inject 3 liters in 300 seconds. 3) The chief adverse reaction was abdominal distention (3/15). 4) The average examination time for the small bowel transit time was 12 minutes and the colo-rectal transit time was 33 minutes. 5) The cleanliness was similar to or better than the current colon capsule endoscopy preparation. 6) The VAS scores for acceptability were better than the scores for current colon capsule endoscopy.
Conclusion: We have developed a simple, inexpensive and practical method for examining the entire GI tract with only one CCE.
Disclosure: Nothing to disclose

P0236 CAPSULE ENDOSCOPY: IS THE SOFTWARE TOP 100 A RELIABLE TOOL IN MID-GASTROINTESTINAL BLEEDING?

Introduction: Capsule endoscopy (CE) is the gold standard for diagnosing mid-gastrointestinal bleeding (MGIB). In 2017 emerged a new functionality in the RAPID Reader® the TOP100, that performs the automatic selection of the 100 most distinct images that may contain abnormalities.
Aims and Methods: We aimed to compare the concordance of findings between the classical CE reading (CR) and the use of TOP 100 in suspected MGIB.
Retrospective study including consecutive patients submitted to CE for suspected MGIB. 2 experienced readers performed CR and reported the most important findings. Another experienced reader, blinded to the CR results, reviewed all SBCE videos using TOP100 and reported the most important findings, excluding false positive results. In MGIB the relevant findings were defined as the presence of P2 lesions, namely angioectasias, ulcers or tumors.
Results: 69 patients were included, 56.5% females, with mean age 60 ± 18 years. 62 patients (89.9%) performed CE for anemia and 7 (10.1%) for obscure-overt gastrointestinal bleeding. The overall diagnostic yield was 42% and the P2 lesions more frequently observed were angioectasias (34.85) followed by ulcers (11.6%). No tumors of the small bowel were observed.
TOP100 detected 53/66 (80.3%) of the P2 lesions, in particular 45/48 (93.75%) of the angioectasias and 8/18 (44.4%) of the ulcers. The TOP 100 identified all active bleeding.

All images that were false positives selected by the TOP 100 were easily identified by an experienced reader.
Conclusion: The TOP100 identified all active bleeding, as well as the vast majority of significant lesions (80%), in particular, detected about 94% of angioectasias. Although CR remains the gold standard in the EC review, these findings demonstrate that TOP100 allows a quick reading with early identification of the most important findings in MGIB, constituting an extraordinary tool in an urgent context.

Introduction: Video Capsule Endoscopy (VCE) is the procedure of choice for the investigation of small bowel pathologies. VCE examinations also provide limited views of the esophagus, good visualization of the stomach/proximal duodenum, and some visualization of the colon. Incidental gastrointestinal pathologies in the upper gastrointestinal tract and colon are often seen during VCE but there is limited data regarding the significance of incidental findings. These pathologies, may not be directly linked to the patient's presenting complaint, may not be clinically significant and can lead to unnecessary investigations and consumption of health care resources.
Aims and Methods: The aim of this study is to evaluate if incidental pathologies found during VCE have any effect on patient outcome. 2 experienced gastroenterologists consultants prospectively reviewed the upper GI segment and colonic segments of VCEs performed over a 5-year period and identified those with UGI and colonic findings. These patients were then reviewed in the electronic databases for follow up visits, investigations, and treatments up to a year following their VCE procedure.
Results: We identified 103/733 (14.15%) patients with incidental findings, of which, 51 patients (49.5%) had completed charts that allowed for analysis. Incidental upper GI pathologies were identified in 45/103 (43.7%) patients in the original VCE reports, and 88/103 (85.4%) in the prospective dedicated VCE reading ($p < 0.001$). Incidental colon pathologies were identified in 7/103 (6.8%) patients in the original reports, and 19/103 (18.4%) in the prospective dedicated VCE reading ($p = 0.012$). 40 (38.8%) patients had only incidental upper GI and/or colon VCE findings without small bowel findings. 32 out of 51 (62.7%) patients with incidental VCE findings were seen for follow up. 19 of 51 (37.3%) patients had further investigations related to pathologies outside the small intestine; 9 underwent repeat EGD only, 4 underwent repeat colonoscopy only, and 6 underwent both repeat EGD and repeat colonoscopy. 5 out of 15 (30%) documented follow up EGDs attributed to a positive incidental finding on VCE were found to have significant findings that were not documented in their respective pre-VCE EGD reports. 2 out of 10 (20%) documented follow-up colonoscopies attributed to a positive incidental finding on VCE were found to have significant findings which were not documented in their respective pre VCE colonoscopy reports. No patients had recorded repeat hospitalizations, required blood products, or invasive interventions during the follow-up period.
[Pertinent Results of VCE Study Outcome]

	Initial VCE Report	Prospective Dedicated VCE Reading	P-value
Upper GI Incidental Pathologies	45/103 (43.7%)	88/103 (85.4%)	<0.001
Colonic Incidental Pathologies	7/103 (6.8%)	19/103 (18.4%)	0.012
New Endoscopic Pathologies Found in Follow Up (n = 9)			
Small Gastric Duodenal Polyps			3/7 (42.9%)
Gastric Erosions			2/7 (28.6%)
Gastric Blood			1/7 (14.3%)
Colonic Polyps			2/2 (100%)

Conclusion: Dedicated readings of additional segments (upper GI and colon) may identify significantly more incidental pathologies compared to current practices. Many of these findings are significant enough to warrant further follow-up. Upper GI and colonic segments of small bowel VCE should be reviewed routinely. Any incidental pathologies should be clearly documented and suggestions for follow up should be made within the VCE reports.
Disclosure: Nothing to disclose

P0238 THE EFFECTIVENESS OF IMPROVED USE OF CHEWING GUM IN INFLUENCING CAPSULE ENDOSCOPY TRANSIT TIME - A PROSPECTIVE RANDOMIZED, CONTROLLED PILOT STUDY

Y Hu, L Huang, B Lyu
First Affiliated Hospital Of Zhejiang Chinese Medical University, Gastroenterology, Hangzhou, China

Contact E-Mail Address: jiuyueqingxuan@163.com
Introduction: Capsule endoscopy (CE) is a powerful tool in the assessment of small bowel pathology. However, approximately 1 in 5 CEs does not visualize the entire small bowel at completion of the examination by the end of the recording time. Data suggest that chewing gum during the whole examination time, simulating sham feeding, may increase CE completion rate, but decrease the small bowel transit time (SBTT) that may be positive correlated with its diagnostic rate.
Aims and Methods: The aim of this study is to determine the effect of chewing gum, during the first 1 hour of examination in patients undergoing CE for GTT and SBTT time and the proportion of cases with complete small bowel examination.
Consecutive patients 16 years of age and older undergoing small-bowel CE from November 2017 to April 2018 were assessed for eligibility. Patients chewed 1 piece of gum for approximately 15 min every 30 min at the first hour of the examination. 2 blinded gastroenterologists examined all studies. The completion rate of CE that reached the caecum within 10 h, gastric transit time (GTT) and small bowel transit time (SBTT) were evaluated in all patients.
Results: 52 consecutive patients were randomized either to use chewing gum ($n = 26$) or not ($n = 26$). The mean age was 47.5 ± 18.3 years and 48.0 ± 19.0 respectively. The GTT in the chewing-gum group was significantly shorter than control [35.5 min (interquartile range: 35.25) vs. 65.5 min (interquartile range: 44.75) ($p = 0.000$)]. There was no significant difference in SBTT between the 2 groups [350.0 min (interquartile range: 236) vs. 384.0 min (interquartile range: 221) ($p = 0.701$)]. The CE percentage passed into the caecum was no difference in the chewing gum group compared with those in the control (88.5% vs. 76.9% respectively, $p = 0.271$).
Conclusion: Chewing gum at the first hour during CE examination could significantly reduce GTT but not SBTT. Its use might improve the likelihood of the diagnostic yield of CE by the unaltered small bowel transit during the procedure.

P0239 ENDOSCOPIC ULTRASOUND-GUIDED TRANSMURAL GALLBLADDER DRAINAGE USING ELECTROCAUTERY-ENHANCED LUMEN-APPOSING METAL STENT VERSUS STANDARD TUBULAR METAL STENT

J Privat[1], H Demmak[1], S.N Fetche[2], B.A Keita[1], M.A Lemaire[1], E Rebillard[1]
[1]*Centre Hospitalier de Vichy, Service de Gastroentérologie, Vichy, France*
[2]*Centre Hospitalier de Vichy, Service de Chirurgie Digestive, Vichy, France*

Contact E-Mail Address: jocelyn.privat@ch-vichy.fr
Introduction: In high-risk patients, EUS-guided gallbladder drainage (EUS-GBD) is a validated alternative to percutaneous transhepatic gallbladder drainage (PT-GBD) based upon the 2018 Tokyo guidelines. The use of electrocautery-enhanced lumen-apposing metal stent (ECE-LAMS) have recently and rapidly disseminating into interventional EUS practice.
We compare in this French study the clinical outcomes of endoscopic ultrasound-guided gallbladder drainage with standard tubular fully covered metallic stents (FCMS) versus ECE-LAMS as a treatment for patients with acute cholecystitis who are unfit for surgery.
Aims and Methods: We performed this retrospective single center study between June 2014 and March 2018. A total of 40 patients (22 women) with acute cholecystitis (25 acalculous) underwent EUS-GBD with FCMS ($n = 19$) or LAMS ($n = 21$). FCMS procedures were executed under general anesthesia with endotracheal intubation and fluoroscopy guidance. Access was achieved with a 19G EUS needle. A.035-inch guidewire was passed through then a 8Fr cystotom was used to create the fistula before we place the FCMS then a plastic double-pigtail stent of 7Fr (stent in stent technique). ECE-LAMS procedures were performed without endotracheal intubation and access was achieved directly and by using only EUS guidance. Data were collected on technical success (stent placement), clinical success (resolution of symptoms within 3 days) and adverse events.
Results: EUS-GBD with FCMS was performed in 19 patients (11 women) with a median age of 77 years (range, 66–92), most with acalculous cholecystitis ($n = 13$; 68.4%). In the ECE-LAMS group, 21 patients (11 women) with a median age of 79 (48–99) were treated for cholecystitis, acalculous in 12 cases (57.1%). Stent placement was technically successful in 38 patients (95%), 18/19 with FCMS and 20/21 with LAMS. 2 of the failure cases required immediate surgery. Resolution of cholecystitis was observed in 37 of 38 patients (97.3%). The medium time of procedure was 22mn (range, 10–40) in the FCMS group and 7mn (range, 3–30) in the ECE-LAMS one. There were 4 adverse events in the FCMS group (15.8%) and 1 in the LAMS group (4.7%). No bleeding occured. We observed 2 late stent migrations and 2 patients had recurrent cholecystitis in the FCMS group, none in the LAMS group with a median follow-up of 267 days (range, 3–1206). Removal of a FCMS was attempted successfully in 1 case at 4 months before a now possible cholecystectomy. The mean postprocedure pain score (2/10) and length of stay in the hospital (4 days) were the same in both groups.
Conclusion: EUS-GBD technique with FCMS or ECE-LAMS appear as a feasible and efficient technique with similar technical (95%) and clinical success (97%) in both group. This results are equivalents to thoses of the PT-GBD and better to thoses of the transcystic endoscopic drainage. The ECE-LAMS has the benefits of a simpler and faster method with less adverse events. We

also observe no stent migration and no recurrence of cholecystitis with the ECE-LAMS, which is contrary to the litteracy.
Disclosure: Privat J.: consultant for Boston Scientific.

Introduction: Jaundice and subsequent biliary infection caused by tumor can be detrimental for the patients with pancreatic cancer. Therefore, stent insertion for biliary decompression is necessary for the patients with biliary obstruction by pancreatic cancer and it is important to keep the stent patent as long as possible. However, few studies have compared stent patency according to chemotherapy itself and chemotherapy regimen.
Aims and Methods:.Therefore, in this study, we aimed to evaluate the difference of stent patency according to chemotherapy and the factors associated with better stent patency. Between January 2015 and May 2017, 102 patients with pancreatic cancer who underwent biliary stent insertion with metal stent for the first time were retrospectively analyzed. The relationship between chemotherapy and stent patency were assessed. Additionally, factors for better stent patency and stent patency according to the chemotherapy regimen were also assessed.
Results: Median stent patency was 163 days for patients with best supportive care, 338 days for patients with chemotherapy, respectively. ($p = 0.041$) Univariate analysis showed that chemotherapy itself and chemotherapy regimen stent were significantly associated with better stent patency. Compared with patients who received best supportive care only, patients who underwent chemotherapy after stent insertion had better stent patency in multivariate analysis (OR 0.494; CI 0.247–0.988; $p = 0.046$). FOLFIRINOX also showed better stent patency than gemcitabine-based chemotherapy in multivariate analysis (OR 0.318; CI 0.113–0.900; $p = 0.031$).
Conclusion: Compared with patients who received best supportive care only, patients who underwent chemotherapy after stent insertion had better stent patency. Better stent patency can be expected for the patients with FOLFIRINOX.

Introduction: EUS (Endoscopy ultrasonore)-guided biliary drainage is now a comparable technique to percutaneous drainage. This drainage can also be performed in cases of complex drainage of the hilum, mainly described for salvage therapy to drain the left liver. In cases of inaccessible papilla or altered anatomy, EUS-guided biliary for hilar stenosis of the liver could be used as the first approach. The limitation of EUS drainage is the drainage of the right liver.
In this feasibility study, we reported the drainage of the right liver using the bridge technique and hepaticogastrostomy.
Aims and Methods: The study is a retrospective work based on a prospective registry from January 2013 to February 2017. Inclusion criteria were patients with inaccessible papilla due to altered anatomy or duodenal invasion and drainage by EUS guidance and bridge technique without previous biliary drainage. The bridge technique was used to place an uncovered biliary stent between the right liver and the left liver. The left liver was drained by performing a hepaticogastrostomy.
Results: 12 patients were included. Stenosis was type II for 9 patients, IIIB for 2 patients, and type IV for 1 patient. Technical success was 100%, and clinical success was 80%. Morbidity was 33% (4 patients), including 3 patients with abdominal pain managed conservatively and 1 patient with a percutaneous salvage drainage. Postoperative mortality was 8% (uncontrolled sepsis). Mean survival was 6 months. Chemotherapy could be administered in 70% of patients in cases of clinical success (7 patients).
Conclusion: The bridge technique under EUS-guidance could be a first alternative for draining malignant hilar stenosis in cases of inaccessible papilla.
Disclosure: No conflict of interest

P0242 FULLY COVERED SELF-EXPANDABLE METALLIC STENT, AS SUPERIOR TREATMENT OPTION FOR BILIARY ANASTOMOSIS STRICTURE AFTER LIVER TRANSPLANTATION COMPARED TO PLASTIC STENTS: A CASE-CONTROL STUDY

J.H Jo, H Chun, H Kang, H.S Lee, J.Y Park, S Bang, S.W Park, S.Y Song, M.J Chung
Severance Hospital, Yonsei University College of Medicine, Division of Gastroenterology, Department of Internal Medicine, Seoul, Korea (Republic of)

Contact E-Mail Address: woforce@naver.com
Introduction: Fully covered self-expandable metallic stent (FCSEMS) was reported as endoscopic treatment option for biliary anastomotic stricture (AS) after liver transplantation (LT). However, there were only few studies compared FCSEMS to conventional plastic stent insertion to biliary strictures. The aim of this case-control study was to evaluate resolution rate of biliary AS and 1-year recurrence rate after stent removal between FCSEMS and plastic stents in LT patient.
Aims and Methods: 35 cases with biliary AS after LT were enrolled between 2012 and 2016. There were 20 patients in plastic group and 15 in FCSEMS group. ERCP were repeated every 3 months for evaluate stent function and AS resolution. Stent was removed if AS resolution was confirmed with radiologic remission. Patients were followed up until 1yr after stent removal for evaluate AS recurrence.
Results: There were no significant differences between groups in age, gender, and other baseline characteristics. The median stent indwelling period was 4.7 vs. 8.9 months in FCSEMS and plastic group ($p = 0.039$). The numbers of ERCPs were 2.3 in FCSEMS group and 3.1 in plastric group ($p = 0.065$). The mean number of inserted stents and ballooning during treatment period were lower in FCSEMS group ($p = 0.004$ and 0.007). The AS resolution rate was superior in FCSEMS group to plastic group (100% vs. 65%, $p = 0.012$). The 1-year AS recurrence rate were lower in FCSEMS group than plastic group (0 of 15 vs. 4 of 13, $p = 0.042$). Complication rate associated with stent insertion was 20% in FCSEMS group and 45% in plastic group ($p = 0.190$).
[Table 1. Comparison of plastic versus Kaffes stent for anastomosis stricture after liver transplantation]

	Plastic (N = 20)	FCSEMS (N = 15)	P-value
Male gender, N (%)	16 (80.0%)	11 (73.3%)	0.700
Age, mean ± SD	53.1 ± 13.9	57.7 ± 4.8	0.183
AS onset from LT, mo., median (range)	12.4 (0.4–76.4)	12.8 (0.17–112.8)	0.482
AS duration, mo., median (range)	12.4 + 27.6	16.2 + 18.6	0.633
Number of ERCPs, mean ± SD	3.1 ± 1.8	2.3 ± 0.6	0.065
Number of stents, mean ± SD	2.6 ± 2.0	1.1 ± 0.3	0.004
- Lenth of FCSEMS, cm		4.9 ± 1.0	
- Width of FCSEMS, mm		6.9 ± 1.0	
Number of ballooning, mean ± SD	1.7 ± 1.8	0.6 ± 0.6	0.017
Stent indwelling period, mo., median (range)	8.9 (0.5–48.5)	4.7 (3.3–11.9)	0.039
Stricture resolution, N (%)	13 (65.0%)	15 (100.0%)	0.012
1-year Recurrence, N (%)	4/13 (28.6%)	0/15 (0%)	0.042
Complication during treatment, N (%)	9 (45.0%)	3 (20.0%)	0.190

Conclusion: FCSEMS was superior compared to plastic stent in aspect of AS resolution rate of and 1year-recurrence rate without increasing complication rate. In addition, stent indwelling period, number of stents and ballooning procedure were reduced in FCSEMS group than plastic group. The FCSEMS is safe and effective treatment option for biliary AS after LT.
Disclosure: Nothing to disclose

P0243 IN VIVO EVALUATION OF A NOVEL ANTIREFLUX BILIARY METAL STENT

Introduction: The efficacy of antireflux valve (ARV) biliary stent has not been well established and previous studies showed mixed results. ARV metal stents may be ineffective due to morphological change of the ARV. A novel ARV metal stent is a graft of 2 different stents, and each part has a different radial force. Distal part, ARV area, can be freely bent in multiple directions and has an unchanging stent lumen.

Aims and Methods: The aim of this *in vivo* animal study was to evaluate the efficacy of a novel ARV metal stent. The ARV metal stents and control metal stents were evenly inserted into the 10 mini-pigs. After 2 weeks, contrast media was injected in all mini-pigs at the duodenal bulb to evaluated for duodenobiliary reflux (contrast injection test), and histopathologic examination was performed to access the degree of duodenobiliary reflux.
Results: Stent placement was technically successful in all mini-pigs. After 2 weeks, 2 of control stents and 2 of ARV stents were distally migrated from the biliary ducts. Morphological change of ARV was not found in all ARV metal stent. In contrast injection test, duodenobiliary reflux was not found in all mini-pigs of ARV stent group, but found in all mini-pigs of control stent group. In histopathologic examination, the severity of inflammation was significantly attenuated in ARV stent group.
Conclusion: The novel ARV metal stents can be resistant to morphologic change and duodenobiliary reflux that can improve ARV dysfunction and stent patency.
Disclosure: Nothing to disclose

P0244 INTRA-DUCTAL MIGRATION OF BILIARY AND PANCREATIC STENTS, HOW TO MANAGE SUCH COMPLICATION? MONO-CENTERED EVALUATION OF A RETRIEVAL TECHNIQUE USING RAT-TOOTH FORCEPS

J.-M Gonzalez[1], A Debourdeau[2], J Bodiou[1], M Barthet[1]

Contact E-Mail Address: jmgonza05@yahoo.fr
Introduction: Intra-ductal stent migration is a common adverse even, and could be difficult to manage. In the major series, the frequency is estimated around 5% for the pancreatic stents and 3.5% for biliary stents.
Several techniques have been proposed for removing those stents, but to date, none has been objectively assessed in terms of technical success and complication rate. Thus, we propose a study with the aim to evaluate the outcomes of the stent removal using rat-tooth forceps.
Aims and Methods: This was a retrospective observational monocentered study. All the patients with intra-ductal stent migration, biliary or pancreatic, with a removal attempted using rat-tooth forceps were included. For each case, the procedure was consisting of first catheterizing the involved duct with a guide wire pushed along the stent, then advance forceps up to the distal tip of the stent, and finally open it for grasping the stent to pull it back outside of the duct. A balloon dilation or an enlargement of sphincterotomy could be applied in association to help for extracting the stent.
The age, sex, pathology of the patients, the indication for ERCP, the location, the type of stent, the presence of a stricture and stones, and the associated techniques have been recorded. The main objective was to document the technical success of stent removal using intra-ductal rat-tooth forceps. The secondary objectives were to elucidate the need for additional technique and the complication rate.
Results: In total, 2152 ERCPs with biliary or pancreatic stenting have been performed between 2009 and 2017. The overall migration rate was 5%, with 2.5% intra-ductal representing 55 patients. Among them, 40 patients had an attempt of stent extraction using rat-tooth forceps, and were kept for analysis. There were 22 men and 18 women, with a mean age of 53 ± 15 years-old. The main pathology indication a stenting was a calcified chronic pancreatitis in 21 cases. The other pathologies were idiopathic or genetic pancreatitis ($n = 4$), cholangitis ($n = 4$), a biliary duct stricture ($n = 4$), an ampulloma ($n = 2$), a pancreas divisum ($n = 2$), or others ($n = 3$).
The migration was involving biliary duct in 19 patients (47.5%), from whom 74% ($n = 14$) were covered self-expandable metallic stents, with a stricture associated in 32% of cases. It was involving the pancreatic duct in 18 patients (45%), from whom 83% were plastic stents, with a stricture associated in 50% of the cases as well as stones. Finally, 3 patients (7.5%) had a double migration in both ducts.
The removal success rate was 90% (17/19) for the intra-biliary migrations, in 3 cases requiring in addition a dilation or an enlargement of sphincterotomy, and 89% for the intra-pancreatic migrations, requiring a dilation in 4 cases or an enlargement of sphincterotomy in 1. An extraction balloon was used as prior technique in 5 cases. In case of double migration, the 2 stents could be removed in 1 case only. The overall technical success rate was 85% (34/40). In case of failure, an additional stent was placed in parallel to the other 1, the 2 stents being removed during the next session in 100% of the cases.
In terms of adverse events, there were 2 sepsis and 2 low grade pancreatitis with quickly favorable evolution. There was only 1 case of necrotic and severe acute pancreatitis. There was no mortality related to this procedure.
Conclusion: The removal of intra-ductal migrated stents using rat-tooth forceps is an effecitve approach in 85% of the cases in 1 single endoscopic session. This technique is also safe, with a low morbidity rate.

P0245 URGENT ERCP AND PANCREATIC DUCT STENTING FOR THE MANAGEMENT OF POST-ERCP PANCREATITIS

S Shapovalianz, S Budzinskiy, E Fedorov, **A Kotieva**
N.I. Pirogov Russian National Research Medical University, Department of Abdominal Surgery, Surgical Gastroenterology and Endoscopy; Moscow University Hospital № 31, Moscow, Russian Federation

Contact E-Mail Address: aza-kot@yandex.ru
Introduction: Post-ERCP pancreatitis (PEP) is the most common and dreadful complication of ERCP, with reported 2–15% incidence rate among patients (pts.). Traditional methods of treatment of acute PEP like surgical approach or conservative treatment are well known, meanwhile endoscopic treatment, in particular duct stenting, are still controversial.
Aims and Methods: to evaluate the results of endoscopic stenting of the main pancreatic duct (MPD) as a new perspective treatment method of PEP.
From 01.01.2009 till 01.01.2016 we performed 3366 endoscopic interventions on major duodenal papilla (MDP). Complications occurred in 57 (1.7%) cases and PEP originated in 33 (0.98%) of them (29 f. and 4 m.; range: 25 - 86 years; mean age 59.7 ± 11.1). The indication for primary endoscopic interventions was jaundice in all cases, caused by stenosis of the MPD and microlithiasis (21), choledocholithiasis (7), duodenal parapapillary diverticulum (2), polyps of the MDP (2) and restenosis after previously performed EPT (1). Acute pancreatitis developed after failed ERCP in 3% (1/33), after balloon papillodilation with extraction of bile stones in 3% (1/33), after biopsy of MDP tumor in 3% (1/33) and after EPT in other 90.9% (30/33) patients, including nonselective EPT in 10 cases and additional pancreatic sphincterotomy in 4, extraction of bile duct stones in 11. PEP diagnosis was confirmed by laboratory (33 cases, level of amylasemia from 882 to 18502 un/l, mean level 4637 ± 3028 un/l) and instrumental methods (abdominal ultrasound in 23 pts. (69.7%), abdominal computer tomography - 8 (24.3%). Frequency of risk factors in patients with PEP was as following. The most frequent risk factors were female gender (29) and stenosis of terminal part of common bile duct (24), the equally often risk factors were young age, nonselective EPT, pancreaticography/cannulation of MPD - 12 cases to each other. The most common combinations of risk factors in patients with PEP were conjunction of 2 (21%), 3 (31%), and 4 (21%) risk factors.
Results: Promptly after confirmation of the diagnosis of acute PEP we tried to perform stenting of the MPD in 25 out of 33 patients, and succeeded in 22 (88.0%) of them. Complications of pancreatic stenting have not been revealed; all patients recovered. Inserted stents were short length, 5 and 7 Fr diameter with perforations on the sides, pig-tail and straight type with flaps by both ends. Pancreatic stents were removed in 5–12 days after their placement. The average time of pancreatic stenting was 11.2 ± 3.2 days. The average length of hospitalization was 10.4 ± 3.7 days. Other 11 (33.3%) pts., including 3 pts. with failed attempts of stenting, underwent medical therapy and 2 of them - surgical intervention afterwards. There were 2 (18.2%) lethal outcomes in this subgroup. The average time of hospitalization was 22 ± 17.1 days.
Conclusion: Endoscopic stenting of the MPD is technically feasible in 88.0% (22/25) of patients with acute PEP and it leads to recovery in all cases. Urgent pancreatic stenting should be done as fast as it is possible, but not more than 24 hours after the primary endoscopic retrograde intervention. Successful stenting is effective and safe method of treatment of this dangerous complication of ERCP. Moreover using pancreatic stenting reduces length of hospitalization by 71.5%, which brings economical benefits. Meanwhile in the subgroup of pts. where pancreatic stenting was not performed or failed, mortality reached 18.2% and average time of hospitalization was in 2 times longer. Prospective randomized trial is needed to prove these promising results.
Disclosure: Nothing to disclose

Introduction: Opioids are known to affect motility, but their effect on fluid absorption and secretion in humans is poorly investigated.
Aims and Methods: This study is aimed at investigating the effect of oral-administered oxycodone on colonic fecal volume and stool dryness by using a novel magnetic resonance imaging (MRI)-based technique. We hypothesized that experimental opioid-induced constipation increases fecal volume and stool dryness. In a randomized, double-blinded, cross-over study, 25 healthy male volunteers were treated for 5 days with prolonged-release oxycodone or placebo, separated by 52 ± 10 days (mean ± SD). Dixon-type Liver Accelerated Volume Acquisition MRI-scans of the abdomen were obtained on day 1 and day 5 in each treatment period. Data were divided in 4 colorectal segments and analyzed with semi-automatic Matlab-based software (Sandberg *et al*., 2015). Fecal volume was quantified excluding gas volume and colon wall. Stool dryness was assessed using

MRI signal intensity (SI) as a biomarker for water content, where higher values means less water.
Results: After oxycodone treatment, total colonic fecal volume was significantly increased [mean 101 mL, 95% CI 15 to 187 mL] compared to placebo treatment [mean −14 mL, 95% CI −74 to 46 mL] ($p = 0.001$), with the largest difference (24%) observed in the ascending colon/cecum ($p = 0.001$). Stool dryness increased after oxycodone treatment [mean 0.09 SI, 95% CI 0.01 to 0.17 SI] compared to placebo [mean −0.02 SI, 95% CI −0.08 to 0.04 SI] ($p = 0.001$).
Conclusion: The MRI analysis methods showed differences in colonic fecal volume and stool dryness after treatment with oxycodone compared to placebo. The MRI-based method for non-invasive analysis of colon content have the potential to characterize gastrointestinal symptoms in general, such as in constipation.

Introduction: High-intensity focused ultrasound (HIFU) is expected to be the new and improved advanced therapy for unresectable intractable cancer (UIC) like pancreatic cancer (PC). The combination of HIFU therapy and chemotherapy can be used to effectively control the locally advanced tumor of unresectable intractable cancer by the site-direct manner. HIFU therapy has showed effectiveness of anti-tumor effect for unrespectable PC. From that, we have developed the new method, Sonodynamic therapy (SDT) in order to enhance anti-tumor effect and limit the damage done to the normal tissues during treatment. SDT is a novel therapeutic method of cancer treatment deriving from the cytotoxicity reaction, which is based on preferential uptake of sonosensitizer with anticancer drug in tumor tissues and subsequent activation of drug by ultrasound irradiation form an extracorporeal.
Aims and Methods: We have evaluated the safety and clinical tolerability of SDT in UIC. This is the prospective exploratory clinical non-random sampling and a series of registration studies. We have treated UIC patients using SDT, with whom an agreement was obtained in adequate IC, from May 2017 in our hospital. This study had received approval from the members of the ethic society of our hospital, and obtained research support from the Japan Agency for Medical Research and Development (AMED). The participants of the study were 12 UIC patients, i.e. 11 of pancreatic cancer and 1 of cholangiocellular carcinoma of Stage IV. The average age of the participants was 63.7 years old. The performance status was PS 0:6 and PS 1:6 patients. 11 of whom have had chemotherapy previously and 1 had no therapy. The HIFU device used was MS-2 (joint production equipment by Hitachi, Ltd., Denso, Inc., Tohoku Universities and Tokyo Women's Medical University, Japan, which was provided by Tokyo Woman's Medical University. The drug used for the study was epirubicin-conjugated polymer micelles; NC-6300 (manufactured by NanoCarrier Co., Ltd. And supplied by Kowa Company, Ltd., Japan). NC-6300 was administered intravenously before 24 ± 2 hours before HIFU treatment. HIFU mode used was the high strength pulse irradiation addition to the usual continuous-wave radiation, and performed HIFU irradiation by the triggered HIFU sequence which induces a cavitation and heightens the SDT effect. 3+3 design for increase in quantity of four steps of HIFU power and doses of NC-6300 was performed. The safety and therapeutic effect of 7 and 30 days after SDT was evaluated.
Results: Side effects of NC-6300 after administration were not seen in which step of [1] $30mg/m^2$+75W; 3 cases, [2] $30\ mg/m^2$+150W; 3 cases, [3] $80mg/m^2$+HIFU75W; 3 cases, and [4] $80mg/m^2$+150W; 3 cases. Treatment data was followed; mean total treatment time: 22.3 min, mean total number of irradiation: 17.4 shots. The effects of HIFU therapy were the following; the rate of complete tumor coagulative necrosis was 33%, the rate of partial tumor coagulative necrosis was 42%, mean tumor reduction rate was 40%, the rate of primary disease control rate (DCR) was 64%, and the rate of symptom relief effect was 33%. No adverse events more than grade 3 were seen during and 7 and 30 days of after treatment. The tolerability of NC-6300 dose was $80mg/\ m^2$ and HIFU power 150W was confirmed.
Conclusion: This study has shown that SDT will be a promising new cancer treatment that is effective and secure which can be done in a lesser time with less risks. It is expected to be a topical therapy for UIC, and the next stage of clinical trial for therapeutic effect is also going to start in the very near future.
Disclosure: This study obtained research support from the Japan Agency for Medical Research and Development (AMED).

P0248 SAFETY AND EFFECTIVENESS OF EUS-GUIDED HEPATICOGASTROSTOMY (EUS-HGS) COMPARED WITH PTBD IN PATIENTS WITH MALIGNANT BILIARY OBSTRUCTION

M Matsuyama, M Sawada, T Katagiri, R Kanata, T Sasaki, M Ozaka, K Takano, N Sasahira
Cancer Institute Hospital of JFCR, Dept. of Gastroenterology, Tokyo, Japan

Contact E-Mail Address: mahsanmahsan2000@yahoo.co.jp
Introduction: EUS-guided hepaticogastrostomy (EUS-HGS) is recognized as an alternative treatment for biliary drainage.
Aims and Methods: We aimed to evaluate the outcome of EUS-HGS and Percutaneous transhepatic biliary drainage(PTBD) treatment, and consider the possibility of EUS-HGS treatment about continuity and further compatibility. We conducted a retrospective study among 13 patient who underwent EUS-HGS and 46 patients who underwent PTBD with malignant biliary obstruction from January 2016 to December 2017. The success rate of the procedure, the response rate of the treatment, short-term complication rate, the length of hospital stay after treatment, the ratio of re-hospital events, and the survival time after treatment were examined.
Results: On PTBD vs. EUS-HGS, the median age was 68 years (38–88 years) vs. 69 years old (43–76 years), male 72% vs. 38% ($p < 0.05$), the primary disease were pancreatic cancer/biliary tract cancer/Gastric cancer/Other 17/10/11/8 vs. 7/6/0/0 ($p < 0.05$). The reasons for choosing PTBD were 17 cases of poor EBD effects, 12 reconstructed intestinal anastomy, 11 EBD failures due to gastrointestinal stricture, 3 ERCP complications, 1 poor treatment effect of EUS-HGS, 2 others. The reasons for choosing EUS-HGS were 5 poor EBD effects, 5 EBD incapacitations due to gastrointestinal stricture, 1 PTBD refractory, 2 PTBD intolerance cases. The success rate of the procedure was 95.7% vs. 100%, the response rate was 83.0% vs. 92.3%, and the complication rate within 2 weeks after the treatment was 10.6% vs. 15.3%. The median length of hospital stay after treatment was 21 days (3–129 days) vs. 11 days (3–22 days), the ratio of re-hospitalization events was 30% vs. 30.7%, the median time from treatment to the event occurrence was 92 days (12–305 Day) vs. 77 days (24–252 days), BSC cases was 43.5% vs. 92.3% ($p < 0.05$), median post survival time was 112 days vs. 89 days.
Conclusion: Most of the EUS-HGS were administered to the patients with biliary and pancreatic cancer premised on BSC cases. Since it has the same degree of safety as PTBD, it seemed possible to continue performing EUS-HGS more positively in terms of QOL. Also, it seemed possible to expand EUS-HGS indication for the cases with any other organ cancer than pancreatic or biliary cancer before chemotherapy, but it is necessary to verify the safety of EUS-HGS in the future.

P0249 ROLE OF INTERVENTIONAL RADIOLOGY IN PEDIATRIC GASTROINTESTINAL DISEASES - A LARGE TERTIARY CENTER EXPERIENCE

Z Nabi, J Singh, R Chavan, U Shava, D.N Reddy
Asian Institute of Gastroenterology, Gastroenterology, Hyderabad, India

Contact E-Mail Address: zaheernabi1978@gmail.com
Introduction: Interventional radiology (IR) is an indispensable component of multidisciplinary care in various gastrointestinal (GI) diseases. The available literature on safety and utility of IR is limited in children with GI disorders.
Aims and Methods: In this study, we aim to analyze the outcomes of IR in various pediatric GI diseases.
The data of children (<18 years) who underwent radiological intervention for various GI disorders during study period (2009–2017) were analyzed, retrospectively. The indications for interventions included vascular (Budd Chiari syndrome, pseudoaneurysm) and nonvascular (pancreatic fluid collections, cholangitis and anastomotic biliary strictures). All the interventions were performed with standard technique. The indications for intervention in children with pancreatic fluid collections included unsuitability of endoscopic drainage or collections at multiple sites. Percutaneous transhepatic biliary drainage was carried out in children in whom endoscopic retrograde cholangiopancreaticography was unsuccessful or not feasible. The outcomes of radiological intervention including success and adverse events were assessed.
Results: A total of 93 children (mean age 13.45 ± 4.09) underwent radiological interventions for vascular (chronic Budd Chiari syndrome 14, pseudoaneurysm 28) or non-vascular (pancreatic fluid collections 33, hepaticojejunostomy strictures or leaks 12, cholangitis 6) indications. Of 33 children who underwent percutaneous drainage of pancreatic fluid collections, clinical success was noticed in 32 children during a mean follow-up of 32.4 ± 21.66 months. 11 children developed persistent pancreaticocutaneous fistula of which 8 children were managed with endoscopic pancreatic ductal stenting and 3 underwent internalization of transgastric drain. In children who underwent stenting of hepatic vein or inferior vena cava for Budd Chiari syndrome, mean stent patency was 78.57% during a follow-up of 24.1 ± 13.78 months. Adverse clinical outcomes were noticed in 4 children (28.57%) including persistence of ascites (1 child), requirement of re-intervention (1 child), and death (2 children: re-occlusion and intracranial

bleeding). In children with pseudoaneurysms, angioembolization with glue and or coils was successfully performed in 92.8% patients. The sites of pseudo-aneurysms were splenic artery in 8, gastroduodenal artery in 7, hepatic artery in 5, superior mesenteric artery in 3, renal artery in 1 and right gastroepiploic artery in 1 child. Re-bleeding was noticed in 2 children. 1 child was managed conservatively and one required re-intervention. Percutaneous transhepatic biliary drainage was performed in 18 children. Resolution of hepaticojejunostomy strictures, leaks and cholangitis was noticed in all the children during a follow-up of 36.1 ± 13.73 months.
Conclusion: Interventional radiology is safe and effective in the management of various pediatric GI diseases. The role of angiotherapy in children with chronic Budd Chiari syndrome needs to be evaluated in future.

P0250 PERCUTANEOUS TRANSHEPATIC BILIARY DRAINAGE HAS LOW CLINICAL SUCCESS AND HIGH COMPLICATION RATE IN PATIENTS WITH MALIGNANT BILIARY STRICTURES

T Stoklosa, K Liu, J Wong, Y Koh, J Baars, P Bhate, M Joanne Manlapig Rubio, F Su, N Perera, N Kortt, T Tsoutsman, A Kaffes, P Saxena
AW Morrow Gastroenterology and Liver Centre, Royal Prince Alfred Hospital, Sydney, Australia

Contact E-Mail Address: tmstoklosa@gmail.com
Introduction: Patients with malignant biliary strictures carry a poor prognosis and the majority present with unresectable disease. Biliary drainage is achieved by endoscopic retrograde cholangiopancreatography (ERCP) in over 75% of cases. Percutaneous transhepatic biliary drainage (PTBD) is commonly employed as second-line method of obtaining biliary drainage in cases of failed ERCP. The aim of this study is to evaluate the efficacy and safety of PTBD for malignant biliary strictures.
Aims and Methods: This is a retrospective study of consecutive patients who underwent PTBD for malignant biliary strictures at an academic tertiary referral centre between 2005 and 2016. Clinical, laboratory, endoscopic and radiological data were obtained from electronic medical records. Technical success was defined as successful biliary cannulation and treatment of obstruction. Clinical success was defined as a 50% reduction in serum bilirubin 7 days post-procedure, or a 75% reduction at 4 weeks post-procedure.
Results: During the study period 205 patients underwent 564 PTBS (61% male, median age 69 years [IQR 59–77]). Causes of malignant stricture included: cholangiocarcinoma in 71 (35%), metastatic disease in 64 (31%), pancreatic adenocarcinoma in 55 (27%), hepatocellular carcinoma in 7 (3%), gallbladder cancer in 6 (3%), ampullary cancer in 1 (0.5%) and lymphoma in 1 (0.5%). The stricture was hilar in 76/205 (37%), distal in 100/205 (48%) and both hilar and distal in 29/205 (14%). Most patients 130/205 (63%), had failed ERCP prior to PTBD. The median serum bilirubin at time of PTBD was 159 μmol/L (IQR 86-271).
The median number of procedures for each patient was 2 (IQR 1-3). Interventions performed included: stenting (154 (75%) including; 105 (51%) covered metal, 26 (13%) uncovered metal, 21 (10%) plastic, and 2 (1%) partially covered metal), balloon dilatation 165 (86%) and external drainage 189 (92%). 63 (33%) of the patients with external drainage had drain removal prior to discharge. Technical success was achieved in 198/205 (96%) and clinical success was achieved in 111/205 (54%). The likelihood of clinical success was significantly lower for strictures with a hilar component when compared to those with distal strictures only (51% vs. 71%, $p = 0.006$). Patients with strictures involving the hilum also required an increased number of procedures compared to those with distal only (3 vs. 2.4, 95%CI 0.02–1.2, $p = 0.04$). Complications occurred in 109/205 (53%) patients and included pain requiring analgesia in 51 (25%), haemobillia in 29 (14%), cholangitis in 27 (13%), bile leak in 21 (10%), non-biliary bleeding in 21 (10%), peritonitis in 3 (1%), and 14 (7%) other. There was 1 case of procedure related mortality at 4 weeks follow-up.
Conclusion: PTBD is unsuccessful in 46% of patients with malignant biliary strictures and complications are seen in 53%. Malignant strictures with a hilar component had significantly reduced clinical success and required more procedures compared with distal lesions. Other techniques should be explored to improve patient outcomes in this setting.

Contact E-Mail Address: tmstoklosa@gmail.com
Introduction: Biliary complications are a common cause of morbidity and mortality in liver transplantation (LT) recipients occurring in 10–25% of patients. Most can be managed successfully with endoscopic retrograde cholangiopancreatography (ERCP) or double-balloon enteroscopy assisted ERCP (depending on the type of anastomosis). Percutaneous transhepatic biliary drainage (PTBD) remains second-line treatment for biliary complications after ERCP failure at most centres. However, its use in patients after cadaveric LT has not been well studied. We aimed to determine the outcomes and safety of PTBD in this setting.
Aims and Methods: This is a retrospective study including all patients who underwent PTBD post-cadaveric LT at a tertiary referral centre between 2005 and 2016. Clinical, laboratory, endoscopic and radiological data were obtained from electronic medical records. Technical success was defined as successful biliary cannulation and treatment of obstruction. Clinical success was defined as a 50% reduction in serum bilirubin 7 days post-procedure, or a 75% reduction at 4 weeks post-procedure. Patient were analysed according to clinical success or failure using standard statistical methods for group comparisons.
Results: During the study period, 44 LT patients underwent 164 PTBDs (89% male, median age 56 years [IQR 52–62]). Causes of liver disease included: hepatitis C (12/44; 27%), PSC (11/44; 25%), alcoholic liver disease (6/44; 14%), hepatitis B (5/44; 11%) and other (13/44 30%). 19 patients had a duct-to-duct anastomosis while 25 patients had a roux-en-Y anastomosis. 4 (9%) patients had more than 1 prior LT. Indications for PTBD were: 22/44 (50%) for anastomotic stricture, 7 (16%) for bile leak, 6 (14%) for focal non-anastomotic strictures, 3 (7%) for ischaemic biliopathy, 3 (7%) for recurrent PSC and 2 (5%) for choledocholithiasis. 15 (34%) patients had failed ERCP and 15 (34%) had failed double balloon enteroscopy assisted-ERCP (DB-ERCP) prior to PTBD, whereas 14 (32%) underwent primary PTBD. The median time from LT to PTBD was 25 months (IQR 3-67). The median serum bilirubin at time of PTBD was 41 μmol/L (IQR 18-103).
Technical success was achieved in 43/44 (98%) and clinical success was achieved in 29/44 (66%) of patients. The median number of procedures for each patient was 3 (IQR 2-6). Patients with clinical success had a lower median time post transplantation; 9 vs. 94 months ($p = < 0.001$) and lower median bilirubin 31 vs. 57 μmol/L ($p = 0.01$). The clinical failure group had no procedures performed for bile leak 0/15 (0%) vs. 7/27 (24%) ($p = 0.04$). There were no other differences observed in baseline characteristics between the clinical success and failure groups including indication for PTBD, number of procedures, prior ERCP and aetiology of liver disease.
Serious adverse events occurred in 25/44 (57%) patients which included: cholangitis in 15 patients (34%), haemobilia in 9 patients (20%), bleeding outside the biliary tree in 6 patients (14%) and bile leak in 5 patients (11%). 10 patients required ICU admission post-procedure (23%). There was no procedure related mortality at 4 weeks follow up.
Conclusion: Although technical success for PTBD for post-LT is high, clinical success is modest at 66% with multiple procedures being generally required. PTBD carries a significant risk of adverse events of 57% in this population and hence should remain a second-line procedure.

P0252 RISK FACTORS OF LYMPH NODE METASTASIS IN PATIENTS WITH EARLY PURE AND MIXED SIGNET RING CELL GASTRIC CARCINOMAS

G Xu[1]
[1]*Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China*

Contact E-Mail Address: 13852293376@163.com
Introduction: Early gastric carcinoma (EGC) with pure signet ring cell (pSRCC) histology limited to the mucosa has been reported to have favourable prognosis and low risk of lymph node metastasis (LNM). However, risk factors for lymph node metastasis(LNM) and clinicopathological features of early mixed signet ring cell gastric (mSRCC) remain poorly investigated.
Aims and Methods: The aim of this study was to identify risk factors of LNM and compare clinicopathological characteristic and prognosis of early pSRCC with early mSRCC.
This retrospective study was conducted at our center between 2005 and 2015 in 796 radical gastric cancer gastrectomies. A total of 160 early signet-ring cell carcinoma (ESRCC) radication resections were reviewed, in which 79 cases were early pSRCC and 81 cases were early mSRCC. Risk factors of LNM and clinicopathologic features of these 2 groups were statistically compared, including age, gender, tumor location, gross pattern, size, invasion depth, lymphovascular invasion (LVI), helicobacter pylori (Hp) infection, atrophic gastritis, and LNM. Patients were follow-up for post-resection survival. The 5-year survival rate and disease-specific survival were estimated with the Kaplain-Meier method with a log-rank test and compared between the two groups.
Results: The overall 5-year survival rate for ESRCC was 96.25%. Univariate analysis reviewed LVI and tumor size as the risk factors of LNM in the mERCC groups but only LVI as the risk factor in the pERCC group. Compared to the pERCC group, the risk factors of LNM in the mERCC included the male gender ($p < 0.0001$), ulcerated gross pattern ($p < 0.05$), LVI ($p < 0.01$), and Hp infection ($p < 0.01$). Multivariable analysis revealed 2 independent risk factors in the mERCC group: 1) tumor size (the odds ratio of 2.075; 95% confidence interval: 1.049 - 4.105) ($p < 0.05$), and 2) LVI (the odds ratio: 22.215 (95% confidence interval: 4.786 - 103.112) ($p < 0.0001$). There was no significant difference in the overall survival and disease-specific survival between the 2 groups.
Conclusion: Although with similar post-resection survival, the independent risk factors of LNM in the mERCC group, compared to those in the pERCC group, included large tumor size and LVI.

P0253 OUR EDUCATIONAL ACTIVITY FOR PERCUTANEOUS TRANS-ESOPHAGEAL GASTRO-TUBING

H Oishi, T Iino
Murayama Medical Center, National Hospital Organization, Department of Surgery, Tokyo, Japan

Contact E-Mail Address: oishi-h@murayama-hosp.jp

Introduction: We developed the percutaneous trans-esophageal gastro-tubing (PTEG) technique in 1994 in Japan for patients in whom it was difficult to create a percutaneous endoscopic gastrostomy (PEG). Initially, PTEG was routinely used for quite a while as a palliative treatment for gastrointestinal decompression in patients with gastrointestinal obstruction due to carcinoma. Then, PTEG began to be used routinely for enteral nutrition. We believe that the establishment of a system to teach the PTEG procedure is essential because we would like PTEG to become a general technique all over the world. Here, we describe our educational activities for PTEG.

Aims and Methods: The PTEG procedure was constructed from 2 existing general techniques. We also developed a rupture-free balloon (RFB) for the standard PTEG technique procedure in 1997. 1 technique was puncturing of the esophagus with a RFB under ultrasonic control. The other was tube placement via the puncture site under fluoroscopic control. The standard PTEG procedure was thus a nonvascular interventional radiological technique that did not require an endoscope. The Japan Association for PTEG (JA-PTEG) was established in 2002, and annual- meetings of JA-PTEG were held every year. From 2005, under the guidance of the Ministry of Welfare, a clinical trial for PTEG was undertaken for 6 years in Japan, which confirmed its safety and efficacy. The Ministry of Welfare approved support for PTEG by Japanese national health insurance in 2012. Hands-on seminars with simulators for the PTEG procedure were held twice a year from 2014. In 2018, JA-PTEG initiated a system to technically certify physicians performing PTEG.

Results: PTEG has been performed in over 25,000 patients in Japan from 1994 to the present. We have also performed PTEG as an educational procedure in 341 patients in 62 institutions. JA-PTEG was formed with 186 individual members, 52 authorized institutions, 43 faculty members and 32 attending physicians. To date in 2018, JA-PTEG certified 8 physicians as those authorized to perform the standard PTEG procedure.

For patients with intractable nausea and vomiting due to gastrointestinal obstruction caused by carcinoma, PTEG as a palliative treatment can quickly and effectively improve a patient's quality of life. PTEG is also highly efficacious in enteral nutrition as an alternative to PEG. PTEG was originally born as a Japanese technique in 1994, and currently, it is still only performed within Japan.

Conclusion: We believe that the PTEG technique should be disseminated safely and effectively throughout the world.

Introduction: Peroral endoscopic myotomy (POEM) is a minimally invasive and curative treatment for esophageal dysmotility (1,2). However, significant pain persists in some cases.

Aims and Methods: This single-center study retrospectively investigated risk factors for pain after POEM.

This study included consecutive patients who underwent POEM and high-resolution manometry (HRM) at the Okayama University Graduate School of Medicine between January 2016 and December 2017. A numerical rating scale (NRS) was used for pain assessment. A pain group (P-group: 3 days to achieve NRS < 1) and a non-pain group (NP-group: < 3 days) were compared. Demographic information, disease, symptoms, and histological findings were obtained from medical records. All study participants provided informed consent. The local ethics review committee granted approval.

Results: Of 22 patients who underwent POEM, 2 were excluded because preoperative HRM was not performed, and 11/20 (55%) had prolonged pain after POEM. There was no significant difference in sex, age, and the amount of analgesic required during hospitalization between the P-group and NP-group. In univariate analysis, high distal contractile integral (DCI) median value on HRM and classification as a straight-type were risk factors for prolonged postoperative pain. In multivariate analysis, high DCI was a risk factor for prolonged postoperative pain.

Conclusion: The intensity of esophageal peristalsis before POEM may be a factor in prolonged postoperative pain.

Contact E-Mail Address: ivannedoluzhko@gmail.com

Introduction: Benign tumors of the ampulla of Vater occur in 0.4% −0.12% of all tumors of the gastrointestinal tract (GI tract). However, malignant transformation occurs in 60–65% of cases, so the common tactic of treatment is their removal. Regardless of the pathohistological structure of the tumor, endoscopic papillectomy is considered reasonably safe and most effective method compared to a more radical interventions such as pancreatoduodenal resection (PDR), transduodenal resection.

Aims and Methods: 37 endoscopic papillectomies were performed at the Moscow Clinical Research Center between April 2014 and January 2018. In most cases, the tumor was detected during a routine examination for other diseases.

The preoperative examination protocol included duodenoscopy with biopsy, endosonography, CT or MRI, which excluded the presence of malignant lesions and the intraductal spread of the adenoma more than 1 cm. The sizes of the adenomas ranged from 1 cm to 5 cm. The aim of the study was to evaluate the effectiveness of endoscopic papillectomy in the treatment of patients with neoplasm of the ampulla of Vater.

Results: 37 patients underwent endoscopic papillectomy, including 16 men and 21 women. Median age: 54 years (26–73). The average time of surgery was 85 minutes. In 26 cases, the removal of the adenoma was performed 'en bloc' (59.5%). In 11 cases, due to the presence of lateral spread of the tumor, fragmentation was performed (40.5%). Pancreatic stenting was successful in 31 patients (83.7%). Stenting was of the common bile duct in 9 patients (24.3%). In all cases there was R0 resection. Morbidity included bleeding in 8 patients (21.6%), 2 cases of intraoperative perforation (5.4%), 1 of them was conservatively treatment. The other was operated in volume: laparotomy, suturing a perforation, drainage of the abdominal cavity. In 2 patients, the postoperative period was complicated by cicatricial stenosis of the bile duct opening (5.4%). The ERCP with the stenting of the common bile duct was performed. No death occured.

Conclusion: Endoscopic papillectomy is characterized by lower morbidity and mortality and a shorter period of hospitalization. Compared with surgery, endoscopic ampullectomy appears to be a preferred treatment modality for small benign ampullary tumors with high success rate of tumor eradication.

Contact E-Mail Address: ivannedoluzhko@gmail.com

Introduction: Surgical interventions on the esophagus belong to the group of 'high-risk' operations, as they can lead to such formidable complications as insolvency, bleeding and the formation of postoperative fistulas and strictures. The results of systematic analysis of the largest series of clinical cases published in the last 20 years show the incidence of postoperative anastomotic leakage about 3% after open and 2.1% after laparoscopic surgery without significant differences determined by the type of surgical access. However, analysis of the cumulative world experience shows the average incidence of anastomotic leakage at the level of 7–8%. These reports suggest that postoperative mortality rates in this patient group reach 30% and have no significant improvement toward reduction. Aggressive approaches to the treatment of patients with traditional surgical interventions lead to an increase in mortality from 20 to 64%, which determines the use of minimally invasive technologies as a priority. Since 2006, a new method of endoscopic vacuum therapy in management of anastomotic leaks has become available in clinical practice.

Aims and Methods: From March 2015 to March 2018, anastomotic leakage of the esophagus was diagnosed in 12 patients (5 women, 7 men), including 9 patients with failure of esophagogastric anastomosis, 3 patients with failure of

esophagojejunal anastomosis. The average age was 67.5 years. Size of anastomotic perforation ranged from 0.8 to 3 cm.
Strategy of treatment for all patients include adequate nutritional support by enteral feeding through the nasogastric tube, parenteral administration of combined nutrients, enterostomy, or a combination of several methods. Early antibiotic therapy is necessary for the prevention and treatment of already developed mediastinitis and septic complications.
The complications were detected on the 1–7 days after surgery. Anastomotic leak was confirmed by radiological and endoscopic methods. Endoscopic vacuum therapy was performed on the day of leakage detection (2–4 days after the surgery). Thus no additional sanation and draining interventions were required due to early diagnosis and adequate drainage of the anastomosis area.
Polyurethane spongy system, slightly smaller diameter or corresponding to the diameter of the esophagus, was mounted on a thermoplastic gastric probe and installed at the level of the perforation. Immediately after installation, the system was connected to a vacuum aspirator with a pressure of 100 - 125 mm Hg. Replacement of the system was carried out every 3–13 days. To fully close the insolvency, it took from 1 to 7 procedures. The decision to complete the therapy was carried out based on the results of endoscopic and X-ray examination in the absence of data for the presence of fistula.
Results: In total 57 procedures were performed: the number of replacements - 4 (1–7), the interval between procedures - 6 days (3–13 days), the duration of treatment -13 days (1–66 days). The success rate was 75%.
There were 3 lethal outcomes, including 2 due to progressive cardiovascular failure with positive dynamics of local treatment. 1 patient died of multiple organ failure.
Conclusion: Endoscopic vacuum therapy is considered to be valuable and cost-effective method of treatment of anastomotic leaks and perforations of the upper GI tract.

P0258 THE SMART APPROACH TO SURGICAL TREATMENT FOR GASTRIC AND DUODENAL GISTS BASED ON PREOPERATIVE EUS-TYPING

S Dzhantukhanova[1], Y Starkov[1], M Vybornyi[2]
[1]*Vishnevsky's Institute of Surgery Dept. of Endoscopic Surgery, Moscow, Russian Federation*
[2]*A.V.Vishnevsky Institute of Surgery, Moscow, Russian Federation*

Contact E-Mail Address: seda-d@mail.ru
Introduction: Surgical treatment is the treatment of choice for the resectable GISTs with objective of surgery being complete R0 resection. No need for extended resections and lymphadenectomy makes minimaly-invasive techniques the treatment of choice.
Aims and Methods: We aimed to develop and demonstrate different surgical techniques of laparoscopic or endoscopic resection for GISTs **based on classification of EUS-typing for optimal choice of treatment**. By the 'smart' approach we imply the approach which allows us to make a surgery less invasive and more accurate, including more functional results with no increase of complications.
The EUS-classification of GISTs was created based on the analysis of treatment of 80 patients with gastric and duodenal GISTs. The principles of classification included the following criteria:
Location of tumor base in relation to GI layer
Size of the tumor base (''growing point'')
Type of growth in relation to GI lumen
The EUS-typing includes Type I, Type II, Type III (a,b,c,d) tumors
Optimal approach for type I
Endoscopic removal of tumor by means of:
Endoscopic submucosal dissection (large size)
Endoscopic mucosal resection (small size)
Type II
Endoscopic enucleation of tumor after resection of covering mucosa
Endoscopic tunneling dissection
Type IIIa
Endoscopic tunnneling dissection
Type IIIb
Laparoscopic atypical resection after gastrotomy (duodenotomy)
Endoscopic tunneling dissection (advanced endoscopic surgeon and small tumor size)
Laparo-endoscopic hybrid procedures
Type IIIc
Laparoscopic atypical (wedge) resection
Type IIId
Laparoscopic enucleation of tumor
Laparoscopic atypical stapler resection.
Results: Patients with gastric and duodenal GISTs underwent laparoscopic resection - 62, endoscopic intraluminal resections - 18 patients (tunneling resection - 7, endoscopic submucosal dissection or endoscopic enucleation of tumor after resection of covering mucosa - 11). Median operation time was 150 min. Recovery was uneventful and median post-op hospital stay was 5 ± 2.4 (2–8) days. The pathology showed R0 resection in all cases. Histology and immunohistochemistry confirmed GIST. 4 patients received adjuvant target therapy and were prescribed Gleevec for 1–2 years. The mean follow-up period was 42 months (range 3–74 months) with no local or distant recurrence or stenosis at the site of surgery.
Conclusion: The classification of GISTs based on EUS-typing allows to select the optimal approach individually for each patient to perform surgery more accurate and less invasive.

Contact E-Mail Address: mj.lahaye@gmail.com
Introduction: Multiple surgical scoring systems have been developed to assess the extent of peritoneal carcinomatosis in colorectal patients. These scoring systems are used as important predictors of surgical outcome in cytoreductive surgery and hyperthermic intraperitoneal chemotherapy (CRS/HIPEC). Diffusion weighted magnetic resonance imaging (DW-MRI) could allow for the assessment of these surgical scores preoperatively and non-invasively.
Aims and Methods: The purpose of the study is to compare the performance of these scoring systems determined on MR images, for predicting whether a complete resection was feasible in CRS/HIPEC candidates with colorectal cancer.
Between February 2016 and October 2017, colorectal cancer patients considered for CRS/HIPEC who underwent DW-MRI were included. The DW-MRI images were, retrospectively and independently, assessed by 2 abdominal radiologists. Both radiologists were blinded for the clinical parameters. Clinical parameters were obtained from the patient files. 5 most-used models were selected, namely the Peritoneal Surface Disease Severity Score (PSDSS), Region Count, Simplified Peritoneal Cancer Index (SPCI), Peritoneal Cancer Index (PCI), and the Colorectal Peritoneal Metastases Prognostic Surgical Score (COMPASS). The performance of the scoring systems was assessed by receiver operator characteristics (ROC) analysis for predicting complete resection and the area under the curve (AUC) was calculated for every model.
Results: In 82 patients, the scores could be accurately constructed for all 5 methods. The mean age was 62.80 (± 10.53) and 46/82 of the patients were female. Of these patients 70% (58/82) had undergone a successful surgical procedure with a curative intent, of which 84% (49/58) underwent a CRS/HIPEC procedure. In 20 patients, an inoperable amount of peritoneal carcinomatosis was determined at surgery. ROC curve analysis for predicting a complete resection showed AUCs of 0.79, 0.79, 0.82, 0.83, and 0.89 for PSDSS, Region Count, SPCI, PCI, and COMPASS, respectively.
Conclusion: This study shows that DW-MRI might be used for less invasive and preoperative patient selection of colorectal patients considered for CRS/HIPEC. The COMPASS model was the best model to select CRS/HIPEC candidates with MRI.

Introduction: Preoperative evaluation of MR images may not be sufficient for precise planning the anal fistulas surgery nor the stem cell therapy. 3D printing allows to obtain spatial structures in 1:1 scale with unprecedented precision.
Aims and Methods: Optima MR360 Advance 1.5T (GE Healthcare) with a 16-channel TOTAL BODY coil was used. The imaging protocol consisted of high-resolution axial and coronal T2-weighted images with a matrix size 512 × 512, a slice thickness of 2 mm and zero spacing scans. DICOM images were imported into 3D Slicer v.4.8.0. Firstly anal fistula was modelled on the basis of axial images. Fistula locations, anus and anal canal were marked with a different color marker. The last step was to mark the skin that was connected to the anus and contact areas of the fistula with the skin. The prepared model was then exported to an STL format file. Blender 2.77a was used to smooth the edges of the model, then 3D program allowing the color to be assigned to individual model element was used. The final version of the model contained 958 layers. The anal fistula model was printed using the 3D ProJet 460 Plus printer (3D Systems). The development of the model, including printing took approx. 9 hours.
Results: Acessability of rotatable 3D before surgery allows more precise detection of the location and the degree of the perianal disease. Moreover, this may also lower the inter-observer bias connected with the different skills to interpret complex MR imaging before planned surgery.

Conclusion: The proposed use of 3D printing technology in the case of anal fistula will allow to effective surgery planning.

Contact E-Mail Address: s.perin@ucl.ac.uk
Introduction: Severe gastrointestinal disorders including chronic intestinal pseudo-obstruction affect the neuromuscular compartment of the small intestine. Very little is known, however, about the repair and regeneration of damaged or dysfunctional smooth muscle.
Aims and Methods: Our study aims to investigate the potential of human foetal gut mesoangioblast-like cells for enteric smooth muscle regeneration as a possible treatment for enteric myopathies and related disorders.
Mesoangioblasts-like cells (MABS), isolated from human foetal midgut (under ethical approval from the UK-Human Developmental Biology Resource at UCL Great Ormond Street Insitute of Child Health), were expanded and TGFß used for 7 or 14 days to induce smooth muscle differentiation *in vitro*. Immunohistochemistry, FACS analysis and calcium imaging were performed to characterise MABS and smooth muscle-derived cells. After eGFP-lentiviral labelling, MABS were transplanted *in vivo* into terminal ileum of NOD-SCID mice (under UK licence, PPL 70/7622) and cell engraftment assessed with immunohistochemistry after 4 weeks.
Results: Immunohistochemistry and FACS analysis showed that foetal gut MABS have high proliferative capacity (~55% of cells are $Ki67^+$) in culture, are positive for mesenchymal markers CD90 and CD146 (~98% for both markers) and for pericyte markers NG2 and PDGFRß (~90% and ~20–30% respectively). After 7 days in culture with TGFß-treatment, MABS expressed smooth muscle proteins SM22 and calponin, and showed intracellular calcium transients in response to carbachol. After 14 days MABS also expressed smoothelin, a marker of mature smooth muscle. *In vivo*, transplanted MABS were able to engraft, distribute in the muscle layers of the ileum and differentiate into SM22 positive smooth muscle cells.
Conclusion: Here we demonstrate that MABS can be successfully isolated from human foetal gut. *In vitro* and with TGFß-treatment MABS showed an increasing ability to generate smooth muscle cells able to respond to carbachol stimulation, thus supporting their functional potential. The ability of MABS to differentiate into mature smooth muscle cells *in vitro* and engraft *in vivo* provides proof of principle for their potential use as a treatment of enteric smooth muscle disorders.

Introduction: Negative circumferential resection margins (CRM) are the cornerstone for curative treatment of patients with locally advanced rectal cancer (LARC). Unfortunately, perioperative techniques for evaluation of resection margins are lacking, whereas standard histopathological examination is time-consuming. In this study, we evaluated the feasibility of optical molecular imaging as a tool for evaluation of resection margins at the surgical theater, i.e. Image-Guided Pathology (IGP), to improve clinical decision making.
Aims and Methods: Fluorescence imaging data of fresh surgical specimens and subsequent bread-loaf slices from patients with LARC (NCT01972373) were analyzed as a side study. All patients were administered intravenously with 4.5 mg of the fluorescent tracer bevacizumab-800CW 2–3 days prior to surgery. 7 patients met the inclusion criteria for correlation of fluorescence intensities in fresh surgical specimens with histology, to evaluate resection margins. For analysis of bevacizumab-800CW localization in bread-loaf slices, sufficient data was available from 17 patients. A receiver operating characteristics (ROC) curve was plotted to determine the mean fluorescence intensity (MFI) cut-off value for tumor detection.
Results: Using IGP, in one patient a histologically confirmed tumor-positive CRM was predicted correctly at the surgical theater. Tumor-negative CRMs were predicted correctly in 4 patients using IGP. 1 tumor-positive CRM could not be detected; however, this positive margin was based on the presence of only an isolated microscopic tumor deposit in the CRM. 1 close CRM (1.4 mm) was identified as tumor-positive. Optical imaging enabled a clear differentiation between tumor and surrounding tissue in the bread-loaf slices ($n = 42$) of all 17 patients *ex vivo*. In our limited sample size, an optimal MFI cut-off value of 5085 was determined based on the ROC curve, with a sensitivity and specificity of 98.2% and 76.8% respectively.
Conclusion: We demonstrate for the first time the potential of IGP for identification of positive resection margins directly after surgery in patients with LARC. Clearly, this might change current peri-operative decision making with regard to additional targeted resections or intraoperative brachytherapy. Based on the initial results from this study, a standardized methodology was developed to confirm these findings in a subsequent larger IGP study.
Disclosure: Nothing to disclose

P0264 SNAPSHOT STUDY ON MRI RESTAGING AFTER CHEMORADIOTHERAPY AND INTERVAL TO SURGERY IN RECTAL CANCER; INFLUENCE ON SHORT AND LONG-TERM OUTCOMES

Introduction: The time interval between CRT and surgery in rectal cancer patients is still subject of debate and concerns exist regarding increased postoperative complication and local recurrence rates after longer waiting.
Aims and Methods: To evaluate the impact on short and long-term outcomes of variation in practice related to MRI restaging and time interval between neoadjuvant chemoradiotherapy (CRT) and surgery in rectal cancer patients. Patients were selected from a collaborative rectal cancer research project including 71 Dutch centers. Patients were subdivided into 2 groups according to the time interval from the start of preoperative CRT to surgery (<14 and ≥ 14 weeks).
Results: From 2095 registered patients, 475 patients received preoperative CRT. MRI restaging was performed in 79.4%, with a median CRT-MRI interval of 10 (IQR 8–11) weeks, and median MRI-surgery interval of 4 (IQR 2–5) weeks. Short and long interval groups consisted of 224 and 251 patients, respectively. Pathological complete response rate ($n = 34$ (15.2%) vs. $n = 47$ (18.7%), $p = 0.305$) and CRM involvement (9.7% vs. 15.9%, $p = 0.145$) did not significantly differ. 30-day surgical complications were similar (20.1% vs, 23.1%, $p = 0.943$). No significant differences were found for local- and distant-recurrence rates and disease-free and overall survival.
Conclusion: These real-life data reflecting routine daily practice in the Netherlands showed substantial variability in use and timing of restaging MRI after preoperative CRT for rectal cancer, as well as time interval to surgery, but with similar short- and long-term outcomes.

Introduction: Laparoscopic ventral mesh rectopexy (LVR) is gaining wider acceptance as the preferred procedure to correct internal as well as external rectal prolapse associated with obstructed defecation syndrome (ODS) and/or faecal incontinence.
Aims and Methods: The aim of our study was to analyse functional outcome and quality of life (HRQL) after laparoscopic ventral rectopexy for symptomatic internal prolapse and/or rectocele with ODS. Prospectively collected data on LVR for internal rectal prolapse were analysed in 46 consecutive female patients operated between January 2011 to April 2018. Mean age was 62 years (range 25 -

79). All patients had internal rectal prolapse (grade 3 or 4) confirmed at the defecogram study and 29 of them an associated rectocele. Functional results of LVR were evaluated in terms of constipation as measured with the Wexner Constipation Score, and HRQL as measured by SF-36, were analysed before the operation and after at least 3–6 months. Finally, HQRL results of LVR patients were compared with sex and age matched healthy controls. Non parametric statistics was used.
Results: Mean operative time was 151 min (range 75 - 240). Conversion rate to open technique was 10,8 %. There was no post-operative mortality or major complications. Median post-operative length of stay was 4 days (range 3 - 28). After a mean follow-up of 26 months (range 3 - 71 months), we observed no recurrence of prolapse or rectocele. Comparing Wexner score before and after LVR we observed an improvement in painful evacuation effort ($p = 0.001$), minutes in lavatory attempt ($p = 0.008$), feeling incomplete evacuation ($p = 0.017$) and abdominal pain ($p = 0.017$). Moreover, the global Wexner score was significantly improved from 13.60 to 10.18 ($p = 0.000$). Similarly, SF-36 items improved after the surgery, especially in term of Physical Functioning ($p = 0.005$). The comparison of preoperative SF-36 score with matched healthy controls demonstrated a significant difference in particular in Physical Functioning ($p = 0.001$) and Bodily Pain ($p = 0.023$). On the contrary, the comparison of post-operative SF-36 scores and healthy controls scores showed a significant difference only in terms of Bodily Pain item ($p = 0.035$). No worsening of continence status, constipation or sexual function was observed. No significant improvement was observed in urinary incontinence. None patient experienced persistence or recurrence of the prolapse.
Conclusion: LVR appears to provide a sustained improvement in HRQL, constipation and incontinence in patients with ODS without worsening constipation with low morbidity and recurrence.

Introduction: Methods for the local treatment of early rectal cancer have been developed in the recent years. In this scenario, the transanal endoscopic microsurgery (TEM) and the endoscopic submucosal dissection (ESD) have played an important role. Both have their own advantages and drawbacks, but there are still few studies comparing them. Previous studies have shown that both techniques have similar short term outcomes (1). Studies assessing long-term outcomes, however, are scarce.
Aims and Methods: To compare long-term outcomes between ESD and TEM for the treatment of early rectal cancer.
From Jun/2008 to Dec/2017, 103 procedures were performed (either ESD or TEM). Lesions submitted to ESD were previously assessed by magnification chromoendoscopy and lesions with high risk of deep submucosal invasion were referred to surgical resection. Lesions treated by TEM were assessed by 3D endorectal ultrasound before the procedure.
Data regarding age, surgical risk, early and late complication rates, recurrence and anatomopathological report were collected retrospectively. Qualitative variables were submitted to a chi-square analysis and the quantitative ones, to a t-Student test.
Results: The mean follow-up of these patients was 34 months, 74 of them (71.8%) were submitted to ESD and 29 to TEM (28.2%). The average age in the ESD group was 65.5 years and 51.3% of those patients were female. Among the patients submitted to TEM, the mean age was 66.51 years and 58.6% of them were female. The surgical risk was equivalent in both groups ($p = 0.97\%$).
The lesions removed by ESD were significantly larger than the ones removed by TEM - 68.9mm against 44.79mm, respectively ($p = 0.002$). The mean procedure duration was 176 min for the ESD and 195 min for the TEM ($p = 0.4$).
In the ESD group, 7 patients (9.46%) had early complications, 2 of which were Clavien I, 3 Clavien II and 2 Clavien III. In the TEM group, 5 patients had complications (17.2%), of which 2 were Clavien I, 1 Clavien II, 1 Clavien III and 1 Clavien IV ($p = 0.19$).
The average days of hospitalization was 3.4 among the ESD patients and 6.9 among the TEM ($p = 0.015$).
During the first post-operative month, 10 patients (13.5%) from the ESD group presented mucorrhea, fecal urgency and/or incontinence and anal stricture requiring dilatation. By the end of 18 months, all patients were asymptomatic. Among the patients undergoing TEM, 7 (24.13%) had rectal pain, diarrhea or fecal incontinence. After 18 months, 6 were asymptomatic and 1 persisted with rectal pain.
The lesions removed either by ESD or TEM had similar rates of en-bloc resection - 89.2% and 96.5%, respectively ($p = 0.23$) and R0 resection - 85.13% and 82.6%, respectively ($p = 0.742$). The anatomopathological analysis of the lesions removed by ESD showed 27% of adenomas, 64.86% of intramucosal adenocarcinoma, 4% sm1 adenocarcinoma and 4.05% of sm≥2 adenocarcinoma (non-curative resection). In the TEM group, 31% were adenomas, 44.8% of intramucosal adenocarcinoma, 7% of sm1 adenocarcinoma and 17.2% of sm≥2 adenocarcinoma. Therefore, the ESD had a higher percentage of curative resections ($p = 0.002$).
Among the patients undergoing TEM, there was a 24.13% recurrence rate, against 1.3% in the ESD group ($p = 0.0001$).
Conclusion: The ESD, compared with the TEM, showed better results, enabling the treatment of significantly larger lesions, with a higher curative rate, less hospitalization days and lower recurrence rates.
Disclosure: Nothing to disclose

P0267 CROSSTALK BETWEEN SEROTONIN AND ENDOCANNABINOID SYSTEMS IN THE GUT CONTRIBUTES TO THE ABDOMINAL PAIN IN COLITIS

M Salaga[1], A Binienda[1], F Piscitelli[2], V Di Marzo[2,3], J Fichna[1]

Contact E-Mail Address: macieks100@wp.pl
Introduction: Abdominal pain is one of the most common symptoms of inflammatory bowel diseases (IBD). However, its molecular basis has not been fully characterized yet. It has been previously shown that chronic elevation of luminal serotonin increases visceral pain and that elevated secretion of this neurotransmitter in the gut leads to the exacerbation of inflammation. On the other hand, it is well established that inhibited endocannabinoid signaling in the gut lowers pain threshold and endogenous cannabinoid receptor agonists reverse this effect and exhibit antinociceptive and anti-inflammatory properties.
Aims and Methods: The aim of this study was to test the hypothesis that chronic administration of serotonin causes disruption of the cannabinoid signaling leading to visceral pain in the course of colitis.
Methods: We used 3% DSS in drinking water to induce colitis in mice. Serotonin was systemically administered for 5 days starting from day 3 post-DSS and each day visceromotor response to colorectal distention (CRD) was measured. Selective 5-HT_3 and 5-HT_4 receptor antagonists were used to examine the mechanism of action of serotonin. Macroscopic evaluation of the colonic damage was performed. Expression of cytokines, serotonin and cannabinoid (CB) receptors as well as enzymes responsible of biosynthesis and degradation of endocannabinoids were investigated. Moreover, serotonin as well as endocannabinoid levels were assessed in all experimental groups by ELISA and mass spectrometry.
Results: DSS caused severe intestinal inflammation represented by increased macroscopic score as well as upregulation of TNFα, IL-1β and IL-6. Chronic, systemic treatment with serotonin led to significant increase in the concentration of this hormone in the colon and simultaneous decrease of the endocannabinoids, anandamide and 2-arachidonylglycerol. The visceromotor response to CRD was significantly higher in the serotonin-treated animals compared to the vehicle group and this effect was dependent on 5-HT_3 but not 5-HT_4 receptors. Moreover, chronic serotonin administration led to the downregulation of CB1, but not CB2, and decreased N-acyl phosphatidylethanolamine-specific phospholipase D (NAPEPLD), which is responsible for synthesis of anandamide and other *N*-acylethanolamines, and these effects were reversed by the 5-HT_3 receptor antagonist graniserton.
Conclusion: Here we present a novel mechanism that may be responsible for the increased visceral pain in intestinal inflammation. Our study suggests that pharmacological blockade of serotonin signaling in the gut might be of benefit in severe cases of abdominal pain in IBD patients.

P0268 UROTENSIN II RECEPTOR EXPRESSION IN ULCERATIVE COLITIS: RELATIONSHIP WITH ENDOSCOPIC AND HISTOLOGICAL ACTIVITY OF THE DISEASE

A.G Gravina[1], **M Dallio**[1], C Tuccillo[1], M Martorano[2], C Loguercio[1], A Federico[1]
[1]*University of Campania 'Luigi Vanvitelli', Division of Hepatogastroenterology, Department of Precision Medicine, Naples, Italy*
[2]*Immacolata Hospital, Gastroenterology Unit, Sapri, Italy*

Contact E-Mail Address: marcello.dallio@gmail.com
Introduction: Urotensin II (U-II) is a vasoactive peptide that interacts with a specific receptor, UTR (1). Recently our group has demonstrated increased UTR expression both in adenocarcinoma cell lines and adenomatous polyps and even greater in colon carcinoma samples when compared to healthy colon samples of the same patients. We also showed that an UTR agonist induced an

increase in colon adenocarcinoma cells growth in vitro, while the UTR block with a specific antagonist caused an inhibition of their growth and an inhibition of about 50% both of motility and cell invasion (2).
Aims and Methods: There are no UTR expression data in the ulcerative colitis (UC), and we therefore evaluated the expression of UTR in ill colon biopsy and in healthy colon biopsies of patients with UC and colon biopsies of healthy patients. We enrolled, prior informed consent, 7 patients (4 males and 3 females, age range 29–78 years, median 55) with first UC diagnosis compared to 7 healthy controls (3 males and 4 females, age range 30–75 years, median 52). 5 patients had a left colitis and two had a proctitis. All patients had histologic examination of moderate to severe disease activity. We have therefore sampled flogistic and healthy tissue. We therefore also have colic tissue samples taken in these subjects. Evaluation of receptor expression was performed by RT-PCR. The ANOVA test ($p < 0.05$) was used for statistical analysis.
Results: We found a) increased expression of UTR in patients with ill mucosa biopsies compared to healthy controls in 5 of the 7 patients ($p < 0.05$); b) increased expression of UTR in ill colon biopsy of UC patients compared to healthy colon biopsies of the same patients in 5 of the 7 patients ($p < 0.05$); c) increased UTR expression in healthy colon biopsy specimens of patients with UC compared to healthy controls in 5 of the 7 patients ($p < 0.05$); d) correlation of UTR expression with endoscopic and histological activity of disease in most study patients. We found a greater expression of UTR in patients with a Mayo Endoscopic Score 2 and with severe histologic only in 4 patients.
Conclusion: UTR could be considered as an inflammatory disease marker. UTR up-regulation in ill mucous is correlated with endoscopic and histological activity of disease in most patients.

Introduction: Tissue hypoxia is predominated in inflammatory intestinal lesions. Hypoxia inhibits hypoxia-inducible factor prolyl hydroxylase (HIF-PH), which stabilizes HIF and induces HIF downstream gene expression in the colon. HIF-1, a complex consisting of inducible HIF-1 alpha and constitutive HIF-1 beta, induces the expression of protective barrier genes in colon epithelial cells and plays a critical role in protecting against inflammatory bowel disease (IBD). HIF-PH inhibitors are thought to have the potential to enhance mucosal barrier function through HIF-1 alpha stabilization. We found out that DS-1093a, a HIF-PH inhibitor, might have the potential to be a novel IBD drug with mucosal healing activity.
Aims and Methods: To elucidate the effect of DS-1093a on IBD, we administered DS-1093a to colitis mice. Experimental colitis was induced in male BL/6 mice by dissolving Dextran Sodium Sulphate (DSS) in their drinking water for 8 days. DS-1093a was administered to DSS mice in the feed for 8 days or by intra-rectal administration (IRA) once a day until day 7. The disease conditions (colon length, body weight, and diarrheal score), histopathology (HE staining, AB-PAS staining, and HIF-1 alpha immunohistochemistry) of colon, and haematological parameters were analysed on day 8. Colon and serum of each mouse were also collected on day 8. The mRNA expression was analysed by qRT-PCR. IRA was conducted by administering the solution between the cecum and the rectum via a catheter through the anus.
Results: DS-1093a improved total body conditions, as shown by body weight, colon length, and diarrheal score in DSS colitis mice. In the histopathological analysis, colitis mice showed intestinal tissue injury; however, treatment of DS-1093a reduced the mucosal injury and increased normal tissue region. AB-PAS (mucin) stained section of the colon showed DS-1093a normalized mucus production in colitis mice. DS-1093a prevented the activation of immune cells by colitis. DS-1093a also suppressed inflammatory cytokine gene expression in the colon epithelial cells. DS-1093a induced HIF-1 alpha accumulation in the nucleus of mucosal epithelial cells.
In contrast, DS-1093a induced excess erythropoiesis by 8-day feeding administration. IRA of DS-1093a led to lower systemic exposure and erythropoiesis than with oral administration. IRA of DS-1093a improved disease conditions and normalized intestinal mucosa in colitis mice.
Conclusion: DS-1093a improved disease conditions, prevented mucosal injury, and normalized the intestinal mucosa of colitis mice. DS-1093a is suggested to maintain the functional integrity of colon epithelial cells. Owing to mucosal barrier improvement, DS-1093a prevented immune cell activation by colitis, suppressed inflammatory cytokine gene expression in colon epithelial cells. Mucosal normalization effect was correlated with the stabilization of HIF-1 alpha. These results suggested that DS-1093a had a strong efficacy for IBD in colitis mice with novel mechanisms for normalizing colitis mucosa. Moreover, topical exposure of DS-1093a to the colon can widen the efficacy margin between IBD and erythropoiesis.

Introduction: Dysbiosis has been proposed to be a key antigenic driver for the inflammation in Crohn's disease (CD). However, the role of the fecal microbial composition for the post-operative disease course in CD patients remains to be established.
Aims and Methods: Our aim was to determine if the fecal microbial composition at the time of ileocaecal resection or 1 year after surgery was associated with endoscopic disease recurrence in CD patients 1 year after surgery.
Patients with CD who had undergone ileocaecal resection were included in the study. Approximately 1 year after surgery, clinical evaluation by ileocolonoscopy was performed. The mucosa in the neoterminal ileum and ileocolonic anastomosis was assessed according to Rutgeerts' scoring system. 5 or less aphtoid lesions were considered as remission (i,0-i,1), and >5 aphtoid lesions, lesions or ulcers confined to the anastomosis or diffuse inflammation were considered as endoscopic disease recurrence (i,2-i,4).
Fecal microbial composition was analyzed using the Genetic Analysis GA-map Dysbiosis test, which consists of 54 DNA probes targeting ≥300 bacteria on different taxonomic levels.
Logarithmic data were analyzed in SIMCA using orthogonal partial least squares discriminate analysis (OPLS-DA) to identify discrimination between groups. Bacteria with the strongest discriminatory power were further analyzed by univariate analysis (Mann-Whitney U-test).
Results: In total, 22 CD patients from Southwestern Sweden (8 women) with median age 30 (17–63) years and median disease duration of 3 (0–11) years at the time of resection was included. At inclusion, 8 patients were treated with 5-aminosalicylic acid (5-ASA), 14 with corticosteroids, 11 with thiopurines, 1 with anti-tumor necrosis factor, and 4 patients had none of the treatments above. At the one year follow up, 9 patients were treated with 5-ASA, 2 with corticosteroids, 6 with thiopurines, and 8 patients had no treatment.
Stool samples were collected by 9 patients at the time of resection and by 21 patients at the 1 year post surgery follow-up. At the 1 year follow up, 13 patients were in endoscopic remission (i,0-i,1) and 9 patients had endoscopic recurrence (i,2-i,3).
At the time of resection, fecal microbial composition discriminated patients whom at the 1 year post surgery follow-up were in endoscopic remission or with recurrence, respectively, although the predictive ability was low ($R2 = 0.94$, $Q2 = -0.1$; i,0-i,1: $n = 5$; i,2-i,3: $n = 4$). Similarly, fecal microbiota at the 1 year post surgery follow-up discriminated patients in endoscopic remission from those in recurrence, yet with low predictability ($R2 = 0.71$, $Q2 = -0.47$; i,0-i,1: $n = 13$; i,2-i,3: $n = 8$).
The OPLS-DA models at the time of resection and at 1 year post surgery follow-up demonstrated that endoscopic remission was associated with a higher bacterial abundance, both among the Firmicutes and Bacteroidetes, as compared to patients with recurrence. In addition, univariate analysis showed that patients in remission one year after surgery tended to have higher abundance of Pseudomonas spp at the time of surgery ($p = 0.06$) and Parabacteroides spp at the 1 year post surgery follow up ($p = 0.08$), as compared to patients with recurrence.
Conclusion: Our results suggest that CD patients with endoscopic disease recurrence 1 year after ileocaecal resection have lower fecal bacterial abundance, both at the time of resection and 1 year after surgery, as compared to patients in remission. Thus, a lower intestinal bacterial abundance may be a contributing factor to disease relapse in these patients.

NHI, Nancy Histological Index; RHI, Robarts Histopathology Index; GHAS, Global Histological Activity Score; IL, interleukin

Introduction: The appropriate biopsy location for assessment of histological disease activity and mRNA expression in patients with Crohn's disease (CD) is unknown.

Aims and Methods: We aimed to identify the location adjacent to existing ulcers corresponding to the maximal histologic disease severity rating and mRNA expression level. This prospective multicenter (Belgium, Netherlands, Slovenia) study enrolled 51 patients with CD with ulcers (>0.5 cm) in the colon and/or (neo)terminal ileum. 2 biopsy specimens were obtained from the ulcer edge (location 1) and non-ulcerated mucosa at distance of 1 (7–8 mm [location 2]) and 3 open forceps (21–24 mm [location 3]) perpendicular to the edge of the largest ulcer in the ileum in 19, colon in 15, and ileum and colon in 17 patients. Ileocolonoscopy videos were centrally assessed to confirm correct biopsy procurement and to score endoscopic disease activity with the Simplified Endoscopic Score-CD (SES-CD). Histological disease activity was blindly assessed in digitized biopsy images with the Global Histological Disease Activity Score (GHAS), and the Robarts Histopathology (RHI) and Nancy Histological (NHI) indices. Expression of interleukin (IL)-6, -8, -23, CD31 and S100A9 mRNA levels were determined by quantitative polymerase chain reaction, normalized against housekeeping genes (β-actin and cyclophilin) and expressed as log-transformed data. The relationship between biopsy location and histological activity/mRNA expression level was analyzed using a mixed model with location, segment and location-segment as fixed effects and an unstructured variance-covariance matrix.

Results: The mean (standard deviation) SES-CD score of the patients was 11 (7.5). A linear relationship was observed between biopsy location and histological disease activity and mRNA expression in both segments ($p<0.05$). All histological disease activity ratings and mRNA expression levels were highest at the ulcer edge (**Table 1**). Significant ($p<0.0001$) differences were observed for all comparisons between the ulcer edge and the other biopsy locations in both segments. Although histological disease activity was statistically different ($p<0.05$) between locations 2 and 3 in the ileum, most other comparisons were not (**Table 1**).

[Table 1. Histological disease activity and mRNA expression (estimates and 95% confidence intervals) according to segment and biopsy location]

Conclusion: Biopsy procurement at the edge of an ulcer in patients with CD yields the greatest histological disease activity and mRNA expression.

Introduction: In Ulcerative colitis (UC), mucosal damage occurs in areas, which are infiltrated with neutrophils, a subset of innate immune cells involved in the defense against pathogens. The anti-microbial function of neutrophils relies in part on the formation of extracellular web-like structures, named neutrophil extracellular traps (NETs) through a process called NETosis. Aberrant NETs formation and/or clearance have been associated with several immune diseases.

Aims and Methods: We examined whether UC-related inflammation is characterized by aberrant formation of NETs and investigated the role of such structures in the control of mucosal inflammation. To this end, we evaluated the expression of PAD4, a key enzyme in the formation of NETs, in intestinal samples of patients with UC and controls by Western blotting and immunohistochemistry. The expression of NET-related proteins such as neutrophil elastase (NE), myeloperoxidase (MPO) and citrullinated histone H3 (citH3) was investigated by Western blotting and immunofluorescence. PAD4 and NET-associated proteins expression was further investigated by immunohistochemistry and immunofluorescence in colonic samples of UC patients before and after anti-TNFα (infliximab) treatment. Furthermore, we tested the capacity of neutrophils to produce NETs *in vitro* upon activation with various inflammatory stimuli. Lamina propria mononuclear cells isolated from the inflamed intestine of UC patients were cultured in presence or absence of NETs and then cytokines expression was evaluated by real-time PCR and ELISA and activation of mitogen-activated protein kinases was assessed by Western blotting. Finally, we assessed whether administration of a specific PAD4 inhibitor to mice reverted dextran sodium sulfate (DSS) colitis.

Results: NET-associated proteins were over-expressed in inflamed colon of UC patients as compared to Crohn's disease patients and normal controls. Circulating neutrophils of UC patients produced NETs in response to TNF-α stimulation, and reduced expression of NET-related proteins and diminished NETs formation were seen in patients receiving anti-TNF. Treatment of UC lamina propria mononuclear cells with NETs activated extracellular signal-regulated kinase-1/2, thus enhancing TNF-α and IL-1β production. NETs were induced in mice with DSS colitis and *in vivo* inhibition of NETs formation attenuated colitis.

Conclusion: Data show that NETosis is induced in UC and suggest a role for NETs in sustaining mucosal inflammation in this disorder.

Introduction: Patients with ulcerative colitis (UC) may suffer from irritable bowel syndrome (IBS)-like symptoms during periods of remission. Due to the low-grade immune activation repeatedly reported in IBS, it has been suggested that the underlying inflammatory mechanisms of the 2 diseases overlap or are part of the same spectrum.

Aims and Methods: We aimed to determine if the systemic protein profiles (SysPP) differ between UC and IBS patients, and if SysPP are linked to presence of inflammation and/or functional symptoms. Patients with active ulcerative colitis (UCA), UC patients in remission with IBS-like symptoms (UCR+IBS), UC patients in remission without IBS-like symptoms (UCR-IBS), IBS patients (IBS) and healthy subjects (HS) were included. UCA patients had an endoscopic Mayo score ≥2 and UCR patients had an endoscopic Mayo score = 0 with no relapse during the previous 3 months. UCR+IBS and IBS patients met Rome III criteria with predominant diarrhea or mixed symptom profiles. Serum samples were analyzed using Olink Proseek Multiplex Inflammation panel including 92 proteins (normalized protein expression (NPX)). Logarithmic data were analyzed in SIMCA using principal component analysis (PCA) and orthogonal projection least square discriminate analysis (OPLS-DA) with a Variable Importance for the Projection (VIP) cut-off of >0.7 to identify proteins discriminating between groups. Univariate analyses were performed using Mann-Whitney U test and false discovery rate analysis.

Results: In total, 166 subjects (UCA, n = 40; UCR-IBS, n = 45; UCR+IBS, n = 20; IBS, n = 40; HS, n = 21) were included in the study. PCA of SysPP of all groups revealed 2 clusters; 1 cluster composed of IBS patients and HS, and 1 cluster composed of all UC patients, irrespective of disease activity or presence of IBS-like symptoms. Variables most important for the clustering were higher levels of co-stimulatory molecules such as CD40 and tumor necrosis factor superfamily member 14 (TNFSF14), cytokines such as interleukin (IL)-8 and IL-6, oncostatin-M (OSM), chemokines such as chemokine ligand 3 (CCL3), other inflammatory markers such as extracellular newly identified receptor for advanced glycation end-products (EN-RAGE), sulfotransferase 1A1 (ST1A1), axin 1 (AXIN1), and an apoptotic marker, caspase-8 (CASP8), among UCA/UC+IBS/UC-IBS as compared to IBS/HC.

When comparing IBS and UCR+IBS patients based on the SysPP, OPLS-DA discriminated the 2 groups with high predictability ($R^2Y = 0.92$, $Q^2 = 0.82$).

UCR+IBS was associated with lower levels of IL-7 ($q < 0.01$) and higher levels of CASP8, ST1A1, AXIN1, TNFSF14, OSM, IL8 and EN-RAGE (all $q < 0.0001$) as compared to IBS. Further, when comparing UCR+IBS and UCR-IBS patients the SysPP discriminated the groups, yet the predictive value was low ($R^2Y = 0.68$, $Q^2 = 0.24$). In more detail, UCR+IBS were associated with higher levels of osteoprotegerin (OPG) and TNF-β, while UCR-IBS was associated with higher levels of proinflammatoy cytokine IL-17A and chemokine ligand 9. The SysPP also discriminated UCA and UCR+IBS patients although with low predictability ($R^2Y = 0.52$, $Q^2 = 0.24$). IBS patients and HS could not be discriminated by SysPP ($R^2Y = 0.20$, $Q^2 = 0.10$).
Conclusion: The systemic protein profiles differentiate between UC patients, irrespective of presence of inflammation or functional symptoms, and IBS patients. This suggests that the systemic protein profiles reflects different underlying mechanisms of the 2 diseases rather than presence of functional symptoms.

Introduction: Crohn's disease (CD) is a chronic inflammatory condition with multiple phenotypes of which the fibrostenotic type carries significant morbidity and risk of surgery. We have shown that stenotic segments are characterised by expansion of several layers of the intestine which can be quantitated by a novel scoring system (1).
Aims and Methods: We aimed to look at histological changes in resected terminal ileal (TI) specimens using this novel scoring system. We identified all patients undergoing surgery for TI CD secondary to symptomatic stricturing disease using the histopathology database at Queen Elizabeth Hospital in Birmingham, United Kingdom, between 2012 and 2017. Phenotypic data were recorded and the resection specimens were reviewed and the most representative section of the stenotic segment was used for microscopic assessment. 2 independent pathologists applied the semi-quantitative scoring system. Data was analysed using the %PMTS (possible maximum total score) recorded by the pathologists.
Results: Among 48 patients (M = 25; median age 45 years, range 21–72 years), 41 were Caucasian, 4 Asian and 3 Afro-Caribbean in ethnicity. The median duration of disease was 7 years (range 3 months −39 years); majority had ileo-colonic distribution with stricturing disease; 16 patients were on thiopurines, 19 on steroids & 4 on biologics. The histological grading showed a variable predominant feature in each layer of the bowel wall (Details in Table 1). In the mucosa, chronic inflammation was more prominent whereas fibrosis was predominant in the submucosa; volume expansion (graded by comparing thickness of the layer with relatively normal regions of the same intestinal tract at the margins) was prominent in the muscularis propria and fibrosis was prominent in the subserosa. Muscular hyperplasia (MPH) was consistently seen to be a prominent feature across all layers of strictured bowel and a statistically significant correlation between MPH and fibrosis noted ($r = 0.648$, $p < 0.001$). Interestingly, adipose hyperplasia was seen to be a feature in submucosal layer.
[Table 1-Results of histological scoring(mean PMTS & standard error of mean)]
Conclusion: Our results suggest that pure fibrostenotic disease is uncommon and chronic inflammation is a prominent feature of this phenotype. In addition to fibrosis, muscle hyperplasia is an important component. Other components such as volume expansion, neuronal hypertrophy and adipose hyperplasia are likely to be important in different layers of the bowel. This suggests that inflammation driven tissue remodelling leading to stricture formation is a complex process resulting in a multitude of changes and not simply characterised by excess deposition of fibrotic tissue.

Contact E-Mail Address: ma170042@tmd.ac.jp
Introduction: Inflammatory bowel diseases (IBD) often involve the ileocecal region of the intestine. In addition, accumulating epidemiological studies have suggested that appendectomy may reduce the risk of ulcerative colitis. These evidences imply that ileocecal immune response may be considered to affect the development of IBD, but the mechanism is still unclear.
Aims and Methods: The aim of this study is to analyze the ileocecal immune response in the setting of IBD. To this end, oxazolone colitis model was induced in mice under various backgrounds, conditions (including appendectomy), and methods (such as 5-dimensional intravital imaging).
Results: Wild type C57BL6 (WT) mice sensitized with oxazolone revealed lymphocyte infiltration and ulcerations in the colon accompanied by expanding cecal lymphoid follicles (CLF), which became the focus of our study. Mice underwent appendectomy before oxazolone treatment resulted in attenuated colitis with regards to both clinical disease activity and histopathology index with associated decrease of pro-inflammatory cytokine production. Similar clinical and histopathological changes were also observed in mice lacking mature B cells, μMT. Real-time analysis of B cell activity in the CLF was accomplished by using mice with B cell-specific Ca^{2+} biosensor, YC3.60, expression. Utilizing intravital imaging, B cell activation with frequent Ca^{2+} influx was observed in the CLF during the early phase of colitis development. B cells in the CLF expressed higher level of activation markers, such as major histocompatibility complexes, compared to that of the non-colitis control, even though there were no significant changes in the ratios of immunoglobulin (Ig) classes on the B cell surface of the CLF.
Conclusion: Abnormal Ig production induced by Th2 cytokine was previously considered to be the major role of B/plasma cells in the pathogenesis of IBD. Our current studies, however, imply that B cells in the CLF contribute to the induction of immune responses during the early phase of colitis development. These mechanisms revealed by intravital imaging help provide insight to the novel B cell function associated with the pathophysiology of IBD.

P0276 THE CHANGE OF THE ANG, ACE2 AND ANG,1-7,ON TNBS-INDUCED EXPERIMENTAL COLITIS IN MICE AND THE RESEARCH ABOUT PROTECTIVE EFFECT OF MICA

B Zhang, **M Shen**, L Ye, B Lv, L.-N Meng
The First Affiliated Hospital of Zhejiang Chinese Medical University, Gastroenterology, Hangzhou, China

Contact E-Mail Address: s167725@163.com
Introduction: Ulcerative colitis (UC), a chronic intestinal inflammatory condition that affects millions of people worldwide, is characterized by leukocyte infiltration and upregulation of proinflammatory cytokines. Mica is a of silicate mineral drug. Previous studies have shown that mica can promote gastrointestinal mucosal epithelial cell regeneration and anti-inflammatory effect.
Aims and Methods: We aimed to explore the roles of Ang,ACE2 and Ang,1-7, in experimental colitis and investigate the prevention and possible mechanism of mica.
30 male BALB/C mice of clean grade were randomly divided into control group, model group and mica group, 10 mice in each group. Experimental colitis mice were made by TNBS. In first day, the model group and mica group were initiated by intrarectal administration of TNBS (250mg/kg/d) to establish the model, control group was initiated by intrarectal administration of saline water (10ml/kg/d). From the second day,the control group and model group were

intrarectally administrated with (10ml/kg/d), the mica group was intrarectally administrated with Mica (180mg/kg/d), until the fourth day, then all the mice were killed. Macroscopic score and histological score were assessed. Protein expressions of Ang,ACE2 and Ang,1-7, were measured by immunohistochemist. ELISA was used to determine colon tissue inflammatory factor IL-17A and IL-10 level.

Results: 1) Macroscopic total damage: Colonic macroscopic damage index of mice in normal, the model group was much higher than that of the control group (4.00 ± 0.89 vs. 0.00 ± 0.00, $p < 0.01$), the mica group was much lower than the model group (2.00 ± 1.53 vs. 4.00 ± 0.89, $p < 0.01$). **2) Colonic tissues histological score:** The histological score of the model group was much higher than the control group (8.17 ± 2.99 vs. 1.33 ± 1.03, $p < 0.01$). Compared with the model group, the histological score in the mica group decreased statistically significantly (3.83 ± 1.47 vs. 8.17 ± 2.99, $p < 0.01$). **3) The level of Ang, ACE2, Ang1-7 in mice colonic tissues:** The level of Ang, and Ang1-7 in the model group were increased compared with the control group (Ang,:4.83 ± 2.11 vs. 2.16 ± 0.41, $p < 0.01$; Ang1-7:2.0 ± 0.63 vs. 0.13 ± 0.14, $p < 0.05$). But in the mica group the level of Ang, and Ang1-7 were significantly decreased compared with the model group (Ang,:2.33 ± 0.52 vs. 4.83 ± 2.11, $p < 0.01$; Ang1-7:1.04 ± 0.56 vs. 2.0 ± 0.63, $p < 0.01$). Compared with the control group, the expression of ACE2 in colonic tissues from mice in the model group was increased (3.50 ± 0.55 vs. 2.04 ± 0.29, $p < 0.05$), and in the mica group it was significantly increased than in the model group (5.13 ± 1.84 vs. 3.50 ± 0.55, $p < 0.05$). **4) The expression of IL-17A in mice colonic tissues:** The expressions of IL-17A in colonic tissues from mice in the model group and the mica group were significantly increased (6.93 ± 0.44 vs. 0.65 ± 0.03, $p < 0.01$; 2.63 ± 0.64 vs. 0.65 ± 0.03, $p < 0.01$). Meanwhile, the expression of IL-17A in the mica group was lower than in the model group (2.63 ± 0.64 vs. 6.93 ± 0.44, $p < 0.01$). **5) Correlation analysis:** Pearson's correlation analysis show that the expression of Ang, was moderate positive correlation with the mice colonic macroscopic damage index ($r = 0.524$, $p < 0.05$),and was high positive correlation with the mice colonic histological score ($r = 0.909$, $p < 0.01$).

Conclusion: There is an imbalance between Ang, and ACE2, Ang,1-7,in the TNBS-induced experimental colitis mice. And mica can reduce colonic tissues inflammation and damage.

Introduction: Inflammatory bowel diseases (IBD) is associated with an increased risk for the development of colorectal cancer. However, the mechanism of immune signaling pathways linked to colitis-associated cancer (CAC) has not been fully elucidated. Tauroursodeoxycholic acid (TUDCA) exhibits anti-inflammatory and anti-cancer activities. The aim of this study is to investigate the role of TUDCA in the pathogenesis of CAC.

Aims and Methods: CAC was induced in mice using azoxymethane (AOM) and dextran sodium sulfate (DSS) administration, and TUDCA's effect on tumor development was evaluated. HCT 116 and COLO 205 were treated with TUDCA or vehicle and then stimulated with tumor necrosis factor-α (TNF-α). Expression of interleukin (IL)-8 was determined by real-time RT-PCR and ELISA, and IκBα phosphorylation and degradation was evaluated by immunoblot assay. The DNA-binding activity of NF-κB was assessed by electrophoretic mobility shift assay (EMSA). Cell viability assay and real-time RT-PCR of *bcl-xL*, *MCL1*, *c-FLIP-L* and *VEGF* were performed.

Results: TUDCA significantly attenuated the development of CAC in mice. Exposure to TUDCA resulted in extensive epithelial apoptosis and reduced levels of phospho-IκB kinase in the colon. In HCT 116 cells stimulated with TNF-α, TUDCA significantly inhibited IL-8 expression and suppressed TNF-α-induced IκBα phosphorylation/degradation and DNA-binding activity of NF-κB. Furthermore, in both HCT 116 and COLO 205 cells, TUDCA reduced cell viability and downregulated the expression of *bcl-xL*, *MCL1*, *c-FLIP-L* and *VEGF*.

Conclusion: These results demonstrated that TUDCA suppresses NF-κB signaling and ameliorates colitis-associated tumorigenesis, suggesting that TUDCA could be a potential treatment for CAC.

Introduction: Anti-TNF alpha represents the best therapeutic option to induce mucosal healing and clinical remission in patients with moderate-severe ulcerative colitis. On the other side, gut microbiota plays a crucial role in pathogenesis of ulcerative colitis but little information exists on how microbiota changes following anti-TNF-alpha therapy and on the role of microbiota in mucosal healing.

Aims and Methods: We aimed to evaluate gut microbiota and adaptive immune system response change following anti TNF-alpha therapy in murine dextransodium sulphate (DSS) colitis. C57BL/6 mice were fed for 5 days with 3% DSS in drinking water. At day 3 of DSS treatment, mice received intravenous administration of 5 mg/Kg of infliximab (IFX), an anti-TNF alpha monoclonal antibody, or placebo. Further 2 groups of mice received IFX or placebo without DSS. Disease severity was scored daily using the 4 points Disease Activity Index (DAI). At day V and XII serum, colon, feces and mesenteric lymph node (MLN) were collected from each animal. Microorganisms belonging to Bacteroides, Clostridiales, Enterobacteriaceae and Fecalibacterium prausnitzii were assessed by qPCR, following bacterial DNA extraction from feces. Th1, Th2, Th17 and Treg cell distribution in the MLN were evaluated by intracellular cytokine staining by flow cytometry.

Results: Anti-inflammatory species (Bacteroides, Clostridiales and Fecalibacterium prausnitzii) decreased during DSS-induced colitis and increased in fecal samples of IFX-treated colitis mice compared to control mice. Conversely, pro-inflammatory microorganisms belonging to Enterococacceae genera increased during colitis and decreased after IFX treatment. Furthermore, in IFX-treated colitic mice, microbial changes are associated to an initial increase (day 5 of the colitis) in Treg cells and a consequent decrease (day 12 of colitis) in Th1, Th2 and Th17 cells. Similarly, healthy mice treated with IFX showed the same histological features, microbial and immune changes of untreated colitic mice.

Conclusion: Anti-TNF alpha treatment in experimental model of colitis improves disease activity trough changes in T cell subsets and in microbiota composition Furthermore, the present study suggests that different components of the microbiota each distinctly influence the differentiation and accumulation of specific populations of immune cells. Further analysis on immune cells within mucosa will be necessary.

Introduction: The gut mucosa is continuously exposed to a vast community of microorganisms, collectively defined as microbiota, establishing a mutualistic relationship with the host and contributing to shape the immune system. Gut microbiota is acquired at birth, and its composition is relatively stable during the entire adult life. Intestinal dysbiosis, defined as a microbial imbalance of gut bacterial communities, can be caused by several factors, including bacterial infections and antibiotic use, and has been associated with an increased risk to develop or exacerbate immune-mediated pathologies, such as allergic reactions, asthma and inflammatory bowel diseases (IBD). Still, the mechanisms by which antibiotic-induced gut dysbiosis may lead to development of mucosal inflammation are still matter of debate.

Aims and Methods: We aimed to evaluate the impact of antibiotic treatment on phenotype and functions of intestinal immune cell populations, including invariant Natural Killer T (iNKT) cells, a subset of lipid specific T cells profoundly influenced by alterations on the commensal microbiota.

A cocktail of broad-spectrum antibiotics was administered for 2 weeks to otherwise healthy mice before re-colonization of the intestinal microbial community with oral gavage of eubiotic or dysbiotic mucosa-associated bacteria and luminal colonic content, followed or not by intestinal inflammation induction.

Results: Short-term antibiotic treatment alters frequency and functions of intestinal iNKT cells, even in the absence of intestinal inflammation. The presence of a dysbiotic microbiota after antibiotic treatment imprints colonic iNKT and

CD4+ T cells towards a pro-inflammatory phenotype that collectively contributes to aggravate intestinal inflammation. Nonetheless, the inflammatory potential of the dysbiotic microbiota decreases over time opening the possibility to temporally intervene on the microbial composition to re-equilibrate dysbiosis thus controlling concomitantly mucosal immune T cell activations.
Conclusion: Antibiotic treatment can induce alterations in the intestinal microbial ecology leading to the activation of colonic pro-inflammatory immune cell responses.

P0280 THERAPEUTIC POTENTIAL OF GLEPAGLUTIDE, A LONG-ACTING GLUCAGON-LIKE PEPTIDE-2 RECEPTOR AGONIST, IN A RAT MODEL OF RECURRENT INDOMETHACIN-INDUCED SMALL INTESTINAL INFLAMMATION

J Skarbaliene[1], C Thorkildsen[1], M Berner-Hansen[1], W Russell[1]
[1]*Zealand Pharma A/S, Glostrup, Denmark*

Contact E-Mail Address: jsk@zealandpharma.com
Introduction: Glepaglutide (ZP1848) is a novel, long-acting GLP-2 receptor agonist that is currently in clinical development for the treatment of short-bowel syndrome. We have previously shown that treatment with glepaglutide in a rat model of indomethacin-induced small intestinal (SI) inflammation enhanced intestinal repair, as measured by increase in intestinal mass and plasma citrulline levels, and decrease in inflammatory markers.
Aims and Methods: The aim was to determine whether pre- and continuous-treatment with glepaglutide would attenuate the SI inflammation response in rats exposed to a second inflammatory episode.
2 cycles of SI inflammation were induced in male Wistar rats by indomethacin administration (7 mg/kg, s.c.) on day 0 and day 1 (primary challenge) and then again on day 18 and day 19 (secondary challenge). Rats were treated with glepaglutide (80 and 400 nmol/kg, s.c.) from day 0 to day 14 (pretreatment), or from day 0 to day 21 (continuous treatment). Groups of rats (n = 8/group) were sacrificed on days 15 and 22. Study endpoints were bodyweight (BW), jejunal and ileal mass/BW, SI length, and SI levels of alpha 1 acid glycoprotein (α-1-AGP; ELISA kit, Life Diagnostics) and myeloperoxidase (MPO; ELISA kit, Hycult Biotechnology).
Results: Pretreatment with glepaglutide (80, 400 nmol/kg) increased jejunal- and ileal mass/BW on day 15 ($p < 0.001$ for both dose levels vs Indomethacin group). The second indomethacin-induced SI inflammation episode was characterized by BW loss, increased jejunal and ileal mass/BW, decreased SI length, and increased SI levels of α-1-AGP and MPO. Pre- (400 nmol/kg) and continuous treatment (80, 400 nmol/kg) with glepaglutide prevented BW loss in animals after the second inflammatory episode ($p < 0.001$ for all comparisons vs Indomethacin group). In addition, both pre- and continuous treatment with glepaglutide (400 nmol/kg) significantly increased ileal mass/BW on day 22, but had no effect on jejunal mass/BW vs Indomethacin group. Both treatment regimens dose-dependently counteracted the shrinking of the SI length, and decreased SI levels of inflammatory markers (α-1-AGP and MPO) during the second phase of inflammation (day 22).
Conclusion: We have demonstrated that pre- and continuous treatment with glepaglutide protected the SI against the recurrent inflammatory episode. In addition, pretreatment with glepaglutide increased SI mass assessed prior to the induction of the second phase of inflammation, suggesting that this increase in SI mass had rendered SI more resistant to the second inflammatory insult. In conclusion, glepaglutide may provide an attractive option for the treatment and/or prevention of the unpredictable course of inflammatory bowel disease.

P0281 CHARACTERISTICS OF MUCOSA-ASSOCIATED GUT MICROBIOTA DURING TREATMENT IN CROHN'S DISEASE

C He, H Wang, X Zhu, W Liao, Z Zhu
The First Affiliated Hospital of Nanchang University, Department of Gastroenterology, Nanchang, China

Contact E-Mail Address: hecong.1987@163.com
Introduction: The dysbiosis of gut microbiome seems relevant to the pathogenesis of Crohn's disease (CD), with differences between patients with CD and healthy subjects (HS) in both diversity and composition. However, it is not clear how the gut microbiota changed from active CD to remission after treatment.
Aims and Methods: The aim of this study was to characterize the dynamic alterations of mucosa-associated intestinal microbiota in CD patients after induction of remission. A 16S rRNA sequencing approach was applied to determine the structures of microbial communities in mucosal samples including terminal ileal, ascending colon and descending colon. The composition and function of mucosa-associated gut microbiota were compared between paired samples from CD patients in active and remission stage during treatment.
Results: There were no significant differences in microbial structure among the three anatomical sites within individuals. Compared to active disease, the alpha diversity of CD in remission was increased and approximately up to the level of HS. The principal coordinate analysis revealed that samples of active CD clearly separated from those in remission which clustered close to HS. 42 genera were identified to be differentially abundant between active and quiescent CD with a loss of *Fusobacterium* and a gain of potential beneficial bacteria including *Lactobacillus*, *Akkermansia*, *Roseburia*, *Ruminococcus* and *Lachnospira* after the induction of remission. The combination of these taxa into a microbial dysbiosis index showed a strong positive correlation with clinical disease severity and negative correlation with species richness.
Conclusion: The dysbiosis of mucosa-associated microbiota was associated with disease phenotype, which could be partly restored after the induction of remission. We speculate that the trajectory of early microbiome changes may represent a predictive factor for relapse.

Introduction: Several experimental data have highlighted the potential role of intestinal macrophages in the pathogenesis of Crohn's Disease (CD). These macrophages present a defect in the control of CD-associated adherent-invasive *E. coli* (AIEC) replication, which could be linked to altered autophagy.
Aims and Methods: We investigated the impact of several CD-associated singer nucleotide polymorphisms (SNPs) including those involved in autophagy on the ability of macrophages from CD patients to eliminate AIEC bacteria. Peripheral blood monocyte-derived macrophages (MDM) were obtained from 95 CD patients, 30 ulcerative colitis (UC) patients and 15 healthy subjects genotyped for CD-associated SNPs related to autophagy, especially *IRGM* (rs10065172) and *ULK1* (rs12303764) and, infected with AIEC LF82 reference strain. Functional assay were performed on MDM after AIEC infection and/or after a short-term silencing of ULK1 gene. The numbers of intracellular bacteria were determined using gentamicin protection assay. IRGM, ULK1 and p62 protein expression was determined by western blot.
Results: AIEC survival was increased within MDM from CD patients compared to those from UC patients or healthy subjects ($p = 0.0019$). MDM from CD patients failed to kill AIEC bacteria especially in patients harboring the CD-associated *IRGM* SNP ($p = 0.045$). In contrast, AIEC survival was decreased in MDM from patients with the CD-associated *ULK1* SNP ($p = 0.046$). ULK1 expression, but not IRGM and p62, was increased in MDM from CD patients infected by AIEC bacteria compared to MDM from UC patients or healthy subjects ($p = 0.0056$) and are significantly correlated with the AIEC survival ($p = 0.0369$). In this line, ULK1 down-regulation within MDM limits the AIEC survival ($p = 0.0018$).
Conclusion: We confirmed that MDM from CD patients failed to eliminate AIEC bacteria compared to those of UC or healthy subjects. Our results highlight a role of CD-associated SNPs, related to autophagy, IRGM and ULK1, on the ability of macrophages from CD patients to mediate AIEC bacterial clearance. At the protein level, our data suggested a role of ULK1, the cornerstone of autophagy initiation, to control AIEC bacteria within macrophages, in patients with CD. This protein could represent a potential new target to alter the interaction between macrophages and AIEC.

Introduction: Alterations in the immunopathogenesis in ulcerative colitis (UC) due to the natural disease course have been proposed but so far data are lacking. We therefore aimed to determine mucosal and systemic immune profiles at the time of diagnosis (early disease) and after 10 years (late disease) in UC patients.
Aims and Methods: Patients with UC provided serum and mucosal biopsies during a flare at the time of diagnosis and after 10 years of disease. mRNA gene expression in biopsies was analyzed using the Qiagen RT^2 Profiler PCR Arrays Antibacterial response and T Helper Cell Differentiation with 84 genes per array, in total 152 unique genes. Serum samples were analyzed using Olink Proseek Inflammation panel including 92 proteins (normalized protein expression (NPX)), but only the 43 proteins related to digestive tract were included in the analyses. Logarithmic data were analyzed in SIMCA using OPLS-DA to identify parameters discriminating between early and late disease, implementing a Variable Importance for the Projection (VIP) cut-off > 1. Identified parameters were used for univariate analysis and false discovery rate analysis. Data are

presented as fold change of means for mRNA analyses and median (interquartile range) for normalized protein expression.
Results: The study included 15 UC patients (mean age 48 years after 10 years of disease, 60% males) where 8 had extensive, 5 left-sided disease and 2 proctitis. No patient had ongoing treatment with corticosteroids or biologics (2 were previously exposed to Infliximab), 3 patients currently used Azathioprine and 10 oral aminosalicylates. When comparing early and late disease, the mRNA profiles in biopsies discriminated the groups and showed high predictability ($R2 = 0.8$, $Q2 = 0.71$). In total, 37 genes were differently expressed during early and late disease (all $q < 0.05$). In more detail, a fold increase of the Th2 response related genes IL-5 (2.5, $q = 0.01$), IL-13 (2.2, $q = 0.04$) and IL1R1 (2.5, $q = 0.008$) was detected during late compared to early disease. Concomitantly, a fold decrease of the Th1 associated genes TNF (0.66, $q = 0.03$) and SOCS1 (0.66, $q = 0.04$) was recorded during late compared to early disease.
Additionally, the profile of 17 serum proteins discriminated early and late disease ($R2 = 0.63$, $Q2 = 0.40$) and 7 of these were differently expressed between the groups (all $q < 0.03$). The growth factor for dendritic cells, Flt3L (8.7 (8.3–9.0) vs. 7.9 (7.5–8.7) NPX), and the chemokine ligand CCL25 (6.3 (5.8–6.6) vs. 5.5 (5.0–6.0) NPX) involved in intestinal homing of lymphocytes were increased during late as compared to early disease. Further, IL-8 (7.4 (6.9–7.9) vs. 8.9 (7.1–14.5) NPX) and MCP3 (2.2 (1.9–2.6) vs. 2.8 (2.3–8.0) NPX), important for recruitment of neutrophils and monocytes, and TNFSF14 (6.7 (5.4–7.2) vs. 7.6 (6.5–8.3) NPX), CCL20 (4.7 (4.4–5.4) vs. 5.8 (5.5–6.2) NPX) and CCL28 (1.4 (1.2–1.6) vs. 1.6 (1.5–1.9) NPX) associated with lymphocyte homing were decreased during late as compared to early disease.
Conclusion: Mucosal and systemic inflammatory profiles differ between early and late disease in UC patients with active disease, with a change from a T Helper 1 to a T Helper 2 cell driven disease. Improved understanding of the variation in immunopathogenesis due to the natural disease course is important to guide individualized treatment decision-making.

P0284 LOW LEVEL OF KNOWLEDGE OF PREGNANCY-RELATED ISSUES IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE IN POLISH POPULATION

M Kukulska[1]
[1]*Wroclaw Medical University, Wrocław, Poland*

Contact E-Mail Address: monika.kukulska@gmail.com
Introduction: Inflammatory bowel diseases (IBDs) belong to the group of chronic diseases, significantly increase the risk of surgery, colorectal cancer and often impact young people of reproductive age, as they may influence their personal life choices regarding family planning and having children.
Aims and Methods: The aim of the work was to assess the knowledge of female patients with IBD regarding pregnancy and fertility issues in respect of the disease. The goal of the work was also to educate the patients. The examinations were based on validated test CCPKnow (Crohn's and Colitis Pregnancy Knowledge Score). The study included 120 women at the age of 18 to 74, including 86 women at the age up to 45 years old, 59 women with CD (Crohn's disease) and 61 women with UC (ulcerative colitis). All the respondents were treated in Department of Gastroenterology and Hepatology of Wrocław Medical University in years 2014–2017.
Results: The average disease duration of each patient was estimated to 8 years, in case of women of reproductive age (up to 45 years old) was estimated to 6.6 years. Majority of the patients claimed to live in a long-time relationship. In the group of patients up to 45 years old, 63% women did not have any children. All the children born after disease diagnosis were healthy. No congenital abnormality was found. 31% of patients of reproductive age declared that they did not plan to have (more) children in the future, more than half underlined that the decision was made with regard to existing disease. The average amount of points gathered in CCPKnow test was estimated to 6.9 of 17 points possible. Through this research we can state that 40–50% female patients assessed by means of CCPKnow test have low level of knowledge regarding pregnancy and fertility, and only 8–10% display good level of knowledge. Female patients over 45 years gained less points in comparison to younger women (4,85 vs. 7,7; $p = 0.0012$). Significantly higher level of knowledge was stated among women, who gave birth during the disease ($p = 0.0003$), also with higher education and medical education ($p = 0.0157$). It was noticed that, patients with IBD have less children than the general population, which seems to be their conscious choice. The patients of a reproductive age, who declare that they do not want to have (more) children in the future and the ones that chose consciously to be childless, have significantly lower level of knowledge assessed by means of CCPKnow test ($p = 0.0131$), which suggests that education of the patients may have a positive influence on their life choices.
Conclusion: Female patients with IBD have less children in comparison to teh general population. The majority of the patients suffering from IBD have a low level of knowledge regarding pregnancy and fertility, especially women over age of 45. Higher levels of knowledge were observed in the group of female patients who gave birth to children during the disease, also those who had high education and medical education. Lower levels of knowledge were found in the group of women in the reproductive age, who declared consciously to be childless or did not want to have children at all in the future. The lowest level of knowledge was stated among the patients with IBD regarding treatment during pregnancy and when making efforts to get pregnant. Educating patients is very important.
Disclosure: Nothing to disclose

[3]*University of Copenhagen, Department of Immunology and Microbiology, Copenhagen N, Denmark*

Contact E-Mail Address: sebastian@kjaergaard.cc
Introduction: The gastrointestinal tuft cells (TCs) have recently been revealed as parasite-sensing cells in rodents. TCs play a key role in initiation of a type-2 immune response and lead to parasite expulsion as well as orchestration of the post-inflammatory restoration of the mucosa (1). However, the role of TCs in human pathophysiological conditions is still an open question.
Aims and Methods: The aim of the present retrospective study was to test the hypothesis that the count of colonic TCs in patients with inflammatory bowel disease (IBD) is altered compared to healthy controls (ctrls).
Endoscopic colonic mucosal biopsies from 58 individuals were included in the study; 14 patients with Ulcerative Colitis (UC) in clinical and endoscopic remission (total Mayo score ≤ 2 and no sub score > 1), 9 with clinical and endoscopic active UC (total Mayo score > 2 and Mayo endoscopic sub score > 1), 10 with colonic Crohn's Disease (CD) in endoscopic and histological remission (1 had slight inflammation of the terminal ileum), 8 with endoscopically and histologically active colon CD, and 17 were endoscopically and histologically healthy and served as controls. The TCs were immunohistochemically identified and quantified using a primary antibody raised against cyclooxygenase-1 enzyme and counted by the first authors (TSRJ, SK and URF) independently and blinded to diagnose. Poisson's regression analysis was employed for statistics. Results were adjusted for size of biopsy, gender and age. Values are presented as mean ± SEM. A $p < 0.05$ was considered significant.
Results: On average controls had 104 ± 21 TCs/mm.^{2} Patients with active UC and UC in remission had a 57 % ($38 \pm 6/mm^2$, $p < 0.001$) and a 56 % ($38 \pm 7/mm^2$, $p < 0.001$) decrease in number of TCs compared to controls. Although less pronounced, patients with CD in remission also presented a decrease in TCs of 10 % ($64 \pm 19/mm^2$, $p < 0.001$). Conversely, patients with active CD demonstrated a 28% increase in numbers of TCs ($89 \pm 35/mm^2$, $p < 0.001$).
Patients with CD in remission had lower number of TCs compared to patients with active CD ($p < 0.001$). No difference was observed when comparing active UC to quiescent UC ($p = 0.621$).
Conclusion: To our knowledge, this study is the first to demonstrate that number of colonic mucosal TCs is altered in both UC and CD patients. The concentration of TCs is considerably higher in controls compared to active- and quiescent UC, while just slightly higher compared to quiescent CD. Compared to active CD, ctrls on average have a smaller concentration of TCs. Data suggest that colonic TCs may play a role in disease course and pathogenesis of IBD patients.

Contact E-Mail Address: tnagaishi.gast@tmd.ac.jp
Introduction: Mice deficient in the megakaryoblastic leukaemia 1 (*Mkl1*) gene are protected from dextran sulphate sodium (DSS)-induced colitis, implying that *Mkl1* plays a pathological role in inflammatory bowel disease (IBD). However, how *Mkl1* contributes to the development of colitis remains unknown. It was found that the expression of *Mkl1* is higher in the colonic lamina propria macrophages (LPMac) of DSS-treated mice than in those of control mice.
Aims and Methods: In this study, we established a transgenic mouse line that overexpresses human *MKL1* (MKL1-Tg) specifically in cells of the monocyte/

macrophage lineage, in order to investigate the potential role of macrophage *MKL1* in the pathogenesis of colitis.
Results: MKL1-Tg mice displayed spontaneous colon shortening and rectal prolapse. Scattered cryptitis was observed among the colons. Flow cytometric and quantitative RT-PCR analyses revealed that, in MKL1-Tg mice compared to littermate controls, the proportion of LPMac was decreased and had an altered inflammatory phenotype indicative of impaired anti-inflammatory properties. MKL1 also orchestrates macrophage polarization. Of note, overexpression of MKL1 impacts transcriptional activities of NF-κB p65 and PPARγ. Furthermore, MKL1-Tg mice had higher susceptibility to DSS-induced colitis, which was accompanied with prominent B cells infiltration and follicle formation.
Conclusion: Together, our observations indicated that MKL1 crucially contributes to the development of colitis via the regulation of the function of macrophages, suggesting that it may be a potential therapeutic target for the prevention of IBD.

P0287 REGULATORY B CELLS CONTRIBUTE TO ALLEVIATE THE ACUTE COLITIS IN CD19$^{-/-}$MICE

X Li, J Tan, Q Xue, Y Li, J Wang
Peking University People's Hospital, Department of Geratology, Beijing, China

Contact E-Mail Address: lixialjay@163.com
Introduction: Epidemiological studies showed that there was an inverse relationship between *Helicobacter pylori* (*H.pylori*) infection and the incidence of inflammatory Bowel Diseases (IBD). It was confirmed that CD4+CD25+Foxp3+Treg cells could protect mice from colitis. Our previous study showed that *H.pylori* infection induced the expansion of regulatory B cells (Breg) ahead of the Treg cells.
Aims and Methods: In this study, we investigated the effect of Breg cells on acute colitis induced by dextran sulphate sodium (DSS). SPF CD19$^{-/-}$mice were utilized. 1x10^{6}Breg or B cells or equal PBS were adoptive transferred to the CD19$^{-/-}$ mice via the tail vein. Twenty-four hours later, acute colitis was induced by 3% DSS for 7 days and PBS for 3 days.
Results: There was no significant difference in body weight changes between each colitis group. Adoptive transfer of Breg or B cells improved the survival rates effectively (100%, 83%, 50% for Breg+DSS, B+DSS, PBS+DSS, respectively). The colon length shortened significantly in colitis mice (PBS+DSS vs. PBS+PBS = 4.7 ± 0.16 vs. 7.7 ± 0.45, $p = 0.001$). Adoptive transfer of Breg cells recovered the colon length to a large extent when comparing to the B cells or PBS adoptive transfer groups (Breg+DSS vs. B+DSS = 6.4 ± 0.59 vs. 4.9 ± 0.7, $p = 0.004$; Breg+DSS vs. PBS+DSS = 6.4 ± 0.59 vs. 4.7 ± 0.16, $p = 0.005$; B+DSS vs. PBS+DSS = 4.9 ± 0.7 vs. 4.7 ± 0.16, $p = 0.683$). Colonic histopathology stained by HE showed that colonic inflammatory induced by DSS was alleviated by adoptive transfer of Breg and B cells, and Breg cells were more efficient than B cells. Treg cells in spleen expanded significantly in colitis mice (PBS+DSS vs. PBS+PBS = 14.1 ± 0.21 vs. 11.78 ± 0.64, $p = 0.036$), and adoptive transfer of Breg cells induced more Treg cells while B cells reduced Treg cells significantly (Breg+DSS vs. PBS+DSS = 17.43 ± 1.73 vs. 14.1 ± 0.21, $p = 0.008$; B+DSS vs. PBS+DSS = 11.3 ± 0.5 vs. 14.1 ± 0.21, $p = 0.039$; Breg+DSS vs. B+DSS = 17.43 ± 1.73 vs. 11.3 ± 0.5, $p < 0.001$). Foxp3 mRNA relative expression level in colon was higher in Breg cells adoptive transfer group than B cells ($p = 0.017$) or PBS groups ($p < 0.001$).
Conclusion: Rather than B cells, adoptive transfer of Breg cells induced CD4+CD25+Foxp3+Treg cells expansion and alleviated acute colitis induced by DSS significantly in CD19$^{-/-}$mice.

P0288 IMPAIRED BUTYRATE INDUCED ANTI-INFLAMMATORY IMMUNE REGULATION IN LAMINA PROPRIA CELLS FROM PATIENTS WITH ACTIVE ULCERATIVE COLITIS

M.K Magnusson, S Isaksson, L Öhman
University of Gothenburg, Dept. of Microbiology and Immunology, Inst. of Biomedicine, Gothenburg, Sweden

Contact E-Mail Address: maria.magnusson@microbio.gu.se
Introduction: Modulation of the gut microbiota has emerged as a therapeutic option for patients with ulcerative colitis (UC), yet with modest effects. Microbial dysbiosis and reduced levels of short-chain fatty acids such as butyrate have been identified as key components of the disease and butyrate is known to have anti-inflammatory properties.
Aims and Methods: Here we aimed to determine and compare immunological effects of butyrate on lamina propria (LP) cells from UC patients with active disease and non-inflamed control (CTR) patients.
Duplicate sigmoidal biopsies were cultivated without (none) or with 1.6 mM butyrate (but) for 6h after which biopsies were collected for RNA purification. mRNA gene expression was analyzed using the Qiagen RT^2 Profiler PCR Arrays Antibacterial response and Innate and Adaptive Immune Responses with 84 genes per array, in total 135 unique genes. Logarithmic data were analyzed using principal component analysis (PCA) and orthogonal partial least squares discriminant analysis (OPLS-DA) with a cut off for Variable Importance for the Projection >1.2. Identified parameters were subject to univariate analysis and false discovery rate analysis and evaluated using Ingenuity Pathway Analysis (IPA). Gene expression data are presented as fold change (FC) of means on a $\log_2$ scale where $\log_2 FC = 1$ and -1 define a 2-fold increase and decrease, respectively.
Results: The study included 8 CTR patients (4 males, age 54 (24–84), median (range)) and 8 patients with UC (6 males, age 38 (32–74)) with a disease duration of 7 (<1–47) years. All UC patients had active disease with endoscopic Mayo score 2 (n = 7) or 1 (n = 1) and all CTR patients had Mayo score 0. Current treatment for UC patients was 5ASA (n = 5), 5ASA and thiopurines (n = 1), corticosteroids (n = 1) and no treatment (n = 1).
PCA analysis of mRNA expression without and with butyrate for UC and CTR revealed differential clustering. UC-none and UC-but were located at the lower and upper right quadrant, respectively, while CTR-none and CTR-but were located at the lower and upper left quadrant, respectively, with only minor overlap between the 4 groups. Highly discriminant and predictive OPLS-DA plots identified 29 genes for UC ($R2 = 0.94$, $Q2 = 0.86$) and 23 genes for CTR ($R2 = 0.90$, $Q2 = 0.71$) that were most regulated by butyrate. Of these genes, 11 were overlapping resulting in a combination of 41 genes used for pathway analysis. The top canonical pathway identified by IPA was "Neuroinflammation Signaling Pathway" (-log(p-value) 39, 27 associated genes) and z-scores of -2.117 and - 0.962 for CTR and UC, respectively, indicated a down regulation in the presence of butyrate for CTR but not for UC. Based on 23 of the 41 genes, IPA mapped 'Inflammatory response' as the top disease function ($p = 2.1 \times 10^{-28}$) and predicted that butyrate decreased the inflammatory response for CTR (z-score = -2.649) but not for UC (z-score = -1.308).
Using univariate analysis, for CTR patients 8 genes were down regulated ($\log_2 FC < -1$, $q < 0.05$; IL2, CXCL10, IL6, IL1a, CD40L, IL1R1, CCL2, FOXP3) and 1 was up regulated ($\log_2 FC > 1$, $q < 0.05$; BIRC3) by butyrate while, for UC patients, 2 genes were downregulated (IL2, XIAP) and 4 were upregulated (TLR5, NLRP3, STAT1, ICAM1) by butyrate.
Conclusion: Butyrate rapidly down regulates pro-inflammatory genes in LP cells from healthy controls but not from UC patients with active inflammation. These discrepancies may at least partly explain why anticipated anti-inflammatory effects of fecal transplantation or local butyrate induction are not always obtained.

Introduction: Mesenchymal stem cell (MSC) have the potential to treat many autoimmune diseases including inflammatory bowel disease. Therapeutic benefit of MSC is due to inhibition of T cell proliferation and polarization of macrophage towards M2 phenotype. MSC derived from different tissues, donors and passages display different immune properties. Although most of MSC research are conducted on MSC derived from bone marrow, MSC of the best quality and greatest benefit have not been defined yet.
Aims and Methods: Our aim is to characterize the effect of MSCs -derived from different origins and passages- on macrophage. Here, we compared the ability of MSC derived from 2 origins [bone marrow (BM-MSC) and adipose tissue (AD-MSC)] and 2 qualities [early-passaged (p1) and late-passaged (p6) BM-MSC] to polarize macrophage towards M1 or M2 phenotype.
Method: We isolated adipose MSC from 10-week-old male C57BL/6 mice and expanded early and late passaged MSC. Then, chemokines and cytokines focused array was performed on the 3 types of cell. MSC were co-cultured with splenocytes for 3 days and after that CD206 and CD86 expression was evaluated by immunohistochemistry. The release of IL10, IL6 and TGF-β were evaluated by ELISA assay before and after co-culture.
Results: Pathway focused PCR array showed that the gene expression profiling of immunomodulatory cytokines and chemokines in MSC was largely different depending on the cell origins and cell qualities. There was a 3-fold increase in *Il6* expression, 36-fold increase in colony stimulating factor 2 (*Csf2*) and 21-fold increase in tumour necrosis factor receptor superfamily member 13b (*Tnfsf13b*) in AD-MSC versus BM-MSC. Late passaged cell decreased the expression of many immune regulatory gene like *Tgfβ2* and tumour necrosis factor receptor superfamily member 11B (*Tnfrsf11b)*. By co-culturing with splenocytes for 3 days, MSC of different qualities showed significantly different properties on regulating the expression of CD206 and CD86 on macrophage. Macrophages were polarized toward M2 phenotype with early-whether derived from adipose tissue or bone marrow- but not with late passaged cells. Cytokines assay showed that only AD-MSC secreted IL10 and that late passaged cell secreted lower level of both IL-6 and TGF-β.
Conclusion: Our data suggests that macrophage polarization by MSC is affected by the cell quality and that passaging of cell could impair its immunomodulatory function.

Introduction: There have been several studies that assessed the association between asthma and inflammatory bowel disease (IBD) including Crohn's disease (CD) and ulcerative colitis (UC). The positive association may be explained through the hygiene hypothesis, which postulates that a reduction in the frequency of infections contributes directly to the increase in the frequency of autoimmune and allergic diseases.
To provide a quantitative assessment of the association of asthma with subsequent IBD risk, we conducted a meta-analysis of observational studies.
Aims and Methods: We identified studies by searching the PubMed databases through February 2018 and by searching bibliographies of relevant articles. Included studies reported IBD as the primary outcome and evaluated asthma before diagnosed with IBD. We included case - control studies or cohort studies published as original articles; cross-sectional, ecological, and prevalence studies were excluded.
Results: A total of 7 observational studies were included in our meta-analysis. Asthma was associated with an increased risk of CD (summary OR 1.45, 95% CI: 1.30–1.61) and UC (summary OR 1.29, 95% CI: 1.02–1.64).
Conclusion: This meta-analysis demonstrates that asthma is associated with an increased risk of developing both CD and UC. Further prospective studies are required to confirm the validity of these observations.
Disclosure: Nothing to disclose

P0291 THE PREVALENCE OF GASTROINTESTINAL CANCERS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE - A DANISH NATIONWIDE COHORT STUDY

P Weimers, D Ankersen, J Burisch, P Munkholm
North Zealand University Hospital, Department of Gastroenterology, Frederikssund, Denmark

Contact E-Mail Address: zld651@alumni.ku.dk

Introduction: Inflammatory Bowel Disease (IBD), mainly represented by Crohn's Disease (CD) and Ulcerative Colitis (UC), is known to be associated with an elevated risk of gastrointestinal (GI) cancer. The pathogenesis is poorly understood, but risk factors seem to be longstanding disease as well as extensive disease and high degree of inflammation. However, the reported magnitude of the risk in IBD patients is still inconsistent and the long-term effects of newer treatment options on the development of cancer have not been investigated thoroughly.
Aims and Methods: To estimate the prevalence of GI cancer development in a cohort of adult IBD, we included all incident patients in the Danish National Patient Register (NPR) between 1997 and 2015, using International Classification of Disease (ICD) codes representing IBD. Minimum 2 diagnostic listings of UC or CD on separate dates were used to improve accuracy and stability of the IBD diagnosis. Patients with a mix of codes for UC and CD during the follow up period were identified as IBD-Unclassified (IBDU). All incident cancer, based on ICD codes, occurring after the index date were included from the national cancer register. Each IBD patient was matched for sex, age and place of residence to reference individuals of the Danish population. P-values for significance between the IBD cohort and reference individuals were calculated by chi-square test.
Results: We identified 35,910 IBD patients (UC = 24,103 (67.1%), CD = 9,740(27.1%) and IBDU = 2,067 (5.8%)) and 1,747,002 reference individuals in the NPR between 1997 and 2015. The median age at IBD diagnosis was 43 (IQR: 30–60). Overall, 4,295 (12.0%) of IBD patients were diagnosed with at least 1 cancer and 487 were diagnosed with 1 or more cancers. Among reference individuals, 174,251 (10.0%) were identified with 1 diagnostic listing of cancer and 20,724 with 2 or more. The overall prevalence of cancer was significantly higher in the IBD population ($p < 0.001$) compared to reference individuals. Characteristics of the study population are shown in table 1.
While colorectal cancer (CRC) was more frequently observed in IBDU (n = 31 (1.5%)) and UC patients (n = 235 (1.0%)) compared to CD (n = 85 (0.9%)), upper GI cancer (including small bowel cancer) was more common in CD patients (n = 72 (0.7%)) compared to UC (n = 111 (0.4%)) and IBDU patients (n = 10 (0.5%). In reference individuals, prevalence of upper GI cancer and CRC was 6,039 (0.4%) and 15,648 (0.9%), respectively and therefore similar to that of the overall IBD population ($p > 0.05$ for both comparisons). However, prevalence of CRC was significantly lower compared to IBDU patients ($p < 0.05$).
Conclusion: In a Danish nationwide cohort of IBD patients, overall cancer as well as neoplasms located to the small bowel, anus/anal canal, liver, bile ducts and pancreas were more prevalent compared to the reference individuals. There was a significant difference in the prevalence of colorectal cancer between reference individuals and IBDU patients, but not compared to the overall IBD cohort.
*[Table 1. Characteristics of study population. N (%) if not otherwise stated. * $p < 0.05$, † $p < 0.001$ compared to the reference population]*

Introduction: Acute severe attack of ulcerative colitis (ASUC) can occur in 12 to 25% of UC patients. This is a challenging and life threatening in elderly patients. Evolution of ASUC in late onset UC diagnosed after the age of 60 years is unknown.
Aims and Methods: The aim of this study was to describe clinical presentation, treatment and prognosis of ASUC in a cohort of late onset UC.
Patients and methods In a Northern France population-based cohort, we identified 472 patients aged >60 years at UC diagnosis ulcerative colitis (UC). These patients were followed for a median time of 6.2 years. Among these patients, those hospitalized with an ASUC according to the Truelove's criteria were analyzed. Clinical presentation, comorbidities (Charlson index), treatment and surgery needs as well as postoperative complication and mortality were recorded.
Results: 23 patients (5%) including 14 men were included. ASUC occurred at diagnosis in 12 patients (52%) and during the first year of follow-up in 19 patients (83%). The Charlson comorbidities score was ≥ 3 in 96% (n = 22) and ≥ 5 in 52% (n = 12) of the cases. First-line treatment was intravenous corticosteroid (64%, n = 14), colectomy (22%, n = 4) or exclusive artificial nutrition (24%, n = 5). No patient received second line medical treatment ciclosporin or infliximab. Among the 18 operated patients, median time between admission for severe acute colitis and intervention was 15 days (Q1 = 7, Q3 = 39). Surgery was a subtotal colectomy with double stomy in 13 cases, a partial colectomy in 3 cases, total colectomy in 1 case and a stomy alone in 1 case. Stoma were definitive in 69% (n = 9) of cases. 1 or more postoperative complications occurred in 6 patients (26%) i.e. renal insufficiency (n = 4), thromboembolic event (n = 4),

Abstract No: P0291

	IBD	UC	CD	IBDU	Controls
Total	35,910	24,103 (67.1)	9,740 (27.1)	2,067 (5.8)	1,747,002

septic shock (n = 2). 5 patients (22%) died, of which 4 after surgery, leading to a 3-month survival rate of 75% (IC95% [58–97]) (Figure 1).
Conclusion: In this population-based study conducted in the prebiotherapy era ASUC in elderly onset UC patient was rare but particularly severe requiring surgery in 74% of patients and life-threatening with a mortality rate close to 25% at 3 months. Management of these severe patients in referral centers is mandatory.

P0294 SMOKING REMAINS A MAJOR CONTRIBUTOR TO THE BURDEN OF CROHN'S DISEASE IN IRELAND AND WARRANTS THE DEVELOPMENT OF A SPECIFIC TARGETED SMOKING CESSATION INTERVENTION

A.R Douglas[1], X Mohess[2], Z Sari[2], I Cotter[2], H Seow[2], C Gallagher[3], B Ryan[4], D McNamara[5]

Introduction: Approximately 15,000 people in Ireland have Crohn's disease (CD) and the incidence is increasing. Previous data suggest smokers are twice as likely to develop CD and active CD smokers have a higher risk of relapse, hospital admissions, steroid therapy and surgery. Despite this, many Irish CD patients continue to smoke perhaps due to lack of knowledge and awareness.
Aims and Methods: To determine current smoking rates and the impact of smoking on CD severity and to assess patient knowledge and awareness of the risks associated with smoking. Following ethical approval, a prospective case control study of Irish CD patients' and age and sex matched non IBD GI patient controls was undertaken. A self-assessment questionnaire was employed to assess smoking habits, basic demographics and education status overall as well as disease characteristics and awareness of the impact of smoking in the CD cohort. Groups were compared using a Chi^2-test, p of less than 0.05 were considered statistically significant and odd ratios were calculated where appropriate.
Results: To date 139 questionnaires have been returned, 56 from CD patients and 83 from Controls. The mean age was 47 years (range 19–80) and 62 (47%) were males. Disappointingly, 52% (n = 72) overall reported having ever smoked with similar rates in CD and Control patients, 57% (n = 32) and 48% (n = 40). Both duration (12.3 and 9.0 yrs) and pack quantity per day (0.6 and 0.5) were similar for CD and Controls. There was no difference in education level achieved with 22/70 (31%) vs. 17/66 (26%) having completed primary education only in smokers compared to non-smokers. However, CD patients were 1.8 times more likely to report being a current smoker compared to Controls, p = 0.3.
Within the CD cohort 52% (n = 30) had previous surgery. Smokers were 1.5 times more likely to have had IBD-related surgery although this did not reach statistical significance; 13/32 (41%) CD vs. 6/24 (25%) controls. HBI results were available for 35 (63%) CD patients. Current smokers reported higher HBIs 13 vs. 5, p = 0.01 (95% CI = 1.91–13.6). In fact, active smokers were twice as likely (80% vs. 37%) to have an elevated HBI > 7, RR = 2.2, p = 0.02. There was no difference in biologic use between the groups.
Only 41% (13/32) of our CD cohort thought smoking was a significant risk factor for IBD. While only 28% (9/32) thought smoking was a risk factor for surgery while just 25% (8/32) thought smoking cessation could significantly decrease the severity of their disease.
Conclusion: Disturbingly, smoking rates remain high in our Irish CD population, with a negative impact on disease severity and need for surgery. Surprisingly few CD patients were aware of the negative impacts of smoking and the potential benefit of cessation. Emphasizing an urgent need for a specific targeted smoking cessation intervention.

[4]*"A. Gemelli" University Policlinic Foundation - Catholic University of Sacred Heart, Complesso Integrato Columbus, Rome, Italy*

Contact E-Mail Address: gianenrico.rizzatti@gmail.com
Introduction: Extra-intestinal manifestations (EIM) are common in inflammatory bowel disease (IBD) occurring in up to 50% of patients, while ocular manifestations are reported in 0.3% to 13.0% of the cases. Reported data, however, mostly rely on not recent population based studies. In fact, the few available prospective studies, suggest a much higher occurrence of ocular diseases, ranging from 29% to 71%.
Aims and Methods: The aim of the study was to assess the prevalence of ocular disease in a cohort of IBD patients followed in tertiary referral Italian center.
IBD patients followed at our center were consecutively enrolled in the study. Enrolled patients underwent ocular evaluation including assessment of visual acuity, examination of fundus oculi and anterior ocular segment as well as a measure of intraocular pressure, Schirmer's test and break up time test, when appropriate.
Results: A total of 193 IBD patients were enrolled in the study, 54.9% females and 45.1% males, 47.7% CD, 43.5% UC, and 8.8% indeterminate colitis, 35.7% of patients had a moderate-severe activity of disease, 39.4% were under active steroid therapy, 35.8% were under anti-TNFalpha and 64.3% were taking mesalamine.
Overall, any ocular disease was identified in 46.1% of enrolled patients, 17.1% CD and 23.8% UC and 5.2% IC. The most common ocular disease was dry eye (12.4%). At multivariate analysis use of mesalamine (OR 2.3, 95% CI 1.1–5.0), steroids (OR 3.6, 95% CI 1.1–11.8) and moderate-severe activity of disease (OR 5.1, 95% CI 2.3–11.1) were all correlated with an increased risk of ocular disease.
Conclusion: Ocular manifestations in IBD patients are more frequent than reported especially in referral center. Patients under treatment with mesalamine or steroids and with a moderate-severe disease activity might benefit of an ophthalmological evaluation.
Disclosure: Nothing to disclose

P0296 INTESTINAL AND EXTRA-INTESTINAL CANCER IN IBD PATIENTS ADMITTED TO AN ITALIAN TERTIARY CENTRE

[5]*"A. Gemelli" University Policlinic Foundation - Catholic University of Sacred Heart, Complesso Integrato Columbus, Rome, Italy*

Contact E-Mail Address: gianenrico.rizzatti@gmail.com
Introduction: Inflammatory bowel disease (IBD) patients are at higher risk to develop colon cancer. While the association between colorectal cancer and ulcerative colitis (UC) is well known, the risk for Crohn's disease (CD) is less defined. Similarly, little information exists on extra-intestinal tumors in different settings of patients.
Aims and Methods: The aim of the study was to assess occurrence of malignancies in IBD patients admitted to the hospital. All patients admitted for CD or UC to Policlinico "A. Gemelli" between 2000 and 2013 were identified using ICD-9-CM codes for IBD.
Occurrence of gastrointestinal or extra-intestinal cancer was assessed for every patient analyzing ICD9-CM codes. Demographic characteristics of admitted patients were also recorded.
Results: A total of 3467 patients were admitted for an IBD between 2000–2013, in particular 42.8% CD and 57.2% UC, 51.8% male and 48.2% female patients, with a median age at admission of 45.7 years. Repeated admissions for the same patient were excluded.
Occurrence of any type of cancer was 5.3%, without significant difference between intestinal and extra-intestinal location (2.8% versus 2.5%, respectively). Malignant tumors, at any site, were more frequent in UC than in CD (7.3% versus 2.7%, respectively; p < 0.01). Cancer occurrence was higher in men in comparison to women (6.1% versus 4.4%, respectively, p < 0.05).
Median age at admission was 44.0 years for patients without a diagnosis of tumor and 63.8 years for those with a diagnosis of cancer.
The occurrence of colon and rectal cancer was 1.7%, with 81% cases affecting UC patients.
The most frequent extra-intestinal malignancies were prostate cancer and myeloproliferative disorders. Colon and rectal cancer accounted for 59.8% of all gastrointestinal cancer.
Conclusion: About 5% of admitted IBD patients presented a cancer diagnosis. Higher cancer occurrence was observed in UC and in older patients, with a median age of about 60 years and more frequently in men. Colorectal cancer occurrence in UC was about 2%.
Disclosure: Nothing to disclose

P0297 LONG-TERM STABILITY OF SEROLOGICAL ANTIBODIES IN A POPULATION-BASED INCEPTION COHORT OF INFLAMMATORY BOWEL DISEASE - THE IBSEN STUDY

Introduction: Serological biomarkers in inflammatory bowel disease (IBD) predicting complicated disease are warranted. Several microbial antibodies and auto-antibodies have been associated with IBD and especially ASCA and pANCA have been proposed as potential biomarkers. Studies have shown that their presence might vary over time thus their clinical impact is still discussed. Long term studies of ASCA and pANCA stability have not been performed in population-based cohorts.

Aims and Methods: The aim of the present study was to investigate potential change in antibody status over time by analysing a panel of relevant serum antibodies at 10 and 20 years after disease onset in a population-based inception cohort of IBD patients (the IBSEN cohort).

The IBSEN cohort is an inception cohort of patients diagnosed with IBD between 1990 and 1994. The patients have been followed prospectively for 20 years. At the 10 and 20 year follow-up visits, the following panel of antibodies was analyzed in serum: pANCA, ASCA IgA and ASCA IgG. All analyses were performed at Prometheus Laboratories Inc. (San Diego, CA). Changes in antibody status within individuals from 10 to 20 years were assessed using Wilcoxon signed ranks test.

Results: Sera were available from 342 and 272 UC patients and 159 and 135 CD patients at the 10 and 20 year follow-up, respectively. The proportions of patients positive for the analyzed antibodies at the 10 and 20 year follow-up are presented in table 1. As previously shown, ASCA was more prevalent in CD than UC and in complicated CD behavior vs. inflammatory CD behavior at the 10 year follow-up (1). On group level, this distribution was similar at the 20 year follow-up. For 228 UC patients and 113 CD patients, sera were available at both time points. The antibody status within individuals changed significantly for ASCA IgG for patients with both UC ($p<0.001$) and CD ($p<0.001$).

Conclusion: In a population-based inception cohort the status of pANCA and ASCA IgA remained stable from 10 to 20 year follow-up. The status of ASCA IgG on the other hand, changed significantly. These findings indicate that pANCA and ASCA IgA might be more useful biomarkers of disease phenotype and potential complications during follw-up.

Introduction: Cancer risk in Inflammatory Bowel Disease (IBD) is still debated.

Aims and Methods: Primary end point was to characterize, in a prospective, multicenter, nested case-control study at 6 years (yrs), incident cases of cancer in IBD. Secondary end point was to evaluate risk factors for cancer overall, including clinical characteristics of IBD versus the use of thiopurines (IS) and/or anti-TNFs.From December 31st, 2011 to December 31st, 2017, all incident cases of cancer in IBD patients (pts) referring to 16 IG-IBD Units (≥2 visits/yr) were recorded. Each IBD pt with incident cancer was matched with 2 IBD pts with no cancer for: IBD type (Crohn's Disase, CD; Ulcerative Colitis, UC), gender, age (±5yrs). Statistical analysis: Data expressed as median (range). Wilcoxon, Chi-squared, Fisher's exact test, multivariate logistic regression analysis (OR [95%CI]).

Results: Incident cancer occurred in 403 IBD pts: 204 CD (CD-K), 199 UC (UC-K). The frequency of cancer was comparable between CD and UC (50.6% vs. 49.4%; $p>0.05$). In IBD, cancer ($n=403$) involved/included (n[%]) digestive system (129 [32%]), skin (60 [14.9%]: 27 NMSC, 31 melanoma, 2 others), urinary tract (39 [9.7%]), lung (28 [6.9%]), breast (22 [5.5%]), genital tract (26 [6.5%]), thyroid (8 [1.98%]), lymphoma (11 [2.72%] all in CD), small bowel cancers (SBC) (16 [3.9%]; 15 CD [7.3%], 1 UC ileal pouch [0.5%]), others (64 [15.9%]). The frequency of cancer was comparable between CD and UC considering (n[%]): digestive system (61 [30%] vs. 6 [34%]); skin (33 [16%] vs. 27 [13.5%]) lung (14 [6.8%] vs. 14 [7.0%]); breast (22 [10.7%] vs. 24 [12.1%]);genital tract (15 [7.3%] vs. 11 [5.5%]; $p>0.05$). Colorectal and urinary tract cancers were more frequent in UC vs CD (58 [29%] vs. 35 [17%]; $p<0.005$; 26 [13%] vs. 13 [6.3%]; $p=0.039$). Extracolonic cancers were more frequent in CD vs. UC (35/204 [17%] vs. 58/199 [29%]; $p<0.005$). Risk factors for any cancer considered in multivariate analysis: age (<40 vs. ≥40 yrs), IBD duration (<10 vs. ≥10 yrs), smoking (Yes/No;Y/N), ISS and/or anti-TNFs (Y/N), IBD-related surgery, UC extent (extensive vs distal; subtotal vs distal), CD pattern (B3 vs B1;B2 vs B1) perianal CD. Significant risk factors for any cancer in UC: UC-related surgery (4.63 [2.62–8.42]), extensive vs distal UC (1.73 [1.10–2.75]). No other risk factors identified in UC (OR 1.30 [0.74–2.39]; 0.92 [0.63–1.35]; 0.92 [0.55–1.52]; 0.84 [0.51–1.38]; 1.54 [0.95–2.51], respectively). In CD, perforating pattern was the only significant risk factor for cancer overall (OR 2.33 [1.33–4.11]), as no other risk factors were identified (OR 0.93 [0.59–1.48]; 0.98 [0.67–1,43]; 0.74 [0.51–1.07]; 1.31 [0.90–1.92]; 0.97 [0.62–1.51]; 1.25 [0.79–2.01]; 1.02 [0.65–1.60], respectively). The percentage of pts with penetrating CD was higher in CD-K vs CD-C (26% [54/204] vs 15% [63/408]; $p=0.0033$), when considering also inflammatory (34% [71/204] vs. 43% [178/ 408]) or fibrostricturing CD (39% [79/204] vs. 41% [167/408]). The percentage of pts with extensive UC was higher in UC-K vs. UC-C (51% [101/199] vs. 38% [152/398]; $p=0.0045$), when considering also distal (21% [43/199] vs. 33% [131/398]) or subtotal UC (28% [55/199] vs. 29% [114/398]). Second ($n=11$) or third incident cancer ($n=2$) occurred in 11 IBD pts.

Conclusion: In a prospective, multicenter, nested-case control study at 6 years, penetrating CD, extensive UC and UC-related surgery were significant risk factors for any incident cancer. Clinical characteristics of severity of IBD may increase the overall cancer risk. Lymphoma and SBC were associated with CD.The high frequency of second and third cancers further supports a higher cancer risk in subgroups of patients.

Introduction: The experience of patients with health care has been related to important outcomes (1).

Aims and Methods: In this work we describe the perception of inflammatory bowel disease (IBD) patients on their experience with chronic health care in Spain through IEXPAC, a validated questionnaire, and the influence of demographic and health care-related factors.

The IEXPAC scale *("Instrument to Evaluate the EXperience of PAtients with Chronic diseases")* was developed and validated in Spain by health care professional and social organizations, experts in quality of health care and chronic patients (2,3). It is structured in 12 items with Likert responses from 'always' to 'never', yields an overall score from 0 (worst) to 10 (best experience), and allows identifying health care areas needing improvement. 3 sub-scores derive from the scale: A) productive interactions (items on patient-health care professionals relationship), B) self-care (on patients' ability to self-care) and C) new relational model (on the use of new technologies and contact with other patients). Consecutive IBD patients from 25 Spanish clinics completed the IEXPAC scale by pre-paid mail. Bivariate comparisons and a multivariate analysis were made to explore the association between scores and demographic and health care-related characteristics.

Results: 575 patients received the survey, 341 (59.3%) returned it (mean age 47 years, 48% women). Mean overall score was 5.9 (SD 2.0), sub-scores were: productive interactions: 7.7 (2.3); self-care: 6.9 (2.4); new relational model: 2.2 (2.3). Scores did not differ by age, sex or degree of education (except new relational model, better in younger and in those with higher education level). Experience score was better in patients followed-up by the same physicians (score 6.0 [1.9]) vs different physicians (5.0 [2.1], $p = 0.002$), if there was follow-up by a nurse (score 6.2 [2.1]) vs no follow-up by nurse (5.6 [1.8], $p < 0.001$) and in those with lower number of medicines ($p = 0.010$). Patients treated with subcutaneous/intravenous (SC/IV) drugs scored higher in the 'productive interactions' sub-score ($p = 0.052$). Multiple linear regression models (table) showed that being followed up by the same physician or by a nurse, and being treated with lower number of medicines or with SC/IV drugs were independently associated to better overall experience scores.

[Multivariate analysis. Variables associated to IEXPAC experience scores. Positive coefficients mean better experience (higher IEXPAC score)]

Conclusion: Through IEXPAC, IBD patients identified important factors that can improve their experience with health care, like having the same physician as reference in the clinic and being followed-up by a nurse. Lower number of treatments was also associated to better experience and treatment with SC/IV drugs to higher 'productive interactions' sub-score, maybe in relation to a more personalized care.

Disclosure: This study was funded by Merck Sharp & Dohme of Spain and endorsed by the Spanish association of patients with Crohn's disease and ulcerative colitis (ACCU). We thank the participant patients for providing this valuable information by completing the survey. Marta Mosquera, Nadia Soto, Berta Juliá and Luis Cea-Calvo are employees at Medical Affairs, Merck Sharp & Dohme of Spain

Introduction: Complementary and alternative medicines (CAM) may be defined as treatments that fall outside of conventional healthcare. Patients with IBD often turn to CAM, mainly without discussing it with their physician. We repetitively collect information on patient-reported CAM use between 2007 and 2016.

Aims and Methods: 1) to assess main categories of patient-reported CAM used by year, 2) to assess factors associated with CAM use in 2016.

The Swiss IBD cohort started in November 2006. At enrollment and on a yearly basis, patients were asked to complete self-reported questionnaires. CAM were collected using a list of previously identified CAM[1,2] and a free text option. Additional clinical and patient-reported data collected within the framework of the cohort was used to characterize CAM users. For descriptive purposes, we classified CAM using recommendations of the US National Center for Complementary and Integrative Health (NCCIH). Changes in life habits (e.g. diet and sportive activities) was taken as an additional category. Dietary and nutritional supplements were not assessed here. Multivariate logistic regressions were performed to search for factors associated with CAM use (i.e. $>= 1$ CAM reported from 2007–2016).

Results: 3334 patients were included since Nov 2006. Overall, CAM were used by 21.7% to 29.3% of patients over years. Types of CAM were natural products and biologically based therapies (range: 6.9% to 11.9%), change in life habits (6.2% to 11.2%), whole medical systems and traditional medicines (5.8% to 9.6%), mind-body interventions (3.2% to 7.7%), body-based interventions (3.5% to 6.9%) and energy therapies (1.9% to 4.6%). When looking to the history of CAM use by patients in 2016, we found that 41.9%/44.4% of CD/UC patients used $>= 1$ CAM. The most frequent CAM used by CD/UC patients were "change in life habits" (20.6%/18.7%), homeopathy (12.5%/14.5%) and acupuncture (9.2%/10.5%). No significant differences were observed regarding CAM use and type of diseases, except for bio-electromagnetic therapies (3.5% for UC, 1.9% for CD; $p = 0.010$). CAM use in CD was significantly higher among women ($OR = 1.9$; $p < 0.001$), French-speakers ($OR = 1.5$; $p = 0.002$) and patients with arthritis complications ($OR = 1.5$; $p = 0.001$) and lower among smokers, higher SF-36 mental scores, higher age at diagnostic and B1p disease behavior profiles. CAM use in UC was significantly higher among women ($OR = 2.3$; $p < 0.001$), patients with arthritis complications ($OR = 1.4$; $p = 0.017$) and aged 36 to 45, and lower with increased IBD QoL score.

Conclusion: CAM were assessed through patients self-report over time. CAM use varied between a fifth and a fourth of IBD patients during 10 years of data collection, without many changes among types of CAM. On average, 43% of patients reported a history of CAM use in 2016. Factors associated with CAM use differed between UC and CD. Some of them seemed to be linked to relieving articular and musculoskeletal pain or improving IBD-specific or mental QoL.

Abstract No: P0299

P0301 FECAL CALPROTECTIN MAY BE A SENSITIVE BIOMARKER IN ASSESMENT OF HISTOLOGIC DISEASE ACTIVITY IN PATIENTS WITH ULCERATIVE COLITIS

T Knezevic Ivanovski[1], S Knezevic Usaj[2], P Svorcan[1], M Protic-Nedeljkovic[3]

Introduction: In patients with ulcerative colitis (UC) histological remission leads to better outcome, whereas presence of histological inflammation in quiescent disease is risk factor of future relaps. Fecal calprotectin (FCP) turned to be good biomarker in assesment of endoscopic and clinical disease activity.

Aims and Methods: The aim was to explore the association of FCP with histologic disease activity

82 patients with UC from a single tertiary IBD Centre were enrolled in this prospective, observational study. Mayo endoscopic sub-score was used to evaluate an endoscopic activity. For the assessment of histological activity, Geboes's, Nancy's and Robart's score were used. Active (structural changes, the presence of polymorphonuclear leucocytes with cryptitis and crypt abscesses, and erosions or mucosal ulcers) and chronic inflammations were estimated. Histologic remission was defined by Geboes score < 3.1 or Nancy's index ≤ 1 or Robart's index < 6. Basal plasmocytosis, as a predictor of relapse, was described as well. Buhlmann rapid test was used to determine FCP using cut off level of 100 μg/g. Statistical analysis was carried out using SPSS 20.0 (Chicago, IL).

Results: 38% (31/82) of patients were in endoscopic remission while 33% (27/82) achieved histological remission. Statistically significant association was observed between FCP and histological indicators of active inflammation: a. structural changes $p = 0.001$, CI ± 8.58; b. presence of the presence of polymorphonuclear leucocytes with cryptitis and crypt abscesses $p < 0.001$, CI ± 10.61; c. presence of erosion and mucosal ulcers $p < 0.001$, CI ± 6.72, as well as with basal plasmocytosis ($p < 0.001$, CI ± 6.42). The association with chronic inflammation was not observed ($p = 0.002$, CI ± 9.37). The correlation was found between FCP and all 3 scores with the strongest for Nancy index ($p < 0.001$, $r = 0.538$- Spearman correlation). The correlation with Robarts score ($p < 0.001$, $r = 0.505$- Spearman correlation) or Geboes ($p < 0.001$, $r = 0.382$- Spearman correlation) were slightly lower.

Conclusion: Fecal calprotecin may be a good, sensitive, noninvasive biomarker in the assesment of histological disease activity and point out a forthcoming relaps. This association with validated histologic score may even enhance the significance of FCP in clinical practice in the future.

Introduction: This study aimed to investigate the relationship between ARE(Arylesterase) and PON-1(Paraoxonase-1) levels in ulcerative colitis (UC) patients and the difference in these levels in UC patients in comparison to the control group.

Aims and Methods: The study population consisted of 66 (73.3%) UC patients and 24 (26.7%) healthy individuals as the control group. The UC patients and the control group were compared in terms of PON-1 and ARE levels as oxidative stress markers. The UC patients were also grouped according to Mayo UC activity scores and the differences in their PON-1 and ARE levels were assessed.

Results: 37 (56.1%) of 66 UC patients included in the study were male and 29 (43.9%) were female. The mean age in the control group was 42.2 ± 12.8 years (age range: 17–66 years). Most of the patients in the ulcerative colitis (UC) group used a combination of oral and rectal mesalamine treatments (20 patients, 33.3%). Most of the patients in the UC group had left-sided colon involvement (30 patients 45.5%). The mean arylesterase (ARE) level in the UC group was 786.32 U/L; the mean ARE level in the control group was 919.56 U/L. The ARE level was higher in the control group than the UC group, and this difference was statistically significant ($p = 0.017$). The mean paraoxonase-1(PON-1) value in the UC group was 264.14 U/L; the mean PON-1 value in the control group was 316.64 U/L. This difference was not statistically significant ($p = 0.33$).

When analysed based on gender, there was no difference in PON-1 levels ($p = 0.23$) and ARE levels ($p = 0.98$) between males and females in the UC group When the Hb value was lower (equal and less than 10 mg/dl) and higher (higher than 10 mg/dl), the ARE value was statistically higher in the group with a high Hb value ($p = 0.016$). When assessed in terms of the Mayo Disease Activity Index (DAI) and Rachmilewitz Colonoscopic Activity (Group A:≤6 and 7≥ Group B) scores, no statistical difference was found between the ARE and PON-1 values for UC patients in Group A and Group B.

The ARE values of 66 UC patients were found to be negatively correlated with their white blood cell counts (r-29; $p = 0.03$). In our study, ARE and PON-1 values were positively correlated in the UC group ($r = 0.27$; $p = 0.026$). Correlations between ARE and albumin ($r = 0.27$; $p = 0.041$) and ferritin ($r = -0.302$, $p = 0.037$) were determined based on our data. There were no correlations between PON-1 and hs-CRP (High sensitive C reactive protein), sedimentation, Hb, B12 and ferritin in the UC group. In the linear regression model, the leukocyte levels ($p = 0.025$) and Mayo UC Scores ($p = 0.004$) were found to have an effect on the ARE levels. In addition, it was found that in linear regression model the hs- CRP ($p = 0.009$) levels were found to have an effect on PON-1 levels.

Conclusion: In conclusion, ARE values that denote oxidative capacity were found to be significantly lower in patients with UC than in healthy patients. The efficacy of PON-1, an antioxidative enzyme, in UC patients is unclear. The results of our analyses suggest that there may be a correlation between ARE and PON-1 values in UC patients. Thus, it might be possible to use ARE levels as indicators of oxidative stress in UC patients. There is a need for larger studies to demonstrate the correlation between UC activity and ARE and PON-1 levels. No correlation between PON-1 and ARE levels and the activity of UC patients was detected in our study.

[Table 1 ulcerative colitis and control groups in terms of paraoxonase-1, arylesterase, high sensitive CRP, hematolog]

	Ulcerative Colitis N:66	Control N:24	P
Paroxonase-1 ± (SD)	264.14 ± 193.39	316.64 ± 231.07	0.33
Arylesterase ± (SD)	786.33 ± 270.33	919.56 ± 208.5	0.017

Introduction: Thiopurines (TPs) are commonly used in treatment of Inflammatory Bowel Disease (IBD). For Azathiopurine (AZA), optimal dosing is determined by patients' weight and commonly titrated to achieve target range of 2–2.5mg/kg. Levels of 6-thioguanine nucleotide (6-TGN), an active metabolite breakdown of thiopurines and 6-Methylmercaptopurine (6-MMP), an inactive metabolite, can be measured to check for efficacy and toxicity respectively, but this is not widely available due to cost and accessibility.
White cell count (WCC), lymphocyte count (LC) and mean corpuscular volume (MCV) have emerged as surrogate markers to monitor TP efficacy. Previous studies have suggested WCC $< 4x10^9$/L and MCV > 100fl correlate with 6-TGN level and with reduced risk of disease relapse.
Aims and Methods: The aim of our study is to assess these surrogate parameters in our patients on TPs. 200 IBD patients being treated with AZA were included in this retrospective, observational study. Data were obtained from our IBD database and review of medical notes. Recent WCC, LC and MCV were recorded, along with body weight, AZA dose and concomitant treatment with biologic therapy (mainly anti-TNF agents).
Disease activity index was assessed using the Harvey Bradshaw index (HBI) for Crohn's disease (CD) and partial Mayo score for ulcerative colitis (UC) at time of blood testing.
Results: There were 108 (54%) females and 92 (46%) males. Of the 200 patients, 144 (72%) were diagnosed with CD, 55 (27.5%) UC and 1 (0.5%) indeterminate colitis. 117 patients (58.5%) were on AZA monotherapy with 83 patients (41.5 %) on combination therapy with a biologic including anti-TNFs' (Infliximab, Adalimumab, Certrolizumab pegol, Golimumab) or Ustekinumab. The mean age for our study population was 49 (19 - 81). The mean WCC count was $6.81x10^9$/L (range 2.8–14.2). Mean LC was $2.86\ x10^9$/L (0.5 to 8.8) with mean MCV of 91.1 fl (78.4 to 104.3).
7/200 (3.5 %) patients had WCC $< 4x10^9$/L and 7/200 (3.5%) also had a MCV > 100fl. In the IBD AZA monotherapy group, 4/117 patients (3.4%) had leucopenia and the same number 4/117 (3.4%) had macrocytosis and only 1 patient (0.9%) had both leucopenia and macrocytosis. In patients on combination therapy, 3/83 (3.6%) had leucopenia and the same number of patients, 3/83 (3.6%), demonstrated macrocytosis. None in this group had both leucopenia and macrocytosis (***Table 1***).
The mean AZA dose to body weight in our study population was 1.7mg/kg. The mean HBI score was 2.9 and for partial MAYO score was 1.7.
Conclusion: A very small percentage of our study population had leucopenia, lymphopenia or macrocytosis suggesting that many may be sub-therapeutic. Notwithstanding this, the majority of patients were in clinical remission. There was no significant difference in these measured parameters between the AZA monotherapy or combination therapy groups. It is not clear how assiduous we should be in escalating TP dose to target MCV and WCC/ LC in order to maximise efficacy in IBD patients. Work is underway to correlate these surrogate markers with TP metabolites levels and disease activity indices.
[Table 1: Comparison *breakdown patients demonstrating leucopenia & macrocytosis blood picture in monotherapy & combination therapy treatment groups]*

	Total patients (n = 200)	Monotherapy (AZA) (n = 117)	Combination therapy (n = 83)
Leucopenia (WCC < 4 x 10^9/L)	7/200 (3.5%)	4/117 (3.4%)	3/83 (3.6%)
Macrocytosis (MCV > 100 fl)	7/200 (3.5%)	4/117 (3.4%)	3/83 (3.6%)
Both leucopenia and macrocytosis	1/200 (0.5%)	1/117 (0.9%)	0

Introduction: Current biomarkers including CRP and fecal calprotectin have limitations in disease activity monitoring of inflammatory bowel disease. Regenerating Family Member 3α (REG3α) is an antimicrobial C-type lectin protein which is excreted from Paneth cell to promote tissue regeneration and a promising biomarker for lower gut GVHD. We evaluate whether REG3α can be a useful blood-based biomarker for differential diagnosis and disease activity in patients with ulcerative colitis (UC).
Aims and Methods: The study group consisted of 32 patients with ulcerative colitis and 18 healthy controls. Patients with UC were further categorized according to clinical disease activity (Mayo Score) and endoscopic activity (Mayo Endoscopic Subscore, MES). Peripheral blood was collected on the day of sigmoidoscopy or colonoscopy. Plasma REG3α levels were measured using ELISA.
Results: Clinical activity of UC patients was remission (n = 12, 38%), mild (n = 11, 34%), and moderate-to-severe (n = 9, 28%), respectively. MES was 0 (n = 10, 31%), 1 (n = 9, 28%), 2 (n = 10, 31%), and 3 (n = 3, 9%), respectively. REG3α level of healthy controls and patients with UC was 7.06 ng/mL and 7.92 ng/mL, respectively, and the difference was not significant ($p = 0.120$). However, REG3α level was significantly correlated with MES ($p = 0.031$, Spearman coefficient 0.382), and clinical activity was not ($p = 0.066$, Spearman coefficient 0.329). When the cut-off level of plasma REG3α was 7.33 ng/mL, diagnostic accuracy for moderate-to-severe disease and MES ≥ 2 was (sensitivity 88.9%, specificity 47.8%) and (sensitivity 84.6%, specificity 52.6%), respectively. 2 patients were followed up, and it was observed that the REG3α also decreases when the clinical activity decreases.
Conclusion: Plasma REG3α is a useful blood-based biomarker for monitoring endoscopic activity in patients with ulcerative colitis. It can also be applied to inflammatory conditions of the intestine like Crohn's disease and celiac disease.

Introduction: In recent years, biological drug infusions have had a significant impact on the management of inflammatory bowel disease (IBD); covering Crohńs disease (CD) and ulcerative colitis (UC). These treatments have led to improved quality of life, fewer hospital visits and fewer side-effects from prolonged corticosteroids use. Nonetheless, due to the nature of biological treatment, there is the risk of infusion-related (type 1) allergic reaction, which can be unpredictable. Therapeutic drug monitoring (TDM) traditionally involves the measurement of drug concentrations in blood. Where there is a defined relationship between drug concentration and clinical effect, TDM can be used to predict patient response and to titrate the biologics to maximise therapeutic benefit. However, blood tests are invasive and not available immediately, thereby delaying clinical decision-making. This study investigates whether breath analysis, using gas chromatography ion-mobility spectrometry (GC-IMS), has the potential to provide a rapid, real-time and non-invasive method of TDM for IBD drug monitoring.
Aims and Methods: The aim of this pilot study is to identify changes in exhaled volatile organic compounds (VOCs) that relate directly to the infusion of biologics. 26 established IBD subjects (13 CD, 13 UC) were recruited at University Hospitals Coventry and Warwickshire (UHCW). Patients received either Vedolizumab or Infliximab, administered as an intravenous (IV) infusion. 4 exhaled breath samples were collected, per patient, at different time intervals throughout the infusion: baseline (t = 0); 15 minutes after starting the infusion (t = 15), 30 minutes after starting the infusion (t = 30); and 20 minutes after finishing the infusion (t = 50/80), depending on the duration of the treatment. Tidal breath samples were captured directly and analysed by GC-IMS (G.A.S. BreathSpec, Dortmund, Germany). Only 4 seconds of exhaled breath are required per sample and measurement results are available in less than 10 minutes.
Results: Mean SCAI and HBI scores were 2.6 and 3.2 for UC and CD patients, respectively. This suggests patients were in remission and that the changes in compound intensities do not relate to disease activity. Data analysis was conducted using G.A.S. processing tools to analyse intensity peaks from subjects with CD and UC, receiving Infliximab or Vedolizumab. 10 peaks of interest were identified, based on intensity changes between the baseline (t = 0) and t = 15 or t = 30 measurements. Using G.A.S. library search software, we were able to identify some of the compounds associated with these peaks, by referencing gas chromatographic retention times and ion mobility drift times in a NIST database. VOC analysis indicates that a compound, identified as dimethyl

sulphide, increased above baseline in both Infliximab and Vedolizumab subjects by 110% and 63%, respectively. For those receiving Vedolizumab (UC subjects), there was an increase of pentanoic acid by 24%. Similarly for those receiving Infliximab (CD subjects), an additional compound (butanoic acid) increased by 39%.

Conclusion: The abundance of certain compounds were observed to increase within the first 15 minutes of a biologic infusion; dimethyl sulphide seems to be a common compound to both Infliximab and Vedoluzimab. The recognised trends are expected to become more pronounced by increasing the number of recruited subjects. Next steps would be to correlate with serum levels at similar times. Based on these early findings, BreathSpec GC-IMS offers the potential of a rapid, real-time method of TDM for IBD patients receiving biological therapy.

Introduction: Inflammatory bowel diseases (IBD) are chronic illness with relevant social impact. Since the great part of data are published by tertiary centers, the real burden of IBD could be not completely defined, both in terms of epidemiology and natural history. We describe the data of a subpopulation of patients with IBD, unaware of it and asymptomatic, incidentally diagnosed in a colorectal cancer (CRC) screening program.

Aims and Methods: We have prospectically evaluated a court of people aged 50–74 undergoing screening colonoscopy after a positive faecal immunological (FIT) test, from November 2011 to March 2018. The screening program is still ongoing, and is focused to early diagnosis and prevention of colorectal cancer. Since then, 4490 patient out of 4714 FIT positive have been evaluated with colonoscopy, while 224 (4.75%) refused further examinations. Patients with known CRC or IBD are excluded. Data are prospectically collected, regarding to CRC, advanced adenoma, polyps and IBD incidence. Patients identified as IBD were then followed in our tertiary center.

Results: Out of 4,490 patients evaluated with colonoscopy, 257 (5.72%) needed virtual colonoscopy to complete the examination. Colorectal cancer has been diagnosed in 186 patients (4.14%), 1 or more adenoma in 1532 patients (34.12%). 21 patients (0.46%) had a diagnosis of IBD (7 F, 14 M, mean age 64.6 years, range: 53–76), namely one Crohn's disease (CD) and 20 Ulcerative colitis (UC).

All patients are currently followed in our tertiary center, with a mean follow-up of 22 months. All UC patients are satisfactory treated with mesalazine. The only patient with CD is treated with azathioprine. Up to now, no patient had extra-intestinal manifestations, nor need for surgery.

Conclusion: There is a consistent percentage of persons with IBD that are not known as affected. There is space for improvement in diagnosis and treatment. Further studies are needed to better understand the real incidence of this condition, and the subsequent evolution of the disease in this group of patients.

Introduction: When performed, the monitoring of ADA is generally restricted to the detection of free ADA (fADA) at the trough, using drug-sensitive ADA assays that do not allow the detection of ADA in complex with the drug (IC). Free ADA may underestimate the frequency of ADA-positive patients. Drug-tolerant ADA assays, based on IC dissociation, are available for routine detection of total ADA (tADA), free and in complex with the drug. The relevance of measuring tADA in daily clinical practice remains unclear.

Aims and Methods: The aim of this study is to evaluate the impact of fADA and tADA on the long-term clinical response to infliximab (IFX) therapy. We conducted a prospective observational study of adult IBD patients on IFX maintenance therapy recruited in 2012–2013 and followed until November 2017. IFX levels, fADA and tADA titters were assessed at trough by an enzyme linked immunosorbent assay (ELISA) (fADA and tADA at baseline and fADA at least at every 6 months). Disease activity (symptoms, laboratory markers, endoscopy and imaging), infusion reactions (IR) and therapy adjustments were recorded. The protocol was approved by the local ethics committee.

Results: 20 patients were included (15 Crohn's disease; 5 ulcerative colitis) who were receiving the standard (n = 16) or an intensified (n = 4) IFX regimen, for a median (IQR) duration of 3.4 (3.8) years. Median (IQR) age at inclusion was 40 (15) years. Patients were followed for a median (IQR) of 3.6 (2.3) years.

At baseline, 35% (n = 7) of patients tested ADA+ in both ADA assays (tADA+/fADA+), 30% (n = 6) although negatives in the drug sensitive ADA assay, tested positive in the drug tolerant assay (tADA+/fADA-), and 35% (n = 7) tested negative in both ADA assays (tADA-/fADA-). Clinical remission (CR) rates and median IFX trough levels were higher in fADA-/tADA- group (CR 100%; median IFX 4.5 ug/ml) compared to the tADA+/fADA- group (CR 17%; IFX 1 ug/ml) and to the tADA+/fADA+ (CR 29%, median IFX 0 ug/mL). Drug dose regimens at baseline were similar between the 3 ADA groups. A higher proportion of patients were receiving concomitant immunosuppression in fADA-/tADA- group (100%) compared to tADA+/fADA- (83%) and fADA+/tADA+ (29%) groups.

During follow-up, all patients in the fADA-/tADA- group remained in CR and none became fADA+. IFX dosing was reduced in 5 of the 7 cases. Conversely, in tADA+/fADA+ group, 2 patients underwent IFX intensification without response and IFX was switched or stopped in all cases. In the tADA+/fADA- group only one patient remained in CR without therapy adjustments, 3 patients switched to adalimumab and 2 patients had IFX intensification with increase in drug levels. Only 1 of the 6 tADA+/fADA- became fADA+ over time. IR occurred exclusively in patients with ADA, being more frequent in the tADA+/fADA+ group when compared with tADA+/fADA- group (57% vs. 17%).

Conclusion: Drug-tolerant ADA assays allow us to identify an additional proportion of ADA+ patients. Compared to tADA-/fADA-, tADA+/fADA- patients had lower IFX levels, lower CR rates and more frequently needed switch or IFX intensification. Responses to IFX intensification were overall more favourable in this group than in the tADA+/fADA+ group. Only a minority of tADA+/fADA- patients became fADA+. Larger studies are warranted to confirm these results and determine the clinical benefit of including tADA assessments, to help guide therapeutic decisions, in routine clinical practice.

Disclosure: The present study has been presented as best poster oral presentation in the 2018 national meeting of the Portuguese inflammatory bowel disease study group. This project also received the 2012 research grant of the District Hospitals Gastroenterology Nucleus. The authors disclose no other conflict of interest.

P0309 CHROMOENDOSCOPY IS SUPERIOR TO WHITE LIGHT ENDOSCOPY FOR THE DETECTION OF ADVANCED COLONIC NEOPLASIA IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

M Chiorean[1], K.O Kim[1,2]

Contact E-Mail Address: michael.chiorean@virginiamason.org

Introduction: Although recent guidelines recommend chromoendoscopy (CE) as a method of choice for neoplasia surveillance in inflammatory bowel disease (IBD), there is still controversy regarding the utility of this technique in clinical practice.

Aims and Methods: The aims of this study were to compare the accuracy of CE and white light endoscopy (WLE) for the detection of overall neoplasia and advanced neoplasia in patients with IBD. Patients who underwent surveillance colonoscopy were identified from a single institution IBD database from 1999 to 2017. Patients with prior history of colon cancer or total colectomy were excluded. CE procedures were compared with their respective WLE controls in a paired comparison and the frequency of all neoplasia, advanced neoplasia and serrated neoplasia was assessed for both targeted and random biopsies. Demographic and clinical data was obtained from review of medical records.

Results: Total 315 procedure performed in 106 individuals were identified over a median follow up 3 years (median 3 colonoscopy/ patients). Among them, 290 procedures performed in 98 individuals were finally included in the analysis. The median age was 56 years (20–87), 55.1% were male, 69.4% had UC and 11.2% had PSC. CE and WLE were performed in 159 and 131 episodes, respectively. CE detected neoplasia in 40.9% of colonoscopies vs. 23.7% with WLE ($p = 0.02$). In addition, CE detected more advanced neoplasia (18.2% vs. 6.1%, $p = 0.002$) and more serrated lesions (14.5% vs. 6.1%, $p = 0.02$). Significantly fewer samples were obtained per procedure with CE (14.9 ± 9.7 vs. 20.9 ± 11.1, $p < 0.01$). Cancer was diagnosed in 2 cases, 1 detected by CE and the other 1 after colectomy.

Conclusion: CE has a higher detection rate than WLE for conventional neoplasia, advanced neoplasia and serrated neoplasia in patients with IBD under surveillance. Considering that significantly fewer biopsies are required, CE may be both more accurate and more cost-effective compared with WLE.

[Table 1. Characteristics of neoplastic lesions detected by chromoendoscopy and whitelight endoscopy]

	Chromoendoscopy (n = 159)	White light Endoscopy (n = 131)	p
Neoplasia per procedure	65 (40.9%)	31 (23.6%)	0.020
Advanced neoplasia per procedure	29 (18.2%)	8 (6.1%)	0.002
Serrated neoplasia per procedure	23 (14.5%)	8 (6.1%)	0.022
Targeted biopsy (mean ± SD)	213 (1.3 ± 1.2)	89 (0.7 ± 1.0)	< 0.001
Neoplasia per targeted biopsy	88	38	0.819
Random biopsy (mean ± SD)	2143 (13.7 ± 9.3)	2630 (20.2 ± 10.6)	< 0.001
Neoplasia per random biopsy	4	5	0.490

Introduction: The combination of positron emission tomography (PET) with ^{18}F-fluorodeoxyglucose (^{18}F-FDG) with magnetic resonance imaging (MRI) as integrated PET/MR enterography in one examination is a new cutting-edge technology for the non-invasive assessment of the inflammatory activity in ulcerative colitis (UC). Regarding the diagnostic goldstandard procedure ileocolonoscopy beside the risk of injury especially the bowel purgation is rated most bothersome.
Aims and Methods: This study's aim was to evaluate whether the inflammatory activity in patients with UC can be detected and accurately quantified by PET/MRI with and without bowel purgation. Patients were randomized to simultaneous PET/MRI (index test) with or without bowel purgation 24h before ileocolonoscopy (reference standard). In every patient the maximum standardized uptake value ratio gut/liver (SUVQuot), an MRI index and an endoscopy index (EI; rated by 2 independent gastroenterologists) were calculated for every segment (ileum, caecum, ascending colon, transverse colon, descending colon, sigmoid colon and rectum). Sensitivity, specificity, positive predictive value, negative predictive value, and diagnostic accuracy were calculated. Furthermore, receiver operating characteristic (ROC) curves for each colon segment were calculated to determine diagnostic accuracy of PET/MRI for the 2 modes of bowel purgation.
Results: $N = 53$ patients were included in the study. Ten patients were included for protocol optimization and 43 were randomized. Three patients were dropouts (two due to activity of disease other than UC, one refused endoscopy). Therefore, 19 patients (mean age = 42.4 years (SD = 11.71), 11 female (57.9%), mean time since diagnosis = 13.42 years) were randomized to PET/MRI with bowel purgation and 21 patients (mean age = 43.2 years (SD = 12.7), 14 female (66.7%), mean time since diagnosis 12 years) to PET/MRI without bowel purgation. Sociodemographic and clinical characteristics did not differ between the groups. SUVQuot and EI correlated significantly for patients without bowel purgation (r = .53, p = .015) but not for those with bowel purgation (r = .46, p = .063). Overall sensitivity, specificity, positive predictive value, negative predictive value, and accuracy using ileocolonoscopy as reference standard are shown in table 1. ROC analyses for each bowel segment show that the diagnostic accuracy of PET was better for patients without bowel purgation (AUC rectum = .87, p = .03; AUC sigmoid colon = .91, $p < .01$; AUC descending colon = .93, $p < .01$; AUC transverse colon = 1, $p < .001$; AUC ascending colon = .85, $p < .01$; AUC caecum = .77, *n.s.*) than for patients with bowel purgation (AUC rectum = .90, p = .03; AUC sigmoid colon = .76, *n.s.*; AUC descending colon = .74, *n.s.*; AUC transverse colon = .82, p = .02; AUC ascending colon = .63, *n.s.*; AUC caecum = .47, *n.s.*).
Conclusion: The inflammatory activity of UC can be detected and quantified by PET/MRI in patients who did not undergo bowel purgation prior to examination. PET/MRI might serve as a valuable complement for goldstandard ileocolonoscopy to extend the variety of non-invasive diagnostic tools in UC especially when bowel purgation is not applicable.
[Table 1. Testing overall sensitivity, specificity, PPV, NPV, and accuracy using ileocolonoscopy as reference standard]

	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	Accuracy (%)
PET with bowel purgation (n = 131 evaluated segments in 19 patients)	87.70	59.46	62.50	86.27	71.76
	81.03	89.89	83.93	87.91	86.39

Introduction: Magnetic resonance imaging (MRI) with the Magnetic Resonance Index of Activity (MaRIA) and the Clermont score as validated MRI activity indices is the gold standard to diagnose and monitor small bowel Crohn's disease (CD). However, noninvasive fecal biomarkers like calprotectin (CAL) and lactoferrin (LF) are increasingly popular and used in all-day patient care and have been evaluated regarding their capacity to differentiate and monitor disease activity in inflammatory bowel disease (IBD).
Aims and Methods: This study's aim was to compare the performance of fecal biomarkers and MRI for monitoring inflammatory activity in patients with CD. Fecal samples were collected to determine LF, CAL, PMN-elastasis (PMN-e), S100 calcium-binding protein A12 (S100A12), and Eosinophil-derived Neurotoxin (EDN) by enzyme immunoassay (EIA). In every patient a MRI was performed, MaRIA and the Clermont score were calculated, and standard cut-offs were applied by two independent experienced radiologists. Receiver operating characteristic (ROC) curves for each fecal biomarker using MaRIA and Clermont score as reference standard were calculated to determine sensitivity, specificity, and accuracy using optimized cut-offs.
Results: $N = 50$ patients with CD (mean age = 43.1 years ($SD = 13.42$), 32 female (64%), mean time since diagnosis = 13.8 years) were included in the study. According the MaRia score n = 41 patients and according to the Clermont score n = 42 patients showed signs of active inflammation. Mean levels for patients with active/inactive inflammation were 12.43/1.90(μg/g) in LF, 224.86/151.17(μg/g) in CAL, 0.17/0.09(μg/g) in PMN-e, 64.91/79.09(μg/g) in S100A12 and 1.4/0.47(μg/g) in EDN. Fecal LF, CAL and EDN were significantly

Abstract No: P0311

	MaRIA				Clermont			
	AUC (p)	Optimized cut-off	Sensitivity	Specificity	AUC (p)	Optimized cut-off	Sensitivity	Specificity
EDN	76 (n.s.)	–	–		81 (0.043)	.27	78.6	75
LF	83 (.016)	5.49	58.5	1	82 (0.035)	5.49	59.5	1
PMN-e	70 (n.s.)	–	–		71 (n.s.)	–	–	–
S100A12	43 (n.s.)	–	–		53 (n.s.)	–	–	–
CAL	71 (n.s.)	–	–		86 (0.017)	195.04	79.4	1

correlated to the Clermont score, however, only LF was correlated to the MaRIA score. Using optimized cut-offs, EDN, LF, and CAL were able to distinguish between active and inactive CD (see table 1).

[Table 1. Testing sensitivity, specificity, and accuracy using optimized cut-offs for MaRIA and Clermont score as reference standard]

Conclusion: These results support the utility of fecal biomarkers for detecting active inflammation in patients with CD.

Introduction: Patients with inflammatory bowel disease (IBD) are at high risk of colorectal cancer (CRC). Today American and European guidelines recommend surveillance colonoscopy rather than colectomy after complete removal of endoscopically resectable dysplastic lesions using chromoendoscopy.[1,2] However very few prospective data exist to evaluate the application of these recommendations and patient outcome. Moreover, the endoscopic technics that should be used for lesion resection is not well defined.

Aims and Methods: Describe within a multi-centric prospective cohort the management and follow-up of dysplasia in IBD patients.

Were included all patients with an Ulcerative Colitis (UC) or a Crohn's Disease (CD) with endoscopical remission (Mayo score < 2 for UC and the absence of visible ulceration for CD) that were eligible to prospective endoscopic follow-up with a diagnosis of dysplasia histologically proven within the previously diseased colonic part in 14 French departments of Gastroenterology since 2004. Other CRC risk factors, IBD treatment, relapse of dysplasia, surgery, endoscopic procedure and histological results were assessed all along the study.

Results: From September 2013 to November 2017, 60 patients were included among 14 centers. 43 patients had UC (71.7%), and 17 patients had CD (28.3%). The median follow-up time from the first diagnosis of dysplasia was of 10 years. The median follow-up time with prospective evaluation was of 1.6 year. The mean disease duration at diagnosis of the first dysplasia was 18.3 years +/- 9.9.

52 patients were initially diagnosed with an adenomatous lesion with low-grade dysplasia (LGD; 86.7%), 6 with an adenomatous lesion with high-grade dysplasia (HGD; 0.1%) and 1 CD patient had a serrated polyp with low-grade dysplasia.

18 patients (30%) presented a new area of dysplasia during the follow-up, 15/52 patients with LGD (28.8%) and 3/6 patients with HGD (50%). 2 patients (3.3%) developed a localized colorectal cancer.

19 patients underwent a colorectal surgery (31.7%), with 6 partial colectomies (10%), 8 total colectomies with ileorectal anastomosis (13.3%) and 5 total colectomies with ileoanal anastomosis (8.3%). The absence of surgery was not associated with a higher risk of relapse (HR:1.03; IC95% {0.2618–4.059}). A history of primary sclerosing cholangitis was the only risk factor associated with the decision to have surgery (OR: 6.96; IC95 {1.21; 40.09}). 8 patients presented a polyp associated with dysplastic adjacent mucosa. Among them 4 patients underwent surgery (50%). The 4 endoscopically-treated patients did not present any CRC after a minimum of 7 months of follow-up (median of follow-up: 8.5 months and 5 to 12 endoscopies).

Chromoendoscopy was used in 66.7% of patient (40/60). Regarding endoscopic treatment, the most frequent technic of resection was piecemeal resection (41/60; 68.3%) vs. mucosal resection (16/60; 26.7%) and submucosal resection (3/60; 5%). Resections were assessed macroscopically as complete in 76.7% of the case (46/60). 42% (6/14) with a macroscopically partial resection presented a newly diagnosed dysplasia at a different site (13 LGD, 1 HGD), vs. 28.3% of patient with a complete resection (13/46).

Conclusion: In accordance with the latest guidelines, endoscopic treatment and follow-up is the main modality of management of dysplastic lesions in IBD patient in this cohort both for HGD and LGD with reassuring results regarding cancer occurrence. The use of chromoendoscopy in the follow-up of IBD is insufficient.

Disclosure: The study was supported by Abbvie.

Introduction: To assess the relevance of including perianal region in routine CT/MR enterography for detection of subclinical perianal disease in Crohn's disease (CD), according to recent consensus recommendations.

Aims and Methods: Identification of patients undergoing enterography. Selection of examinations performed with perianal extension in patients with CD. Montreal classification with identification of perianal disease. Evaluation of enterographies for signs of perianal disease, blinded to Montreal classification. Statistics: Kappa concordance test ($p < 0.05$). Radiation increase estimation due to perianal extension, in a Siemens Somaton® 16 CT equipment with filtered back projection (FBP) reconstruction.

Results: 259 patients underwent 325 enterographies, 135 having CD (161 CT, 39 MR, mean 2 examinations/patient). Among CD patients, 24 had clinically apparent perianal disease at the time of first imaging examination. Extended enterographies showed perianal disease in 26 patients with CD, with an additional diagnosis of only 2 cases. The agreement between clinical and radiological detection of perianal disease was $24/26 = 92.3\%$ (Kappa 0.9, $p = 0.000$). The *number-needed-to-detect* perianal disease in the population with CD was 62.5 examinations. The estimated additional radiation associated with perianal extension in CT enterography was 15–18% (dose length product (DLP)).

Conclusion: The extension of enterography to the perianal region has not shown to be superior to clinical evaluation for detection of perianal disease in CD. The consensus recommendation may be prudent only for MR enterography, since CT enterography incurs a non-negligible added radiation and exposure of radiosensitive organs, that otherwise would not be covered.

Introduction: Inflammatory Bowel Disease (IBD) patients are at risk of Malignant Melanoma (MM) and non-melanoma skin cancer (NMSC). Simple photo protective measures and early detection through increased vigilance can reduce the incidence and the burden of disease. Traditional educational methodologies have had limited impact and newer valided educational tools are needed.

Aims and Methods: To assess the impact and validate a novel IBD educational video animation on skin cancer awareness in a cohort of Irish IBD subjects.

Prospective non-randomised educational interventional study using our novel, recently trialled IBD tailored educational animation video based on the Irish Cancer Society 'Sunsmart Guidelines'.

Self assessment questionnaires were employed to collect patient demographics and assess sun smart behaviour awareness at 2 sequential IBD clinics, one where the video was played in the outpatient waiting area (exposed group) and another without any video (control group). The questionnaire included sections on what factor suncream to wear and how often to re-apply it, when to stay in the shade, and how to perform a self skin check including what suspicious changes to look for in a suspicious mole. Results were compared among groups using a Chi Squared test ($p < 0.05$ was considered significant) and an odds ratio (OR) calculated where appropriate.

Results: In all, 84 completed questionnaires were returned, 40 and 44 from the exposed and control groups respectively. Mean age 44 years (Range 16–79), 50 (60%) were women, 46 (55%) had Crohn's disease, 54 (64%) never smoked, 38 (45%) were on biologics.
Not surprisingly this Irish cohort were a high-risk phenotype for the development of skin cancer with 62% (n = 53) having light coloured eyes, 56% (n = 48) had fair skin, 53% (n = 46) had freckles and 30% (n = 26) had red or blonde hair. Shockingly 36% (n = 31) used sunbeds and 57% (n = 49) had blistering sunburn, while 29% (n = 25) worked outdoors. In addition, 13% (n = 11) had a family history and 7% (n = 6) a personal history of skin cancer.
The proportion of correct responses was higher for all questions in the exposed group. The exposed group did statistically significantly better on factor protection, 34/40 (85%) vs. 22/44 (50%), p = 0.001, OR 5.6 and on skin screening techniques 23/40 (58%) vs. 10/44 (23%), p < 0.001, OR 4.6.
In addition, 93% (n = 37) of the exposed cohort found the video useful and 90% (n = 36) felt it was a better medium than traditional patient leaflets. Furthermore, 90% (n = 36) would like more of their education delivered in this format.
Conclusion: The 'TAGG SunCare Video' performed well in this study and following its successful validation it can be rolled out for regular use with a view to reduce skin cancer burden in our cohort.

P0315 IBD PATIENTS ARE FOUR TIMES MORE LIKELY TO DEVELOP ALL TYPES OF SKIN CANCER POSSIBLY RELATED TO HIGH RATES OF IMMUNOSUPPRESSION; WITH YOUNG PATIENTS PARTICULARLY AT RISK OF MELANOMA

C Gallagher[1,2], F MacMahon[3], L White[3], S Ismail[2], B Ryan[2], A O'Connor[2], A.M Tobin[1], D McNamara[2]
[1]*Tallaght Hospital, Dermatology, Dublin, Ireland*
[2]*Tallaght Hospital, Gastroenterology, Dublin, Ireland*
[3]*Tallaght Hospital, Clinical Medicine, Dublin, Ireland*

Contact E-Mail Address: gallagc6@tcd.ie
Introduction: Increased rates of non-melanoma skin cancer (NMSC) is a recognised complication of immunosuppression therapy for inflammatory bowel disease (IBD), while little is known of malignant melanoma (MM) risk. Newer therapies, including biologics, their early age of introduction and longer duration may further increase skin cancer risk.
Aims and Methods: To compare the incidence of both NMSC and MM in an Irish IBD cohort compared to controls.
Retrospective single centre case-control study from 2012–2017. Known IBD patients and age and sex matched controls were identified from an IBD and polyp database respectively. Both cohorts were cross-referenced with our hospital's pathology database for NMSC and MM. Patients otherwise at risk of skin cancer including transplant recipients or other indications for long-term immunosuppression and skin cancer genetic syndromes were excluded following review of patient electronic records.
The rates of NMSC and MM were compared among groups using a Chi-squared test ($p < 0.05$ was considered significant), and the impact of age, gender and immunosuppression was examined. Relative risk (RR) and numbers needed to treat (NNT) were calculated where appropriate.
Results: In all, 931 IBD and 1090 age and sex matched controls were identified. The incidence of NMSC was significantly higher in IBD vs controls, 1.18% (n = 11/931) vs. 0.28% (3/1090), p < 0.03 with a RR of 1.7 (p = 0.0001, 95% CI 1.29–2.26) and a NNT of 3.
Melanoma was also more frequent in IBD patients although not reaching statistical significance; 0.43% (n = 4/931) vs. 0.09% (n = 1/1090) p = 0.18, with a similar RR as NMSC, 1.7 (p = 0.01, 95% CI 1.1196- 2.70) and a NNT of 2.94.
MM patients were younger 51.4 years vs. 72.3 years in NMSC (p < 0.004, 95% CI 1.21–40.65)
Immunosuppression use was frequent with 70% (n = 3/4) of MM and 75% (n = 7/11) of NMSC occurring while on immunosuppression.
Conclusion: In addition to all IBD patients being at risk of NMSC, our study has shown for the first time that younger IBD patients also appear to be at a higher risk of malignant melanoma, RR 1.7 and supports a further nested case control study to identify modifiable risk factors, as well as supporting the establishment of a specific IBD skin cancer awareness campaign.

Introduction: Iron metabolism is regulated by hepcidin, polypeptide synthetized primarily by hepatocytes. Hepcidin synthesis may be altered due to hypoxia, inflammation, erythropoiesis and other multiple factors that have an influence on total iron body storage.
Aims and Methods: Our aim was to determine serum hepcidin levels in patients inflammatory bowel disease (IBD) as well to investigate whether there is correlation of hepcidin levels with disease acitivity.
A case-control study was performed among 30 newly diagnosed IBD patients (18 UC, 12 CD) and the same number age, sex-matched healthy controls. All patients underwent a total colonoscopy with ileoscopy. Complete blood count was obtained in addition to inflammatory markers (CRP, erythrocyte sedimentation rate-ESR). Serum levels of hepcidin were determined with commercially available enzyme-linked immunosorbent assay (DRG Instruments, Marburg, Germany). Serum iron, TIBC, UIBC were assesed with an electrochemiluminesence immunoassay and sTfR was assessed using an immunoturbidimetric method. Mayo score and CDAI respectively were calculated for each patient. Statistical analyses were performed using SPSS software version 20.0 for Windows.
Results: There was high statistically significant difference between IBD patients and controls in levels of hepcidin (p < 0.01). Serum hepcidin levels were significantly higher in control group (9.77 ± 2.71 vs. 6.40 ± 2.42 ng/ml, p = 0.00). Serum ferritin (394 ± 515 vs. 119 ± 124 ng/ml, p = 0.00) as well serum hepcidin to ferritin ratio (0.34 ± 0.17 vs. 0.22 ± 0.09, p = 0.02) were significantly higher in control group. There was no statistically significant correlation of serum hepcidin with CRP, Mayo score or CDAI respectively (p > 0.05). However we have found statisticaly significant negative correlation of sTfR, TIBC with hepcidin (p < 0.01).
Conclusion: Serum hepcidin is a very important novel marker in patients with iron deificinecy anemia (IDA), and it shoud be used in IBD patients considering difficulties in establishing IDA diagnosis due to inflammation.

Introduction: Histological healing in ulcerative colitis (UC) may be a better predictor than macroscopic appearance or clinical criteria for time to relapse. Histological assessment revealed that indicators of acute mucosal inflammation, including crypt abscesses, mucin depletion or an acute inflammatory cell infiltrate which are used in the Riley Score or the Nancy index were associated with a 2- to 3-fold increase in the risk of UC relapse during 12 months' follow-up. However histologic assessment requires invasive endoscopy and gaining of biopsy. Non-invasive surrogates of mucosal healing like fecal biomarkers would help to lower risks, costs and might increase patient acceptance.
Aims and Methods: The study aimed to investigate the performance of non-invasive fecal biomarkers compared to the Riley Score and Nancy index in patients with UC. Colonoscopy was performed in every patient and a fecal sample was harvested within 72 hours. 3 biopsies were taken from the macroscopically most inflamed location or random from each colonic segment and the Riley Score and Nancy index were calculated. For each patient the highest calculated score was compared to the fecal biomarkers Lactoferrin (LF), Calprotectin (CALPREST - CalP), PMN elastase (PMN-E), S100 calcium-binding protein A12 (S100A12) and Eosinophil-derived Neurotoxin (EDN). In addition, a Kruskal-Wallis test was performed to evaluate if the median levels of the fecal markers differ significantly between the grades 0–4 of the Nancy index.
Results: 50 patients (32 female), mean age 42.9 ± 12.3 years (range 23–67) with diagnosed UC were included in the study. The Riley score and the Nancy index were correlated significantly with EDN (r (49) = 0.561; p = 0.001/ r (49) = 0.445; p = 0.001), S100A12 (r (49) = 0.327; p = 0.022/ r (49) = 0.346; p = 0.015), PMN-e (r (49) = 0.314; p = 0.028/ r (49) = 0.289; p = 0.044) and LF (r (49) = 0.452; p = 0.001/ r (49) = 0.345; p = 0.015), but not with CalP (p > 0.05). The median levels of the fecal markers according to the grades 0–4 of the Nancy index and the results of the Kruskal-Wallis test are presented in table 1. Only LF, EDN and S100A12 differed significantly between the grades. Subsequent post-hoc tests showed that LF differed significantly between the grades 2 and 3 (z = −3.125, p = 0.011), EDN between the grades 2 and 4 (z = −3.006, p = 0.016) and S100A12 between the grades 2 and 3 (z = −3.968, p = 0.000) and 2 and 4 (z = −3.067, p = 0.013).
Conclusion: The fecal biomarkers LF, EDN, S100A12 and PMN-e were correlated significantly with the Riley and Nancy index, LF, EDN and S100A12 differed significantly between the grades of the Nancy index. The results support the utility of fecal biomarkers for detecting active histologic inflammation in patients with ulcerative colitis.
[Table 1. Median levels (range) of the fecal markers PMN-e, LF, EDN, CalP and S100A12]

P0318 AZATHIOPRINE METABOLITE (6-TGN) LEVELS WITHIN A DEFINED THERAPEUTIC RANGE ARE ASSOCIATED WITH LOWER FECAL CALPROTECTIN IN CROHN'S DISEASE - A RETROSPECTIVE ANALYSIS

J Essmann[1], C Keil[1], O Unruh[1], A Otte[2], M Manns[1], **O Bachmann**[1]

Introduction: Azathioprine/6-mercaptopurine (AZA/6-MP) are first-line immunosuppressants for the treatment of Crohn's disease. While recent meta-analyses have reported a positive association of their active metabolite 6-thioguanine (6-TGN) with clinical outcomes, 6-TGN levels have not been correlated with surrogate markers of mucosal healing, which is an increasingly recognised therapeutic goal.

Aims and Methods: We therefore investigated whether 6-TGN levels are inversely associated with fecal calprotectin (FC) in Crohn's disease patients on azathioprine monotherapy. 6-TGN and FC levels of 96 Crohn's disease patients on AZA/6-MP monotherapy visiting the IBD outpatient clinic between 2009 and 2016 were retrospectively analysed. In a small sub-cohort with serial 6-TGN measurements, longitudinal FC measurements were assessed.

Results: In patients with 6-TGN levels within a defined range (250–450 pmol/8×10^8RBCs), FC levels were significantly lower (median FC 149 vs. 346 mg/kg, $p = 0.007$), and hemoglobin concentrations as well as transferrin saturation levels were significantly higher than in patients with lower or higher metabolites. CRP and protein levels were not different. In the small cohort that was followed longitudinally, all patients achieved an increase in 6-TGN levels upon dose escalation, and fecal calprotectin levels decreased in 54%.

Conclusion: In our retrospective analysis on Crohn's disease patients receiving AZA/6-MP monotherapy, 6-TGN levels within a defined range (250–450 pmol/8×10^8red blood cells) were associated with significantly lower fecal calprotectin levels. A treat-to target concept directed by 6-TGN levels to reach mucosal healing appears promising, but requires prospective studies (DRKS00013246).

Introduction: The MaRIA index is the best-characterized Magnetic Resonance Enterography (MRE)
index for the assessment of luminal Crohn's disease (CD) activity. However, a number of limitations had been recognized.

Aims and Methods: The aim of this study was to develop and to validate a simplified and accurate Magnetic Resonance Index of Activity (sMaRIA) for assessing disease activity and therapeutic response of luminal CD.
MRE data from 98 patients, including active and inactive segments (colon and terminal ileum), from 2 prospective studies were re-analyzed to develop the sMaRIA using endoscopy (CDEIS) as gold standard. Further analysis of responsiveness and reliability, in an independent cohort of 37 patients who underwent MRE and endoscopy before and after a therapeutic intervention was performed. Comparison of the diagnostic performance between the original MaRIA and sMARIA for detecting active/severe lesions was performed.

Results: Logistic regression analysis showed that wall thickness >3 mm, presence of mural edema, ulcers and perienteric fat stranding were independent predictors of disease activity and were used therefore as descriptors of sMaRIA. The sensitivity and specificity of sMaRIA at segment level for detecting active disease using a cutoff point ≥1 were 90% and 81% (AUC 0.91, 95% CI 0.88–0.94), and for detecting severe lesions (ulcers) using a cutoff point ≥2 were 85% and 92% (AUC 0.94, 95% CI 0.91–0.96), respectively. Correlation between sMaRIA and CDEIS/MaRIA was excellent ($r = 0.82$ and $r = 0.91$, respectively; $p < 0.001$). There were no differences with regard to diagnostic performance between the sMaRIA and the original MaRIA for detecting active ($p = 0.7$) and severe disease ($p = 0.5$). The sMaRIA accurately detected changes in lesion severity in response to a therapeutic intervention and was as reliable as endoscopy for the assessment of mucosal healing.

Conclusion: Simplified MaRIA index allows a faster and easier assessment of inflammation in CD by keeping high accuracy for both diagnosis and therapeutic response. Main advantages over MaRIA include a less time-consuming calculation and that is not confounded by missing segments.

Introduction: The ulcerative colitis endoscopic index of severity (UCEIS) is a novel, validated instrument to evaluate endoscopic disease activity in ulcerative colitis (UC) (1). Recent studies have demonstrated that the UCEIS outperforms the more widely used Mayo endoscopic score (MES) in predicting long-term prognosis (2,3), including the need for colectomy (4). It also has precise item definitions and is likely to be more responsive than the MES score by virtue of its greater number of stratifications (scores range between 0–8, as opposed to 0–3). However, despite these potential benefits many gastroenterologists still prefer to use MES, because its operating characteristics are better defined and its grades are more readily applicable to clinical decision making; a MES ≥ 2 is generally accepted as the cut-off for treatment escalation (5). The equivalent for the UCEIS cut-off is not yet defined, which limits its clinical utility.

Aims and Methods: Our aims were to determine a UCEIS threshold most closely associated with the need for treatment escalation as well as to perform a validation exercise using clinical, biochemical and histological measures of disease activity. Colonoscopies and sigmoidoscopies performed in UC patients between Nov 2016-Jan 2018 at Guy's and St Thomas' Hospital were retrospectively reviewed. Data regarding demographics, UC phenotype and medication, Simple Clinical Colitis Activity Index (SCCAI), UCEIS, MES, CRP and Nancy Histological Index (NHI) were collected as well as treatment alteration decisions based on endoscopic findings.

The measure of agreement between the UCEIS and the Mayo score was examined using Kappa (κ) statistics. A UCEIS cut-off for the perceived need for treatment escalation was calculated using a Chi square test, receiver operating characteristic (ROC) curve and area under the curve (AUC) analyses. Pearson correlation coefficient was used to compare the linear relationship between the UCEIS and SCCAI, CRP and NHI.

Results: 363 endoscopic procedures were carried out in 295 patients during the data collection period. 201 of the 363 procedures (56%) documented both the UCEIS and MES. These scores demonstrated a substantial agreement between the indices ($\kappa = 0.713$, $p < 0.001$).

Overall, treatment escalation was considered necessary following 199 (56%) procedures, but was not in the remaining 156 (44%). ROC analysis of the perceived need for treatment escalation showed the highest sensitivity and specificity (0.80 and 0.93, respectively) for UCEIS ≥ 4 with an AUC of 0.93. Of 170 patients with a UCEIS ≥ 4, treatment escalation was considered necessary for 159 (94%), but not for 11 (6%). Of 185 patients with a UCEIS ≤ 3, treatment escalation was considered necessary in 40 (22%), cases but was not in 145 (78%) cases ($p < 0.001$).

UCEIS values demonstrated moderate correlation with SCCAI (0.671, $p < 0.001$) scores and strong correlation with NHI values (0.723, $p < 0.001$), but only weak correlation with CRP measurements (0.279, $p < 0.001$).

Conclusion: Our data demonstrate that a UCEIS score ≥ 4 was significantly associated with the perceived need for treatment escalation. This cut-off could/should therefore be used to support clinical decision-making based on endoscopic findings. Our study also showed that UCEIS has strong correlation with histological disease activity, moderate correlation with a clinical activity index, but only weak correlation with CRP.

Introduction: Recently, there is growing interest in the assessment of muscular mass in inflammatory bowel disease (IBD) as sarcopenia is associated with important outcomes.

Aim of the study was to evaluate prevalence of reduced muscular mass in IBD patients and assess its correlation with fatigue.

Aims and Methods: A first cohort underwent Dual Energy X-ray Absorptiometry (DEXA), a second cohort underwent Bio-Impendensometric Analysis (BIA). For DEXA, skeletal muscular mass index (ASMI), was calculated. Reduced muscular mass was defined for values of ASMI < 7.23 Kg/m^2 for men and ASMI < 5.67 Kg/m^2 for women. For BIA, skeletal muscle mass index (SMI) was calculated. Reduced muscular mass was defined for values of SMI < 10.75 Kg/m^2 for men and SMI < 6.75 Kg/m^2 for women. For comparison we also enrolled a control group for every cohort. Fatigue was assessed by means of visual analogue scale (VAS) evaluating patient reported 'current strenght'. Fatigue was defined for a VAS score < 70.

Results: For the first cohort, 42 IBD patients, 53% Crohn's Disease (CD), 47% ulcerative colitis (UC), and 45 healthy controls were enrolled and evaluated by DEXA. For the second cohort 68 IBD patients, 58% CD and 42% UC, and 35 healthy controls were enrolled and evaluated by BIA.

Reduced muscular mass was more frequent in IBD patients in comparison to controls both for DEXA (50% versus 9%, respectively, $p < 0.01$) and for BIA (29% versus 9%, respectively, $p < 0.05$).

Reduced muscular mass was found in 57% of underweight, 55% of normal weight, 17% of overweight and 0% of obese patients ($p < 0.001$). Fatigue was present in 62% of patients compared to 44% of controls ($p < 0.05$, ODD ratio $= 2.07$, 95% CI $= 1.06$ to 4.09).

Concomitant reduction in muscular mass and fatigue was present in 27% of patients compared to 1% of controls. This difference is statistically significant, with an increased risk for patients to meet both criteria in comparison to controls ($p < 0.001$; ODD $= 204.27$; 95% CI $= 32.54$–8049.00).

Conclusion: Reduced muscular mass indicating sarcopenia is common in IBD patients and can be evaluated with either DEXA or BIA. Assessing fatigue by means of VAS scale might help to identify patients requiring nutritional assessment.

Introduction: Enteropathic spondyloarthritis (eSpA) is a chronic inflammatory disease associated with inflammatory bowel disease (IBD).

Aims and Methods: In a prospective study at 2 years, we aimed to assess the diagnosis and outcome of IBD patients with musculoskeletal pain assessed by a combined gastro-rheumatological approach. At this purpose, IBD patients referring arthralgias to IBD-dedicated gastroenterologists were evaluated in a multidisciplinary gastro-rheumatological assessment. At baseline and at 3,6,12,24 months, the following parameters were recorded in a database: diagnosis, scores, biochemical, SpA and IBD activity scores, treatments, bDMARDs (biological disease-modifying anti-rheumatic drugs), csDMARDs (conventional synthetic DMARDs). Associations between treatments and IBD characteristics were evaluated by logistic regression (Adjusted Odds Ratio, AOR [95% CI]).

Results: Overall, 229 IBD patients were referred to rheumatologists, including 141 (61.6%) with CD, 88 (38.4%) with UC. Among these 229 patients, eSpA was diagnosed in 147 (64.2%), while in the remaining 82 (35.8%) patients arthralgias were not related to IBD (No-eSpA). The median age was higher in patients without vs with eSpA (52.5 [41–62] vs 46 [37–56]; $p = 0.022$). Among the 147 patients with eSpA, 96 (65.3%) showed peripheral and 51 (34.7%) axial

involvement (age: 46 [37–56]; females: 99 (67.3%); IBD duration: 14.6±9.7). bDMARD treatments increased over the follow-up (baseline to 24 months: 32.6–60%; AOR 3.45 [1.93–6.2]; $p < 0.001$). bDMARD use was less frequent in elderly patients (AOR 0.73 [0.56–0.96], $p = 0.023$), in UC (AOR 0.43 [0.2–0.94]; $p = 0.034$) and in patients with peripheral involvement (AOR 0.53 [0.3–1.04]; $p = 0.067$). csDMARD use was increased in patients with peripheral involvement (AOR 4.65 [2.09–10.33]; $p < 0.001$) and with UC (AOR 2.30 [1.13–4.67]; $p = 0.021$). CRP, ESR, ASDAS-ESR (Ankylosing Spondylitis Disease Activity Score) and BASFI (Bath Ankylosing Spondylitis Functional Index) significantly decreased over the follow up ($p \leq 0.022$; $p \leq 0.033$; $p = 0.05$; $p = 0.03$, respectively). The same was not observed for UC activity score (pMayo), Ankylosing Spondylitis Disease Activity Index (BASDAI) and Health Assessment Questionnaire for SpA (HAQ-S).

Conclusion: In a prospective study at 2 years, a multidisciplinary gastro-reumathological approach showed to optimize the diagnosis, therapeutic management and outcome of IBD patients referring arthralgias. In patients with eSpA, bDMARD use paralleled an improvement in disease activity scores and confirmed a good safety profile.

P0323 EVALUATION OF CROHN'S DISEASE BY USING A NOVEL CAPSULE ENDOSCOPY SCORING METHOD: CROHN'S DISEASE ACTIVITY IN CAPSULE ENDOSCOPY (CDACE)

T. Omori, K. Yasuhiro, S. Murasugi, H. Kambayashi, A. Ito, M. Yonezawa, S. Nakamura, K. Tokushige
Tokyo Women's Medical University, Institute of Gastroenterology, Tokyo, Japan

Contact E-Mail Address: tohmori@ige.twmu.ac.jp

Introduction: Small bowel capsule endoscopy (SBCE) for Crohn's disease (CD) with small bowel lesions is a low-invasive method that enables visualization of the small bowel mucosa. 2 scoring methods are used to evaluate the images obtained: the Lewis score (LS) and the capsule endoscopy Crohn's disease activity index (CECDAI). However, CD shows varied pathology, including inflammation and stenosis; it is difficult to assess the disease state, including the range of lesions, and presence/absence of stenosis solely on the basis of sum scores obtained by either one of the scoring methods.

Aims and Methods: To develop and evaluate a novel scoring method with which pathology can readily be assessed from sum scores by using SBCE data of CD patients with small bowel lesions. The subjects included 93 CD patients with small bowel lesions who underwent SBCE between June 2010 and May 2017. SBCE was carried out a total of 162 times in these patients, including 104 times in men, 49 times for small bowel CD, and 113 times for small-and-large bowel CD. The novel scoring method was established as Crohn's disease activity in capsule endoscopy (CDACE), and its correlations with the scoring methods in current use, LS and CECDAI, and also with the clinical disease activity index (CDAI) and biomarkers, were analyzed. In CDACE, the small bowel was divided into four zones according to Rapid software analysis, and for each zone, the inflammation was scored on a scale of 0 to 4, giving a total score of 0 to 16 (inflammation score: A). In addition, inflammation present was scored on a scale of 0 to 4 (zone score: B) and the severity of stenosis was scored on a scale of 0 to 3 (stenosis score: C). CDACE was calculated as the sum of $A \times 100 + B \times 10 + C$.

Results: The correlations between CDACE and the existing scoring methods were as follows: CDACE and the LS: $r = 0.44$ ($p < 0.0001$) and CDACE and the CECDAI: $r = 0.83$ ($p < 0.0001$). Thus, the correlation with the CECDAI was higher. With respect to CDACE, the LS, and the CECDAI, respectively, the correlations of each with the CDAI and biomarkers were as follows: CDAI: $r = 0.39$ ($p < 0.0001$), $r = 0.19$ ($p = 0.0119$), and $r = 0.37$ ($p < 0.0001$) and C-reactive protein (CRP): $r = 0.23$ ($p = 0.0027$), $r = 0.05$ ($p = 0.5201$), and $r = 0.24$ ($p = 0.0018$). Therefore, CDACE and the CECDAI showed approximately the same correlations with the CDAI and CRP.

Conclusion: With CDACE, it is possible to interpret the inflammation morphology (the second / third / forth digit) and the severity and presence/absence of stenosis (the first digit) in the small bowel on the basis of the sum scores obtained. In addition, the correlation with the CECDAI has been clearly demonstrated. Therefore, CDACE represents a novel, useful scoring method in clinical practice for patients who underwent SBCE for CD with small bowel lesions.

P0324 LONG-TERM OBSERVATION REGISTRY -CEDUR - IN GERMAN IBD PATIENTS

S. Howaldt[1], T. Ochsenkuehn[2]
[1]*HaFCED e.K., Hamburg, Germany*
[2]*Isarklinikum, Gastroenterology, Munic, Germany*

Contact E-Mail Address: howaldt@hafced.de

Introduction: Inflammatory bowel disease (IBD) is diagnosed in approximately 350000 patients in Germany with increasing incidence and prevalence. Although on-going inflammation can result in irreversible damage to the GI tract, undertreatment and reluctance to use immunmodulatory therapies earlier in the course of disease are present. On the other hand, costs for therapies, surgeries and hospitalization are high, once damage has occurred. In 2015 we therefore implemented an independent national IBD registry (CEDUR) to methodically collect real-life data of IBD patients with regard to the usefulness and comparability of immunmodulatory strategies.

Aims and Methods: CEDUR is a web-based, descriptive registry of large tertiary IBD centers throughout Germany, using time sparing documentation in an adapted medical charts-software via GDT interface. Patients with IBD who are willing to participate have visits every 3 months and fill in questionnaires that are later-on completed and controlled by their physicians. Since 2015 and for at least 10 years, data on phenotypes, therapeutic effects including efficacy, safety and economy as well as hospitalizations, surgeries, comorbidities, day-off-work and quality of life are continuously collected in patients with Crohn's disease (CD) and ulcerative colitis (UC).

Results: So far, 1856 IBD patients (UC: 859, CD: 992, indeterminate colitis 5) were enrolled, of whom 47% are men and 53% are women.

In CD and UC, 24.3% were younger than 21 years, 38.6 between 21 and 30, 19.0% between 31 and 40, 10.5% between 41 and 50 and 7.5% older than 50 years. In CD, age at first diagnosis was younger than 21 in 29.8% and older than 50 years in 6.5%. In UC, age at first diagnosis was younger than 21 years in 17.6% and older than 50 years in 28.8%. In CD, biologics were used in 73.9% of patients, of those anti-integrins in 6.0% and IL-12/23 blockers in 5.6%. 31.4% of patients with TNF-blockers were treated for more than 4 years. 54.2 % of patients under infliximab received infusions every 7 to 9 weeks, 31.6% every 4 to 6 weeks. 49.5 % of patients under adalimumab received injections of 40mg every 2 weeks, and 38.4 % at least 80mg every 2 weeks.

In UC, TNF-blockers or other biologics were used in 59.0% of patients, of those anti-integrins in 12.05% and IL-12/23 blockers in 0.2%. 24.8% of patients with TNF-blockers were treated longer than 4 years. 47.1 % of patients under infliximab received infusions every 7 to 9 weeks, 36.9% every 4 to 6 weeks. 52.7 % of patients under adalimumab received injections of 40mg every 2 weeks, and 37.9% at least 80mg every 2 weeks.

Conclusion: We successfully implemented a large national IBD registry for the collection of real-life data by a contribution of patients and physicians from tertiary IBD centers throughout Germany.

As a first result we can present the data on the use of biologic therapy in more than 1800 Crohn's disease and ulcerative colitis patients. IBD significantly affect patients in their young ages, biologic therapies seem to be necessary in much more patients than commonly assumed and standard treatment has to be adapted to higher doses in TNF-blockers in UC more than CD and in adalimumab more than infliximab.

Our registry can serve as database for a wide range of efficacy, safety and economy issues in IBD patients.

Introduction: DiBiCol® is a diagnostic test that can differentiate between ulcerative colitis (UC), Crohn's disease (CD) and non-inflammatory bowel disease (Non-IBD). DiBiCol® is a PCR-based method that monitors 7 proprietary biomarkers from a single colonic biopsy. By applying a specially designed algorithm, a diagnosis of UC, CD and Non-IBD can be made with a high degree of certainty. The algorithm was established in 3 clinical studies. Since 2009 the DiBiCol® test has been used in Sweden in clinical routine practice at a large number of clinics and colonic biopsies from more than 1200 patients have been analysed.

Aims and Methods: The aim of the study is to retrospectively evaluate the clinical application and the outcome of the multigene analysis test DiBiCol® in differentiating between UC, CD and Non-IBD.

In this retrospective analysis the clinical application and the outcome of the DiBiCol® test was studied in 1110 patients. The consistency of the DiBiCol test result from duplicate colonic biopsy samples were compared in 300 patients. In a subset of 79 patients, DiBiCol® test results were compared to clinical diagnosis and histopathology diagnosis retrospectively.

Results: Based on the data compiled from over 30 IBD units in Sweden over 2 years the causes for requesting the DiBiCol® test were in 52% cases of unclassified IBD, in 16% patients representing IBD like symptoms for the first time, in 13% cases of indeterminate colitis, in 8% cases before surgery to confirm diagnosis, in 6% cases of changing symptoms and in 5% other reasons.

In 994 out of 1110 samples a conclusive diagnosis with more than 70% probability could be made, UC in 492 cases, CD in 431 cases and 71 cases of Non-IBD, while in 116 cases the test result was inconclusive for different reasons. Duplicate colonic biopsy samples taken at the same time were available in 300 patients and provided the same test results in 83% of the cases. In 52/300 patients the test result was different between the 2 biopsies but only in 24 patients a different diagnosis with $\geq$ 90% probability was evident meaning a clearly different test results only in 8% of cases (24/300). In 34 patients DiBiCol® was tested at 2 time points 4 weeks apart and in 94% of cases the test results were in alignment with each other.

In a subset of 79 patients the clinical and histological diagnosis were compared to the DiBiCol® test results and the data showed that 93% of these cases, in which the clinical diagnosis matched with histopathology, were correctly diagnosed by DiBiCol® with $\geq$ 70% probability. The sensitivity / specificity of the DiBiCol®

test was calculated to be 97% / 92% for UC diagnosis and 78% / 88% for CD diagnosis. There was a better correlation between the DiBiCol® result and the histopathology evaluation than the clinical diagnosis in this subset.
Conclusion: Real-world data on the use of DiBiCol® demonstrate that this multigene analysis test is a useful diagnostic tool and can support physicians to diagnose IBD and to differentiate CD from UC.

P0326 FAECAL CALPROTECTIN DISCRIMINATES CRYPTOGLANDULAR FROM CROHN'S DISEASE PERIANAL FISTULAE

T Stevens[1], G D'Haens[1], M Duijvestein[1], C.J Buskens[2], W.A Bemelman[2], K.B Gecse[1]

[2]*Academic Medical Center, Department of Surgery, Amsterdam, Netherlands*

Contact E-Mail Address: t.w.stevens@amc.uva.nl
Introduction: Faecal calprotectin (FC) is a surrogate marker of mucosal inflammation. Our aims were to determine the diagnostic accuracy of FC for (i) the differentiation between cryptoglandular (CG) perianal fistulae and perianal fistulising Crohn's disease (pCD) and (ii) the detection of intestinal ulcers in pCD patients with an active perianal fistula.
Aims and Methods: This was a retrospective single-center study. Patients with a perianal fistula between 2009 and 2017 were identified by an institutional database search. Adult patients with an active perianal fistula, an available FC concentration and a complete ileocolonoscopy within a time window of 10 weeks were included. Active fistulae were defined by spontaneous drainage or upon gentle finger compression as reported by patient or physician. Patients with an abscess or GI infection were excluded. Endoscopy images and reports were independently reviewed for the presence of ulcers.
Results: 56 patients were included (pCD, $n = 37$; CG perianal fistula, $n = 19$). Intestinal ulcers were present in 19 of the pCD patients (51.4%). FC was significantly higher in patients with pCD compared to CG perianal fistulae (median [interquartile range]) (708.0 [207.0–1705.0] vs. 32.0 [23.0–77.0] µg/g, $p < 0.001$). Area-under-the-curve (AUC) value for FC receiver operating characteristic (ROC) statistics was 0.900, 95% confidence interval (CI) [0.818–0.982]. Optimal FC cut-off was achieved for a value of ≥150 µg/g (sensitivity 0.81, specificity 0.89, positive predictive value 93.8%, negative predictive value 70.8% and overall accuracy 83.9%). When the analysis was limited to patients without intestinal ulcers, FC could still accurately discriminate active CG perianal fistulae from pCD with the same optimal cut-off value of 150 µg/g (AUC 0.857 [0.733–0.980]; sensitivity 0.67, specificity 0.90, positive predictive value 85.7%, negative predictive value 73.9% and overall accuracy 78.4%). In the pCD population, FC was significantly increased in the presence of ulcers (1672.0 [403.0–1800.0] vs. 238.0 [75.8–795.0], $p = 0.004$). AUC value was 0.776, 95%CI [0.622–0.931]. Optimal FC cut-off was achieved for a value of ≥250µg/g (sensitivity 0.89, specificity 0.56, positive predictive value 68.0%, negative predictive value 83.0% and overall accuracy 73.0%). Of the pCD patients with a FC above the determined optimal cut-off value of 250 ($n = 25$), 32% had a false positive result and in fact had endoscopically quiescent disease.
Conclusion: FC is an accurate and clinically useful tool to distinguish between active CG perianal fistulae and active Crohn's disease perianal fistulae, even in the absence of intestinal ulcers. In pCD patients with an active fistula, an elevated FC does not accurately predict the presence of intestinal ulcers and should be interpreted with caution.

P0327 QUALITY OF LIFE IS ASSOCIATED WITH WEARABLE-BASED PHYSICAL ACTIVITY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: A PROSPECTIVE, OBSERVATIONAL STUDY

M Wiestler[1], F Kockelmann[1], M Kück[2], U Tegtbur[2], M Manns[1], M Attaran-Bandarabadi[1], O Bachmann[1]

Introduction: Patient-reported outcomes such as quality of life are gaining in importance in the assessment of patients suffering from inflammatory bowel disease (IBD). The association of objectively measured physical activity and quality of life in IBD patients has not been studied in depth.
Aims and Methods: To investigate the association of disease-specific quality of life and physical activity as well as clinical and biochemical disease activity in IBD patients, 91 IBD patients were stratified into 4 groups (Crohn's disease - CD and ulcerative colitis - UC, in remission and with moderate-severe activity, respectively), and evaluated with respect to disease-specific quality of life (IBDQ), physical activity (accelerometry), body composition (bioelectrical impedance analysis, BIA), as well as clinical (HBI, SCCAI) and biochemical (CRP, fecal calprotectin) parameters of disease activity.
Results: In patients with moderate-severe disease activity, IBDQ was significantly lower as compared to patients in remission (Mann-Whitney-U test and Kruskal-Wallis test, $p < 0.001$). The physical activity level (PAL) was higher in remission than in active disease (Mann-Whitney-U test, $p < 0.05$). IBDQ was significantly correlated with the duration of strenuous physical activity per day ($p = 0.029178$, $r = 0.235$), skeletal muscle mass ($p = 0.033829$, $r = 0.229$), and biomarkers of inflammation (CRP: $p < 0.005$, $r = -0.335$, fecal calprotectin: $p < 0.005$, $r = -0.385$, Spearman's rank correlation).
Conclusion: In this prospective, cross-sectional study, disease-specific quality of life was significantly associated with accelerometrically determined physical activity in patients with inflammatory bowel disease. This may be related to a reciprocal impact of both factors (DRKS00011370).

Introduction: Abnormal mental health symptomatology in Crohn's disease (CD) and ulcerative colitis (UC) occurs commonly. However, the nature of these symptoms and the identity of their predictors at different levels of disease activity remain incompletely understood.
Aims and Methods: Consecutive unselected consenting adult patients (age ≥ 18 years) with CD and UC, with psychiatric illness and medication excluded, were recruited at out-patient clinics and via the CD and UC Patients' Association, and provided demographic and economic information. Disease activity was self-scored by the Patient Harvey-Bradshaw Index (P-HBI) in CD, or the Patient Simple Clinical Colitis Activity Index (P-SCCAI) for UC. Active disease was defined by a score of P-HBI ≥5 or P-SCCAI ≥ 3. Mental health was measured by the self-report Brief Symptom Inventory (BSI) of 53 symptoms grouped in nine 'categories': depression, somatization, obsession-compulsive, interpersonal sensitivity, anxiety, hostility, phobic anxiety, paranoid ideation and psychoticism. The BSI yields three 'summary' scores: (1) General Severity Index (GSI, mean of category scores, range 0–4), (2) Positive Symptom Total (PST, sum of recorded symptoms, range 0–53); (3) Positive Symptom Distress Index (PSDI, summation of the item values divided by PST, range 0–4). Higher scores indicate more mental ill-health.
Results: There were 289 CD patients with active and 390 with remittent disease; in UC, 110 and 106 patients, respectively. CD patients were aged 37.7 ± 14.0 years, UC patients 48.9 ± 16.2 years ($p < 0.001$). In CD 58.3% were females; in UC 54.4% females. In univariate analysis, GSI, PST, PSDI, depression, somatization, obsession-compulsive, interpersonal sensitivity, anxiety, hostility, phobic anxiety, paranoid ideation and psychoticism were all scored higher (were worse) in active versus remittent CD ($p < 0.001$). All summary and category scores except paranoid ideation were higher in active versus remittent UC ($p < 0.01$-0.001). All summary and category scores were higher in active CD versus active UC ($p < 0.03$-0.001). Scores in remittent disease were lower than in active disease, yet CD demonstrated higher scores than UC ($p < 0.02$-0.001) in all categories except interpersonal sensitivity ($p = 0.07$). Based on these findings, a linear regression analysis comparing CD and UC was performed, controlling for patients' age, gender and economic status (Table). Somatization, anxiety and paranoid ideation were significantly higher in active CD versus UC. Somatization and anxiety were significantly higher in remittent CD versus UC. GSI, PST and PSDI were significantly higher in active CD versus active UC, whereas in remittent CD versus remittent UC the summary scores were not statistically different.
Conclusion: Mental health is significantly worse in patients with CD compared with UC, and in the active disease state. However, differences of mental health between CD and UC in the remittent state largely disappeared when controlling for age, gender and economic status, whereas active CD patients remained more severely affected mentally compared with active UC patients in the categories of somatization, anxiety and paranoid ideation. Awareness of possible mental aberrations will lead to prompt treatment.

Variable	Active CD	Active UC	β	p	Remittent CD	Remittent UC	β	p
Somatization	1.6±.9	1.2±.9	−0.164	0.002	.9±.8	.5±.5	−0.136	0.007

Introduction: Patients with ulcerative colitis (UC) experience periods of recurring and episodic clinical signs and symptoms. This study sought to establish the association between disease activity and health-related quality of life and other patient-reported outcomes.
Aims and Methods: Data from the 2015 and 2017 Adelphi Inflammatory Bowel Disease Specific Programmes (IBD-DSP) were used. The IBD-DSP is a database of patient chart information abstracted by selected gastroenterologists across the European Union Five ([EU5]; i.e., France, Germany, Italy, Spain, and the United Kingdom [UK]). Eligible gastroenterologists who agreed to participate were asked to complete patient record forms for their next 7 consecutive eligible adult patients with UC. Using available chart information (including endoscopy results based on Mayo scoring), physicians classified their patients into 1 of the following categories: remission with an endoscopic score = 0 (''deep remission''), remission without an endoscopic score = 0 (''remission''), or active disease. Patients were then invited to complete a survey including various patient-reported outcomes: EuroQoL-5D (EQ-5D), Short Quality of Life in Inflammatory Bowel Disease Questionnaire (SIBDQ), and Work Productivity and Activity Impairment-Ulcerative Colitis (WPAI-UC) questionnaire. Only patients with moderate-to-severe UC were included in the analysis (defined as those who had used either an immunomodulator [IM] or a biologic). Differences among disease activity categories with respect to patient-reported outcomes were analyzed using generalized linear models, controlling for demographic (age, sex, country) and clinical factors (body mass index, smoking history, years diagnosed, and the Charlson comorbidity index) as confounders.
Results: A total of N = 1037 patient charts with linked surveys were included (France: N = 347 Germany: N = 379, Italy: N = 55, Spain: N = 171, UK: N = 85; 55.6% male, mean age = 39.2 SD = 13.8). Patients had been diagnosed for a mean of 5.3 years (SD = 5.9). 33.6% had active disease, 53.0% were in remission, and 13.3% were in deep remission. Patients with active disease reported significantly lower levels of EQ-5D health state utilities (Adjusted Mean [AdjM] = 0.78) compared with remission (AdjM = 0.91) and deep remission (AdjM = 0.91) (both $p < 0.05$). Similar findings were observed with the total score of the SIBDQ (AdjMs = 4.2, 5.6, and 5.7, respectively; both $p < 0.05$ compared with active disease). Both overall work impairment and activity impairment (from the WPAI-UC) were also highest among patients with active disease (AdjMs = 54.4% and 47.6% impairment, respectively) followed by remission (AdjMs = 19.4%, 18.9%) and deep remission (AdjMs = 13.8%, 15.7%) (both $p < 0.05$ compared with active disease).
Conclusion: Among patients with moderate-to-severe UC in EU5, active disease was associated with significant impairments in health-related quality of life and impairments in work and leisure activities.

Contact E-Mail Address: qi.guo@abbvie.com
Introduction: Crohn's Disease (CD) features segmental inflammation, which can affect any part of the gastrointestinal tract, with lesions extending across all tissue layers. Although endoscopy and histology can be used to monitor mucosal disease, in vivo assessment of progression and regression of transmural lesions, especially in the small bowel remains challenging. The 18 kDa translocator protein (TSPO), located on the mitochondrial outer membrane, is overexpressed in activated macrophages, and has been used as a marker of inflammation. PET imaging with TSPO selective radioligands allows for the quantification of inflammation, and has been used extensively in both brain and peripheral inflammatory diseases.
Aims and Methods: Here we aim to evaluate the utility of TSPO PET, using radioligand [^{11}C]PBR28, for assessing the inflammation in the gastrointestinal tract in subjects with CD compared to healthy subjects. Subjects were recruited by Hammersmith Medicines Research. For subjects with CD, inclusion criteria included CD confirmed by endoscopy, and them being naïve to biologics. 4 CD patients (2 males and 2 females) and 5 healthy volunteers (3 males and 2 females) have been recruited to date and undergone 2 dynamic [^{11}C]PBR28 PET-CT scans: baseline and 2 hours post a 90 mg oral dose of XBD173 on the same day. XBD173 is a TSPO selective compound and is thereby used to confirm the specificity of the signal in this particular application. Patient Crohn's Disease Activity Index (CDAI), C-reactive protein (CRP), Faecal Calprotectin (FC) as well as TSPO rs6971 genotype (a common polymorphism in the TSPO gene which affects ligand binding affinity[1]) were measured at screening. Regions of interest (ROIs) were manually delineated on the terminal ileum, small bowel, descending colon, sigmoid colon, and skeletal muscle in each subject based on PET and CT co-registered images. The mean and max standard uptake value (SUV, radioactivity concentration normalized by total injected activity and body weight) were estimated in these ROIs.
Results: The CDAI of the CD patients range from 116 to 172, with CRP ranges from 0.2 to 3.8 mg/L, and FC from 49 to 510 mg/kg. Among the 4 CD patients, 3 are high affinity binders (HABs) and 1 is a mixed affinity binder (MAB). There are 2 HABs and 3 MABs in the control group. Compared to healthy controls, CD patients showed a trend of higher heterogeneous ligand uptake in the GI tract, especially in the small bowel. The mean SUVs in different ROIs are listed in the table below.
Conclusion: Preliminary data suggest that the observed PET signal in the small bowel of CD patients can be attributed to TSPO, and by inference inflammatory activity. Should these results to be confirmed, TSPO PET may allow the identification of inflammatory foci in the GI tract of Crohn's patients even with mild disease activities, providing a non-invasive method to assess and quantify inflammatory activity not captured by endoscopy. Recruitment into this pilot study continues.

	Terminal ileum	Small bowel	Descending colon	Sigmoid colon	Muscle
Healthy controls	1.33±0.30	2.01±0.55	1.40±0.74	1.15±0.31	1.25±0.83
CD patients	1.95±0.47	2.68±0.45	1.23±0.43	1.46±0.30	1.32±0.65

[Regional mean SUVs (30–60 min) in healthy and Crohn's patients (mean ± sd).]
Disclosure: Qi Guo, Just Genius, Yanping Luo, and Robert Comley are employees of AbbVie. Gaia Rizzo, Eugenii Rabiner and Azeem Saleem are employees of Invicro. Mavi Walther and Matilde Luce are employees of Hammersmith Medicines Research.

P0331 DEPENDENCE OF THE LEVEL OF INFLAMMATION MARKERS ON THE PRESENCE OF CLOSTRIDIAL INFECTION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

O Knyazev, **A Kagramanova**, A Lishchinskaya, I Korneeva, A Parfenov
Moscow Clinical Scientific Center named after A. S. Loginov, Inflammatory Bowel Diseases, Moscow, Russian Federation

Contact E-Mail Address: kagramanova@me.com
Introduction: In patients with inflammatory bowel disease (IBD), there was a more frequent development of clostridial infection (CI) and much higher morbidity and mortality rates compared with patients without IBD. Immunosuppressive therapy is a risk factor.
Aims and Methods: We aimed to determine the frequency of clostridial infection (CI) in patients with inflammatory bowel disease undergoing treatment in the Department of treatment of IBD Moscow Clinical Research Center.
Of the 1224 patients with IBD, 764 were found to have toxins A and B in *Clostridium difficile* in feces by enzyme immunoassay. Comparative analysis

between the groups was performed by the method of 4-field tables using non-parametric statistical criteria.
Results: CI was found in 132 (17.3%) patients of IBD, patients without CI - 632 (82.7%). Among IBD patients with CI men - 61 (46.2%), without CI men - 313 (49.5%). Extraintestinal manifestations were present in 37 (28.1%) patients with IBD with CI, in 174 (27.5%) - without CI ($p > 0.05$). The mean albumin level in patients with CI was 28.4±2.83 g/l, in the group without CI - 35.6±3.79 g/l ($p = 0.128376$). The mean level of C-RP among patients with CI was 65.9±4.8 mg/l, in the group without CI - 37.8±3.7 mg/l ($p = 0.000004$). The mean level of ESR in patients with CI was 43.5±6.5 mm/h, in the group without CI - 19.4±3.3 mm/h ($p = 0.000991$). The mean level of fecal calprotectin among patients with CI was 1680±120 mg/g, in the group without CI - 480±95 mg/g ($p = 0.00000$).
Conclusion: The activity of the inflammatory process is higher in patients with inflammatory bowel diseases with associated clostridial infection.
Disclosure: Nothing to disclose

P0332 MICROBIOTA PROFILE AND DYSBIOSIS ASSESSMENT IN CLINICAL PRACTICE: A PILOT STUDY ON IBD PATIENTS

S Facchin[1], A Buda[2], B Perini[1], R D'inca[1], E.V Savarino[1]
[1]*University of Padua, Department Of Surgery, Oncology And Gastroenterology, Padova, Italy*
[2]*UOC Gastroenterology, GI Oncological Surgery, Feltre, Italy*

Contact E-Mail Address: sonia.facchin@unipd.it
Introduction: A growing body of evidence suggests that dysbiosis plays a key role in the pathogenesis of inflammatory bowel disease (IBD). However, due to intrinsic limitations in current diagnostic methods and lack of agreement on the appropriate test to use, in clinical practice the characterization of dysbiosis in IBD patients remains challenging.
Aims and Methods: We compared a commercially available dysbiosis test and a stool standard analysis test to profile the microbiota at phylum level in IBD patients and healthy control subjects.
Human fecal samples from 13 IBD patients and 4 healthy control subjects were examined by the GA-map™ Dysbiosis Test (Oslo, Norway) and Illumina Mi-Seq test by BMR-genomics (Padova, Italy). GA-Map is a 16S rRNA test that utilize 54 DNA probes based on 7 variable regions (V3-V9) and recognizing gut bacteria profiles for identification and characterization of dysbiosis. The BMR-genomic test applies the universal primer based on the V3-V4 hypervariable region of 16S rRNA using an Illumina Mi-Seq next-generation sequencer. The correlation between variation of microbiota expressed as the Dysbiosis Index (DI) and fecal calprotectin (FC) levels in IBD patients was also investigated.
Results: BMR-genomics reports on the relative abundance (*ra*) of the major *phyla* on IBDs microbiota. So far, we compared the trend of *ra* with normalized signal for fluorescent probes of DI between the 2 techniques. From descriptive analysis, the 2 methods show a similar trend for *Actinobacteria, Bacteroidetes* and *Proteobacteria,* especially on CD disease (Figure 1). However, there was a substantial difference in the trend on *Firmicutes*. FC levels were correlated with the DI in CD but not in UC patients ($r = 0.74$ vs $r = 0.2$, respectively). Indeed, 100% of CD patients and 75% of UC patients with dysbiosis (DI 3–5) showed an increased FC (>50μg/g). Finally, only by BMR-genomics analysis we found a significant variation on *Faecalbacterium prausnitzii* between IBD and controls ($p < 0.05$).
Conclusion: We observed that GA-Map™ Dysbiosis Test and the BMR-genomic test produce comparable results in terms of degree of variation of microbiota in IBD patients and thus both can be used to identify and characterize dysbiosis in IBD patients. Furthermore, dysbiosis as assessed by these methods seems to well correlate with biochemical activity in CD patients and thus could be considered a potential target for treatment.

Contact E-Mail Address: t.vanstappen@r-biopharm.de
Introduction: Therapeutic drug monitoring of adalimumab (ADM) is increasingly implemented in clinical practice to improve clinical decision-making and maximize treatment outcomes in patients with inflammatory bowel disease (IBD). However, classical assays (e.g. ELISA) are time-consuming and require simultaneous assessment of multiple samples. Hence, timely dose adjustments and tight disease control are delayed. Here, we would like to present the validation of the RIDA®QUICK ADM Monitoring, a rapid test for adalimumab drug concentration monitoring.
Aims and Methods: The aim of our study was to validate a rapid test for the quantitative measurement of ADM drug concentrations. In the RIDA®QUICK ADM Monitoring (R-Biopharm AG, Darmstadt, Germany), serum samples are diluted 1:50 and incubated with a mixture of reagent A and B (final dilution 1:500) for 5 minutes. Next, 100 μL of the 1:500 dilution is applied to the sample pad of a lateral flow test strip and read after 15 minutes using the RIDA®QUICK SCAN II. The limit of quantification and precision were determined based on CLSI guideline EP17-A2 and EP05-A3, respectively. The recovery was determined by spiking 3 reference samples with varying concentrations of ADM and was analyzed using 2 different lots. Method comparison was performed with 212 serum samples of patients with IBD, which were withdrawn just before the next dose administration at week 0 ($n = 30$), week 4 ($n = 100$) or week 12 ($n = 82$) of ADM therapy, versus the RIDASCREEN® ADM Monitoring (ELISA; R-Biopharm AG). Both assays use the same monoclonal anti-ADM antibody clone 40D8, derived at KU Leuven.[1]
Results: The limit of quantification and measuring range of the RIDA®QUICK ADM Monitoring were 0.5 μg/mL ADM and 0.5–25 μg/mL ADM, respectively. The mean recovery (defined as the % deviation of the observed versus the expected concentration) and imprecision (%CV) were ≤ 10% and ≤ 17%, respectively. An excellent agreement with the RIDASCREEN® ADM Monitoring was observed: Pearson r and intraclass correlation coefficients (ICC) were 0.95;0.92 (Pearson r;ICC) and 0.98;0.97, for patient samples collected at week 4 and week 12, respectively. All 30 week 0 samples were below the limit of quantification in both assays.
Conclusion: The RIDA®QUICK ADM Monitoring allows accurate and precise quantification of adalimumab within the clinically relevant 0.5–25 μg/mL concentration range. The RIDA®QUICK ADM Monitoring shows excellent agreement with the RIDASCREEN® ADM Monitoring, which uses the same highly specific antibody clone to improve assay harmonization. The RIDA®QUICK ADM Monitoring is easily accessible and supports timely dose adjustments of patients receiving adalimumab treatment in routine clinical practice.

Introduction: Golimumab is approved as a therapy for ulcerative colitis (UC) patients. Recent data also demonstrate efficacy and mucosal healing in Crohn's disease (CD); however, little is known regarding target drug levels. Our aim is to identify trough golimumab levels in IBD associated with endoscopic remission.
Aims and Methods: This was a retrospective analysis of patients on maintenance golimumab for a minimum of 4 months. Concomitant therapies, disease status at the time of levels, endoscopic and clinical response (significant reduction in symptoms and biochemical markers with weaning of steroids) were recorded. Endoscopic and radiology records approximate to the date of the assay were reviewed. Primary outcome was mucosal healing defined as Mayo 0–1 or SES-CD score < 5. Secondary outcomes included clinical remission and endoscopic improvement. Drug levels were measured with Dynacare assay, mean trough levels compared using Kruskal-Wallis test, and used logistic regression to construct a probabilistic model determining sensitivity and specificity of levels predicting mucosal healing.
Results: 55 patients were included ($n = 39$ CD, $n = 16$ UC/IBD-U). Median time on drug was 11 months (range 4–48). 34% ($n = 19$) were co-treated with an immunomodulator, 88% ($n = 49$) of patients were anti-TNF experienced and 14% ($n = 8$) had 3 or more prior biologic therapies. During induction, intravenous golimumab was used in 20% ($n = 11$), and 9% ($n = 5$) received standard induction dose with the remainder receiving higher doses. Maintenance dosing varied, ranging from 50 mg monthly to 400 mg every 2 weeks. The endoscopic response rate was 21% ($n = 9$ CD, $n = 3$ UC/IBD-U), and 45% ($n = 17$ CD, $n = 8$ UC/IBD-U) achieved mucosal healing. The rate of antibody formation was low (3.6%, $n = 2$), although the assay used was drug-sensitive which may have masked the presence of low titre antibodies. In CD, golimumab trough levels were higher in patients with mucosal healing ($n = 17$, mean 9.1 μg/ml) compared with non-response ($n = 11$, mean 4.1 μg/ml, $p = 0.001$) and in patients with endoscopic improvement ($n = 28$, mean 7.8 μg/ml) vs non-response ($n = 11$, mean 4.1 μg/ml, $p = 0.02$). After calculation of an ROC curve for mucosal healing vs non-response, AUC was 0.84 (std error 0.09, 95% CI 0.67–1, $p = 0.003$) and a trough golimumab level > 6.1 μg/ml was associated with mucosal healing with 81.3% sensitivity and 88% specificity and a likelihood ratio of 4.9. In UC/IBD-U, the

Abstract No: P0335

Endpoint, n (%)	Placebo n = 103	Adalimumab n = 102	P value*
Primary Endpoint: Clinical remission (CDAI <150) at Week 4	7 (6.8)	38 (37.3)	< 0.001

Contact E-Mail Address: chenbaili05@163.com
Introduction: The efficacy and safety of adalimumab induction and maintenance treatment in Chinese patients with moderately and severely active Crohn's disease (CD) were assessed in a 26-week, phase 3, randomized, double-blind, placebo-controlled, multicenter study.
Aims and Methods: Adult patients naïve to anti-TNF therapy (CD Activity Index [CDAI] 220–450, hs-CRP≥3 mg/L) were stratified by CDAI (≤300/>300) and corticosteroid use (yes/no) at baseline and randomized (1:1) to double-blind adalimumab 160/80 mg at weeks 0/2, 40 mg at weeks 4/6 or placebo at weeks 0/2 followed by blinded adalimumab 160/80 mg at weeks 4/6. At week 8, all patients received open label (OL) 40 mg adalimumab every other week for up to 18 weeks. The primary endpoint (clinical remission [CDAI < 150]) and key secondary endpoints (Table) were assessed at week 4 between adalimumab and placebo using the Cochran-Mantel-Haenszel (CMH) test and stratified by the randomization factors. Clinical remission at week 26 was assessed in patients with response (decrease CDAI≥70 points from baseline) at week 8 and compared with a clinically meaningful threshold of 30% using the 1 sample Exact test. Adverse events (AE) were collected throughout the study.
Results: Of 205 randomized patients (65 [31.7%] female, 32.9 [9.9] mean [SD] years of age and 2.7 [3.0] years disease duration), 196 (95.6%) completed the induction period and 159 (77.6%) completed OL treatment to week 26. The primary endpoint and key secondary endpoints were met (Table). Serious AEs and serious infections, respectively, were reported in 2/102 (2.0%) and 0 patients with adalimumab, 1/103 (1.0%) and 0 patients with placebo during double-blind treatment and in 36/200 (18.0%) and 7/200 (3.5%) patients receiving any adalimumab during the trial.
Conclusion: Adalimumab induced and maintained clinical remission and response in Chinese patients with CD who failed conventional therapy. The safety profile of adalimumab was generally comparable with placebo and consistent with the known safety profile of adalimumab.[1]
[Table. Primary and key secondary endpoints.]

Introduction: Upadacitinib (UPA) is an oral selective Janus kinase 1 inhibitor that is being assessed in patients with ulcerative colitis (UC). The effects of UPA on patient-reported outcomes (PRO) were evaluated in the double-blind placebo-controlled dose-ranging 8-week induction portion of the phase 2b/3 study (U-ACHIEVE [NCT02819635]).
Aims and Methods: Adult patients with moderately to severely active UC (Adapted Mayo score [Mayo score without Physician Global Assessment] 5–9 points and centrally-read endoscopy subscore 2–3) who had inadequate response or intolerance to immunosuppressants, corticosteroids, or biologics were randomly assigned in a 1:1:1:1:1 ratio to double-blind induction therapy with placebo (PBO) or the modified-release formulation of UPA at 7.5, 15, 30, or 45mg once daily (QD) for 8 weeks. Patients answered the following PRO questionnaires at baseline, and Weeks 2, 4, and 8: Inflammatory Bowel Disease Questionnaire (IBDQ), EuroQol-5 dimensions (EQ-5D), 36-Item Short Form Health Survey (SF-36), Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), and Work Productivity and Activity Impairment (WPAI). Mean change from baseline to Week 8 was assessed using analysis of covariance; missing data were reported using last observation carried forward. The percentage of patients with IBDQ response, defined as increase ≥16 points from baseline to Week 8, was determined; comparisons between UPA dosage groups and PBO were based on Cochran-Mantel-Haenszel tests and missing data were reported using non-responder imputation.
Results: A total of 250 patients with mean age 42.3 years, 60% male, and mean UC duration 8 years were analysed. At baseline, mean IBDQ was 125, EQ-5D visual analogue scale (VAS) was 53, SF-36 Physical Component Summary (PCS) was 42, SF-36 Mental Component Summary (MCS) was 41, FACIT-F was 29, WPAI activity impairment was 52%, and overall work impairment was 51%. Significant improvements in all PROs were consistently observed as early as Week 2 in patients receiving 45mg QD ($p < 0.05$). At Week 8, IBDQ response was reported by significantly more patients taking UPA (67%, 62%, and 77% for 15, 30, and 45mg QD, respectively) than PBO (35%) (all $p < 0.05$). For patients treated with UPA compared to PBO, significant improvements from baseline to Week 8 were reported in IBDQ score, EQ-5D VAS, and SF-36 PCS for all UPA doses (all $p < 0.05$; Table). Significant improvements were also shown for FACIT-F and overall work impairment and activity impairment in 15, 30, and 45mg QD (Table).
[Table. IBDQ Response and Mean Change from Baseline to Week 8 in Patient-Reported Outcomes]
Conclusion: Patients with moderately to severely active UC treated with 8-week UPA induction therapy reported significant and clinically meaningful improvements in disease-specific and general health-related quality of life, fatigue, work performance, and ability to perform daily activities. Improvements in all PROs were seen as early as Week 2.

Introduction: 5-aminosalicylic acid (5-ASA) is the mainstay of treatment of patients with ulcerative colitis (UC). 5-ASA acts locally in the colonic mucosa and mucosal concentrations of 5-ASA are inversely correlated to disease activity(1–4). Previous studies suggest that treatment with Asacol (pH-dependent release formulation) yields higher mucosal 5-ASA concentrations than Pentasa (time-dependent release formulation)(1, 5). However the different 5-ASA formulations are often considered clinically equally efficient (6). After Mezavant (MMX formulation) was marketed, it has not been published studies comparing mucosal 5-ASA concentrations of Mezavant, Asacol and Pentasa.

Aims and Methods: In this cross-sectional non-randomized study, we have measured mucosal concentration of 5-ASA and its inactive metabolite acetyl-5-ASA (Ac-5-ASA) in the left hemicolon and rectum in patients with quiescent UC taking Mezavant, Asacol or Pentasa. Patients with quiescent UC using oral mesalazine monotherapy in the maximal dose recommended by the manufacturers (4.0–4.8g o.d.) were included. 8 hours after ingestion of mesalazine, patients underwent blood sample collection, followed by bowel preparation with enema and sigmoidoscopy. A total of 5 mucosal biopsies were collected 10, 25 and 40 cm from the anal verge. 5-ASA and Ac-5-ASA concentrations were measured in biopsies and serum by high-performance liquid chromatography. Disease activity was assessed by Mayo score (MS), Geboes histological score (GS) and measurement of plasma ESR, CRP, blood leukocytes and fecal calprotectin concentrations. Kruskal-Wallis test and ANOVA analyses were applied to compare demographic and clinical characteristics. Linear mixed model was used to compare the 5-ASA concentrations (log transformed) at different locations and between the different formulations.

Results: 42 patients (23 male) were included, 18 patients using Mezavant, 14 using Asacol and 10 using Pentasa. No significant differences in demographic or clinical characteristics between the groups were found, except for leukocyte concentration ($p = 0.036$) and endoscopic MS ($p = 0.01$). Mean leukocytes (SD) were all within normal ranges; 6.7 (1.4), 8.1 (2), 6.6 (1.1) for Mezavant, Asacol and Pentasa, respectively. Median (IQR) endoscopic Mayo score were 1.0 (2.0) for Mezavant and 0.0 (1.0) for both Asacol and Pentasa. 67% of Mezavant, 79% of Asacol and 70% Pentasa patients were in deep remission (GS < 2.1 and endoscopic MS ≤1), $p = 0.750$. The geometric mean 5-ASA concentrations for Mezavant, Asacol and Pentasa, averaged over locations were 2.39 (CI 1.09–5.28) ng/mg, 1.60 (CI 0.65–3.91) ng/mg and 0.57 (CI 0.20–1.64) ng/mg, respectively ($p = 0.099$, test for overall difference in adjusted mean). When adjusting for remission the results did not change notably. Whereas the inter-individual difference was large, the intra-individual variation was small. The pairwise comparisons revealed a significant difference between Mezavant and Pentasa ($p = 0.033$), but not between Mezavant and Asacol ($p = 0.50$). The mucosal concentration of Ac-5-ASA decreased in oral to anal direction, and did not differ between the formulations. There was no significant differences in serum 5-ASA ($p = 0.202$) or serum Ac-5-ASA ($p = 0.20$) between the formulations.

Conclusion: Patients using Mezavant had significantly higher mucosal 5-ASA concentrations than patients using Pentasa, despite higher endoscopic MS. There was small intra-individual variations, but large inter-individual variations in mucosal 5-ASA concentrations in the left hemicolon of patients with UC using oral mesalazine preparations.

Introduction: The efficacy and safety of mirikizumab (miri), an IL-23p19 antibody, has been evaluated in moderate-to-severe ulcerative colitis (UC) in a phase 2, randomized, double-blind, placebo (pbo)-controlled trial (AMAC, NCT02589665; presented at DDW 2018). Miri demonstrated efficacy on multiple measures in the 12-week induction treatment.

Aims and Methods: This analysis evaluated the effects of miri on health-related quality of life (HRQoL) in patients with UC. Patients with moderate-to-severe UC (Mayo score 6–12; Endoscopic subscore ≥2) were randomised 1:1:1:1 to receive intravenous miri 50 mg (N = 63) or 200 mg (N = 62), both with possible exposure-based increase (2–12 fold or 1.5–3 fold, respectively, to a maximum 600 mg dose), or fixed dose miri 600 mg (N = 61), or pbo (N = 63) at Weeks 0, 4, and 8. Patients could receive oral 5-ASA, corticosteroids (≤20 mg/d prednisone equivalent), or thiopurines; must have failed ≥1 conventional UC therapy; and were either naïve to or had prior exposure to biologics. HRQoL was measured by the Inflammatory Bowel Disease Questionnaire (IBDQ) and evaluated using a mixed model repeated measures (MMRM) analysis. The percentage of patients at Week 12 with clinical response,[1] endoscopic healing,[2] IBDQ total score ≥170, and IBDQ improvement ≥16 were also assessed.

Results: As early as Week 4, and continuing through Week 12, IBDQ total scores improved versus baseline and versus pbo across all miri groups except miri 50 mg versus pbo at Week 12 (Table). At Week 12, the proportions of patients with IBDQ total score ≥170 were higher with miri 50 mg, 200 mg, and 600 mg than

pbo (44%, 56%, 54% vs. 30%, respectively) and higher proportions of miri- than pbo-treated patients had improvements ≥16 points from baseline in IBDQ total score. At Week 12, clinical response and endoscopic healing rates were greater for miri 50 mg and 200 mg versus pbo (Table).

	Pbo	Miri 50 mg	Miri 200 mg	Miri 600 mg
	N = 63	N = 63	N = 62	N = 61
Baseline IBDQ total score, mean (SD)	124 (30)	123 (29)	133 (35)	126 (34)
IBDQ total score change from baseline, LS mean (SE)				
Week 4	14 (3)	24 (3)[a,c]	29 (3)[b,c]	27 (3)[a,c]
Week 12	22 (4)	33 (5)[c]	42 (4)[b,c]	44 (5)[b,c]
Clinical response at Week 12, n (%) NRI	13 (21)	26 (41)[a]	37 (60)[b]	30 (49)[a]
Endoscopic healing at Week 12, n (%) NRI	4 (6)	15 (24)[a]	19 (31)[b]	8 (13)

Nominal p-value, vs. placebo [a]$p < 0.05$, [b]$p < 0.001$; vs. baseline [c]$p < 0.001$; MMRM includes baseline, geographic region, prior biologic therapy, treatment, time and treatment*time as variables (IBDQ) or logistic regression to compare rates (clinical response, endoscopic healing). NRI: nonresponder imputation, used for missing values.
[1]Clinical response: 9-point Mayo subscore decrease ≥2 points and ≥35% change from baseline, with rectal bleeding = 0,1 or decrease ≥1, excluding PGA. [2]Endoscopic healing: Mayo endoscopic subscore = 0 or 1.
Conclusion: Induction treatment with miri was associated with HRQoL improvement in patients with UC. These are the first data evaluating the effects of an IL-23p19 antibody on the HRQoL of patients with UC.

Introduction: Patients with inflammatory bowel disease (IBD) experienced more frequent development of Clostridial infection and much higher rates of morbidity and mortality compared to patients without IBD. Risk factors are immunosuppressive therapy.
Aims and Methods: The aim is to compare the frequency of Clostridial infection (CI) in patients with ulcerative colitis (UC) receiving bone marrow mesenchymal stromal cells (MSC) and biological therapy.
Materials and methods. The patients were divided into 3 groups: the first group (n = 23) received the MSCs culture according to the scheme (0-1-2 weeks, then every 26 weeks); the second group of patients with UC (n = 21) received infliximab (IFX) in combination with azathioprine (AZA) according to the recommended scheme, the third group received only IFX according to the scheme. The toxins A and B of *Clostridium difficile* were determined by the enzyme immunoassay in the stool. The comparative analysis was carried out using the method of 4-field tables using nonparametric statistical criteria.
Results: In patients of the 1st group, toxin A was detected in 1/23 patients (4.3%), in the 2nd group - in 2/21 (9.5%) (RR - 0.45, 95% CI 0.04–4.6, x^2 −0.46, p > 0.05), in the third - in 2/18 (11.1%) (RR-0.4, 95% CI 0.04–3.98, x^2- 0.7, p > 0.05). In patients of the 1st group, toxin B was detected in 2/23 patients (8.6%), in the second group in 3/21 (14.3%) patients (RR −0.6, 95% CI 0, 1–3.3, x^2 −0.3, p > 0.05), in the third - in 2/18 (11.1%) (RR-0.8, 95% CI 0.12–5, 03; x^2 −0.07; p > 0.05). In patients of the 1st group toxins A and B were not detected - 0/23 (0,0%), in the 2nd group toxins A and B were detected in 7/21 (33.3%) patients (x^2 - 9.5, $p < 0.05$), in the third - in 5/18 (27.8%) (x^2 −7.3, $p < 0.05$). Totally in patients of the 1st group, *Clostridium difficile* toxin A and B was detected in 3/23 patients (13.1%), in the second group - in 12/21 (57.1%) patients with UC (RR-0.23, 95 % CI 0.075–0.7, x^2 -9.5, $p < 0.05$), in the third - in 9/18 (50.0%) (RR-0.26, 95% CI 0.08- 0.82, x^2 -6.6, $p < 0.05$).
Conclusion: The frequency of Clostridial infection in patients with ulcerative colitis receiving mesenchymal stromal cells is significantly lower than in patients with ulcerative colitis receiving biological immunosuppressive preparations.
Disclosure: Nothing to disclose

P0340 CORRELATION OF BIOMARKERS OF INFLAMMATION WITH CLINICAL AND ENDOSCOPIC ENDPOINTS IN PATIENTS WITH MODERATE-TO-SEVERE CROHN'S DISEASE: DATA FROM CELEST

Introduction: Treatment with upadacitinib (UPA) has shown dose-dependent improvements in clinical and endoscopic outcomes and markers of inflammation in a Phase 2b study (CELEST; NCT02365649) in patients with Crohn's disease (CD) (1,2). In this report, the correlation between the markers of inflammation serum C-reactive protein (CRP) and faecal calprotectin (FC), and clinical and endoscopic endpoints is assessed.
Aims and Methods: CELEST enrolled 220 adults with moderately to severely active CD who received induction treatment with placebo or the immediate release formulation of UPA 3 mg, 6 mg, 12 mg, 24 mg twice daily (BID), or 24 mg once daily (QD) for 16 weeks. Patients who completed Week 16 were re-randomised to receive UPA 3 mg, 6 mg, 12 mg BID, or 24 mg QD for 36 weeks. For this analysis, patients who received UPA induction treatment (N = 183, combined) were included in the Week 16 evaluation, and patients who achieved clinical response to UPA at Week 16 (N = 94, combined) were included in the Week 52 evaluation.
The proportion of patients who achieved clinical remission at Week 16 and 52 (stool frequency [SF]≤2.8 and abdominal pain [AP]≤1.0, neither worse than baseline [BL]), and endoscopic improvement at Week 12/16 and 52 (decrease in SES-CD > 50% from BL or endoscopic remission; defined as SES-CD ≤4 and ≥2-point reduction from baseline, with no subscore of > 1) were analysed by high sensitivity (hs)CRP (< 5 or ≥5 mg/L) and FC (< 250 or ≥250 μg/g) levels at Week 16 and 52 using Chi-square test. Correlation between clinical remission and endoscopic improvement (yes/no) with hsCRP (< 5 or ≥5 mg/L) and FC (< 250 or ≥250 μg/g) levels at BL and Week 16 or 52 was assessed with polychoric correlation and 2-sided Wald Chi-square test.
Results: A statistically significant higher proportion of patients with hsCRP levels < 5 mg/L at Week 16 and 52, and FC levels < 250 μg/g at Week 52 achieved clinical remission compared to patients with hsCRP ≥5 mg/L and FC ≥250 μg/g, respectively (Table). Significantly more patients with hsCRP < 5 mg/L and FC < 250 μg/g at both Weeks 12/16 and 52 achieved endoscopic improvement. Moderate to high correlation was observed between hsCRP status (elevated at BL and < 5 mg/L at Week 16) and clinical remission at Week 16 ($\rho = 0.59$, $p < 0.001$), and endoscopic improvement at Week 12/16 ($\rho = 0.50$, $p < 0.001$) or hsCRP status (elevated at BL and < 5 mg/L at Week 52) and clinical remission at Week 52 ($\rho = 0.73$, $p < 0.001$), and endoscopic improvement at Week 52 ($\rho = 0.78$, $p < 0.001$). Moderate to high correlation was observed for FC status (elevated at BL and < 250 mg/L at Week 16 [$\rho = 0.68$, $p < 0.001$] or elevated at BL and < 250 mg/L at Week 52 [$\rho = 0.52$, $p = 0.006$]) and endoscopic improvement at Week 16 and Week 52. A high correlation between clinical remission and FC status was only observed at Week 52 (elevated at BL and < 250 mg/L at Week 52; $\rho = 0.60$, $p < 0.001$).

Abstract No: P0340

		hs-CRP			Faecal calprotectin		
Endpoint	Week	< 5 mg/L	≥5 mg/L	P value	< 250 μg/g	≥250 μg/g	P value
Clinical Remission*, n/N (%)	16	26/68 (38.2)	14/71 (19.7)	0.016	8/32 (25.0)	20/58 (34.5)	0.352
Clinical Remission*, n/N (%)	52	27/37 (73.0)	8/31 (25.8)	< 0.001	21/27 (77.8)	10/24 (41.7)	0.008
Endoscopic improvement^, n/N (%)	12/16	29/73 (39.7)	12/77 (15.6)	< 0.001	17/31 (54.8)	11/62 (17.7)	< 0.001
Endoscopic improvement^, n/N (%)	52	26/39 (66.7)	10/33 (30.3)	0.002	20/28 (71.4)	9/25 (36.0)	0.010

Data are reported as observed * Clinical remission defined as very soft/liquid stool frequency (SF)≤2.8 and abdominal pain (AP) score ≤1.0, both not worse than baseline, among subjects with baseline very soft/liquid SF > 4.0 or AP score > 2.0 ^Endoscopic improvement defined as a decrease in SES-CD > 50% from BL or endoscopic remission (SES-CD ≤4 and ≥2-point reduction from baseline, with no subscore of > 1)

[Proportion of patients meeting clinical and endoscopic endpoints by hsCRP and faecal calprotectin status Week 12/16 and 52.]

Conclusion: In this phase 2b study with upadacitinib, normalization of hsCRP levels was associated with achieving clinical remission and endoscopic improvement, whereas normalization of FC levels was mostly associated with endoscopic improvement.

Introduction: We demonstrated similarity of efficacy, safety and pharmacokinetics (PK) between CT-P13 and Innovator Infliximab (INX) in the phase 3 randomized control trial in moderate to severe Crohn's disease (CD) patients (1). Recent studies suggested an association between higher infliximab trough concentrations and better clinical outcomes in the treatment of inflammatory bowel disease (2), which has to be examined in a prospective observation.

Aims and Methods: This *post-hoc* analysis of the CT-P13 3.4 study (NCT02096861) assessed whether early C_{trough} level could be used as a predictor of subsequent clinical efficacy. A total of 198 patients who underwent efficacy analysis at Week 54 and had PK parameters at Week 6 (pre-dose concentration at Week 14) and Week 14 (pre-dose concentration at Week 22) were included in this analysis. All PK parameters were analyzed while the patients received INX or CT-P13 at 5 mg/kg with no dose escalation until week 22. Mann-Whitney U test was used to analyze the difference of C_{trough} level in patients achieving or not achieving clinical response at Week 54, and between CT-P13 and INX treatment groups among responders. Receiver operating characteristic (ROC) curves were constructed for sensitivity (S) and specificity (Sp) analyses of C_{trough} and efficacy at Week 54.

Results: Median Week 6 C_{trough} levels were 3.7 and 3.6 μg/ml, and Week 14 C_{trough} levels were and 2.6 and 2.2 μg/ml in the CT-P13 and INX groups, respectively. C_{trough} levels were significantly higher ($p < 0.01$) in Week 54 responders (CDAI < 150) than in non-responders in both CT-P13 and INX treatment groups. Since overall C_{trough} levels in responders were not significantly different between CT-P13 and INX treatment groups ($p > 0.05$), both groups were pooled for further analysis. In a ROC analysis, Week 14 C_{trough} were much more specific to predict clinical success (specificities > 90%) than Week 6. Suggested diagnostic cut-offs to predict clinical remission were C_{trough} > 4.5 μg/ml at Week 6 (ROC: 0.71 S: 51.2%, Sp: 77.1%), and, 4.0 μg/ml at Week 14 (ROC: 0.71, S: 39.7%, Sp: 93.3%). *[C_{trough} level in the CT-P13 and INX according to clinical response at Week 54]*

Conclusion: Week 6 C_{trough} and Week 14 C_{trough} of CT-P13 and INX have predictive value for late efficacy (Week 54) in terms of CDAI-70, CDAI-100, and remission. There was no difference in C_{trough} levels among responders between CT-P13 and INX. We suggest a critical minimum of C_{trough} level > 4.5 μg/ml at Week 6, and C_{trough} level > 4.0 μg/ml at Week 14 as a predictor of subsequent clinical remission. In addition, Week 14 levels appear to be more specific to predict one year outcome than Week 6 levels.

Introduction: Although concomitant elemental diet (ED) and anti TNF-alfa inhibitor (Anti-TNF) is known to be effective as a maintenance therapy for Crohn's disease (CD), there is no prospective study on this topic. The aim of this study is to clarify an additional power of ED diet on maintenance Anti-TNF.

Aims and Methods: 17 institutions participated this multicenter, prospective, non-randomized cohort study. CD patients who received initial Anti-TNF induction therapy and provided informed consent for this study were enrolled. Patients who achieved clinical response (defined as delta CDAI > 70 and CDAI < 200) at 10–14 weeks after the starting of infliximab (IFX, 5mg/kg at 0, 2, 6 weeks) or adalimumab (ADA, 160mg at 0, 80mg at 2 weeks) were included. Eligible patients took a tolerability examination of ED (900kcal/day) at least for 3 days. Then patients who prefer to ED during Anti-TNF maintenance therapy

Abstract No: P0341

	CT-P13 Median(IQR) (μg/ml)			INX Median(IQR) (μg/ml)		
Week 6 C_{trough}	Responder	Non-responder	p-value	Responder	Non-responder	p-value

CDAI-100	3.96 (1.80–7.30)	2.88 (0.55–5.56)	0.083	4.02 (2.15–7.16)	2.17 (0.91–4.20)	0.018
Clinical remission	4.9 (2.32–8.06)	1.72 (0.55–4.39)	0.001	4.45 (2.5–8.49)	2.17 (0.91–3.71)	0.0005
Week 14 C_{trough}	**Responder**	**Non-responder**	**p-value**	**Responder**	**Non-responder**	**p-value**
CDAI-70	2.98 (0.74–6.14)	0.61 (0.55–1.42)	0.020	2.47 (0.88–4.14)	0.55 (0.55–2.35)	0.012
CDAI-100	2.98 (0.74–6.14)	0.61 (0.55–2.13)	0.016	2.85 (0.94–4.6.)	0.61 (0.55–2.11)	0.004
Clinical remission	3.40 (1.14–6.56)	0.68 (0.55–2.54)	0.0002	3.11 (0.94–6.03)	1.17 (0.55–2.68)	0.001

Note. Lower limit of quantitation of serum Infliximab concentration was 0.55 μg/ml

(IFX: 5mg/kg every 8 weeks, ADA: 40mg every other weeks) and confirmed tolerability of ED were allocated to ED group and administered elemental diet 900kcal/day or more. Other patients were allocated to Non-ED group. Primary endpoint was the cumulative remission rate at 2 years after baseline. CDAI was calculated at each visit during 2 years after baseline. Clinical relapse defined as 200 < CDAI and/or need for additional treatment including dose escalation of Anti-TNF and surgery. Adherence of ED was confirmed by clinician's interview to patients at each visit and amount of prescriptions.
Results: 88 patients were enrolled and 16 patients were excluded due to no response of Anti-TNF induction therapy. Of the 72 patients, 37 were allocated to ED group and 35 subjects were allocated to Non-ED group. As for clinical features, previous enteral nutrition was more frequent observed in ED group ($p = 0.03$). The cumulative remission rate at 2 years was no significant difference between two groups (60.9% in ED group, 56.7% in Non-ED group, $p = 0.98$). In a multivariate analysis, intestinal stricture (HR: 5.0, 95% CI: 1.6–15.2), previous steroid therapy (HR: 4.0, 95% CI: 1.1–14.9) and CRP > 5mg/L (HR: 6.5, 95% CI: 1.8–24.4) at baseline were risk factors of clinical relapse. Adherence of ED in ED group was relatively low and only 11 patients had been kept 900kcal /day or more of ED.
Conclusion: Additional power of ED for CD patients who responded to initial Anti-TNF induction therapy could not be confirmed. Efficacy of concomitant ED in other clinical setting such as loss of response need to be clarified in the future. Moreover, improvement of adherence might be important in order to obtain clinical efficacy of ED.

Contact E-Mail Address: cristina.alba@telefonica.net
Introduction: Data assessing outcomes of SC golimumab (GLM) dose optimization in patients with ulcerative colitis (UC) are lacking. According to the summary of product characteristics by the European Medicines Agency (EMA) patients with body weight less than 80 kg received GLM maintenance doses of 50 mg every 4 weeks (q4wk) starting at week 6 (1). The benefit of GLM dose escalation from 50 mg q4wk to 100 mg q4wk has not been evaluated in clinical practice.
Aims and Methods: The aim of this study was to evaluate outcomes of early optimization of GLM from 50 mg q4wk to 100 mg q4wk in UC patients with inadequate response to GLM induction treatment.
This observational multicentre cohort study included consecutive UC patients without response to GLM induction doses, in which weight-based GLM maintenance doses (according to European labelling) of 50 mg q4wk were optimized to 100 mg q4wk before week 14. At week 14, we assessed outcomes based in partial Mayo score. We defined response as an improvement ≥3 points from week 0 and remission as a final score ≤2. Long-term cumulative probabilities of GLM failure-free survival and colectomy-free survival were calculated during follow-up. GLM failure was defined as discontinuation of the drug due to intolerance or complete loss of response despite dose optimization.
Results: We evaluated 24 UC patients with body weight below 80 kg, 18 (75%) were female, 18 (75%) had extensive colitis and 5 (20%) left-sided colitis. The mean age of the patients was 47 (standard deviation 14), and the median disease duration was 9.5 years (interquartile range [IQR] 4–14). 14 patients (58%) had previous anti-TNF failure (4 infliximab, 2 adalimumab and 8 both). All patients received induction with GLM 200 mg/100 mg at weeks 0 and 2. In all patients GLM 50 mg q4wk was optimized to 100 mg q4wk, starting at week 6 in 10 patients and at week 10 in 14 patients. At week 14, 16 of 24 patients (67%; 12 were corticosteroid-free) recovered clinical response. Of these, 4 patients (17%) achieved corticosteroid-free remission. After a median follow-up of 12 months (IQR 10–22), 13 of 24 patients (54%) avoided GLM failure. 13 of 16 patients (81%; all but 1 were corticosteroid-free) who achieved delayed response at week 14 maintained clinical benefit with GLM 100 mg e4wkat last follow-up. Eleven of 24 patients (46%) had GLM failure. Reasons for GLM discontinuation were nonresponse at week 14 in 8 patients (73%) and secondary loss of response in 3 patients (27%) who had delayed response at week 14. None of the patients experienced adverse events leading to GLM withdrawal. All 24 patients avoided colectomy at last follow-up. None of the patients were dose de-escalated to GLM 50 mg q4wk.
Conclusion: Early optimization of GLM from 50 mg q4wk to 100 mg q4wk induces delayed response (by partial Mayo score) at week 14 in two thirds of UC patients with body weight below 80 kg who were non-responders to GLM induction. Continuing GLM 100mg q4wk in patients who do not demonstrate an early clinical response to GLM induction but achieve a delayed response was safe and leads to long-term clinical benefit.

Introduction: Inflammatory bowel disease (IBD) is associated with elevated myeloid lineage leucocytes, which show activation behaviour (1) including the CD14+CD16+DR++ phenotype known as proinflammatory monocytes and a major source of tumour necrosis factor-α (2). Accordingly selective depletion of myeloid leucocytes by granulocyte/monocyte apheresis (GMA) with an Adacolumn is expected to promote remission and enhance drug efficacy. However, hitherto studies in IBD have reported contrasting efficacy outcomes, ranging from an 85% (3) to a statistically insignificant level (4). Patients' demographic features should guide to select responder patients.
Aims and Methods: In a single-centre retrospective setting, we looked at the baseline clinical and endoscopic features of responders and non-responders to adsorptive GMA in 145 consecutive ulcerative colitis patients who had undergone GMA as remission induction therapy. 73 patients were steroid naive, 70 were steroid dependent, and 2 were steroid refractory. Patients had received up to 11 GMA sessions over 10 weeks. At entry and week 12, patients were clinically and endoscopically evaluated, allowing each patient to serve as her or his own control. Clinical activity index (CAI) ≤4 was defined as remission. Biopsies from endoscopically detectable inflamed mucosa were processed to see the impact of GMA on leucocytes within the mucosa.
Results: At entry, the average CAI was 12.8, range 10–17. 93 patients (64.1%) had responded to GMA, 52 of 73 steroid naïve (71.2%), 40 of 70 steroid dependent (57.1%), and 1 of the 2 steroid refractory cases. On average remission was sustained for 8.6 months in steroid naïve patients and for 10.4 months in steroid dependent cohort. Mucosal biopsies revealed that infiltrating leucocytes were mostly neutrophils and monocytes. There was a marked reduction of infiltrating leucocytes in the biopsies from the responder patients. Patients with extensive deep UC lesions together with loss of the mucosal tissue at the lesions were non-responders. Patients with the first UC episode were identified as the best responders (100%), followed by steroid naive patients. Further, a short duration of active UC prior to GMA marked a patient as a likely responder.
Conclusion: Patients who responded well to GMA attained a favourable long-term clinical course. GMA was more effective if applied immediately after a relapse than after a lag time. In general, GMA is favoured by patients for its safety profile and for being a non-drug remission induction option. Patients with extensive deep ulcers, with long duration of UC refractory to multiple pharmacologicals are unlikely to benefit from GMA. In therapeutic settings, knowing baseline features, which may identify responder patients should help to avoid futile use of medical resources.

Contact E-Mail Address: sherman.picardo@health.wa.gov.au

Introduction: Anti-tumour necrosis factor alpha (anti-TNF) therapies are effective and widely used in the management of patients with inflammatory bowel disease (IBD). Patients may develop a distinct 'lupus like' syndrome, recently termed anti-TNF induced lupus (ATIL). The widely-accepted diagnostic criteria for this syndrome being (1) a temporal relationship between symptoms and anti-TNF therapy and resolution of symptoms following cessation of the offending medication, (2) at least 1 serologic American College of Rheumatology criteria of systemic lupus erythematosus (SLE), either a positive ANA or anti-dsDNA, and (3) at least 1 non-serological criteria such as arthritis, serositis or rash (1). ATIL is increasingly recognised and described in the rheumatology literature, however, data remains limited in IBD populations due to lack of recognition of the condition as well as difficulty making a diagnosis as there is significant overlap in symptoms with the extraintestinal manifestations of IBD.
Aims and Methods: To evaluate the incidence, clinical and serological markers, as well as risk factors for developing ATIL in an IBD population. A retrospective observational cohort study of all IBD patients that completed induction as well as at least one maintenance dose of anti-TNF therapy (infliximab or adalimumab) at Royal Perth Hospital between January 2008 and December 2017. A diagnosis of ATIL was confirmed based on the criteria outlined above. Demographic, clinical and serological parameters were obtained from electronic and paper records.
Results: 454 patient treatment courses with anti-TNF therapy (300 infliximab and 154 adalimumab) were included. 17 (5.7%) patients that received infliximab and 1 patient (0.6%) on adalimumab developed ATIL. Patients that developed ATIL were more likely to be older at commencement of anti-TNF (46.47 years ± 13.79 years vs. 38.85 years ± 14.75 years, $p = 0.033$) and there was a trend they were more likely to be female (72.2% vs. 47.0%, $p = 0.052$). 5/18 patients were on concurrent immunomodulator therapy at time of ATIL diagnosis. We were unable to establish whether concurrent immunomodulator therapy was a preventative factor, as patients were on varying doses and durations during their anti-TNF course. The mean duration of anti-TNF therapy till development of ATIL was 19.78 months ± 15.76 months. The most common clinical symptom was polyarthritis in 15 patients (83.3%) with rash occurring in 5 patients (27.8%). All patients with a diagnosis of ATIL demonstrated an elevated ANA with results ranging from 7 to 30 IU/ml. In those patients who had a baseline ANA performed prior to commencing anti-TNF therapy (14 patients), the ANA level increased compared with their baseline level. Other serological markers in patients that developed ATIL included anti-dsDNA in 10/15 (67%), anti-histone antibodies (marker for drug induced lupus) 2/15 (13%), anti-Smith antibodies (marker for idiopathic SLE) 0/15 (0%), Rheumatoid Factor (autoimmune arthropathy) 0/8 (0%) and anti-CCP (Rheumatoid arthritis) 0/5 (0%).
Conclusion: Our study suggests, 1 in every 20 patients that commences infliximab will develop ATIL. The incidence of ATIL, 5.7% for infliximab and 0.6% for adalimumab are much higher than post-marketing study reports of 0.22% and 0.10% respectively (2). Older age at commencement of therapy is a risk factor for development. A panel of serological markers is useful to confirm the diagnosis and exclude other autoimmune conditions, which may mimic ATIL. Increasing recognition of the condition and diagnostic criteria among physicians treating patients with IBD is essential.

Introduction: Although the prevalence of inflammatory bowel disease (IBD) continues to rise globally, particularly in Asia, there exists limited knowledge regarding the variation in IBD management among different countries.
Aims and Methods: We evaluated the differences in medical and surgical management within 1 year (yr) of diagnosis (dx) of Crohn's disease (CD) and ulcerative colitis (UC) for patients recruited from China, India, and the United States (US). Patients, during a clinic visit or online, completed a questionnaire, which collected demographic and clinical characteristics, medication history (amino-salicylates [ASA], immunomodulators [IMM], biologics, and steroids), and types and dates of IBD-related surgeries. Multivariable logistic regressions examine the differences in medication use and surgical history by country.
Results: Of 746 recruited participants, CD patients were more likely to participate in China (68%) and the US (55%); more UC patients participated in India (74%). Age at dx ranged from 4 to 77 yrs. Duration of disease at the time of questionnaire was greater in the US (13 yrs) compared to China and India (3 yrs). Majority of IBD participants were female (57%) in China and the US; fewer CD (21%) and UC (43%) females were recruited from India. ASAs were commonly used within 1 yr of CD (India 88%, US 49%, China 45%) and UC (India 94%, China 87%, US 57%) dx. Steroids were similarly used within 1 yr of CD (India 71%, US 43%, China 31%) and UC (India 66%, US 38%, China 32%) dx. IMM use within 1 yr varied by country and IBD type, and it was more commonly used for CD (China 30%, US 26%, India 25%) than UC (India 31%, US 15%, China 6%). Among those diagnosed in 2008 and later (when biologics were available in all countries), biologics were most commonly used within 1 yr of dx in the US (28%), followed by China (12%) and India (2%). After adjustment of diagnosis after 2008, participants with CD from the US (Odds Ratio [OR], 95% Confidence Interval [CI]: 23.1, 8.7–61.1) were more likely to report ever use of biologics relative to those in China. UC participants from the US (OR, 95% CI: 14.0, 0.01–4.7) were also more likely to have used biologics relative to China. IBD-related surgery was reported in China (26%), the US (21%), and India (4%). For CD, surgery within 1 yr was common in China (13%), the US (10%), and India (8%). For UC, surgery within 1 yr was more common in China (2%) than the US (1%) and India (0%). After adjustment, CD participants from China (OR, 95% CI: 2.06, 1.03–4.10) were more likely to undergo IBD-related surgery relative to the US; there were no differences among countries in odds of surgery for UC.
Conclusion: IBD patients in India and China, relative to those in the US, were less likely to report the use of biologics within 1 year of disease diagnosis, but were equally likely to utilize ASA and steroids, Additionally, IBD patients in China were more likely to undergo surgery for CD. Our findings may reflect the differential availability of biologics among these countries. Barriers to health-care access, including IBD specialist availability and medication costs, or varying disease activity may play a role in management disparities. Further research to evaluate the underlying reasons for variation in utilization may be integral to globally optimizing pharmacologic therapy and surgery for patients with IBD.

P0347 EXPOSURE-RESPONSE ANALYSES OF UPADACITINIB (ABT-494) EFFICACY IN SUBJECTS WITH MODERATELY TO SEVERELY ACTIVE ULCERATIVE COLITIS-ANALYSES OF A PHASE 2 DOSE RANGING INDUCTION STUDY

M Minocha[1], B Engelhardt[2], S Stodtmann[2], W Zhou[1], A.A Othman[1]

[2]*AbbVie Deutschland GmbH & Co KG, Ludwigshafen am Rhein, Germany*

Contact E-Mail Address: mukul.minocha@abbvie.com

Introduction: Upadacitinib (ABT-494) is an oral selective JAK1 inhibitor currently in development for the treatment of several inflammatory diseases including ulcerative colitis (UC).
Aims and Methods: To characterize the pharmacokinetics of upadacitinib and the exposure-response relationships for the effect of upadacitinib on different efficacy endpoints, following 8 week induction treatment in subjects with moderately to severely active UC who have had inadequate response, loss of response or intolerance to corticosteroids, immunosuppressants or biologic therapies in the Phase 2b Study U-Achieve. The analyses dataset included 250 subjects randomized to upadacitinib extended-release 7.5 mg [once-daily (QD); N = 47], 15 mg QD (N = 49), 30 mg QD (N = 52), 45 mg QD (N = 56) or placebo (N = 46). Upadacitinib population pharmacokinetic model was developed using pooled data from Phase 1 single and multiple ascending dose studies (intensive sampling), and available data from Phase 2 studies in subjects with rheumatoid arthritis, Crohn's disease, atopic dermatitis, and UC (sparse sampling). Quartile plots were generated for graphical exploration and population models using logistic regression analyses were developed to characterize the relationships between upadacitinib average plasma exposure over the dosing interval and efficacy endpoints (clinical response & clinical remission per adapted Mayo, clinical remission per full Mayo, endoscopic improvement and endoscopic remission) at Week 8. Effect of key demographic and baseline disease characteristics on upadacitinib exposure-response relationships was also explored.
Results: Upadacitinib plasma exposures increased dose proportionally in UC patients and were comparable to those previously observed in healthy subjects. A significant exposure-dependent increase in efficacy was observed. Highest percentage of subjects achieving clinical response per adapted Mayo, clinical remission per adapted and full Mayo, endoscopic improvement and endoscopic remission were associated with the upadacitinib exposures corresponding to the 45 mg QD dose. With the exception of endoscopic remission, the plateau of key efficacy endpoints (clinical remission, clinical response, and endoscopic improvement) was established at Week 8 within the range of exposures evaluated. The exposure-response relationship was comparable between percentage of subjects achieving clinical remission per adapted and full Mayo scores. Simulation results using the final exposure-response models for a population similar to that evaluated in Phase 2b are shown in the Table for the key efficacy endpoints at Week 8, and for different upadacitinib induction regimens. A dose lower than 45 mg QD is predicted to provide lower efficacy across endpoints (~2% to 10% relative to 45 mg QD).
Conclusion: Upadacitinib plasma exposures were comparable to those previously observed in healthy subjects. Upadacitinib exposures corresponding to the 45 mg QD regimen are predicted to maximize the efficacy in subjects with UC.

Abstract No: P0347

Endpoint, Median Predicted Efficacy, % (5th-95th Percentile); NRI	Placebo	7.5 mg QD	15 mg QD	30 mg QD	45 mg QD
Clinical Remission per Adapted Mayo	0	7 (4–10)	12 (9–14)	16 (14–20)	19 (16–22)

Introduction: Upadacitinib (UPA) is an oral selective Janus kinase 1 inhibitor that is being assessed in patients with ulcerative colitis (UC). In addition to the symptoms captured in the Mayo score, the effects of UPA on other patient-reported UC symptoms including bowel urgency and abdominal pain were evaluated in the double-blind placebo-controlled dose-ranging 8-week induction portion of the phase 2b/3 study (U-ACHIEVE [NCT02819635]).
Aims and Methods: Adult patients with active UC (Adapted Mayo score [Mayo score without Physician Global Assessment] 5–9 points and centrally-read endoscopy subscore 2–3) who had inadequate response or intolerance to corticosteroids, immunosuppressants, or biologics were randomized to the modified-release formulation 7.5, 15, 30, or 45 mg once daily (QD) UPA or PBO (1:1:1:1:1) for 8 weeks. UC symptoms including bowel urgency (yes/no) and abdominal pain (0 = none, 1 = mild, 2 = moderate, 3 = severe) were collected in the patient daily diary. The total number of days with bowel urgency, average score of abdominal pain, Mayo rectal bleeding subscore (RBS), and stool frequency subscore (SFS) over the most recent 3-consecutive days prior to the study visits were calculated. The proportions of patients who reported no bowel urgency and abdominal pain score = 0 (which were considered the most stringent endpoints), along with RBS = 0 and SFS ≤ 1 at week 8, respectively, were compared between UPA and PBO groups using the Cochran-Mantel-Haenszel test adjusted for previous biologic use, baseline corticosteroid use, and baseline Adapted Mayo score (≤ 7 and > 7). Non-responder imputation was used for missing values. Sensitivity analyses were conducted by excluding patients with no bowel urgency or those with none to mild abdominal pain (average abdominal pain score ≤ 1) at baseline.
Results: A total of 250 patients with mean age 42.3 years, 60% males, and mean UC duration 8 years were analysed. At baseline, 83% of subjects reported 3 of 3 days with bowel urgency and 41% of subjects had an average abdominal pain score > 1. As early as week 2, more UPA-treated patients reported no bowel urgency over the 3 days and less abdominal pain compared with PBO. At week 8, significantly higher proportions of patients reported no bowel urgency over the 3 days; abdominal pain score = 0, RBS = 0, and SFS ≤ 1 in most UPA groups compared with the placebo group with a potential dose effect across the 7.5 mg, 15 mg, 30 mg, and 45 mg QD dose groups (Table). In the sensitivity analyses, the risk difference between UPA groups and PBO was similar to the primary analyses when excluding patients with no bowel urgency, or excluding those with none to mild abdominal pain at baseline.***, **, *, $^{+}$ statistically significant at 0.001, 0.01, 0.05, and 0.1 level for treatment group vs PBO.
[a]Patients with no bowel urgency at baseline were excluded.
[b]Patients with none or mild abdominal pain (≤ 1.0) at baseline were excluded.
[Table. Proportion of UC patients who reported UC symptoms at Week 8]
Conclusion: Patients with moderately to severely active UC treated with 8-week UPA induction therapy reported significant improvements as early as week 2 in meaningful UC symptoms of bowel urgency and abdominal pain in addition to the improvement in rectal bleeding and stool frequency.

P0349 AN IBD RISK VARIANT WITHIN THE PTPN2 GENE LOCUS ENHANCES ANTI-INFLAMMATORY EFFECTS OF SPERMIDINE IN INTESTINAL EPITHELIAL CELLS AND PERIPHERAL BLOOD MONONUCLEAR CELLS FROM IBD PATIENTS

A Niechcial[1], M Butter[1], N Obialo[1], K Bäbler[1], L van der Lely[1], S Lang[1], C Gottier[1], M Scharl[1], M.R Spalinger[1]
[1]*University Hospital Zurich, Division of Gastroenterology and Hepatology, Zürich, Switzerland*

Introduction: Genome-wide association studies revealed that single nucleotide polymorphisms within the gene encoding protein tyrosine phosphatise non-receptor type 2 (PTPN2) are associated with the onset of inflammatory bowel diseases (IBD) and other chronic inflammatory disorders. PTPN2 is involved in maintaining intestinal homeostasis *in vivo* via regulating inflammatory signalling pathways and protecting intestinal epithelial barrier function. Previously, we have shown that spermidine, a naturally occurring polyamine, exerts anti-inflammatory effects in mouse colitis models *in vivo* via pharmacologic activation of PTPN2 enzymatic phosphatase activity.

Aims and Methods: The aim of this study was to investigate the anti-inflammatory effect of spermidine in human colonic cell lines and in peripheral blood mononuclear cells (PBMC) isolated from IBD patients, and to investigate how presence of the PTPN2 risk allele (SNP rs1893217) affects the outcome of spermidine treatment.

T84 and HT29 human colonic cell lines, either homozygous for the major (TT) allele or heterozygous (CT) for SNP rs1893217 in PTPN2 respectively, were treated with IFN-γ (100ng/ml) and/or spermidine (10nM). PBMC were isolated from IBD patients heterozygous for SNP rs1893217 (CT; n = 4) or homozygous for the major allele (TT; n = 4), as well as from healthy controls (all TT; n = 5), and treated in the same manner. mRNA expression of *IFNG, PTPN2, ICAM1*(which encodes for intercellular adhesion molecule 1) and *NOD2* (encoding for nucleotide-binding oligomerization domain-containing protein 2) was analysed in both experiments by performing quantitative-PCR.

Results: IFN-γ treatment resulted in increased mRNA expression of *ICAM1, PTPN2* and *NOD2* genes in all cells. Of interest, however, in cells expressing CT genotype, basal mRNA expression of those genes was already elevated, and their mRNA expression level following IFN-γ treatment was clearly higher than those observed in PTPN2 wild-type cells. In line with this, cells carrying the CT variant showed reduced PTPN2 activity in basal and IFN-γ treated conditions. Activation of PTPN2 by spermidine clearly reduced IFN-γ induced elevation of *ICAM1, IFNG* and *NOD2* expression in T84 and HT29 cells ($p < 0.05$). Despite initially elevated IFN-γ responses, spermidine treatment was more effective in HT29 cells expressing the CT variant ($p < 0.05$), resulting in elevated activation of PTPN2, and more pronounced reduction of *ICAM1, INFG* and *NOD2* mRNA. In line with those findings, we observed that upon spermidine treatment, reduction of IFN-γ response was also more pronounced in PBMC from patients carrying the CT variant ($p < 0.05$).

Conclusion: Spermidine treatment effectively reduced inflammatory response in T84 and HT29 cell lines and in PBMC from IBD patients. Reduction of the inflammatory responses is more pronounced in case of the presence of C (variant) allele in PTPN2 SNP rs1893217 carriers. Taken together our data indicates that spermidine might be a new promising therapeutic agent in IBD treatment, furthermore the presence of the PTPN2 C allele might serve as a good prediction marker for treatment response.

Introduction: Most patients with microscopic colitis (MC) can be successfully treated with antidiarrheals or budesonide. Evidence for second-line therapy in patients failing budesonide is scarce, although anti-tumor necrosing factors (anti-TNFs), methotrexate and azathioprine have been reported to be effective in cases series. Vedolizumab, a monoclonal antibody targeting $\alpha 4\beta 7$-integrin, prevents homing of memory T-cells to the gut. We evaluated clinical and histological remission with vedolizumab in budesonide-refractory MC patients.

Aims and Methods: We solicited gastroenterologists in Europe and Canada for cases of MC treated with vedolizumab. All patients had histologically proven MC. Vedolizumab 300 mg IV was administered at weeks 0, 2 and 6, and then every 8 weeks. Clinical remission and histological remission were defined as < 3 stools per day and normalization of histology, respectively.

Results: Eleven cases were available for analysis from 4 referral centers in 4 different countries [9 females, median age at diagnosis 49 years, lymphocytic colitis (LC) n = 5, collagenous colitis (CC) n = 6]. Median (IQR) disease duration at vedolizumab initiation was 51 (29–70) months and median stool frequency was 8 (5–12) per day. All patients had previously received budesonide therapy. Patients had also been exposed to mesalamine (5/11), cholestyramine (5/11), azathioprine (6/11), methotrexate (3/11) and 10/11 had failed at least 1 anti-TNF agents (8/11 infliximab, 5/11 adalimumab, 1/11 golimumab). Reasons for anti-TNF cessation were inefficacy (8/10), loss of response (1/10) and delayed infusion reaction (1/10). After 3 infusions of vedolizumab, clinical remission was observed in 5/11 patients (2 LC and 3 CC) of whom 3 remained well with maintenance therapy (median duration of 13 months). Vedolizumab was stopped due to intolerance in 1 patient (post-infusion hypertensive crisis) and loss of response for 1 patient. Biopsies after induction were obtained from 9/11 patients. Histological remission was observed in 3/4 patients with clinical remission (2/3 CC, 1/1 LC) and 0/5 patients without clinical improvement. Rescue therapies in failures were budesonide (n = 1), systemic steroids (n = 1), methotrexate (n = 1), experimental drug (n = 1) and loop-ileostomy (n = 1).

Conclusion: In a series of highly refractory microscopic colitis patients, vedolizumab induced clinical remission in 5/11 subjects and disappearance of histological inflammation in 3/4. Larger randomized trials are needed to assess the efficacy of vedolizumab in patients with MC.

Introduction: Accumulating evidence indicates that early intervention may be the best way to change patients' (pts') disease course in Crohn's disease (CD) (1), however evidence to support an early intervention approach in ulcerative colitis (UC) is more limited. A consensus definition of early CD was published in 2012 (2), but early UC is less clearly defined. This systematic literature review (SLR) examined definitions of 'early disease' applied in CD and UC.

Aims and Methods: The Cochrane library, MEDLINE and EMBASE were searched using key words and indexing terms. Eligible papers reported the characteristics and/or treatment (tx) of adult pts (≥18 years) with 'early' inflammatory bowel disease (IBD) from clinical or observational studies published January 2008 - March 2018. There was no intervention or comparator restriction and no assumption on the definition of 'early'. Papers published before 2008, not in English, in paediatric or non-IBD pts were excluded. Uncertainty as to study eligibility was reconciled by a second independent reviewer.

Results: The SLR returned 1,742 abstracts; 107 papers (16 clinical studies; 91 observational studies) met inclusion criteria. A mean 6.2 papers per year (/yr)

Abstract No: P0351

UC Patient characteristics, range (min-max) [n studies]		UC: clinical trial (n = 6)	UC: observational study (n = 49)	CD Patient characteristics, range (min-max) [n studies]		CD: clinical trial (n = 11)	CD: observational study (n = 63)
UC Treatment History	Prior IMM use (%)	6 [1]	0.2–21 [7]	**CD Treatment History**	Prior IMM use (%)	70–94 [2]	3–100 [9]
	Prior biologic use (%)	1 [1]	0–6 [5]		Prior biologic use (%)	0–27 [4]	0–27 [6]
	Prior surgery (%)		3–69 [4]		Prior surgery (%)	9 [1]	3–51 [7]
UC Disease Location	Ulcerative proctitis (%)	17–22 [4]	4–52 [33]	**CD Disease Location**	Ileum or colon only (%)	44–68 [5]	18–83 [44]
	Left–sided (%)	26–41 [4]	0–51 [32]		Ileocolon (%)	21–59 [7]	10–71 [48]
	Extensive / pancolitis (%)	39–55 [5]	9–100 [34]	**CD Disease Behaviour**	Stricturing (%)	8–18 [3]	0–64 [37]
					Non-stricturing (%)	64–92 [2]	6–100 [28]
					Penetrating (%)	0–12 [3]	4–48 [27]
					Active fistula (%)	10 [1]	9–14 [4]

were published 2008–2012 and 16.0/yr in 2013–2017. 'Early disease' was explicitly defined in 33 papers (19 CD; 7 UC; 1 CD and UC; 6 IBD overall): 22 (67%) used time since diagnosis (Dx) only; 9 (27%) combined this with tx history; 1 (3%) tx history and symptom duration; and 1 (3%) tx history and time since first IBD prescription. Definitions in UC used time since Dx only (6 papers), combined with tx history (1 paper), or tx history and symptom duration (1 paper). Cut-off points for time since Dx were applied in 30 papers: ≤3 months (20%), 3–6 months (17%), 6–12 months (27%), 1–2 yrs (17%) and >2 yrs (20%). Definitions based on tx history specified pts should be immunomodulator (IMM) and biologic naïve (7 papers) or additionally corticosteroid (CS) naïve (4 papers). 'Early disease' pt characteristics were stratified by CD and UC. Median disease duration ranged between 0.2–10.6 yrs in CD and 1.1–5.4 yrs in UC. CD cohorts included pts with stricturing (max 64%), penetrating (max 48%) or fistulising (max 14%) disease and prior surgery (max 51%); UC cohorts included pts with pancolitis (max 100%) and prior surgery (max 69%) (see Table). 'Early' CD cohorts met the consensus criteria (disease duration ≤18 months and IMM and biologic naïve) in only 2 papers published since 2012.

Conclusion: The characteristics of 'early' CD and UC pts have increasingly come under focus as the concept of early intervention in IBD has gained traction. Early disease has predominantly been defined by time since Dx (± other variables) but the disease duration of 'early' cohorts can be very long. Often 'early' pts already have complex disease, which may mean the 'window of opportunity' for intervention is missed. The consensus definition of 'early CD' has not been consistently applied since being developed. Robust definitions of early CD and UC are required to accurately evaluate the potential of early biologic tx to improve outcomes.

Introduction: In ulcerative colitis (UC), uncontrolled inflammation may result in disease progression requiring colectomy. Mucosal healing (MH) has been associated with avoidance of colectomy (1).

Aims and Methods: We investigated the rate and predictors of colectomy in the PURSUIT-Maintenance (PURSUIT-M) study of golimumab in patients with moderate to severe UC. Among 1228 patients in PURSUIT-M including the Induction Responders (IR; n = 593 who achieved clinical response at week 6 [Wk6]) and Induction Non-Responders (INR; n = 635), all colectomy cases were assessed through Wk54. MH at Wk6 was assessed by Mayo endoscopy score. Kaplan Meier (K-M) analysis was used to assess colectomy-free survival through Wk54.

Results: 47 patients required colectomy through Wk54 in PURSUIT-M. Most (34 [72.3%]) of the 47 colectomies occurred in INR, and a higher proportion of INR than IR required colectomy (5.4% vs 2.2%). Patients who responded to induction and still required colectomy (n = 13) had longer disease duration; they also tended to have more extensive disease, more severe UC, and more frequent extra-intestinal manifestations at baseline of induction, when compared to the IR without colectomy (Table). By K-M analysis, overall colectomy-free survival was significantly associated with Wk6 endoscopy score (p = 0.0077).

Conclusion: This post-hoc analysis of PURSUIT-M confirms that colectomy is associated with absence of early clinical response and MH at Wk6 in moderate to severe UC patients treated with golimumab. In patients who achieved clinical response at Wk6, colectomy was associated with longer disease duration.

Introduction: Vedolizumab (VDZ), a gut-selective humanised immunoglobulin G1 monoclonal antibody that binds to α4β7 integrin, is indicated in Canada for the treatment (Tx) of moderately-to-severely active ulcerative colitis (UC;19 May 2015) and Crohn's disease (CD;19 May 2016). Real-world data on Tx patterns, clinical effectiveness and safety outcomes in biologic (bio)-naïve patients treated with VDZ in Canada are limited.

Aims and Methods: A retrospective cohort study was conducted in adult (≥18 years) UC and CD patients who were bio-naïve and newly initiated VDZ between 19 May 2015 and 31 Dec 2016. Data collection spanned from Tx initiation to earliest of death, chart abstraction date or 6 months post-VDZ Tx discontinuation. Interim analysis used descriptive statistics. Time to first dose escalation and Tx persistence were analysed by Kaplan Meier method. Active disease, clinical remission and mucosal healing were assessed based on available data from symptomatic/endoscopic clinical assessments at baseline (closest assessment to index ≤6 months prior [active disease]) and follow-up (assessments closest to 6 and 12 months [±3 months] post-Tx initiation [remission, mucosal healing]).

Results: Interim analysis included 156 patients (UC: 108; CD: 48) from 11 sites: mean (SD) age, 42.1 (16.9) years, 61.5 % male, median (range: min-max) disease duration of 3.2 (0.01–35.0) years, and median (range) observation period of 16.5 (9.1–30.8) months. At VDZ initiation, 95.5% [85/89] of UC and 86.6% [26/30] of CD patients with assessable data had active disease. 41 patients (26.3%) had ≥1 VDZ dose escalation with a median (range) time to first dose escalation of 6.0 (2.4–22.7) months (UC: 6.6 [2.4–22.7]; CD: 5.7 [2.4–16.7]). At 12 months, 119 patients (83.8%) (UC: n = 85 [86.7%] and CD: n = 34 [77.3%]) persisted on VDZ Tx. Overall, 12.0% and 5.5% of UC and 8.3% and 6.3% of CD patients discontinued VDZ due to primary non-response and secondary loss of response, respectively. 2 CD patients discontinued Tx due to serious adverse events (neurological disorder and bronchitis; bronchitis related to VDZ). During VDZ Tx,12.0% of UC and 6.3% of CD patients had ≥1 IBD-related hospitalization and 5.6% of UC and 2.1% of CD patients had ≥1 surgical procedure. Additional outcomes are reported in Table 1.

[Concomitant Corticosteroid Use, Clinical Effectiveness and Safety Outcomes Among Bio-naïve Patients Treated with Vedolizumab]

Conclusion: These interim data support the long-term effectiveness and safety of VDZ in bio-naive UC and CD patients in real-world clinical practice. Findings will be confirmed in the final EVOLVE study cohort.

Introduction: The role of the gut microbiota in inflammatory bowel disease (IBD) pathogenesis is established and fecal microbiota transplantation (FMT) has shown some efficacy inducing remission in active ulcerative colitis in three randomized controlled clinical trials (RCT) to date. However there is no RCT result available in Crohn's disease (CD). Moreover it is not known whether the best timing to perform FMT is during a flare or after having achieved remission.
Aims and Methods: A randomized, single-blind, sham-controlled pilot trial of FMT in adults with colonic or ileo-colonic CD was performed. Patients were included while in flare (Harvey Bradshaw index [HBI] > 4) and treated with oral corticosteroid. Following clinical remission (HBI < 5), patients were randomized to receive either FMT (50–100g of stool from a single donor suspended in 250–350ml of physiological serum and administered fresh) or sham transplantation (physiological serum) during a colonoscopy. Corticosteroids were tapered and a second colonoscopy was performed at week 6. Crohn's Disease Endoscopic Index of Severity (CDEIS) was assessed during each colonoscopy. The primary endpoint was the implantation of the donor microbiota in the receiver at week 6 defined by a receiver's fecal microbiota at week 6 closer to the donor (with Sorensen index $\geq$0.6 [Sorensen index = 1- Bray Curtis index]) than to the patient before FMT. Clinical, biological and endoscopic efficacy endpoints were also evaluated (NCT02097797).
Results: Overall, 21 patients were randomized, 8 received donor FMT, 9 received sham-transplantation and 4 were ineligible for transplantation (3 because of pathogen identification and 1 for unavailability of donor). In the FMT group, none of the patients reached the primary endpoint. However, patients from the FMT group had a microbiota composition at 6 weeks closer to donors compared to patients in the Sham-transplantation group ($p = 0.016$). The steroid-free clinical remission rate at 10 and 24 weeks were 44.4% and 33.3% in the Sham-transplantation group and 87.5% and 57.1% in the FMT group ($p = 0.13$ and $p = 0.6$ respectively at week 10 and 24). CDEIS decreased 6 weeks after FMT (8.5 [4.6;13.0] vs. 3.5 [1.0;8.9]; $p = 0.03$) but not after Sham-transplantation (2.4 [0.0;8.3] vs. 2.7 [0.7;10.0]; $p = 0.8$). Conversely, CRP level increased 6 weeks after Sham-transplantation (3.0 [3.0; 4.2] vs. 6.9 [4.0; 8.7] mg/l; $p = 0.008$) but not after FMT (3.0 [3.0;3.0] vs. 3.0 [3.0;14.2] mg/l; $p = 0.5$). Failure to achieve steroid-free clinical remission at week 24 in FMT group was associated with absence of donor microbiota engraftment at week 6 and with the absence of increase in alpha diversity. The microbiota composition at week 6 was predictive of steroid-free clinical remission at week 24. No safety signal was identified.
Conclusion: None of the patients reached the primary endpoint related to the level of implantation of the donor microbiota. However, this pilot study in CD suggests that FMT performed after achieving clinical remission by corticosteroids could be effective as a maintenance treatment. A larger randomized control trial is now required to confirm the efficacy of this strategy.

P0355 TOPICAL APPLICATION OF HUMAN UMBILICAL CORD-DERIVED MESENCHYMAL STEM CELLS GEL MATRIX ACCELERATE THE CLOSURE OF ENTEROCUTANEOUS FISTULA ON MOUSE MODEL

H Hou[1], X Cao[2], K Li[3], A He[3], G Liu[3], Y Liu[1], L Duan[1], Z Han[4]

Contact E-Mail Address: hhx@189.cn

Introduction: Mesenchymal stem cell therapy is an emerging field of regenerative medicine. However low ratio cell retention after transplantation limit the successful application of stem cell. Recently local application of MSCs represents a novel approach for the treatment of perianal fistula in patients with Crohn's disease. Engineered microenvironments of a gel matrix have been increasingly successful in protecting stem cell survival by mimicking niche of native stem cell.
Aims and Methods: To investigate the efficacy of Local application of human umbilical cord-derived Mesenchymal Stem Cells (hUSCs) supported by a gel matrix on the closure of enterocutaneous fistula of mouse model. Isolated hUSCs were labeled with luciferase and green fluorescent protein by lentivirus transfection and the distribution of implanted hUSCs were detected by BLI (bioluminescence). A caecostomy was used as a fistula model in 24 male BALB/c mice on day 0. Animals were randomly assigned to groups given daubs of hUSCs supported by a gel matrix (n = 8, group A), and blank gel matrix (n = 8, group B) or placebo (n = 8, group C) in the perifistular tissue after fistula formation. Fistula drainage assessment was used to evaluate the fistula healing on day 15. And their clinical and pathological conditions were evaluated by body weight, histological analysis of perifistular tissue. Simultaneously, Cell viability and distribution was detected using an IVIS Luminar camera on days 0, 2, 4 and 6 after application of D-luciferin.
Results: The fistula was identified as healed in 7 (87.5%) mice in group A vs. 3 case (37.5%) in group B vs. 1 case (12.5%) in group C on day 15. The body weight was minimum when the fistula was formed and recovered faster in group A comparing with the other 2 groups. Furthermore, histological analysis indicate more normalized histological structure of perifistular tissue in group A. The BLI was strongest immediately after administration of hUSCs and the values fell dramatically within the first 2 days but it was still higher in animals with healed fistulas 6 days after injection.
Conclusion: Local application of hUSCs supported by a gel matrix stimulated fistula healing with significantly higher fistula closure rate on an animal model. BLI monitoring showed rapid reduction of the hUSCs mass after application. More viable cells were detected in animals with healed fistula. Topical transplanted hUSCs may play a therapeutic role in fistula healing. Mesenchymal stem cells supported by gel matrix may be a promising therapeutic approach for fistulas of Crohn's disease.

P0356 MEASURING THIOGUANINE NUCLEOTIDE (6-TGN) LEVELS AND CLINICAL RESPONSE IN IBD

M Yalchin, L Kamieniarz, R Cama, S Tribich, L Lake, H Joyce, **A Koutsoumpas**
Royal Free Hospital, London, United Kingdom

Contact E-Mail Address: andreas.koutsoumpas@nhs.net

Introduction: Monitoring levels of 6-TGN and titrating dose of Azathioprine (AZA) and Mercaptopurine (6-MP) accordingly to achieve therapeutic concentrations of 6-TGN has been reported to improve outcomes in the treatment of Ulcerative colitis (UC) and Crohn's Disease (CD).

Aims and Methods: The aim of our study was to show how levels of 6-TGN corresponds to clinical outcome. This was a single centre (Royal Free Hospital), retrospective study, of patients receiving AZA or 6MP. We identified our patients by collating those who had been dispensed AZA or 6MP over the past 2 years. We were then able to access their electronic database, and record whether 6-TGN levels were subsequently taken to titrate treatment, and assess clinical outcome.

Results: 359 from 426 patients have so far been analysed (F = 153 [42.6%], UC = 160 [44%], CD = 190 [53%], indeterminate/other colitis = 9 [3%]).

Mean duration on thiopurines was 5.7 years. Mean disease duration was 12.7 years. Out of 359 IBD patients on thiopurines, 275 [77%] had 6-TGN levels measured at some stage. 177/275 (64%) had therapeutic levels, whilst 98/275 (36%) did not. 166/275 (60.5%) were in clinical remission. 94/275 (34.5%) were not. For 15 patients (5%), no data was available. Of those that had therapeutic levels of 6-TGN, 112/177 (63%) were in clinical remission. 19/112 (17%) were in total remission (clinical, biochemical [normal CRP/WCC], endoscopic and histological). 60/112 (53%) were on Azathioprine (AZA), 48/112 (43%) were on mercaptopurine (6MP). For 4/112 (4%) patients there was no thiopurine treatment data or the treatment was stopped. 46/112 (41%) were on combined therapy with biologics. Of those that had non-therapeutic levels of 6-TGN, 54/98 (55%) were in clinical remission. 13/54 (24%) were in total remission. 37/54 (68%) AZA. 15/54 (28%) 6MP. 2/54 (4%) data not complete/purines were stopped. 24/54 (44%) were on combined therapy with biologics. Of those with therapeutic levels of 6-TGN, 53/177 (30%) were not in clinical remission. 30/53 (57%) AZA, 22/53 (41%) 6MP, 1/53 (2%) patient data not complete/purines were stopped. 41/53 (77%) were on combined therapy with biologics. Of the cohort that had non-therapeutic levels of 6-TGN, 41/98 (42%) were not in clinical remission. 21/41 (51%) AZA, 15/41 (37%) 6MP, 5/41 (12%) data not complete/purines were stopped. 29/41 (71%) were on combined therapy. (Note: 12 of the 177 patients with therapeutic 6-TGN had no data on remission status. 3 of the 98 patients with non-therapeutic levels of 6-TGN had no data on remission status).

Conclusion: Our study so far suggests that in IBD patients on thiopurines (sole or combined therapy), clinical remission rates were similar (63% vs. 55%) for those who had therapeutic 6-TGN levels and for those who had not. It also shows that even without achieving therapeutic levels of 6-TGN, 55% of patients were still in clinical remission. Moreover, there is no significant relationship between achieving therapeutic 6-TGN levels and clinical remission when looked separately for those only on thiopurines or on combined therapy (p = 0.074 and p = 0.13 respectively). Our study interestingly highlights that even with therapeutic levels of 6-TGN and with three quarters of patients on combined biologics - 30% were still not in remission. This preliminary study suggests interesting trends, that will be assessed further across the entire population (n = 426) and compared with other European data.

Introduction: This is the largest nationwide study to know the epidemiology of IBD in the 21th century in Spain.

Aims and Methods: i) to assess the incidence of inflammatory bowel disease (IBD) in Spain; ii) to describe the characteristics of patients at diagnosis, and iii) to evaluate the need for immunomodulators or biologics.

Prospective and population-based nationwide study in Spain. Adult patients diagnosed with IBD -Crohn's disease (CD), ulcerative colitis (UC) or indeterminate colitis (IC)- during 2017 in the 17 Spanish regions were included and followed-up for 12 months after diagnosis. Data were captured in a web-based database (AEG-REDCap).

Results: 3,469 incident cases from 116 centres covering approximately 50% of the Spanish population were included. The incidence of IBD was 16 per 100,000 person-years: 7.2 in CD, 8 in UC, and 0.7 per 100,000 person-years in IC. Median follow-up was 3 months both in UC and CD patients. Median age at diagnosis was lower in CD than in UC (40 vs. 45 years, $p < 0.01$). The mean time from symptoms onset to IBD diagnosis was longer in CD (5 vs. 2 months, $p < 0.01$); 10% of CD patients had no symptoms at diagnosis vs. 6% of UC ($p < 0.01$). The proportion of patients with family history of IBD was higher in CD (18 vs. 13%, $p < 0.01$). At the time of diagnosis, 12% of CD patients had extra-intestinal manifestations vs. 5.8% in UC. In CD patients, 55% had ileal location, 19% colonic, 26% ileocolonic, 3% upper gastrointestinal tract involvement, and 11% perianal disease. 11% of patients had stenosing and 7% fistulising behaviour at the time of diagnosis. 1.8% evolved to more severe phenotype after 3 months of follow-up. In UC patients, 34% had extensive colitis and 31% left-sided colitis at diagnosis, and 0.5% had progression of disease extension after 3 months. For the diagnosis work-up, 98% of patients underwent colonoscopy; among CD patients, 32% underwent MRI-enterography, 29% CT-scan, 13% upper endoscopy, 1.6% exploration under anesthesia, 5.6% capsule-endoscopy, 4% perianal MRI and 3% small bowel follow-through. Pharmacological exposures were higher in CD than in CU (table 1). The cumulative incidence of exposure to thiopurines was 32% at 3 months and 65% at 12 months in CD, and 6% at 3 months and 12% at 12 months in UC ($p < 0.01$). The cumulative incidence of anti-TNF exposure was 13% at 3 months and 35% at 12 months in CD, and 6% at 3 months and 12% at 12 months in UC ($p < 0.01$). There was not difference in median time to intravenous steroids, to thiopurines, methotrexate or anti-TNF treatment between UC and CD patients.

Conclusion: The incidence of IBD in Spain is high and similar to figures reported in the North of Europe. Up to 20% of CD patients showed an aggressive clinical phenotype -stenosing or fistulising- at diagnosis. The use of pharmacological treatments and diagnostic resources were remarkable in IBD patients, and were higher in CD than in CU patients.

	CD	UC	P
Oral mesalazine (%)	33	71	<0.01
Rectal mesalazine (%)	4	69	<0.01
Rectal budesonide (%)	0.6	4	<0.01

Introduction: Strictures are a common complication of Crohn's disease (CD) and may develop in all segments of the gastrointestinal (GI) tract. While colonoscopy has been proven suitable and effective for balloon dilation therapy of CD-associated strictures of the ileocecum (1,2), the published evidence on efficacy and safety of balloon-assisted endoscopy (BAE) for balloon dilation therapy of CD strictures of the small intestine is scarce. We therefore performed a combined efficacy and safety analysis based on all published studies of BAE for small intestinal strictures available in the literature.

Aims and Methods: A formal systematic literature review was performed to assess all relevant citations found in Embase, Medline and the Cochrane library regarding BAE used for EBD of small intestinal stricture. In addition, conference proceedings including Digestive Disease Week 2010–2017, European Crohn's and Colitis Foundation 2011–2017, United European Gastroenterology Week 2013–2016, Advances in IBD 2015–2017, American College of Gastroenterology 2016–2017, German Gastroenterology Congress 2013–2017 were screened for additional data. Available technical and clinical variables were extracted from all studies available for a descriptive pooled data analysis. Weighted efficacy averages were calculated for sub-groups.

Results: 18 publications with a total of 445 CD patients and 773 performed dilation procedures were included. 19.3% were anastomotic strictures. Technical success rate was 88.1%, resulting in clinical efficacy in 78% of patients. Major complications with regard to dilation, defined as perforation, bleeding or dilation-related surgery, occurred in 3.7% of all procedures. During a median follow-up period of 16 months, 45.7% of patients reported symptomatic recurrence, while 38.1% of patients needed to undergo re-dilation and 27.5% required surgical intervention. Currently, there is no study available investigating the impact of concomitant therapeutic approaches such as steroid injection, cutting techniques or stent placement on the outcome of BAE EBD for small bowel GI strictures in CD patients.

Conclusion: BAE for dilatation therapy of CD-associated strictures of the small intestine possesses a high rate of short-term technical and clinical success and may represent an alternative to surgery in stricturing CD. BAE-associated complication rates appear comparable to those related to dilation therapy of ileocecal strictures during colonoscopy. Larger, controlled studies are warranted to further evaluate BAE for dilation therapy of CD strictures of the small intestine.

Introduction: The endothelial adhesion protein MAdCAM-1 is a promising novel drug target in inflammatory bowel disease; the fully human IgG_2 anti-MAdCAM-1 monoclonal antibody SHP647 is in development for induction and maintenance of remission in patients with Crohn's disease (CD) and ulcerative colitis.

Aims and Methods: OPERA II was a multicentre, open-label, phase 2 extension study (NCT01298492), designed to assess the long-term safety and efficacy of SHP647 in patients with moderate-to-severe CD. Eligible patients had completed 12 weeks' induction treatment (placebo or 22.5 mg, 75 mg or 225 mg s.c. SHP647) in OPERA I (NCT01276509), or had a clinical response (≥3-point decrease in Harvey Bradshaw Index score) to 225 mg SHP647 in the open-label study, TOSCA (NCT01387594). Patients received SHP647 (75 mg, s.c.) every 4 weeks from baseline to week 72, and were followed up for safety assessments monthly for a further 24 weeks. Dose de-escalation to 22.5 mg owing to intolerance/treatment-emergent adverse events (TEAEs), or escalation to 225 mg owing to clinical deterioration/poor response, was allowed as judged by the investigator. Primary endpoints were frequency of TEAEs, TEAEs leading to withdrawal and SAEs. Concentrations of serum SHP647, high-sensitivity C-reactive protein (hsCRP) and faecal calprotectin (FC) were assessed as secondary endpoints.

Results: Of the 268 patients who enrolled and entered the treatment period, 149 completed the study. Table 1 shows the proportions of patients experiencing TEAEs, TEAEs leading to withdrawal and serious adverse events (SAEs). The most common treatment-related TEAEs in the treatment period were arthralgia (6.0%), nasopharyngitis (5.6%) and headache (5.2%). 2 patients died: 1 during treatment (75 mg) of multiple organ failure after postoperative aspiration following a resection of the terminal ileum (female, 30 years, SHP647 75 mg) and 1 during follow-up due to metastatic adenocarcinoma (unknown primary; male, 36 years, SHP647 225 mg); neither death was considered drug-related. No patients de-escalated their dose, and 157 patients increased their dose to 225 mg SHP647 after a median time of 28 weeks. Serum trough concentrations of SHP647 averaged 7051 ng/mL at week 4 and remained constant over time with a steady-state concentration of 7300 ng/mL at week 72. 3 months after dose escalation to 225 mg, patients achieved a new steady-state level of 16190 ng/mL, which is consistent with the pharmacokinetics determined previously. Patients whose dose escalated appeared to have more severe disease, with higher hsCRP (24.12±26.23 mg/L) and FC (2771.5±3583 mg/kg) levels at baseline than patients who remained on 75 mg, who had hsCRP and FC levels of 19.12±24.33 mg/L and 1823±2178 mg/Kg, respectively. Concentrations of hsCRP decreased steadily over time from week 0 to 72; the pattern was similar in patients who received 75 mg and those who escalated to 225 mg, though at the end of the study, patients who had escalated their dose had higher values than those who had not. FC levels decreased over time consistently in both groups.

Conclusion: SHP647 75 mg (with potential dose escalation to 225 mg) was generally well-tolerated in patients with Crohn's disease over 72 weeks. These results add to evidence for the long-term safety of SHP647.

[Table 1. All-cause and treatment-related adverse events in the treatment and follow-up periods.]

Introduction: There is growing evidence indicating that gut 'dysbiosis' is one of the factors in the pathogenesis of Inflammatory Bowel Disease IBD (1).
Fecal Microbiota Transplantation (FMT) from healthy donors is an effective treatment of recurrent *Clostridium difficile* infections both when administered by endoscopy or through oral capsules (2).
In addition, FMT appears to be promising in Ulcerative Colitis remission induction (3). However long-term safety and effects on ulcerative colitis remain unclear.
Aims and Methods: The aim was to test if multi-donor FMT capsules, manufactured at the laboratory at Aleris-Hamlet Hospital, Copenhagen, could lower Fecal (F) Calprotectin and improve symptoms in patients with Ulcerative Colitis and to test the safety of the treatment.
7 patients, aged 27 to 51 years, with Ulcerative Colitis, a Simple Clinical Colitis Activity Index (SCCAI) between 4 and 10, and F-Calprotectin $>$ 250 mg/kg were treated with 25 multi-donor FMT capsules daily for 50 days as a supplement to each individual patient's stable dose of standard treatment throughout the period of intervention. The 4 fecal donors were healthy individuals who were screened according to current guidelines (4) and recruited through postings in the area around the hospital. Participants were followed with fecal samples and SCAAI throughout the study period. We used Mann-Whitney U tests to compare F-Calprotectin and SCAAI levels at each time-point after baseline with the levels at baseline.
Results: Median F-Calprotectin at baseline was $\geq$1800 mg/kg (the upper limit for Calprotectin at our laboratory was 1800 mg/kg). After 4 weeks of treatment F-Calprotectin was lowered in 6 of the 7 participants, and there was a significant decrease in median F-Calprotectin of 912 mg/kg ($p = 0.004$). 1 week after the intervention had stopped, at 8 weeks from baseline, the median decrease in F-Calprotectin from baseline of 551 mg/kg was no longer statistically significant ($p = 0.14$).
The participants had a median SCAAI of 6 at baseline. After both 4 and 8 weeks all participants had lowered their SCAAI and there was a significant decrease in median SCAAI of, respectively, 5 ($p = 0.001$) and 6 ($p = 0.001$).
All participants completed the treatment and no serious adverse events were registered throughout the study period.
Conclusion: Daily multidonor FMT-capsules were safe and significantly lowered F-Calprotectin in Ulcerative Colitis patients with SCCAI between 4 and 10 after 4 weeks of active treatment. The participants also experienced a significant improvement in symptoms throughout the study period.
FMT administered in various forms appears promising in the treatment of Ulcerative Colitis but many questions remain. In particular, the type of administration, donor- and patient-selection, and dosing must be investigated in future placebo-controlled studies.

P0361 POPULATION PHARMACOKINETIC AND PHARMACODYNAMIC ANALYSIS OF SHP647, A FULLY HUMAN MONOCLONAL ANTIBODY AGAINST MUCOSAL ADDRESSIN CELL ADHESION MOLECULE 1 (ANTI-MADCAM-1), IN PATIENTS WITH ULCERATIVE COLITIS OR CROHN'S DISEASE

Introduction: The mucosal addressin cell adhesion molecule-1 (MAdCAM-1) plays a role in gut immune surveillance and facilitates excessive lymphocyte infiltration under conditions of chronic gastrointestinal inflammation. SHP647 is a fully human immunoglobulin G2 anti-human MAdCAM-1 monoclonal antibody, which is being developed for the induction and maintenance of remission of ulcerative colitis (UC) and Crohn's disease (CD).
Aims and Methods: Clinical studies (NCT01276509; NCT01620255) were performed to assess efficacy, safety, pharmacokinetics (PK) and pharmacodynamics (PD) of SHP647 in patients with UC or CD. Population PK and PK/PD analyses of SHP647 and MAdCAM-1 following repeated subcutaneous (SC) administration of 7.5, 22.5, 75, and 225 mg every 4 weeks was performed to identify sources of variability and support dosing in adult patients with UC/CD. A total of 440 patients were included in the analysis, of whom 249 (56.6%) had UC and 191 (43.4%) had CD. Population PK analysis of SHP647 included models with non-linear and/or linear elimination. Covariate analysis was performed using a stepwise covariate approach. The following covariates were explored: age, sex, race, markers of renal and liver function (i.e., creatinine clearance, bilirubin, AST, ALT) as well as renal impairment categories (normal, mild, moderate, severe), disease (UC/CD), anti-drug antibody (ADA), free MAdCAM-1 levels and various laboratory measurements (C-reactive protein [CRP], albumin, fecal calprotectin, and colonoscopy score). PK and PK/PD analyses were performed using nonlinear mixed effect modeling.
Results: Patients with UC/CD presented with similar mean age (40.4 and 36.0 years, respectively) and body weight (72.5 kg and 70.6, respectively). SHP647 was very well tolerated in patients with UC/CD. A 2-compartment model with linear and non-linear elimination resulted in an adequate characterization of concentration-time profiles. An empirical allometric function was used on clearance and volume parameters. The absorption of SHP647 was described with a first-order rate constant of absorption (Ka) and absorption lag time. Population estimates of apparent clearance (CL/F) and volume of distribution (Vc/F) were 0.0127 L/h (0.305 L/day) and 6.53 L, respectively. The CL/F was mainly dependent on baseline CRP and albumin while Vc/F was mainly dependent on body weight. No differences were observed in patients with UC/CD. ADA was not identified as a covariate explaining the variability of CL/F. The Michaelis-Menten constant (Km) was very low (19.0 ng/mL) suggesting that the nonlinear elimination (target-mediated) occurred at very low concentrations, and was less likely to contribute to the elimination half-life at therapeutic concentrations and under steady state conditions. The apparent SHP647 half-life associated with average steady state concentrations for the 7.5, 22.5, 75, and 225 mg dose levels were 7.04, 12.3, 16.5 and 18.6 days, respectively. A linear PK/PD model was used to describe the relationship between concentrations of SHP647 and MAdCAM-1 levels. Based on minimum concentrations of SHP647 under steady state conditions, the 75 and 225 mg doses were associated with $>$95% suppression of circulating MAdCAM-1 levels.
Conclusion: Nonlinear elimination of SHP647 occurred at very low concentrations and was less likely to contribute to the elimination half-life at therapeutic concentrations. Repeated SC administration of SHP647 resulted in a marked suppression of circulating MAdCAM-1 levels in patients with UC/CD.

Introduction: Tofacitinib (TOFA) is an oral, small molecule Janus kinase inhibitor that is being investigated for ulcerative colitis (UC). We performed a systematic literature review and network meta-analysis (NMA) to compare the efficacy of TOFA to other agents approved as induction and maintenance therapy in adults with moderately-to-severely active UC.
Aims and Methods: Literature searches were conducted in EMBASE, MEDLINE, CENTRAL, DARE, and CINAHL databases to identify randomized controlled trials published as of February 2017. Conference proceedings were also reviewed. 2 researchers independently assessed studies based on prespecified criteria. Feasibility assessments evaluated data availability, clinical heterogeneity, and risk of bias to identify studies suitable for inclusion. A Bayesian multinomial likelihood model with a probit link was conducted to compare induction and maintenance treatments on a 3-level mutually exclusive efficacy variable (no response, response without remission, remission) using the average placebo rate across trials as a common anchor. Results were stratified by prior tumor necrosis factor inhibitor (TNFi) exposure, where possible. Agents included in the analyses were TOFA, infliximab (IFX), golimumab (GOL), adalimumab (ADA), and vedolizumab (VDZ). 2 sets of maintenance analyses were conducted, 1 based on trials that re-randomized subjects between induction and maintenance phases (re-randomization or "RR") and the other based on trials that kept subjects on the treatment received during the induction phase (treat-through or "TT"). Data extrapolation methods were employed to integrate RR trials into the TT analyses. Results are reported as probability of response and remission along with 95% credible intervals; the probability of TOFA being superior to other treatments is also reported.
Results: 16 trials were included (10 induction only, 2 maintenance only, and 4 induction and maintenance). Among TNFi-naïve patients in induction, IFX had the greatest efficacy (response = 72%, remission = 36%). Among TNFi-exposed

patients in induction, TOFA 10mg BID had the greatest efficacy (60% and 18%) and had >99% probability of having better efficacy compared with ADA (36% and 7%). Among RR trials, TOFA had the greatest efficacy (5mg BID: 71% and 54%; 10mg BID: 72% and 56%) and had a 70–99% probability (depending on the comparator) of having better efficacy than other agents in the TNFi-naïve subpopulation. TOFA 10mg BID had the greatest efficacy (61% and 49%) and a 72–79% probability of having better efficacy than other agents in the TNFi-exposed subpopulation. Results among TT trials were similar. The probability of TOFA having better efficacy than other agents was 83–98% and 67–91% for TNFi-naïve and TNFi-exposed, respectively.
Conclusion: Except compared with IFX in the TNFi-naïve induction setting, TOFA has similar or superior efficacy compared with biologics as induction and maintenance therapy for moderately-to-severely active UC.

[2]*Centro Hospitalar Lisboa Norte, Hospital Santa Maria, Lisboa, Portugal*

Contact E-Mail Address: soniamcb@hotmail.com
Introduction: Up to one-third of patients with acute severe Ulcerative Colitis (ASUC) will fail intravenous corticosteroids (IVCT) treatment, requiring rescue therapy with Cyclosporin (Cy), Infliximab (IFX) or colectomy. Although several scores for predicting response to IVCT exist, formal comparison is lacking.
Aims and Methods: This was a retrospective cohort single-center study. The endoscopic Mayo score and the Oxford, Edinburgh and Lindgren scores were determined at admission and on the 3rd day of IVCT treatment, respectively. Outcomes included prediction of steroid refractoriness, need for rescue medical therapy and surgery
Results: From 489 patients with Ulcerative Colitis, 112 presented with ASUC; 58% were male with a median age of 33.5 years (range 18–80). The median of Truelove and Witts score was 4 (range 2–5). 35% of patients showed an incomplete or absent response to IVCT, 28.6% received rescue medical therapy (65.6% with IFX, 31.3% with Cy and 3.1% received sequential therapy with Cy and IFX) and 13.4% were colectomized up to 1 year from admission. The Lindgren score was superior to the Edinburgh score (AUC 0.856 [0.784–0.928] vs 0.775 [0.682–0.869], p = 0.01) and the Mayo score (AUC 0,699 [0,597–0,801], p = 0,02), but not to the Oxford score (AUC 0.746 [9.651–0.841], p = 0.14) in predicting steroid refractoriness. The Lindgren score was superior to the Mayo (AUC 0.826 [0.749–0.902] vs 0.637 [0.525–0.749], p = 0.002) and Oxford scores (AUC 0.719 [0.617–0.821], p = 0.03), but similar to the Edinburgh score (AUC 0.771 [0.678–0.865], p = 0.18) in predicting the need for medical rescue therapy. Finally, the Lindgren score was also a better predictor of the need of colectomy than the Edinburgh (AUC 0.836 [0.712–0.960] vs 0.753 [0.608–0.897], p = 0.03) and Oxford scores (AUC 0.712 [0.587–0.837], p = 0.003), but not to Mayo score (AUC 0.782 [0.685–0.879], p = 0.47). In multivariate regression analysis, the Lindgren score was an independent predictor for steroid refractoriness (OR 1.647 1.111–2.441, p = 0.013) and need for medical rescue therapy (OR 1.410 1.033–1.926, p = 0.03). A Lindgren score >9 had a positive and negative predictive value for IVCT failure of
91.7% and 72.9%, respectively.
Conclusion: In our series, the Lindgren score was superior to the Edinburgh, Oxford and endoscopic Mayo scores in predicting steroid refractoriness, need for rescue medical therapy and colectomy.

Contact E-Mail Address: tj23.kim@samsung.com
Introduction: Risk of venous thromboembolism (VTE) of inflammatory bowel disease (IBD) patient is higher than general population. Guidelines recommend primary prophylaxis of venous thromboembolism for certain periods. However, little is known about the magnitude of the risk of VTE development in those periods. We estimated the risk of VTE during a hospitalized flare, a non-hospitalized flare, a hospitalization without flare, IBD-related surgery, and other major surgeries.
Aims and Methods: Using the National Health Insurance claims data for the entire Korean population, we included 33,131 patients with IBD from January 2012 until December 2013 with 198,825 age- and sex-matched controls, and followed up until December 2016. We used Cox regression models to identify whether the risk of VTE varies by hospitalization, disease flare, surgery and/or presence of other risk factors.
Results: Of 33,131 patients with IBD and 198,825 matched controls, 110 patients and 376 controls developed VTE. The overall VTE risk was higher in patients with IBD [adjusted hazard ratio (aHR), 2.10; 95% confidence interval (CI), 1.70.–2.61], compared to controls. The risk of VTE during a non-hospitalized flare of IBD patients was higher compared with controls (aHR, 3.14; 95% CI, 1.90–5.19). The risks of VTE were increased much more during a hospitalization with non-flare (aHR, 16.23; 95% CI, 10.71–24.58) and a hospitalized flare (aHR, 27.20; 95% CI, 14.90–49.65). The risk of VTE was highest at the time of IBD-related surgery (aHR, 39.66; 95% CI, 9.87–159.33). Also, the risk at the time of other major surgeries was increased (aHR, 15.59; 95% CI, 7.73–31.43).
Conclusion: The prophylaxis of VTE for Asian patients with IBD should be considered at the time of a hospitalized flare and IBD-related surgery. However, the prevention of VTE is not needed for non-hospitalized patients with flare.
[Risk of venous thromboembolism by disease activity, hospitalization, and surgery.]

Introduction: The need for surgery and hospital admission in newly diagnosed inflammatory bowel disease (IBD) patients in the biological era is largely unknown.

Aims and Methods: i) To assess the frequency of surgery and hospital admission in an inception cohort of adults newly diagnosed with IBD; ii) to describe the characteristics and indications for surgical interventions; and iii) and to evaluate the causes of hospital admissions.

Prospective and population-based nationwide study in Spain. Adult patients diagnosed with IBD –Crohn's disease (CD), ulcerative colitis (UC) or indeterminate colitis (IC)– during 2017 in the 17 Spanish regions were included and followed-up for 12 months after diagnosis. Data were captured in a web-based database (AEG-REDCap).

Results: 3,469 incident cases from 116 centres covering approximately 50% of the Spanish population were included. Of them, 53% were males, with mean age of 43 years. 50% had UC, 45% CD, and 5% IC. About 14% of patients had a family history of IBD. In CD patients, 55% had ileal and 26% ileocolonic location, and 11% perianal disease. 11% of patients had stenosing and 7% fistulising behaviour at the time of diagnosis. In UC patients, 34% had extensive colitis and 31% left-sided colitis at diagnosis. At present, median follow-up is 3 months (range 0–12 months). 149 patients (4.3%) underwent 188 surgical interventions: 131 (8.3%) in CD and 18 (0.9%) in UC ($p < 0.01$). Regarding the first surgical procedure, 60% were urgent and 60% entailed abdominal surgery (30% for perforation, 28% for stenosis and 26% for abdominal abscess). CD patients with inflammatory behaviour had lower rates of surgery than those with strictures or fistula (5.6%, 14%, and 32%, respectively, $p < 0.01$). Surgery was also more frequent among CD patients with perianal disease than in those without it (34 vs. 5.2%, $p = 0.01$). Other variables, such as family history of IBD, or smoking habit were not associated with the need of surgery. A total of 892 patients (26%) had 1,038 hospital admisions during follow-up, with disease diagnosis as major driver (81%). Median time from diagnosis to admission was 0 months (range 0–9 months). Reasons for hospital admissions are summarized in table 1.

Conclusion: In this large nationwide inception cohort in the biological era, a substantial proportion of IBD patients underwent surgery, which was urgent in over 2/3 of the cases. Stricturing and fistulizing complications in CD patients were the main drivers for surgery in these patients. 1/4 of patients were hospitalised –most of them at disease diagnosis– within the first 3 months of follow-up.

	CD (N = 507)	UC (N = 385)

Introduction: It is usual clinical practice to start infliximab as combination treatment with azathioprine in patients with inflammatory bowel disease (IBD) and to de-escalate from combination treatment to infliximab (IFX) monotherapy once disease remission is reached. It is however unclear if the addition of azathioprine during introduction of IFX improves long-term clinical outcomes and pharmacokinetics in patients who previously failed azathioprine.

Aims and Methods: We aimed to study the effect of short-term (6–12 months) co-treatment with azathioprine on long-term clinical outcome and on consumption of IFX in patients who escalated from azathioprine to either IFX monotherapy or to combination of azathioprine and IFX due to inefficacy of azathioprine.

We included 149 patients (94 Crohn's disease, 55 ulcerative colitis) who started IFX between 2011 and 2016 for active IBD in a tertiary referral centre. To study the effect of azathioprine co-treatment we compared patients who started IFX as combination treatment with azathioprine and then de-escalated to IFX monotherapy after disease remission was reached (IFX combo) with patients who started IFX as monotherapy from the beginning (IFX mono).

Results: The study population included 78 (52%) IFX combo patients and 71 (48%) IFX mono patients. IFX combo (Crohn's disease: ileocolonic 71%, perianal 42%; ulcerative colitis: pancolitis 62%) and IFX mono (Crohn's disease: ileocolonic 74%, perianal 29%; ulcerative colitis: pancolitis 69%) groups did not differ in disease phenotype.

During a median follow-up of 19 months [interquartile range (IQR): 12–40 months] 38/149 (26%) patients permanently lost response to IFX.

Short-term (median 9 months [IQR: 6–13 months] azathioprine co-treatment did not impact clinical outcome after one year of treatment (loss of response in 8/78 (10.3%) in IFX mono vs. 12/71 (16.9%) in IFX combo ($p = 0.235$) nor did it impact long term outcome at the end of follow-up (loss of response in 18/71 (25.4%) in IFX mono vs. 20/78 (25.6 %) in IFX combo ($P = 0.968$).

However, azathioprine co-treatment decreased IFX consumption during the first year of treatment by approximately 25% and improved pharmacokinetics as the IFX combo group achieved higher IFX trough levels with lower IFX maintenance doses. However, at the end of follow-up, i.e. after a median of 14 months [IQR: 3–33 months] after withdrawal of azathioprine, the IFX-sparing effect, that was enjoyed while patients were co-treated with azathioprine, was attenuated with both groups of patents receiving similar doses of IFX and having similar IFX trough levels (Table 1).

Conclusion: Short-term (6–12 months) combination treatment with azathioprine after initiation of infliximab does not impact the long-term outcome of patients with inflammatory bowel disease but it decreases consumption of infliximab by approximately 25% during the first year of treatment. However, this infliximab-sparing effect is lost after de-escalation from combination treatment to infliximab monotherapy.

Introduction: Tofacitinib is an oral, small molecule JAK inhibitor that is being investigated for ulcerative colitis (UC). The efficacy and safety of tofacitinib were demonstrated in 3 Phase (P) 3, randomised, placebo-controlled studies (OCTAVE Induction 1, NCT01465763; OCTAVE Induction 2, NCT01458951; OCTAVE Sustain, NCT01458574) in patients (pts) with moderate to severe UC.[1] An ongoing P3, multicentre, open-label, long-term extension study (OLE; NCT01470612) included pts from OCTAVE Induction 1 or 2, or OCTAVE Sustain.

Aims and Methods: We present an update (as of 10 Nov 2017) of previous analyses of the OLE study maintenance remission subpopulation (pts in remission [total Mayo score ≤2, no individual subscore >1, rectal bleeding subscore of 0] at Week [Wk] 52 of OCTAVE Sustain).[2] Pts in remission at Wk 52 of OCTAVE Sustain received tofacitinib 5 mg twice daily (BID) in the OLE study. Efficacy data, including remission, mucosal healing (Mayo endoscopic subscore of 0 or 1), clinical response (decrease from induction baseline total Mayo score of ≥3 points and ≥30%, and decrease in rectal bleeding subscore ≥1 or absolute rectal bleeding subscore of 0 or 1; all based on local read) and partial Mayo score (PMS) remission (PMS ≤2, no individual subscore >1), up to Month 24 of the OLE study (as observed and with non-responder imputation), are presented for pts in remission after receiving tofacitinib in OCTAVE Sustain. Safety data are reported for all pts who received tofacitinib 5 mg BID in the OLE study.

Results: Of 944 pts who received ≥1 dose of study drug in the OLE study, 163 (mean age: 45 years; 46.0% female) were in remission at Wk 52 of OCTAVE Sustain. Of these, 142 had received tofacitinib 5 mg (n = 66) or 10 mg (n = 76) BID in OCTAVE Sustain. 40/163 (24.5%) pts discontinued in the OLE study (13 [8.0%] due to insufficient clinical response; 12 [7.4%] due to adverse events [AEs] excluding worsening UC).

Binary efficacy endpoints at baseline and up to Month 24 of the OLE study are shown in the Table. Efficacy over 24 months was similar irrespective of tofacitinib dose previously received in OCTAVE Sustain.

Among all pts receiving tofacitinib 5 mg BID in the OLE study, 78.9% reported treatment-emergent AEs (TEAEs). Serious and severe AEs occurred in 12.0% and 8.0% of pts, respectively. The most frequent TEAEs by preferred term were 'nasopharyngitis' and 'worsening of UC'. 5 pts (2.9%) had serious infections and 10 (5.7%) had herpes zoster (all mild or moderate severity). Malignancy excluding non-melanoma skin cancer was reported in 1 (0.6%) pt (lung cancer).

Conclusion: The majority of pts with moderate to severe UC who achieved remission after 52 wks of tofacitinib 5 or 10 mg BID in OCTAVE Sustain maintained remission, mucosal healing, clinical response and PMS remission with tofacitinib 5 mg BID for up to 24 months in the OLE study (up to 3 years from maintenance study baseline). No new safety risks were identified.

Introduction: Tofacitinib is an oral, small molecule Janus kinase inhibitor that is being investigated for ulcerative colitis (UC). The efficacy and safety of tofacitinib was demonstrated as induction and maintenance therapy in patients (pts) with moderate to severe UC in 3 Phase (P) 3, randomised, placebo-controlled studies.[1] Safety and efficacy of tofacitinib for UC are being evaluated in an ongoing, open-label, long-term extension (OLE) study.[2]

Aims and Methods: We present an update (as of 10 Nov 2017) of previously presented safety and efficacy data[2] of an ongoing P3, multicentre, OLE study (NCT01470612) in pts who completed or demonstrated treatment failure in OCTAVE Sustain (NCT01458574) or were non-responders in OCTAVE Induction 1 or 2 (NCT01458951, NCT01458574). Eligibility was determined per Week (Wk) 8 data from OCTAVE Induction 1 & 2, or Wk 52 data (for completers) or early termination data from OCTAVE Sustain. Pts in remission (total Mayo score ≤2, no individual subscore >1, rectal bleeding subscore of 0) at Wk 52 of OCTAVE Sustain (per central read) were assigned to tofacitinib 5 mg twice daily (BID) in the OLE study; all others were assigned to 10 mg BID. At Month 2, all pts underwent endoscopy, and induction non-responders were mandated to withdraw if they did not show a clinical response. Binary efficacy endpoints were derived from Mayo score per local read.

Results: Of 944 pts who received ≥1 dose of study drug (for up to 4.9 years), 769 (81.5%) pts received tofacitinib 10 mg BID; 326 (34.5%) pts discontinued due to insufficient clinical response, and 65 (6.9%) discontinued due to adverse events [AEs] excluding worsening UC. Serious and severe AEs occurred in 14.8% and 9.9% of pts, respectively. The most frequent treatment-emergent AE (TEAE) classes were infections and gastrointestinal disorders. The most frequent TEAEs were nasopharyngitis, worsening UC and increased blood creatine phosphokinase. Serious infections were reported in 5 (2.9%) and 23 (3.0%) pts, herpes zoster in 10 (5.7%) and 47 (6.1%) pts, and major adverse cardiovascular events in 1 (0.6%) and 1 (0.1%) pts in the 5 and 10 mg BID groups, respectively. Malignancies excluding non-melanoma skin cancer (NMSC) were reported in 1 (0.6%) and 12 (1.6%) pts, and NMSC in 4 (2.3%) and 9 (1.2%) pts, in the 5 and 10 mg BID groups, respectively (with no clustering of malignancy type). No new safety risks were identified. Available remission, mucosal healing and clinical response data up to Month 24 are shown (Table).

Conclusion: In pts with moderate to severe UC in the OLE study, no new safety risks emerged compared with those observed with tofacitinib in rheumatoid arthritis. Efficacy data from the OLE study continue to support long-term efficacy with tofacitinib 5 or 10 mg BID up to 24 months beyond Wk 52 of OCTAVE Sustain.

[a]Patients in remission, based on central endoscopic reading, at Wk 52 of OCTAVE Sustain (all receiving tofacitinib 5 mg BID in OLE study); [b]Patients were treated as non-responders after the time of discontinuation up to the visit they would have reached if they had stayed in the study. No imputation for missing data was applied for ongoing patients.

All values are per local read of endoscopy, unless otherwise stated (baseline values are per central read). Remission was defined as a total Mayo score ≤2 with no individual subscore >1, and rectal bleeding subscore of 0; mucosal healing was defined by a Mayo endoscopic subscore ≤1; PMS remission was defined as a PMS ≤2 with no individual subscore >1.

BID, twice daily; n, number of patients in the maintenance remission subpopulation with the specified response within the given category; N, number of randomised patients in the maintenance remission subpopulation; N1, number of patients in the remission subpopulation who could have reached the specified time point (based on enrolment date and last non-missing total Mayo score [endoscopy for mucosal healing]); NRI, non-responder imputation; OLE, open-label long-term extension; PMS, partial Mayo score; Wk, Week.

research support from Pfizer Inc, and has been on advisory boards for J&J, Pfizer Inc, Tillotts, Takeda; N Lawendy, G Chan, GS Friedman, H Zhang, W Wang, AJ Thorpe, CI Nduaka, C Su are Pfizer Inc employees and shareholders.

[a]Baseline mean total Mayo score was not available for 2 patients in the tofacitinib 10 mg BID group; therefore, Tofacitinib 10 mg BID, N = 767 and Tofacitinib All, N = 942; [b]AEs of worsening UC leading to discontinuation were designated as insufficient clinical response; [c]Induction non-responders were mandated to withdraw if they did not have evidence of clinical response at Month 2; [d]2 cases were reported as severe (number of cases): appendicitis (1), gastroenteritis norovirus (1); [e]9 cases were reported as severe (number of cases): appendicitis (3), arthritis bacterial (1), atypical pneumonia (1), herpes zoster (2), herpes zoster meningitis (1), meningitis herpes (1); [f]4 cases were reported as severe; [g]Adjudicated events; [h]A case of cerebellar haemorrhage; [i]A case of cerebrovascular accident; [j]Malignancy: pulmonary mass; [k]Malignancy (number of cases): cervical dysplasia (1), hepatic angiosarcoma (1), invasive ductal breast carcinoma (1), adenocarcinoma of colon (2), essential thrombocythaemia (1), acute myeloid leukaemia (1), cholangiocarcinoma (1), cutaneous leiomyosarcoma (1), Epstein-Barr virus-associated lymphoma (1), renal cell carcinoma (1), malignant melanoma (1); [l]Patients were treated as non-responders after the time of discontinuation up to the visit they would have reached if they had stayed in the study. No imputation for missing data was applied for ongoing patients.

Remission was defined as a Mayo score ≤2 with no individual subscore >1, and rectal bleeding subscore of 0; Mucosal healing was defined by a Mayo endoscopic subscore ≤1; Clinical response was defined by a decrease from study baseline Mayo score of ≥3 points and ≥30%, accompanied by a decrease in rectal bleeding subscore of ≥1 or an absolute rectal bleeding subscore of 0 or 1.

AE, adverse event; BID, twice daily; FAS, full analysis set; GI, gastrointestinal; n, number of patients with the specified response within the given category; MACE, major adverse cardiovascular event; N, number of randomised patients in the total population; N1, number of patients in the specified category with non-missing values; NMSC, non-melanoma skin cancer; NRI, non-responder imputation; OLE, open-label long-term extension; SAEs, serious AEs; SD, standard deviation; SOC, system organ class; TEAEs, treatment-emergent AEs; UC, ulcerative colitis.

Introduction: Azathioprine (AZA) and thiopurine are widely used for induction and maintenance of remission in steroid dependent patients with inflammatory bowel disease (IBD).

Aims and Methods: Aim of this study has been to investigate its efficacy and safety in maintaining steroid-free remission in steroid dependent IBD patients seven year after the institution of treatment. Data from consecutive IBD outpatients referred in our Institution, between 1985–2016, were reviewed and all patients treated with AZA were included in this retrospective study. AZA was administered at the recommended dose of 2–2.5 mg/kg.

Results: Out of 2802 consecutive IBD outpatients visited in the index period, AZA was prescribed to 433 patients, 236 (54.5%) were affected by Crohn's disease (CD) and 197 (45.5%) by ulcerative colitis (UC). 179 patients with a follow-up < 84 months were excluded from the study. 254 patients were evaluated, 141 (55.5%) with CD and 113 (44.5%) with UC. 139 (54.7%) were male

and 115 (45.3%) female (average age of 35.62 ± 14.20 SD years, range 14–74 y.). 7 years after the institution of treatment, 127 (50%) patients still were in steroid-free remission (83 CD vs 44 UC, 58.8% and 38.9%, respectively, p = 0.0024), 71 (27.9%) had a relapse requiring retreatment with steroids (29 CD vs 42 UC, 20.6% and 37.2%, respectively, p = 0.0047), 56 (22.1%) discontinued the treatment due to side effects (29 CD vs 27 UC, 20.6% and 23.9%, respectively). Loss of response from 1st to 7th year of follow-up was low, about 20%.
Conclusion: 7 year after the onset of treatment 50% of patients did not require further steroid courses. After the first year loss of response was low in 6 subsequent years. In the present series the maintenance of steroid-free remission was significantly higher in CD than in UC patients. The occurrence of side effects leading to the withdrawal of AZA treatment has been low.
Disclosure: Nothing to disclose

P0370 EARLY CHANGE OF PATIENT-REPORTED RECTAL BLEEDING AND STOOL FREQUENCY SCORE AND FECAL CALPROTECTIN LEVEL ARE ASSOCIATED WITH COLECTOMY OUTCOME AT 1 YEAR IN PURSUIT-MAINTENANCE TRIAL

F Cornillie[1], A Khalifa[2], G Philip[3], L Peyrin-Biroulet[4]

Introduction: In ulcerative colitis (UC), uncontrolled inflammation may result in progressive mucosal damage requiring colectomy. Absence of short-term clinical response to medical therapy and absence of early mucosal healing (MH) are predictors of colectomy (1, 2).
Aims and Methods: We investigated the association of colectomy with early clinical and endoscopic response, and change of fecal calprotectin (FC) in the PURSUIT-Maintenance (PURSUIT-M) study of golimumab in patients with moderate to severe UC. We assessed whether early change of patient-reported outcomes (PRO) Mayo rectal bleeding score (RBS) and Mayo stool frequency score (SFS) and biomarker FC are associated with colectomy. PRO2 (RBS and SFS), Physician Global Assessment (PGA), Mayo score, Mayo endoscopic score (ES) and FC data were obtained at baseline and wk6 (end of induction). Data were compared between patients with and without colectomy by wk54 of maintenance in PURSUIT-M. A total of 1228 patients were included for colectomy analysis.
Results: N = 47 patients required colectomy by wk54 of maintenance in PURSUIT-M (3.8%). Of these, 34 (72.3%) were non-responders to sc or iv golimumab induction regimens. Responders to induction who underwent colectomy by wk54 (n = 9) received either 100mg (n = 2), 50mg (n = 4) or placebo (n = 3) maintenance therapy. 4 additional patients who responded to placebo induction and were maintained on placebo had colectomy. Baseline and wk6 Mayo score, Mayo ES, RBS, SFS, PGA, and log of FC value are shown in the table. At baseline, Mayo score, Mayo ES, and PGA were different between the 2 groups, whereas at wk6 Mayo score, Mayo ES, PGA as well as RBS, SFS and FC were different between the colectomy and non-colectomy groups.
Conclusion: This post-hoc analysis of colectomy outcome in PURSUIT-M shows that early (wk6 of induction) reductions of PRO2 (RBS and SFS) score and FC level are associated with a reduced likelihood of colectomy over 1 year of treatment. These data suggest that PRO2 (RBS and SFS) and FC are markers of disease activity that may inform colectomy risk stratification in UC patients treated with golimumab.

P0371 MEASURING THIOGUANINE NUCLEOTIDE (6-TGN) LEVELS AND CLINICAL RESPONSE IN IBD; COMPARING SINGLE AND COMBINED THERAPIES

M Yalchin, L Kamieniarz, R Cama, S Tribich, L Lake, H Joyce, **A Koutsoumpas**
Royal Free Hospital, London, United Kingdom

Contact E-Mail Address: andreas.koutsoumpas@nhs.net
Introduction: Monitoring levels of 6-TGN and titrating dose of Azathioprine (AZA) and Mercaptopurine (6-MP) accordingly to achieve therapeutic concentrations of 6-TGN has been reported to improve outcomes in the treatment of Ulcerative colitis (UC) and Crohn's Disease (CD).
Aims and Methods: The aim of our study was to show how levels of 6-TGN corresponds to clinical outcome, and compare those on sole therapy and those combined with biologics. This was a single centre (Royal Free Hospital), retrospective study, of patients receiving AZA or 6MP. We identified our patients by collating those who had been dispensed AZA or 6MP over the past 2 years. We were then able to access their electronic database, and record whether 6-TGN levels were subsequently taken to titrate treatment, and assess clinical outcome.
Results: 359 from 426 patients have so far been analysed (F = 153 [42.6%], UC = 160 [44%], CD = 190 [53%], indeterminate/other colitis = 9 [3%]).
Mean duration on thiopurines was 5.7 years. Mean disease duration was 12.7 years.
Out of patients with IBD (359), 275 [77%] had 6-TGN levels measured at some stage.
177/275 (64%) had therapeutic levels, whilst 98/275 (36%) did not.
166/275 (60.5%) were in clinical remission. 94/275 (34.5%) were not. For 15 patients (5%), no data was available.
Of those that had therapeutic levels of 6-TGN, 112/177 (63%) were in clinical remission. 46/112 (41%) were on combined therapy with biologics. 66/112 (59%) were on purines alone. Of these 66, 37 (56%) were on Azathioprine (AZA), 26 (39%) were on mercaptopurine (6MP). For 3/66 (5%) patients there was no thiopurine treatment data or the treatment was stopped.
Of those that had non-therapeutic levels of 6-TGN, 54/98 (55%) were in clinical remission. 23/54 (44%) were on combined therapy with biologics. 31/54 (57%) were on purines alone. Of those who were not on biologics 21/31 (68%) were on AZA. 9/31 (29%) were on 6MP. 1/31 (3%) data not complete/purines were stopped.
Of those with therapeutic levels of 6-TGN, 53/177 (30%) were not in clinical remission. 40/53 (75%) were on combined therapy with biologics. 13/53 (25%) were on purines alone. Of those who were not on biologics 7/13 (54%) were on AZA, 5/13 (38%) were on 6MP, 1/13 (8%) data not complete/purines were stopped.
Of the cohort that had non-therapeutic levels of 6-TGN, 41/98 (42%) were not in clinical remission. 29/41 (71%) were on combined therapy. 12/41 (29%) were on purines alone. 9/12 (75%) were on AZA, 1/12 (8%) on 6MP, 2/12 (17%) data not complete/purines were stopped.
(Note: 12 of the 177 patients with therapeutic 6-TGN had no data on remission status. 3 of the 98 patients with non-therapeutic levels of 6-TGN had no data on remission status).
Conclusion: Interestingly our study suggests that if you had therapeutic levels of 6-TGN, you were more likely to be in clinical remission if you were on purines alone as compared to combined with biologics (59% vs. 41%). These interesting trends need further analysis to ascertain more comprehensive conclusions between the groups of sole therapy and combined biologics.

Introduction: To evaluate the efficacy of granulocyte and monocyte apheresis (GMA) in corticosteroid naïve patients with active ulcerative colitis (UC) without concomitant corticosteroids therapy in remission induction and sustained remission.

Aims and Methods: In this multicenter retrospective study, ninety corticosteroids naïve patients with active UC received GMA as remission induction therapy between 2012 and 2018 in 4 Japanese institutes were enrolled. Each patient received weekly or intensive (2–3 sessions/week) GMA up to 11 sessions. Partial Mayo score ≤ 2 meant remission, while ≤ 1 in Mayo endoscopic subscore meant mucosal healing. Concomitant medication with corticosteroids, biologics or calcineurin inhibitors were not allowed, but medication with 5-ASA and immune-modulators were permitted.

Results: The overall remission and mucosal healing rates were 71.1% (64/90) and 64.5% (49/76), respectively. Subjects who achieved a remission were clinically and endoscopically followed for 12 months after a course of GMA. After 12 months follow up, a sustained remission was recorded in 66.7% (44/66) of those treated with GMA. The patients who had obtained a remission after a course of GMA showed relapses up to 33.3% (22/66) and mean time to relapse was 10.0 months.

Conclusion: The overall remission and mucosal healing rates were 71.1% (64/90) and 64.5% (49/76), respectively. Subjects who achieved a remission were clinically and endoscopically followed for 12 months after a course of GMA. After 12 months follow up, a sustained remission was recorded in 66.7% (44/66) of those treated with GMA. The patients who had obtained a remission after a course of GMA showed relapses up to 33.3% (22/66) and mean time to relapse was 10.0 months.

Introduction: The introduction of anti-TNF therapy has dramatically changed the treatment of refractory inflammatory bowel disease (IBD-Crohn's disease [CD], ulcerative colitis [UC]). However, the clinical use of anti-TNF therapies is limited by loss of response posing significant challenge for clinicians. Therapeutic drug monitoring has gained increasing popularity in the management of IBD. However, relationship between clinical outcomes and serum anti-TNF levels is complex and controversial in many cases.

Aims and Methods: The aim of this study is to simultaneously analyse the serum, mucosal and fecal infliximab and adalimumab levels, to determine the mucosal expression of TNF-α and to assess the relationship between the levels of anti TNF-α in the above mentioned biological samples with endoscopic and clinical activities of IBD patients receiving anti-TNF maintenance therapy.

Patients with luminal CD and UC receiving maintenance anti TNF-α therapy have been started to enroll in the study and the enrollment is still ongoing. Clinical disease activity is assessed, blood samples and fecal specimens are collected and colonoscopy with biopsy samples is performed in every patient. Biopsy samples are obtained from inflamed and uninflamed tissue from the colon. Mucosal TNF-α expression is detected by confocal microscopy after immunofluorescent staining. Serum, mucosal and fecal anti TNF-α and anti drug antibody levels is determined by ELISA assay. Kendall-tau correlation coefficient was used to assess bivariate correlations.

Results: Data of 34 patients have been analyzed (20 CD, 14 UC; 17 infliximab, 17 adalimumab). The number of TNF-α positive cells was significantly higher in mucosal samples of active vs. inactive part of the bowel ($p < 0.001$). Mucosal drug level proved to be significantly higher in samples obtained from the inactive vs. active part of the bowel ($p < 0.001$). However, no association could be detected between the number of TNF-α positive cells and either endoscopic activity or mucosal drug levels. Serum drug level was significantly lower in patients who developed anti drug antibody ($p = 0.043$). We did not find any correlation between serum drug level and fecal calprotectin concentration, however, calprotectin level was higher in patients with anti-drug antibody positivity ($p = 0.0134$). No correlation was detected between serum and mucosal anti TNF levels.

Conclusion: Our study would be the first that simultaneously examine serum, tissue and fecal concentrations of anti TNF-α comparing with clinical and endoscopic activities. We were unable to find evidence against the hypothesis of no association between serum drug levels and mucosal anti TNF-α concentration. However, the sample size is currently very low, and more data is needed to be collected in order to better investigate the association between serum and tissue drug levels or disease activity. Nevertheless, it is hoped that these measurements will allow a better overview of the drug distribution and clearance and may help to identify a useful surrogate marker of clinical and endoscopic activity.

Introduction: The majority of patients with Crohn's disease (CD) need surgery during their lifetime. Within 1 year, 80% of the operated patients has endoscopic postoperative recurrence (POR). However, there is no widely accepted consensus on the prevention of POR.

Aims and Methods: Our aim was to compare the efficacy of biological agents and that of conventional therapy as prophylactic treatment options for POR and also to compare the efficacy of prophylactic biological treatment in high risk vs. non-selected patient populations. We searched Pubmed, Cochrane Library, EMBASE, and Web of Science for English-language studies published from inception up to 15 April 2017. The PICO items were, as follows: (P) adults with CD who had intestinal resection, (I) biological therapy (adalimumab, infliximab), (C) conventional therapies (mesalamine, thiopurines and placebo), and (O) clinical, endoscopic, and severe endoscopic POR. Patients were considered at 'high risk' for POR if they had ≥ 1 of the following risk factors: active smoking, young age at diagnosis, penetrating or perianal disease at diagnosis, ≥ 1 resections, and resection within 3 years. Odd ratios (OR) and 95% confidence intervals (CI) were calculated. PROSPERO registration number is CRD42017083679.

Results: The data of 2 observational and 8 randomized controlled trials, including 709 CD patients, were analysed. Anti-TNFα agents were significantly more effective in preventing clinical and endoscopic POR compared to conventional therapies (OR: 0.501, 0.319–0.786, $p = 0.003$, and OR: 0.157, 0.069–0.359, $p < 0.001$, respectively). We could demonstrate an overall benefit of biological therapy in unselected patient groups of CD patients regarding clinical, endoscopic and severe endoscopic POR (OR: 0.449, 0.272–0.741, $p = 0.002$; OR: 0.132, 0.055–0.317, $p < 0.001$, and OR: 0.263, 0.085–0.817, $p = 0.021$, respectively). In the course of direct comparison, there was no significant difference in POR rates between the 2 anti-TNF agents. Patients previously treated with biologics were less likely to maintain remission after surgery (OR: 0.509, 0.303–0.853, $p = 0.010$).

Conclusion: Compared to the conventional therapies, biological agents are more effective in preventing clinical and endoscopic POR both in unselected and high-risk CD patients. In addition, biologics should be continued after surgery in patients with preoperative anti-TNFα treatment to maintain remission.

P0375 EFFICACY AND SAFETY OF GRANULOCYTE ADSORPTION APHERESIS IN ELDERLY PATIENTS WITH ULCERATIVE COLITIS

A Ito, S Murasugi, T Omori, K Tokushige
Tokyou Womens Medical University, Dept. medicine, Inst. Gastroentelorgy, Tokyo, Japan

Contact E-Mail Address: itoayumi@ige.twmu.ac.jp

Introduction: The number of elderly patients with ulcerative colitis (UC) has been increasing. Elderly UC patients differ from younger patients with respect to the course of their disease, response to treatment, risk of adverse effects, and influence of UC on the quality of life. At our hospital, granulocyte adsorption apheresis (CAP) is often used to treat elderly UC patients.

[A2] It is abbreviated as GCAP or GMA apheresis in other reports. GMA = granulocyte/monocyte absorption; this is logical.

GAA = granulocyte absorption apheresis is also logical.

Aims and Methods: Here we retrospectively analyzed the cases of elderly patients with moderate or severe UC who underwent CAP for remission induction therapy in a comparison with younger patients. From April 2000 to March 2016, 96 patients with UC underwent CAP at our hospital. Patients who concurrently received tacrolimus, biological agents, or high-dose steroid therapy (PSL at > 0.5 mg/kg) were excluded. The remaining 80 patients were evaluated. We divided them into an elderly group (aged ≥ 65 years) and a younger group (< 65 years old), and then we compared the groups' (1) clinical characteristics, (2) the efficacy and adverse effects of CAP, and (3) the complications of PSL therapy.

Results: The remission rate was 70.8% in the elderly group and 87.5% in the younger group, and CAP demonstrated efficacy in both groups. There were significant differences between the 2 groups with respect to the age at the onset

of UC, the estimated glomerular filtration rate on admission, underlying diseases, and complications of PSL therapy (all $p < 0.05$). Adverse effects of CAP included headache ($n = 2$ in both groups), complications of blood reinfusion ($n = 1$ in the younger group), heparin allergy ($n = 1$ in the younger group), hypotension ($n = 1$ in the elderly group), and failure of blood removal ($n = 2$ in the elderly group). There were significant differences between the 2 groups with respect to the complications of PSL therapy (all $p < 0.05$).
Conclusion: Although the elderly group had longer durations of UC, a higher prevalence of underlying diseases, and a higher frequency of adverse events due to PSL therapy, CAP was effective in both groups. No serious adverse effects that required the discontinuation of CAP occurred in either group. Thus, CAP was safe and effective in both younger and elderly UC patients. CAP should be considered as a useful treatment option for UC, especially in patients with adverse events due to PSL therapy and elderly patients with underlying diseases.

Introduction: Thiopurines are the most commonly used immunsuppressive therapies in mild-to-moderate IBD. Therapeutic concentration of 6-TG is between 235–450 pmol/8×10^8 red blood cell count (RBC). The effect of body composition on 6-TG level was never been studied. Furthermore clinical data suggests a synergistic effect between thiopurine and anti-tumour necrosis factor (anti-TNF) therapy in IBD.
Aims and Methods: This is a cross-sectional study involving 96 IBD patients. Consecutive IBD patients on maintenance AZA ($n = 32$) and on IFX/AZA or ADA/AZA combinations ($n = 32$) and activity indices-based pair-matched controls on IFX or ADA monotherapy ($n = 32$) were prospectively enrolled. 6-TG level was measured with high performance liquid chromatography, IFX and ADA levels were assessed by ELISA method. Body composition analysis was performed with bioelectrical impedance analysis.
Results: Therapeutic concentration of 6-TG was found in 50 patients (78%), they received AZA for a mean 5.9 years. 14 patients (21.8%) had lower blood 6-TG level, they received AZA for an average of 7.5 years. The level of AZA metabolite 6-TG correlated with body weight-based AZA doses ($p = 0.017$) however it did not correlate with body surface area-based AZA doses ($p = 0.081$). With statistical analysis correlation was found with some of the investigated body composition parameters: total body water ($r = -0.33$, $p = 0.011$), intra-, extracellular water ($r = -0.325$ and -0.334, $p = 0.008$ and $p = 0.008$, respectively), sceletal muscle mass ($r = -0.326$, $p = 0.01$). However no correlation was found with body fat mass ($r = -0.091$, $p = 0.487$). 32 patients received concomitant biological therapy (14 ADA, 18 IFX). Difference was found in ADA trough levels between those on combined ADA/AZA therapy and those on ADA monotherapy (5.22 ± 5.17 mcg/ml vs. 18.04 ± 14.84 mcg/ml, $p = 0.006$). In contrast, no difference was found in IFX trough levels between those on combined IFX/AZA therapy and those on IFX monotherapy (8.95 ± 10.08 mcg/ml vs. 12.13 ± 12.61 mcg/ml, $p = 0.374$).
Conclusion: Our study revealed that 6-TG level besides body weight-based AZA doses correlate with total body water, intra-, extracellular water and sceletal muscle mass. We found a significant difference in ADA trough levels between the ADA/AZA combination group and the ADA monotherapy group. Preliminary results of our study suggest that favourable outcomes of combination therapy may related to a synergistic effect between AZA metabolites and IFX or ADA trough levels. However the small number of the patients requires further investigations.

[4]*Hospital da Senhora da Oliveira, Guimarães, Gastroenterology Department, Guimarães, Portugal*

Contact E-Mail Address: tiagomcg@hotmail.com
Introduction: Patients with stricturing Crohn's disease (CD) are frequently hospitalized and a significant percentage requires surgery in the course of the disease.
Aims and Methods: We aimed to assess if there are any predictors of surgical management by the time of the first admission to hospital with obstructed bowel symptoms.
Retrospective unicentric study. Patients over 18 years old, with structuring ileal or ileocolonic involvement, with at least 1 hospitalization and a minimum follow-up of 1 year were included. Excluded patients with penetrating disease, those who had their first hospitalization before anti-TNF agents became available in our center and those without appropriate records. Several clinical, analytical and radiological variables were assessed. Statistical analysis was performed using SPSS v23.0.
Results: Included 43 patients of which 53.5% underwent surgery to treat structuring disease. Patients had a mean age of 43.3 ± 10.8 years, 53.5% were females and the median follow up time was 11.0 ± 7.0 years.
Comparing patients with and without need for surgery, no significant differences were found between groups regarding age at diagnosis, presence of perianal disease, family history and smoking habits, however females were more frequently submitted to surgery (73.9% vs 30.0%, $p = 0.004$) as well as patients who already had a structuring behavior at diagnosis when compared with those with inflammatory behavior at diagnosis (65.6% vs 18.2%, $p = 0.006$).
At the first hospitalization, patients with need for surgery were less frequently under anti-TNF (0.0% vs 20.0%, $p = 0.039$), presented with longer-standing obstructed bowel symptoms (3.0 ± 1.5 days vs 1.0 ± 1.0 days, $p = 0.010$), higher leukocytes count ($12.0 \pm 5.3 \times 10^3$/uL vs 9.2 ± 6.9 x10^3/uL, $p = 0.037$) and admission computerized tomography (CT) more frequently showed proximal small bowel dilation (86.4% vs 40.0%, $p = 0.002$) and longer extent of small bowel involved (8.0 ± 12.0cm vs 5.0 ± 7.0cm, $p = 0.016$). Also, patients that were diagnosed by the time of the first hospitalization were more frequently submitted to surgery than those who already had a CD diagnosis (60.9% vs 39.1%, $p = 0.043$).
Conclusion: Females, patients with structuring behavior from diagnosis and those diagnosed in the first hospitalization were more frequently submitted to surgery. Small bowel dilation and extent of small bowel involved in admission CT, leukocyte count and duration of obstructed bowel symptoms at the first admission were also predictors of need for surgery. Anti-TNF therapy before the first admission seems to reduce need for surgery in this group of patients.
Disclosure: Nothing to declare

P0378 THE ROLE OF STOMA FOR COLONIC AND PERIANAL CROHN'S DISEASE IN THE BIOLOGICAL ERA

Introduction: In the biological era, surgical treatment continues to play an active role in some patients with colorectal or perianal Crohn's disease (CD).
Aims and Methods: Epidemiological analysis, surgical indication and clinical evolution of patients with CD with colorectal and/or perianal disease undergoing surgical treatment.
Retrospective study of patients with colonic and/or perianal CD who underwent colectomy, total proctocolectomy, or diverting ileostomy /colostomy between 2000–2016 in a tertiary hospital. Demographic and clinical data were collected.
Results: 20 patients were included, 70.0% were women, mean age was 44.5 years. The disease was located in the ileum and colon in 7, solely in the colon in 11 patients and in the ileum (L1p) in 2. 13 patients had perianal disease and 18 rectal involvement. The behaviour of CD according to the Vienna classification was non-stricturing non-penetrating in 12 patients, stricturing in 5 and penetrating in 3. Prior to surgery, 15 patients were treated with combination therapy, 2 with anti-TNF (previous withdrawal of azathioprine due to adverse events) and 3 had no medical treatment due to inaugural disease at the time of surgery. The mean duration of disease before colectomy was 9.1 years. Surgical indications were: refractoriness to medical treatment in 8 patients with luminal disease and 8 with perianal fistulizing disease, perforation in 3 and Hodgkińs lymphoma of the rectum in 1. 9 patients required more than 1 surgical intervention, including 4 urgent surgeries. The surgeries performed were proctocolectomy in 10 patients, total colectomy with ileostomy in 3, protectomy with colostomy in 2, segmental colectomy with colostomy in 1 and ostomy in 4 (3 colostomy and 1 ileostomy). The mean follow-up time was 5.4 years. Postoperative evolution: high-output ileostomy in 1 patient; pelvic floor dyssynergia in the patient with ileo-anal pouch; 5 patients with relapse of CD in the ileum; 2 with proctitis (1 underwent

proctectomy later); 1 with perianal disease and 1 death due to adenocarcinoma in fistulous tract. At the last follow-up, 9 patients were with combination therapy, 3 with biological therapy and 2 with methotrexate.
Conclusion: In this study, 95% remained with stoma. More than half of the patients maintain/restart biological treatment.
Disclosure: Nothing to disclose

P0379 ENTERIC RESECTION IN CROHN'S DISEASE - IS THERE A RELATIONSHIP BETWEEN THE TIMING OF IMMUNOSUPPRESSION ONSET AND THE EXTENSION OF THE RESSECTED SMALL BOWEL?

P Costa-Moreira, P Andrade, S Lopes, A.L Santos, C.R Nunes A, G Macedo
Centro Hospitalar de São João, Gastroenterology, Porto, Portugal

Contact E-Mail Address: pedromoreira.med@gmail.com
Introduction: Intestinal function is closely related to its length. An individualized approach regarding the need for resection of each affected segment of the bowel should be applied to the patient with Crohn's disease (CD) requiring surgery. Several studies have been evaluating the relationship between the date of onset of anti-tumor necrosis factor (anti-TNF) agents or immunomodulators and the need of surgical procedures in CD.
However, it is still unclear if the timing of the immunosuppression onset has impact in the length of the resected small bowel.
Aims and Methods: We propose to evaluate the relationship between the early treatment of CD patients with anti-TNF agents or immunomodulators with the extension of the resected small bowel.
We perform a retrospective data analysis of a sample of cases with CD submitted to surgery. For each case, the date of diagnosis, immunomodulators or anti-TNF onset, and surgery was recorded. The extension of the resected small bowel was based on the anatomopathological report.
Results: A total of 314 cases diagnosed between 1975 and 2017 (172 men (50.7%), mean age at diagnosis 28.9 ± 12.8 years) were evaluated. Multiple surgeries were performed in 20% ($n = 63$) of the cases. The most frequently performed surgery was the right ileocolectomy (77.3%, $n = 245$).
The median time between diagnosis and the first surgery was 31 months (IQR 5–83 months). On average, the patients underwent resection of 23.6 ± 18.4cm of the small bowel. Prior to the first surgery, 46.7% ($n = 148$) of the patients were treated with an immunomodulator (median time of therapy 16 months, IQR 3–42 months) and 21.8% ($n = 69$) were treated with an anti-TNF agent (median time of therapy of 38 months, IQR 7–100 months). Neither immunomodulatory therapy (mean 23.2 ± 16.5cm vs. 24.3 ± 20.4cm, $p = 0.67$) nor anti-TNF therapy (mean 22.6 ± 15.9cm vs 24.0 ± 19.2cm, $p = 0.61$) was associated with lower extension of resected small bowel. No correlation was found between the time elapsed since diagnosis and introduction of the immunomodulator ($r = 0.07$, $p = 0.43$) or anti-TNF agent ($r = 0.06$, $p = 0.531$) and the extension of resected small bowel. Also, there was no correlation between the time elapsed between the introduction of immunomodulator ($r = 0.06$, $p = 0.47$) or anti-TNF agent ($r = 0.08$, $p = 0.53$) and time to surgery with the extension of resected small bowel.
Conclusion: In this group of patients, we found that the timing of introduction of immunomodulator or anti-TNF therapy did not influence the extent of the resected bowel.
Disclosure: Nothing to disclose

P0380 HIGHER BMI BUT NOT SYSTEMIC IMMUNE SUPPRESSION INCREASES THE RISK OF SHORT-TERM POSTOPERATIVE COMPLICATIONS IN CROHN'S DISEASE PATIENTS

D Podmanicky[1], V Bak[1], M Krizko[2], Z Zelinkova[2]
[1]*St Michaels Hospital, Department of Surgery, Bratislava, Slovakia*
[2]*St Michaels Hospital, Department of Gastroenterology, Bratislava, Slovakia*

Contact E-Mail Address: dusan.podmanicky@nsmas.sk
Introduction: Several studies have focused at the risk factors of postoperative complications in Crohn's disease (CD) patients with no conclusive results. Thus far, it is unclear whether immune suppression should be adjusted in a CD patient awaiting surgery for CD complications.
Aims and Methods: The aim of this study was to determine the risk factors associated with the postoperative complications in CD patients operated for luminal disease complications.
All consecutive CD patients operated on in 1 tertiary center between January 2015 and September 2017 were included. Complications within 30 days following surgery were categorized according to Clavian-Dindo classification. Patients' demographics, nutritional status, disease localization and behavior, type of medication, previous surgical interventions, type of surgical approach and duration of surgical intervention were noted. The association of postoperative complications with these factors was analyzed.
Results: In total, 91 procedures were performed in 86 CD patients (47.3% males; mean age 38 years, range 19–71; 56 pts (61.5%) with ileo-colonic disease, 11 pts (12.1%) with small bowel and 21 pts (23.1%) large bowel localization; 62 (68.1%) with stricturing disease). Based on body mass index, 23 (25.3%) patients were underweight, 42 (46.2%) had normal weight and 21 (23.1%) were overweighed. Minority of patients had steroids (16 pts; 17.6%); 36 pts (39.6%) were using azathioprine; 33 (36.3%) antiTNF; 7 (7.7%) vedolizumab and 1 patient was using trial medication.
The procedure was elective in 60.4% and one-third had repetitive surgery. Median duration of the procedure was 150 minutes (range 30–335) and median hospital stay was 6 days (range 3–32). 51 pts (56%) had simple resection, 24 (26.4%) had multiple resections, in 16 cases an ostomy was created. Laparoscopic approach was used in 44 cases (48.4%; 8 pts had single port laparoscopic procedure), 46 pts (50.5%) had laparotomy.
There were 10 complications (11%) out of which 5 (5.5%) major complications (Clavian-Dindo IIIb and above). There was a significant difference in BMI between patients with major complications compared with patients without complications (respective medians 26 and 21 in the group with major complications vs. group without complications; $p = 0.035$). None of the other factors were associated with unfavorable postoperative outcomes.
Conclusion: Overweight represents a risk factor for postoperative complications in Crohn's disease patients operated for luminal disease complications. Immune suppressive therapy, including systemic corticosteroids and antiTNF biologics does not seem to confer an increased risk for surgical complications.

Contact E-Mail Address: k.a.wasmann@amc.nl
Introduction: Randomized controlled trials (RCT) are the gold standard of assessing efficacy in clinical medicine. However, many eligible trial participants have a preference for 1 of the intervention of the RCT, and therefore may decline randomization. Consequently, this could limit the extrapolation of the results to the clinical population (i.e. reduce external validity by randomization bias). Patients randomly allocated to their non-preferred intervention may experience resentful demoralization, which may lead to worse outcomes (i.e. reduce internal validity by preference bias). Especially studies with a substation difference in interventions (e.g. surgery vs. medication), and studies with a subjective primary outcome (e.g. quality of life), are prone for randomization and preference bias. The aim of this study was to determine whether preferences affect external and internal validity in trials.
Aims and Methods: A systematic review with meta-analyses was performed. 2 reviewers independently searched in MEDLINE, EMBASE, PsychINFO, and the Cochrane library for RCTs with a preference-arm published between 2005 and 2018. The trials that reported on allocation of patients to random or preference cohorts using the same inclusion criteria and protocol were included. We extracted data on study design, measurement of preference, recruitment, attrition, cross-over, and primary outcome at baseline and end of follow-up.
Results: In total 117 out of 3734 identified articles met screening criteria and 35 were eligible (to compare baseline and primary outcome difference between the randomised and preference cohort, 32 and 20 articles were included, resp.) Acceptance of randomization in all 35 trials varied from 1% to 81% and was lower than 50% in 23 of 35 studies. Higher education level, female, older age, race, and prior experience with 1 treatment arm were baseline characteristics of patients declining randomization. The primary outcome of the trials between randomized and preference groups was comparable, the difference in effect of the experimental intervention was 0.093 (95% CI −0.364–0.178), $p = 0.502$. After comparing only the 7 trials that adjusted for baseline difference the effect was even smaller, 0.026 (95%CI −0.211–0.263), $p = 0.832$.
Conclusion: Treatment preference led to a substantial proportion of a specific patient group refusing randomization, while it did not affect the primary outcome. Therefore, patients preference trials could increase external validity without compromising the internal validity compared to randomization controlled trials.

P0382 EARLY CLOSURE OF ILEAL POUCH-ANAL ANASTOMOTIC LEAKAGE PRESERVES POUCH FUNCTION; A PROSPECTIVE COHORT STUDY

K Wasmann[1], M Reijntjes[2], M Stellingwerf[2], C.Y Ponsioen[3], C.J Buskens[4], R Hompes[4], P Tanis[4], W.A Bemelman[4]

Contact E-Mail Address: k.a.wasmann@amc.nl
Introduction: In case of ileal pouch-anal anastomotic (IPAA) leakage, Endosponge®-assisted early surgical closure prevents chronic presacral abscesses compared to conventional treatment (defunctioning ileostomy and passive drainage). It was hypothesised that early closure would also improve long-term pouch function. The aim of this study was to compare pouch function and failure after early closure to conventional management of anastomotic leakage and to control IPAA patients without anastomotic leakage.

Aims and Methods: In this prospective cohort study, all consecutive patients who underwent IPAA for ulcerative colitis (UC) between 2002 and 2016, were sent a validated pouch dysfunction questionnaire. Early surgical closure after Endosponge® treatment under a defunctioning ileostomy became standard practice in our center from 2010 onwards. The primary outcomes were pouch function (none-minor or some-major dysfunction) and pouch failure (defunctioning ileostomy or pouch excision) compared between control IPAA, early closure, and conventional management using a chi-square test for trend. Secondary outcomes were short-term outcomes, e.g. anastomotic healing at 6 months, and time to closure of anastomotic defect.
Results: In total, 308 patients were included and 84% returned the questionnaire (n = 255), of whom 41 patients had anastomotic leakage (n = 18 early closure and n = 23 conventional). Some-major pouch dysfunction was comparable between control IPAA (n = 75/216, 35%) and early closure (n = 7/17, 41%), but significantly more dysfunction after conventional management was seen (n = 15/22, 59%) (p = 0.03). Pouch failure was comparable between control IPAA (n = 11, 4%) and early closure (n = 1, 6%), while conventional management (n = 5, 22%) showed significantly more failures (p = 0.001). Early closure resulted in 100% (n:17/17) closed anastomosis at 6 months, compared to 64% (n:14/17) after conventional treatment (p = 0.006), and accelerated closure time 8 (7–15) days vs. after 76 (50–332) days, resp. (p < 0.001).
Conclusion: Early closure of IPAA leakage for UC patients is associated with a prevention of pouch failure and preservation of long-term pouch function compared to conventional management.

Introduction: Nivolumab is a immune-checkpoint inhibitor and it enhances cancer-related immune responses by inhibiting programmed cell death protein (PD-1). Nivolumab is efficacious for the management of patients with metastatic melanoma and other solid tumors. However, immune-related adverse events (irAEs) are known as serious side effects of immune-checkpoint inhibitors. The purpose of this study is to clarify the clinicopathological characteristics of colitis occurring as an irAE in patients treated by nivolumab (nivolumab-induced colitis).
Aims and Methods: During a period from December 2015 until February 2018, we encountered 7 patients who were suspected of having nivolumab-induced colitis. There were 2 women and 5 men with ages ranging from 51 to 81 years (mean, 66 years). We retrospectively investigated clinical features, endoscopic findings and pathologic characteristics of the patients. Nivolumab-induced colitis was defined as 1) diarrhea occurring during nivolumab treatment, 2) exclusion of other causes of diarrhea, and 3) histological confirmation of apoptosis colonic epithelial cells.
Results: The underlying tumor was malignant melanoma in 3 patients, non-small cell lung cancer in 2 patients and renal cell carcinoma in 2 patients. In addition to diarrhea, 2 patients complained of hematochezia. C-reactive protein value at the time of colonoscopy ranged from 0.1 to 9.1 mg/dl with a mean of 2.0 mg/dl, and white blood cell count from 3330 to 10480/μl with a mean of 6430/μl. 3 of 7 patients fulfilled the diagnostic criteria of nivolumab-induced colitis. The remaining 4 patients manifested diarrhea and they were free from other causes of diarrhea, apoptosis was not evident in these patients. 3 patients with nivolumab-induced colitis manifested clinical symptoms after administrations of nivolumab for 4 to 5 times, and 2 patients complained of hematochezia. Colonoscopic findings of nivolumab-induced colitis included friable erythematous mucosa of the rectum and granular mucosa of the colon, which were apparently compatible with ulcerative colitis. These patients were treated by prednisolone, which was effective in patient. 2 patients intractable to prednisolone were treated by infliximab, but a patient failed to respond to infliximab. 4 patients without nivolumab-induced colitis had normal colonoscopic findings and they continued nivolumab without any specific treatment.
Conclusion: Colitis mimicking ulcerative colitis is 1 of irAEs induced nivolumab. Our diagnostic criteria, which include apoptosis of colonic epithelial cells, may be appropriate in consideration of mucosal damages and subsequent clinical course.

P0385 FECAL TRANSPLANTATION FOR AUTISM SPECTRUM DISORDERS

V Urbonas[1], J Cervinskiene[2], J Sakalinskiene[2]
[1]*Vilnius University Medical Faculty Clinic for Children's Diseases, Vilnius, Lithuania*
[2]*Children's Hospital of Vilnius University Hospital Santaros Klinikos, Vilnius, Lithuania*

Contact E-Mail Address: uvaidas@cheerful.com
Introduction: The prevalence of children with autism spectrum disorders (ASD) is increasing worldwide (1). The cause of ASD is poorly understood and involves interplay of different genetic and environmental factors where gut microbiota could have a significant impact. The aims of the study were to evaluate fecal microbiota transplantation (FMT) effectiveness in children with ASD in treating autism spectrum disorders and gastrointestinal (GI) symptoms.
Aims and Methods: We performed FMT in 5 boys (5–8 yrs., every month, 3 times for every patient) with ASD and mild GI symptoms. The donor was the same 7 yrs. old healthy, unrelated girl. Her feces were infused into the cecum during colonoscopy. The patients' gut before FMT was prepared with polyethylene glycol 4000 (Fortrans). Symptoms were checked every week after FMT with parent global impression score (PGI-R; the symptoms were rated on a scale of 1–7, where 1 = much worse, 7 = much better compared to baseline) (2) for ASD and gastrointestinal symptom rating scale (GSRS; 1 represents absence of troublesome symptoms and 7 represents very troublesome symptoms) (3).
Results: We filled GSRS and PGI-R scores by asking parents about their child's health during phone call or when the patient came to the hospital for FMT. The total GSRS and PGI-R scores improved in all (1–5) patients after FMT (Table 1). The best improvement was seen after 2 wk. post FMT, less before second and third FMT. The FMT treatments were generally well-tolerated, without adverse effects.
[GSRS and PGI-R scores before and after FMT]
Conclusion: 1. FMT has positive effect on GI and autism spectrum disorders symptoms.
2. The FMT treatments were well-tolerated.
Disclosure: Nothing to disclose

Introduction: Although mortality is declining globally, acute diarrhea is leading cause more than 2 milion deaths annually and is a major cause of outpatient visits, hospitalizations, and reduced quality of life for domestic setting and traveling abroad.
Aims and Methods: We aimed to investigate whether stool PCR could have a beneficial effect on the duration of hospitalization induced by acute diarrhea. Between March 2015 and February 2018, patients were admitted with acute diarrhea, stool PCR was performed in 116 patients. Patients were divided into 2 groups: stool PCR (n = 58) and non-stool PCR (n = 58). The positive rate in stool PCR and the change in treatment modality were examined and the prognosis was compared between groups.

Abstract No: P0385

Patient	Before FMT	Before FMT	After 2 wks	After 2 wks	After 1 mo	After 1 mo	After 2 mo	After 2 mo
	GSRS	PGI-R	GSRS	PGI-R	GSRS	PGI-R	GSRS	PGI-R
1	35	–	20	53	22	50	23	49
2	33	–	19	56	21	52	22	53
3	33	–	20	55	20	52	20	51
4	36	–	21	52	25	52	24	50
5	37	–	26	56	27	55	28	54

Results: Overall, 29 (50%) of 58 samples were positive for pathogen at stool PCR. The positive rate for virus was 1.7%. Enteric adenovirus was detected in 1 sample, respectively. The positive rate for bacteria was 48.3% (28/58). *C. perfringens was* the most frequently detected, followed by *campylobacter spp*., *C.difficile toxin B*.
The rate of antibiotics change, antidiarrhea agent or probiotics change, additional endoscopy and image study(CT) were significantly higher in stool PCR positive group ($p = 0.007$, $p < 0.001$, $p = 0.018$ and $p = 0.027$, respectively).
There were no significant diffrences between groups in terms of antibiotics use and hospitalization, however, hospital of day decreased significantly in stool PCR positive group ($p = 0.032$).
On multivariate analysis, stool PCR positive was associated with increased rates of history of diabetes mellitus type 2, fluid therapy and anti-diarrheal agent use (HR, 8.357; 95% CI 2.381–29.328; $p = 0.001$ / HR 2.940; 95% CI 1.184–7.303; $p = 0.020$ / HR 2.945; 95% CI 1.522–5.699; $p = 0.001$).
Conclusion: With stool PCR positive, antibiotics changes and drug modification were associated shortening of hospitalization perioid, espicially in patients with diabetes.
Disclosure: Nothing to disclose

P0387 FECAL MICROBIOTA TRANSPLANTATION IN CLOSTRIDIUM DIFFICILE INFECTION: REAL-LIFE EXPERIENCE FROM AN ACADEMIC ITALIAN HOSPITAL

B Barberio, S Facchin, E.V Savarino, R D'inca, F Zingone, M Cola, M Ghisa, G Lorenzon, A Rigo, C Marinelli, M Inferrera, G.C Sturniolo

Introduction: Gut microbiota helps us to regulate homeostasis functions. Its key features are resilience and biodiversity. Antibiotic therapies can create an ecological vacuum, and some opportunistic pathogens, especially *Clostridium difficile*, may take advantage of it. Faecal microbiota transplantation (FMT), has been recently proven to be extremely effective ($\approx 80\%$) in controlling this infection.
Aims and Methods: The aim of the study is a preliminary clinical and microbiological evaluation of the implementation of faecal microbiota transplantation in Padua Hospital. In addition, efforts were made to provide guidance on the use of biodiversity indices to assess changes in intestinal microbiosis.
13 FMTs were performed in 12 patients (12 F/2 M, mean age 68.7) in 1 year. In 9 FMT donor and recipients faecal samples were collected before and after (2–8 days) transplantation, and in 4 patients even at 4–6 months (follow-up). In 1 patient faecal suspensions resulting from the combination of 2 donors were used, whereas in another patient frozen feces instead of fresh stool were infused. Stool samples were analyzed using the Illumina (NGS) technique. Statistical analysis was performed with the Wilcoxon Signed Ranks Test and a bilateral hypothesis system. We calculated Shannońs biodiversity indices and Simpsońs equipartition indices.
Results: The primary resolution of CDI was obtained in 100% of the cases, although an early relapse at 3-month from FMT was observed. Among the donors, the most numerous phyla were Bacteroidetes ($57.8\% \pm 23.45\%$) and Firmicutes ($35.0\% \pm 20.1\%$). Patients' fecal samples taken the day before FMT revealed a marked dysbiosis: Proteobacteria levels were excessively high ($58.1\% \pm 28.2\%$) compared to Bacteroidetes ($2.8\% \pm 4.8\%$), as usually occurs in CDI. In fecal samples taken after transplantation (between 2 and 8 days) an increase in Bacteroidetes levels ($65.2\% \pm 18.5\%$) and a specular decline in Proteobacteria were immediately observable ($10.6\% \pm 11.1\%$). The Shannon index correlated to changes in intestinal flora before and after faecal transplantation, with a good level of significance (p-value = 0.03906; $\Delta M = 0.67$). Using Simpson's equipartition index we showed that the 4 patients, in whom the microbial analysis was performed at 4–6 month, did not demonstrate significant changes compared to the samples taken immediately after FMT (p-value $\sim = 1$; $\Delta M = 0.01$). No safety issues were observed during the FMT and after it.
Conclusion: Our data confirmed that FMT is an effective, safe and simple practice for treating CDI. Even the transplant performed using frozen fecal material provided similar good results. Therefore, it is desirable to implement this procedure in clinical practice. Finally, the index of equipartition who seems able to provide us with a measure of disturbances of the microbiota in the long term, may prove to be a valuable tool to orient ourselves in the diagnosis, treatment and monitoring of many pathologies.
Disclosure: Nothing to disclose

P0388 GASTRIC ACID SUPPRESSION MAY LEAD TO AN INCREASED RISK OF VANCOMYCIN-RESISTANT ENTEROCOCCUS COLONIZATION

Introduction: Gastric acid suppression therapy has been reported to change the gastrointestinal microbiome, resulting in increased gastrointestinal infections. However, the effect of gastric acid suppression therapy on vancomycin-resistant enterococcus (VRE) colonization has not been investigated.
Aims and Methods: Subjects who had surveillance rectal swabs for VRE at a university hospital were investigated. Surveillance was performed on subjects with prior hospitalization within 3 months, history of VRE colonization/infection, or positive VRE findings from an adjacent patient. Gastric acid suppression therapy was defined as use of proton pump inhibitor or histamine-receptor-2 antagonists.
Results: Of 886 subjects who underwent VRE screening, 452 were included with 69 VRE positive and 383 VRE negative subjects. In univariable analysis, gastric acid suppression therapy, antibiotics use, male gender and prior hospitalization were significant risk factors for VRE colonization. Multivariable analysis showed that gastric acid suppression therapy (OR 2.873, 95% CI 1.473–5.605, $p = 0.002$) and antibiotics use (OR 3.896, 95% CI 2.019–7.520, $p < 0.001$) significantly increased VRE risk. Of antibiotics, carbapenems (OR 3.836, 95% CI 1.603–9.182, $p = 0.003$) glycopeptides (OR 2.784, 95% CI 1.155–6.712, $p = 0.023$), and cephalosporins (OR 2.210, 95% CI 1.213–4.025, $p = 0.010$) were most significantly associated with VRE colonization. The unfavorable effect of gastric acid suppression therapy on VRE colonization was consistent, regardless of antibiotics type.
Conclusion: Gastric acid suppression therapy significantly increased VRE colonization risk. Gastric acid suppression should be administered according to strict guidelines. Physicians should be made aware of the increased VRE risk, and should consider VRE surveillance in those under long-term gastric suppression therapy.

Introduction: Fecal microbial transplantation (FMT) has been established as an effective and safe therapy for recurrent *Clostridium difficile* infection (CDI), with cure rates of 85–95% [1]. In Israel, FMT for the treatment of recurrent CDI, has been approved for the past 5 years and is currently available in 5 medical centers, at which FMT is performed in ambulatory as well as in hospitalized patients using multiple methods including colonoscopy, gastroscopy, and capsules [2–3].
Aims and Methods: We evaluated and described the efficacy and safety of FMT for CDI patients in a national retrospective cohort of the 5 medical centers performing FMT in Israel. All patients who received FMT for recurrent (recurrence within 8 weeks of the previous treatment), refractory (ongoing diarrhea despite antimicrobial treatment) or severe CDI (WBC $\geq$ 15,000 c/μl $\pm$ Cr $\geq$ 1.5 times the premorbid level) from 2013 through 2017 were included.
Stool donors were screened according to the Israeli Ministry of Health guidelines. Fecal filtrates were locally prepared and stored frozen in -80^0c.
Clinical and laboratory data of patients were collected from patients' medical files in which indications for FMT, risk factors and outcomes at 1 week, 2 and 6 months post FMT are routinely recorded.
Results: A total of 111 FMTs for CDI were performed: 45% via the lower GI route (LGI) through a colonoscopy, 22% via gastroscopy or feeding tube (upper GI - UGI), and 33% via oral capsules. A summary of patients' characteristics, risk factors for CDI, indications and outcomes is depicted in Table 1.
Recurrent CDI was the leading indication for FMT in 74% of the patients while refractory and severe CDI were treated in 21% and 18% patients, respectively.

Abstract No: P0389

	Overall N (valid)	Overall % (IQR)	Upper GI N	Upper GI % (IQR)	Lower GI N	Lower GI % (IQR)	Capsules N	Capsules % (IQR)	p value
Patients, no.	111	100%	24	22%	50	45%	37	33%	
Male gender, no.	47 (111)	42%	16	67%	19	38%	12	32%	0.02
Age, median (IQR)	70 (111)	(53–82)	68	(51–86)	78	(61–83)	68	(45–75)	0.11
Charlson score, median	79±9 (81)	(69–93)	79±9	(69–93)	84±4	(75–93)	73±9	(69–98)	0.73
Abx use, past 3 months, no.	66 (108)	59%	15	63%	15	30%	36	97%	0.01
Previous CDI episode, median	2 (107)	(2–3)	2	(1–3)	2	(1–3)	3	(2–4)	0.29
Severe CDI, no.	20 (111)	18%	8	33.3%	10	20%	2	5.4%	0.02
Refractory, no.	23 (111)	21%	6	25%	13	26%	4	11%	0.19
Recurrent, no.	82 (111)	74%	18	75%	31	62%	33	89%	0.02
Outpatient, no.	78 (111)	70%	12	50%	36	72%	30	81%	0.03
Recurrence at 6 months	16 (99)	16.2%	3	15.8%	5	11.4%	8	22.2%	0.14
Total death, no.	11 (111)	9.9%	5	21%	6	12%	0	0%	0.02
No. of adverse events	19 (107)	17.1%	1	4%	14	28%	4	11%	0.01
Success	97 (111)	87.4%	19	79%	44	88%	34	92%	0.34

Overall success rate was 87.4% (97 patients), with no significant difference between administration routs.
Patients who achieved cure, were younger (age 63±22 compared with 73±12, $p < 0.05$), were less often defined as severe CDI, and were more likely to be treated as outpatients.
Patients who were younger than 60 years old (n = 35), were mostly outpatients, compared to the elderly group, (86% vs. 63%, respectively, $p < 0.05$) and underwent FMT at a much later time from first disease episode (mean time from 1st CDI −198±279 vs. 102±112 days, $p < 0.05$).
11 patients died during the follow-up, none was attributed to the FMT procedure itself; 2 patients suffered from post-endoscopy aspiration (1 UGI, 1 LGI). Other side effects were mild and self-limited. No FMT related infections were recorded.
Conclusion: FMT is a safe and effective treatment for CDI, which occurs in growing numbers in the young population. FMT via capsules emerges as a successful and well tolerated alternative for endoscopy.*[Study population characteristics and outcomes by FMT mode]*

Introduction: *Clostridium difficile* infection (CDI) has emerged as a major healthcare-associated infection, because of the changing molecular epidemiology of the *C. difficile*, and the ageing of the population, without neglecting frequent exposure to broad-spectrum antibiotics and other predisposing medications, the presence of comorbidities, and the risk of hospitalization. In the last decade, analyses of hospitalization records and data on multiple causes of death demonstrated an important and constant increase in CDI rates.
Aims and Methods: To evaluate the impact of CDI on hospitalization in Veneto Region (North-East Italy, approximately 4,900,000 inhabitants), a retrospective analysis was carried out from a population-based archives represented by hospital discharge records (HDR) according to the ICD9-CM. All discharges from 1 January 2007 to 31 December 2016 of Veneto population with a code for CDI (008.45) ad principal or secondary diagnosis were extracted form the regional anonymous archive of discharge records. The Standardized Hospitalisation Rate (SHR) and in-hospital Mortality Rate (SMR) were calculated per 5-year age group (ref. pop. Veneto 2012) and expressed per 100 000 population.
Results: 7,557 discharges with CDI were tracked in the study period and **88%** of these hospitalizations **involved subjects aged over 65 years**, with CDI diagnosis as the primary in over 1-third of cases and an overall lenght of stay (LOS) of 25.6±22.7 days. Hospitalization distribution by gender showed a prevalence of **females** (63.2%) characterized by an **higher mean age** (80.2±14.6 vs. 75.6±16.4 yrs; $p < 0.001$). The **SHR** was 15.25 and **SMR** 1,72 both increased steeply and constantly in the analyzed period, and from the comparison of first and last year of the period emerged a rise of SHR (Chi square for trend: 141.702; $p < 0.001$) from 10.6 to 24.5 and also of SMR (Chi square for trend: 45.381; $p < 0.001$) from 0.6 to 3.7 per 100 000 inhabitants. **The rate of CDI** diagnoses per 100000 overall admissions **increased steeply with age**, and reached a peak of 222.4 every 100,000 discharges among the very elderly (> 85 years). In the frame of over 65 years patients the age class distribution showed an **higher risk in 75–84** (OR: 1.62; CI95%: 1.23–2.13; $p < 0.001$) and an almost **double in >85 years** (OR: 2.1; CI95%: 1.62–2.74; $p < 0.001$) **respect to 65–74 age class**.
Over 65 years patients admission with CDI diagnosis represent **2.1% of overall ordinary admission** and cause to the **LOS excess of 15.7 days and represent 5.4% of overall hospitalization days**. **Also in-hospital mortality rate showed an excess risk attributable to CDI** (OR: 1.91 95% CI: 1.77–2.05; $p < 0.001$).
Conclusion: In the observation period SHR for CDI was almost doubled and SMR even increased 6-fold in 2016 respect to 2007. What emerged confirms the literature's data about the time course of CD infections, with an increase in their frequency, as well as in their severity and in the additional days of hospitalization. These dramatic scenary imposing the adoption of adequate containment measures to deal with a now epidemic phenomenon, mainly through policies to optimize antibiotic therapy both in the intra- and extra-hospital environment.

Introduction: *Clostridium difficile* infection, especially in its severe clinical picture, is a risk factor for bloodstream infections (BSI). A considerable body of evidence shows that fecal microbiota transplantation (FMT) is more effective than standard antibiotic regimens in treating recurrent CDI), although its efficacy in reducing CDI-related BSI has not yet been demonstrated.
Aims and Methods: The aim of this study is to assess the rate of BSI in a cohort of patients with CDI treated with FMT or with standard antibiotic therapy. This is a single-centre, retrospective cohort study of patients with CDI treated with FMT either with standard antibiotic regimens (metronidazole or vancomycin or fidaxomicin). The date of first fecal infusion and the starting date of antibiotic treatment were considered as time 0 for the analysis.
Results: At November 2017, 282 subjects (F = 91, M = 171, mean age 74 years) were analysed for this study. Of them, 101 patients (36%) were treated with FMT from healthy donor and 181 (64%) received antibiotic therapy for CDI. No differences were found on demographic and clinical characteristics of the 2 study groups.
47 patients developed a BSI after FMT or standard antibiotic therapy. Compared to those who received antibiotic treatment for CDI, patients in the FMT group had a significant lower risk of overall BSI (21.1% versus 8.9%; $p = 0.008$), fungal BSI (6.6% versus 1%, $p = 0.036$), polimicrobial BSI (6.1% versus 1%, $p = 0.016$). Subjects in the FMT group experienced also a significantly shorter length of hospitalisation compared to those in the antibiotic group (13.4 days versus 29.8 days on average; $p < 0.001$) and a reduced death risk at 60 days (7.7% versus 1%; $p = 0.015$). Adverse events were similar between the 2 groups.
Conclusion: In our cohort, subjects with recurrent CDI treated with FMT experienced a significantly lower incidence of bloodstream infections, a shorter length

of hospitalization and a reduced 60-day risk of death compared to those who received antibiotics. We can argue that a rapid restoration of healthy microbiota in people with CDI treated with FMT could explain the present results. Should these preliminary results be confirmed by prospective, randomized trials, the reduction of BSI in patients with recurrent CDI may be considered an additional relevant benefit of FMT.

P0393 FAECAL MICROBIOTA TRANSPLANTATION: ESTABLISHMENT OF A DONOR STOOL BANK BASED ON TISSUE ACT CRITERIA

A.A Rode[1,2], P Bytzer[1,2], J Engberg[3]

Introduction: Faecal Microbiota Transplantation (FMT) is a promising therapeutic option, especially as a highly effective treatment for recurrent *Clostridium difficile* infection. However, implementing FMT as a treatment in a large-scale setting is very challenging due to safety issues and the need for immediate access to donor faeces.
Aims and Methods: We here describe the establishment of a donor stool bank for FMT in Region Zealand, Denmark.
Stool donors are recruited among blood donors. Donors are asked to donate 5 times within one month. Donors need to go through a screening-questionnaire, a medical consultation and a long list of blood and faecal tests. All this is repeated after the last donation.
Donations are made at home and immediately transported to the lab, where 50 g of filtered faeces are suspended with saline and 20 mL glycerol up to 170 mL before freezing at −80°C, no later than 2 hours after defecation.
A batch number is assigned and all critical material and steps are documented for traceability. All steps and passed lab reports are checked before quarantined material is released for clinical use. Material is stored for up to 1 year.
Procedures are based on the European Tissue Act, although there is currently no legislation on FMT in Denmark.
Results: At establishment, 8 donors were found eligible at the first screening and began donation. Reasons for not consenting were primarily logistic and aesthetic. Reasons for not being eligible were primarily BMI > 25 kg/m^3 or use of antimicrobials within 6 months.
All 8 donors donated 5 times each, each donation yielding 1–6 portions (median 3.5) and thus 86 portions in total. No donors had positive findings in any blood or faeces tests. At the second screening, after the last donation, 1 donor reported use of NSAIDS 2 days prior to a donation - material from this was destroyed (n = 2). No other findings were identified at the second screening. 84 portions were thus released for clinical use.
Conclusion: Recruiting stool donors among active blood donors is very feasible. Establishment of a donor stool bank with frozen pretested material secures effective and immediate access to FMT treatment.

P0394 RISING BURDEN OF DIFFICULT TO TREAT AND MULTI-DRUG RESISTANT ABDOMINAL TUBERCULOSIS IN ASIAN CHILDREN

M Sen Sarma, P.R Tripathi, C.K Thunga, S.K Yachha, A Srivastava, U Poddar
Sanjay Gandhi Postgraduate Institute of Medical Sciences, Pediatric Gastroenterology, Lucknow, India

Contact E-Mail Address: moinaksen@yahoo.com
Introduction: Incidence of tuberculosis (TB) especially multidrug resistant TB (MDR-TB) is steeply rising in developing countries despite efforts for global control. Abdominal MDR-TB is underreported, more so in children. Inaccessible tissue for histopathology or microbiology and poor sensitivity (64%) of molecular techniques from smear-negative, non-respiratory samples limit the confirmation of diagnosis. Hence, the choice of alternative drugs and duration of therapy in MDR-TB are based on clinical ± radiological assessments and drug toxicity profile.
Aims and Methods: We aimed to study the profile and predictors of difficult to treat (DTT-TB) inclusive of MDR-TB patients of all the confirmed cases of abdominal TB. Clinical, laboratory and radiological data of abdominal TB (n = 83) were analysed from 2012–2017. Disease rates of previous years (2000-11) were compared. DTT-TB was defined as 1 of the following: 1) prolonged (>9months) WHO category-1 antitubercular therapy (ATT), 2) MDR-TB (failed WHO category-2 ± category-1 ATT or proven on GeneXpert) requiring second line therapy. DTT-TB was compared with standard ATT (WHO category 1 or 2 responsive of ≤9months duration of therapy) cases.
Results: Of all abdominal TB, MDR-TB was diagnosed in 3 of 38 (8%; 2000-11)[1] and 13 of 83 (16%; 2012-17). An additional 7 of 83 children (2012-17) had prolonged category-1 ATT finally constituting 20 (24%) as DTT-TB. Table 1 shows the comparison of DTT-TB and standard therapy. Overall confirmation of diagnosis (n = 83) was 56 (67%) by microbiology or histology (caseating granuloma), the rest by discriminatory radiological ± laboratory features. Younger age, higher microbiological yield, presence of extra-abdominal, thoracic, and abdominal lymph node involvement and paucity of luminal involvement were significant in DTT-TB than standard therapy. In the DTT-TB group, prolonged ATT (n = 7) was administered for 17.7±5.1 months and MDR-TB (n = 13) for 18±6.9 months. At the end of 18 months, 3 of 13 (23%) MDR-TB were non-responsive to various second line agents and were labeled extended drug resistant TB.
Conclusion: An alarming rise of overall abdominal TB, MDR-TB and extended drug resistant TB is currently encountered in developing countries. MDR-TB is multibacillary and presents as disseminated disease affecting younger age groups*[Table 1: Comparison of difficult to treat TB versus standard therapy TB]*

Introduction: Diagnosing human intestinal spirochetosis (HIS), a colorectal infectious disease caused by *Brachyspira* species bacteria, depends on pathologists finding the so-called fringes on the mucosal epithelial surface. In routine practice, cases in which hematoxylin-eosin (HE) sections raise suspicions of HIS are further examined using Giemsa or silver stain, or immunohistochemistry (IHC). Whether IHC could itself raise suspicion of HIS is unexploited.
Aims and Methods: We aimed to elucidate whether an initial IHC application might increase the proportion of cases considering HIS-suspicious. Focusing on the so-called fringes, we compared HE and IHC (using a polyclonal anti-Treponema pallidum antibody) results in 1 month's consecutive lower GI endoscopic specimens in the pathology department at a single hospital.
Results: Among the 140 individuals examined (M:F = 86:54; 20–94 yrs; median 64 yrs) during the period, 10 HIS-IHC cases (7.1%; M:F = 5:5; 34–75 yrs; median 57 yrs) were diagnosed, while HE pathology found eight HIS-HE cases (so-called fringes were thick and distinct; 5.7%) and 2 possible cases. All 8 HIS-HE cases matched HIS-IHC cases. However, the 2 possible HIS-HE cases were denied by IHC, while another 2 of the HIS-IHC cases were overlooked by HE. In the HIS-IHC cases, so-called fringes were confirmed in 73.9% of the sections. At this time, four HIS-IHC cases have received endoscopy as follow-up for polyps, 1 for ulcerative colitis, 2 for fecal occult blood, and 1 for watery diarrhea.
Conclusion: The hallmark of HIS can be overlooked histologically, and an initial IHC application might find more HIS cases in routine practice.

Introduction: The recommended strategy of the use of colonoscopy after preparation by oral lavage at patients with low-intestinal bleeding identifies the source of bleeding in 25% -40%. The frequency of these sources are significantly different. Incorrect identification of the source of bleeding involves the wrong tactics and volume of treatment. What is more important at low intestinal bleeding: total colonoscopy or search for the true source of the bleeding?
Aims and Methods: Compare the structure identified during colonoscopy sources of lower intestinal bleeding at patients prepared by oral lavage versus patients who performed urgent colonoscopy without bowel preparation.
A randomized cohort study. Included 252 patients admitted from the signs of intestinal hemorrhage in 2006–2015. 118 men, women 134. The average age of the patients was 60.15 ± 15.7 years. In Hosp No 29 colonoscopy was performed at admission without prior preparation of the colon, the patient in Hosp No 1 performed lavage or enema preparation prior to colonoscopy within 24–48 hours of hospital stay.
Results: Significant differences in the structure of intestinal bleeding sources ($\chi 2 = 4.500000$, $p = 0.03390$) are revealed. In patients without bowel preparation the most frequently detected were bleeding diverticula and cancers - 17%, ulcerative colitis - 10%, intestinal bleeding - 16%, upper bleeding - 16%. In preliminary bowel preparation the most often likely causes of bleeding detected were cancers - 22%, ulcerative colitis - 15%, angiodysplasia - 13%. The number of endoscopic findings in bowel preparation was 1.5 times higher against emergency colonoscopy without bowel preparation. The number and structure of the observed changes were significantly different between both groups, and depending on the sex of patients ($\chi 2 = 112.4894$, $p < 0.0000$). There were no complications in both groups. Another aspect of the question consists of the need to use hemostasis methods. In our observations at active bleedings we used hemostasis methods in only 3 patients (1.2%). It not in favor of an early colonoscopy without preliminary preparation of a colon. These data differ from other authors who use a hemostasis in 25% or 40%. Apparently, tactical decisions in favor of using a colonoscopy without bowel preparation should be based on experience of clinic and regional features of nosological forms.
Conclusion: Performing a colonoscopy at an altitude of bleeding without colon preparation is safe, but significantly alters the structure of the true sources (causes) of bleeding. Colonoscopy after preliminary bowel preparation has significantly higher diagnostic capabilities, which complicates the identification of the true source of bleeding. The choice in favor of a colonoscopy without intestinal preparation should be individual.
Disclosure: Nothing to disclose

Introduction: The number of nonagenarians hospitalized for various reasons including acute lower gastrointestinal bleeding (ALGIB) is increasing worldwide.
Aims and Methods: Our aim was to evaluate whether clinical characteristics and outcome in nonagenarians with ALGIB differ from younger patients.
Data from all nonagenarians with ALGIB hospitalized in our hospital over a 7s-year period were compared with those < 90 years old. Hemodynamic resuscitation, management of antithrombotic agents, early colonoscopy following bowel cleansing, capsule enteroscopy and endoscopic hemostasis when needed were the main steps in the management of patients with ALGIB. In cases of hemodynamic instability, emergent CTA was performed with embolization when appropriate.
Results: Data of 32 nonagenarians (91.8 ± 2.1, 90–99) were compared with that of 496 patients <90years (68.8 ± 14.1, 17–89). Nonagenarians were more commonly female (24/32 vs 232/496, $p = 0.003$) with higher serum creatinine levels (1.4 ± 0.8 vs 1.0 ± 0.7, $p = 0.046$) and higher rate of coexisting diseases (32/32 vs 430/496, $p = 0.023$), mainly cardiovascular (23/32 vs 241/496, $p = 0.017$). Proper bowel preparation (25/32 vs 438/496) and endoscopic examination (29/32 vs 477/496) did not differ. The cause of bleeding was not different (mainly diverticula, ischemic colitis and neoplasia in 8, 9 and 4/32 nonagenarians respectively). No significant difference was observed between the 2 groups regarding transfusions (1.1±1.8 vs 0.9±1.9, $p = 0.524$), hospitalization days (5.0 ± 2.6 vs 4.3 ± 3.2, $p = 0.150$), recurrence of bleeding (1/32 vs 36/496, $p = 0.72$), urgent surgical hemostasis (0/32 vs 6/496, $p = 0.69$) and mortality (2/32 vs 11/496, $p = 0.19$).
Conclusion: Despite the age and the higher prevalence of concomitant diseases, management of ALGIBs in nonagenarians should not differ from that of younger patients.
Disclosure: Nothing to disclose

P0398 MANAGEMENT OF ANTITHROMBOTIC AGENTS IN PATIENTS WITH PRESUMPTIVE DIVERTICULAR HEMORRHAGE

A Takasu[1], T Ikeya[1], K Fukuda[1], K Nakamura[1]
[1]*St. Luke's International Hospital, Gastroenterology, Tokyo, Japan*

Contact E-Mail Address: takasuay@gmail.com
Introduction: It has been reported 5~15% of definite diverticular hemorrhage patients experience re-bleeding within 30 days regardless of status of re-initiation of antithrombotic agents. However, about 65% of diverticular hemorrhage patients are diagnosed as presumptive hemorrhage.
Aims and Methods: This study aimed to elucidate risk factors predicting re-bleeding in patients with presumptive diverticular hemorrhage. A total of 231 patients with presumptive diverticular hemorrhage from January 2004 to September 2017 were included retrospectively. The primary outcome was post-endoscopy re-bleeding among patients with presumptive diverticular hemorrhage. Age, sex, past medical history, laboratory results, colonoscopy procedure length, and site of diverticula, as well as use of antithrombotic agents were compared between patient with and without re-bleeding. In addition, among patients with presumptive diverticular hemorrhage using antithrombotic agents, we examined relationship between re-bleeding and when they restart their agents.
Results: 63 (27.3%) patients experienced re-bleeding. Colonoscopy procedure was longer in patients who had re-bleeding afterward (46.8 minutes VS 40.2 minutes $p = 0.01$). None of other variables including use of antithrombotic agents was associated with re-bleeding. 23 (38.1%) of the 63 re-bleeding patients were taking antithrombotic agents. Duration from colonoscopy to re-bleeding in patients taking antithrombotic agents and those not taking was 1.70 and 1.92 days, respectively ($p = 0.23$). In addition, 17 of the 23 re-bleeding patients under antithrombotic agents had their antithrombotic agents re-initiated after the index

re-bleeding, with none of them experiencing another re-bleeding during the follow-up.
Conclusion: Use of antithrombotic agents was not associated with re-bleeding in patients with presumptive diverticular hemorrhage after colonoscopy, potentially indicating the safety of reinitiating antithrombotic agents.

	re-bleedng (n = 63)	non re-bleeding (n = 168)	P-value

Introduction: Faecal Immunochemical Test (FIT) for haemoglobin is widely used in colorectal cancer screening programmes to select those participants with higher risk of neoplasia undergoing to colonoscopy. However excretion of haemoglobin to faeces (fHb) is intermittent and can be due to difference causes other than neoplasia. Moreover, it has been shown that FIT pre analytics have sources of variability and that the concentration of fHb is related with age and gender. For instances, an individual may present a positive result followed by a negative result or vice versa only in a few days.
Aims and Methods: Our hypothesis is that the cumulative concentration of fHb in consecutive rounds might be useful to detect those individuals with high risk neoplasia (HRN), even amongst FIT negative participants. We have evaluated 1771 average-risk participants (50–69 years old) from the Barcelona colorectal cancer screening programme with a negative FIT (< 20 μg Hb/g faeces) in the first and second round and with a positive test in the third round. We have established 3 groups based on the mean fHb concentration of the 2 first rounds (< 4 μg/g; 4–9 μg/g; >9 μg/g). This classification, in combination with gender and age, has been correlated to endoscopic findings. The principal outcome has been HRN defined as colorectal cancer and/or 5 ≥ adenoma / serrated lesions and/or lesion size ≥20 mm.
Results: A multivariate logistic regression analysis identified gender (men: odds ratio [OR], 1.70; 95% confidence interval (CI), 1.30–2.22), and mean fHb concentration of the first 2 rounds (>9 μg/g: OR, 3.08; 95% CI, 2.02–4.70) as independent predictive factors for HRN. Combining these factors, different risk categories have been established. A 6.59-fold (95% CI, 3.80–11.42) higher risk of HRN was found between the 2 extremes categories (see table). The positive predictive value for HRN ranged from 8.8% to 38.9%. Interestingly, negative predictive values for CRC, ranged from 93.1% to 98.5%.
Conclusion: Cumulative fHb concentration together with gender in FIT negative participants could be a useful tool to assess the presence or absence of HRN in subsequent screening rounds and can help in the design of strategies and the management of the programmes to enhance their efficiency.

	Women	Men
<4 μg/g	1 (613)	1.82 [1.26–2.61] p = 0.001 (543)
4–9 μg/g	2.35 [1.51–3.64] P < .001 (222)	3.08 [2.07–4.59] p < 0.001 (266)
>9 μg/g	2.30 [1.10–4.83] P = .027 (55)	6.59 [3.80–11.42] p < 0.001 (72)

P0400 TO IDENTIFY A LOW-RISK GROUP OF INDIVIDUALS WITH IRON DEFICIENCY ANAEMIA WITHOUT GASTROINTESTINAL SYMPTOMS

M Wong, A Bagust, M.P Tanudisastro, D Chiam, A Majumdar, P Saxena, A Kaffes
AW Morrow Gastroenterology and Liver, Department of Gastroenterology, Camperdown, Australia

Contact E-Mail Address: may.wong1@health.nsw.gov.au
Introduction: Iron deficiency anemia (IDA) is one of the most common indications for investigation with gastroscopy and colonoscopy. However, there is a dearth of data on the diagnostic yield of endoscopic evaluation in patients with asymptomatic IDA. Identification of a low-risk subgroup without compromising the diagnosis of clinically significant lesions can have the potential to avoid invasive investigations and reduce burden on endoscopy departments. The aims of this study were:
1) To identify positive predictors of malignancy in patients with IDA.
2) To use the negative predictive values of the above to identify patients who can safely avoid bidirectional endoscopy (BDE) (low probability of significant gastrointestinal malignancy).
Aims and Methods: This was a retrospective study of consecutive subjects who underwent BDE between July 2014 and July 2017 for IDA. Patients with a history of GI bleeding, active gastrointestinal symptoms, and/or signs of overt gastrointestinal bleeding were excluded. Endoscopic findings were documented as presence/absence of a bleeding related lesion. Gastrointestinal neoplasm was the primary outcome. Model discrimination was defined using ROC curves and calibration assessed using the Hosmer-Lemeshow statistic.
Results: A total of 158 patients were included, of whom 94 (59.0%) were female with a median age of 59 years (IQR: 48–71). The mean Hb was 97 g/L (IQR: 80–116). The mean MCV was 79 fL. A total of 6 patients (3.2%) had gastrointestinal malignancy, all of which were colorectal. 50 (31.6%) had a cause for their IDA identified on BDE. 27 patients had causes identified on gastroscopy, 14 patients had causes identified on colonoscopy and 9 patients had causes identified on both procedures. Logistic regression analysis revealed that cancer was almost 3 times more likely to be diagnosed for every 10 years of increased age (OR 2.5, 95%CI 1.1–6.1, p = 0.04) and 51% more likely for every 10g/L reduction in Hb (OR 1.51, 95% CI 1.1–2.3, p = 0.04). When applying an age threshold of greater than or equal to 70, the OR was 6.0 (95% CI 1.1–34.1, p = 0.04). We found that other biochemical variables (such as iron, ferritin and transferrin saturation) and clinical variables (such as presence of weight loss, smoking and family history of gastrointestinal cancer) do not appear to contribute to cancer risk prediction. The statistically significant parameters of age and Hb demonstrate satisfactory calibration (Hosmer-Lemeshow p = 0.96) and similar discrimination (C-statistic 0.93). Using the cut off age of less than 55 and Hb greater than 105, this can exclude all patients with gastrointestinal pathology and malignancy.
Conclusion: Age and serum Hb can provide useful discrimination for significant gastrointestinal pathology in patients with asymptomatic IDA. These findings need further validation in large scale cohorts. In doing so, we can identify patients with a low pre-test probability to reduce the number of low-value investigations in IDA.
Disclosure: Nothing to disclose

P0401 ASSOCIATION OF COLORECTAL CANCERS AND SYNCHRONOUS POLYPS IN A PERIOD OF 15 YEARS: CHANGING PATTERN?

S Vrakas, G Michalopoulos, V Ntouli, K Makris, C Kapizioni, K Milioni, G Koutoufaris, P Kourkoulis, P Giannelis, V Xourgias
Tzaneion General Hospital of Piraeus, Gastroenterology, Piraeus, Greece

Contact E-Mail Address: sbrakas@yahoo.gr
Introduction: Primary tumor location is an important prognostic factor owing to distinct biological features. Moreover right colon polyps are recognised as a cause of interval cancers. Thus characterization of colorectal cancer (CRC) and synchronous polyps has emerged as an important feature of current endoscopic practices.
Aims and Methods: To investigate possible changes in CRC characteristics as well as their association with synchronous polyps in a 15 year period (2000–2015)

	G1: 2001-2005	G2: 2006-2010	G3: 2011-2015
Left colon	153 (71.5%)	177 (64.36%)	189 (62.79%)
Right colon	61 (28.5%)	98 (35.64%)	112 (37.21%)

[table]
All patients with a CRC diagnosis, identified by total colonoscopy in a time frame of 15 years (2000–2015) in a tertiary medical center in Greece, were included in the study. Patients with familial polyposis syndromes were excluded. Data regarding year of diagnosis, location of CRC, sex, presence of synchronous polyps and their location were collected. Patients were categorized in 3 groups according to year of CRC diagnosis: G1 (2000–2005), G2 (2006–2010), G3 (2011–2015). X^2 and t-test were used for statistical analysis.
Results: 790 CRC cases (404 men, 51.1%) and 443 synchronous polyps were identified. CRC was equally diagnosed in men and women throughout the 3 studied periods (p > 0.05). Right-sided CRCs were significantly increased in G3 compared to G1 (37.21% vs 28.5%, p = 0.04), while in G2 compared to G1 the

increase did not reach statistical significance (35.64% vs 28.5%, p = .09). Location of CRC in the 3 different groups is depicted in the table.
Synchronous polyps were more commonly found in the right colon during G3 compared to G2 and G1 (G3 = 40.76% vs G2 = 17.12% vs G1 = 23.14%, $p < 0.0001$). Statistical significance remained even when analyzed separately for sex (females-right colon polyps G3 = 35.94% vs G2 = 2.7% vs G1 = 8.7%, $p < 0.0001$ and males right colon polyps G3 = 42.86% vs G2 = 24.32% vs G1 = 32%, p = 0.019).
Conclusion: Right colon CRCs as well as synchronous right colon polyps are significantly more frequently diagnosed in a single endoscopic center during the last 15 years. This may be due to better colon preparation, use of high definition endoscopes or increased awareness of right colon cancers by gastroenterologists.
Disclosure: Nothing to disclose

P0402 AGE AT MENARCHE AND RISK OF COLORECTAL ADENOMA

S.K Kim[1], N.H Kim[2], J.H Park[1], D.I Park[1], C.I Sohn[1], K Choi[1], Y.S Jung[1]

Introduction: Limited data are available regarding the association between age at menarche and the risk of colorectal adenoma. Therefore, we aimed to evaluate the relationship between reproductive factors including age at menarche and the risk of colorectal adenoma.
Aims and Methods: A cross-sectional study was performed on asymptomatic female subjects who underwent colonoscopy between 2010 and 2014 as part of a comprehensive health screening program in Korea. The association between reproductive factors including age at menarche and the presence of adenomas was assessed using multivariate logistic regression analysis.
Results: Among 32,620 asymptomatic female subjects, the proportion of patients with menarche at 10–11, 12–13, 14–15, 16–17, and 18–19 years of age was 4.1%, 31.7%, 45.4%, 14.9%, and 4.0%, respectively. Age at menarche was not significantly associated with the risk of any adenoma (adjusted odds ratio [AOR], 0.99; 95% confidence interval [CI], 0.97 to 1.02; p = 0.500) and advanced adenoma (AOR, 0.98; 95% CI, 0.91 to 1.04; p = 0.468) after adjusting for confounding factors. Age at menarche was not significantly associated with the risk of adenoma even among the similar age group. In addition, parity, use of female hormones, and menopause were not associated with the risk of adenoma.
Conclusion: Age at menarche, parity, use of female hormones, and menopause were not significantly associated with the risk of colorectal adenoma. Our findings indicate that reproductive factors including age at menarche do not affect the development of colorectal adenoma.

	Any Adenoma		Advanced Adenoma	
Participants' age groups	adjusted odds ratio(95% CI)	p value	adjusted odds ratio(95% CI)	p value
30–34 (years)	1.01 (0.93–1.99)	0.816	0.98 (0.78–1.24)	0.880
35–39	0.94 (0.88–1.00)	0.052	1.04 (0.88–1.21)	0.672
40–44	0.97 (0.92–1.04)	0.403	0.89 (0.75–1.07)	0.231
45–49	1.06 (0.99–1.14)	0.098	1.11 (0.90–1.36)	0.327

P0403 METABOLIC FACTORS, LIFESTYLE HABITS AND AGING ARE ASSOCIATED WITH DEVELOPMENT OF COLORECTAL NEOPLASIA IN JAPAN

N Inoue, K Kashiwagi, T Yoshida, Y Sugino, Y Iwao
Keio University School of Medicine, Center For Preventive Medicine, Tokyo, Japan

Contact E-Mail Address: nagamu@z6.keio.jp
Introduction: For the past decades, the incidence and mortality rate of colorectal cancer (CRC) has been increased in Japan and CRC is the third leading cause of cancer death in Japan. This may reflect economic development and concomitant shifts from traditional lifestyle towards a westernized lifestyle. The association of metabolic syndrome (MetS) and CRC has been reported in several studies, however, individual factors contributing to CRC occurrence have been obscure, especially in Japan.
Aims and Methods: In the present study, we investigated the risk factors such as metabolic and lifestyle factors for the occurrence of colorectal neoplasia (CRN; adenomatous polyp ≥ 5 mm in size and cancer) and advanced neoplasia (AN; advanced adenoma and cancer, ref.) by using comprehensive health checkup data. We conducted a retrospective analysis in clinical practice at a single center. Among 10138 subjects who took comprehensive health checkup at our hospital between in August 2012 and December 2016, 2769 subjects who also underwent screening colonoscopy were enrolled. A diagnosis of MetS was made by Metabolic Syndrome Diagnostic Criteria Exploratory Committee in Japan. Demographic characteristics, anthropometric measurements, visceral fat area (VFA) measured at the umbilical level by CT, hematological metabolic parameters, degree of liver fat evaluated by ultrasonography, and current smoking and drinking habits were assessed. Association between variables and CRN or AN was evaluated by univariate analysis using t-test, X^2 test, Mann-Whitney test, and then by multivariate analysis using multiple logistic regression model. A $p\ value < 0.05$ was considered statistically significant.
Results: Of 2769 subjects analyzed, 327 subjects had CRN (11.8%) and 99 had AN (3.3%). 676 subjects were diagnosed as MetS (24.4%) and presence of MetS was significantly associated with CRN and AN. (p = 0.000, 0.004). Univariate analysis identified significant association of CRN with sex, age, body mass index (BMI), VFA, systolic and diastolic blood pressure (SBP/DBP), low-density lipoprotein (LDL)-cholesterol, triglycerides (TG), fasting plasma glucose (FBS), hemoglobin A1c (HbA1c), fatty liver, smoking habits, drinking habits and ≥ 10 kg weight gain compared with the body weight at the age of 20. Logistic regression analysis revealed that age, BMI, SBP, LDL TG, current smoking and drinking habits were independent factors associated with CRN (Table). Moreover, age, LDL TG and current smoking were recognized as independent factors associated with AN.
Conclusion: The present study demonstrated that metabolic factors, especially dyslipidemia, aging and current smoking were risk factors for development of colorectal neoplasia in Japan.
[Results of logistic regression analyzes]

P0404 COMPARISON OF COLORECTAL POLYPS WITH SIZE BETWEEN 6 AND 20 MILLIMETERS IN YOUNGER AND OLDER INDIVIDUALS

C.-W Chen, W.-R Lin, C.-T Chiu
Linkou Chang Gung Memorial Hospital, Department of Gastroenterology and Hepatology, Taoyuan, Taiwan

Contact E-Mail Address: 8902088@adm.cgmh.org.tw
Introduction: According to the recommendation by the U.S. Multi-Society Task Force on Colorectal Cancer, colonoscopy screening for colorectal neoplasm should be performed for individuals for 50 years old and over. Over the last decades, the incidence and mortality of colorectal cancers (CRCs) in individuals who are 50 or more years old have been decreasing. In contrast, the incidence of CRCs in individuals less than 50 years old has been increasing. Several studies demonstrated that CRCs in older individuals have a different biology compared to younger individuals. However, the data on the characteristics of colon polyp in individuals aged < 50 years is limited.
Aims and Methods: The aim of this study was to investigate the characteristics of colorectal neoplasm in individuals aged < 50 years and to compared them to those of individuals > = 50 years old. From Jan 1, 2015, to Jan 31, 2017, patients

Abstract No: P0403

	for CRN			for AN		
	OR	95% CI	p value	OR	95% CI	p value
Age (per 1 year increment)	1.041	1.029–1.053	0.000	1.051	1.032–1.070	0.000
BMI (per 1 kg/m2 increment)	1.049	1.013–1.086	0.008			N.S.
systolic blood pressure (per 1 mmHg increment)	1.011	1.005–1.018	0.001			N.S.
LDL-cholesterol (per 1 mg/dL increment)	1.009	1.005–1.013	0.000	1.007	1.000–1.014	0.048
triglyceride (per 1 mg/dL increment)	1.001	1.000–1.002	0.028	1.002	1.001–1.003	0.002
current smoking (vs non-smoker)	2.205	1.562–3.113	0.000	1.923	1.114–3.317	0.019
drinking habits (vs those without habits)	1.567	1.216–2.017	0.001			N.S.

who underwent snare polypectomy with polyp's size between 6 and 20 millimeters (mm) were enrolled in this study in a tertiary medical center of northern Taiwan. The demography of patients and the polyp characteristics, including pathological findings, size, morphology and location, were recorded. Descriptive statistics and frequency distributions were calculated. The data were analyzed by using either the Mann-Whitney U test for continuous variables or chi-square test for categorical variables. Statistical significance was defined as $p < 0.05$.
Results: A total of 1925 polyps in 1424 patients were included in this study. There were 323 polyps in 264 patients < 50 years old (younger group) and 1602 polyps in 1160 patients $>= 50$ years old (older group). In the younger group, 183 patients were male (69.3 %), with a median age of 44 years old (range: 19–49 years old). The median size of polyps was 10 mm (range: 6–20 mm) in the younger group. Most polyps in the younger group were in the distal colon (62.8%) and had a sessile shape (83.6%). Compared to the older group, the prevalence of the distal colon polyp and pedunculated polyp was significantly higher in the younger group (62.8% vs. 55.2%, $p = 0.011$; 16.4% vs 12.3%, $p = 0.045$) respectively. In the polyp pathological findings, there were 57 (17.6%) hyperplastic polyps, 20 (6.2%) sessile serrated adenomas, 158 (48.9%) tubular adenoma, 52 (16.1%) tubulovillous adenoma, 6 (1.9%) villous adenoma and 2 (0.6%) high-grade dysplasia in the younger group. In the high-risk polyp subgroup, the prevalence of sessile serrated adenoma and $\geq$10 mm serrated adenoma was significantly higher in the younger group compared to the older group (6.2% vs 2.7%, $p = 0.002$; 3.4% vs. 1.4%, $p = 0.042$) respectively. The prevalence of polyps with high-grade dysplasia was significantly higher in the older group (3.0 % vs 0.6 %, $p = 0.014$). There was no significant difference between both groups in terms of polyps with size $>= 10$ mm and polyps with villous component.
Conclusion: In the polyps with size between 6 and 20 mm, the prevalence of left side colon polyp and pedunculated polyp is significantly higher in patients < 50 years old. In the high-risk polyp subgroup, the prevalence of sessile serrated adenoma is higher in younger group.

Contact E-Mail Address: chen036543@yahoo.com.tw
Introduction: The outcomes of interval colorectal cancer (ICRC) varied in previous studies without accounting for lead time bias.
Aims and Methods: This nationwide cohort analysis estimates expected years of life lost (EYLL) to adjust for lead time bias and comparison between patients with ICRC and detectable colorectal cancer (DCRC). Patients with colorectal cancer (CRC) registered in Taiwan Cancer Registry during 2002 to 2009 were enrolled, including 22,169 CRC confirmed within 6 months after colonoscopy grouped as detected CRC (DCRC) and 1,653 CRC diagnosed during 6–60 months after a negative colonoscopy grouped as ICRC. All patients were followed up until the end of 2011. We simulated age- and sex-matched references from life tables in Taiwan National Vital Statistics using Monte Carlo method. Lifetime survival function of the cancer patients was obtained from extrapolation of logit transform of the survival ratio between cancer cohorts and age- and sex-matched references. The LE (life expectancy) and EYLL were calculated after stratification by genders and tumor stages.
Results: Comparing with DCRC, ICRC were predominantly older age, more on proximal sites, and more endoscopic polypectomy procedures ($p < 0.001$). Patients with ICRC had consistently shorter LEs than those of DCRC after stratification by genders and stages (all $p < 0.001$). There is no such trend if the comparison is performed through EYLL, or, adjustment for age at diagnosis and/or lead time bias. There is a linear trend for increasing proportion of ICRC from distal to proximal colon, which seems to corroborate with different cancer registries internationally.
Conclusion: The evidence corroborates the hypothesis that the worse long-term outcome or shorter LE of ICRC largely results from lead time bias. Improving the quality of colonoscopy and regular surveillance of patients with detected and resected polyp are crucial to reduce ICRC.

Introduction: Cancer stem cells are capable of cell division and survival against cancer therapies, leading to tumor progression and recurrence. The inhibitory agents against cancer stem cells may be efficient for eradicating tumors.
Aims and Methods: This study aimed to uncover the relevant driver genes maintaining cancer stemness in epidermal growth factor receptor (EGFR)-positive colorectal cancer cells, and to discover the efficiently therapeutic agents. EGFR-positive HCT116- and HT29-derived cancer stem-like cells (CSCs) were induced *in vitro* as studying models in this study. RNAseq technique following by bioinformatics analysis was applied to identify the differential genes maintaining CSCs. Moreover, a panel containing 172 therapeutic agents targeting to the documental pathways of stem cells were applied to search for the efficient therapeutics against CSCs.
Results: RNAseq revealed that 654 genes were significantly up-regulated and 840 genes were down-regulated in the HCT16CSCs. Among the genes, notably, plateletderived growth factorA (PDGFA) and signal transducer and activator of transcription 3 (STAT3) were relevant to Pathway in Cancer analyzed by NetworkAnalyst. Furthermore, the therapeutics screening indicated that the agents targeting to STAT3 and Wnt signaling pathways were efficient to reduce the cell viabilities of HCT116 and HT29 cells. Consequently, we figured out that inhibition of STAT3 by its specific inhibitors such as homoharringtonine and knockdown technique significantly reduced the formation and survival of the HT29-derived tumorspheres, whereas STAT3 phosphorylation was majorly regulated by EGF to induce PDGFA and Wnt signaling cascade.
Conclusion: This study demonstrated the potential genes involving in the tumorsphere formation and survival in the selective EGFR-positive colorectal cancers. The data suggested that EGF-STAT3 signaling pathway promoted and maintained the colorectal cancer stemness as a putative therapeutic target, where STAT3 may be through inducing PDGFA to activate Wnt signaling pathway.

[6]*AbbVie Inc., Chicago, United States*

Contact E-Mail Address: isaalr9@zonmail.pt
Introduction: Colorectal cancer (CRC) is the second most common cancer in developed countries. More than a quarter of these patients eventually receive chemotherapy. Several pathways leading to CRC are currently recognized, which may impact on therapy success. Although both short-term culture of tumor sections and xeno-transplantation have been used to determine drug efficacy, there are no available long-term validated models to test chemotherapy in patient-derived cultures, namely in the different carcinogenesis pathways.
Aims and Methods: We aim to develop an efficient methodology for culture of CRC samples originated from different carcinogenesis pathways.
In this prospective study we cultured patient-derived tissue microfragments in stirred-tank culture systems (PDEs) - we studied culture viability (metabolic and morphologic evaluations), phenotype [gland and/or villi formation, mucin production, presence of tumor infiltrating lymphocytes (TILs), p53 staining, mismatch repair protein expression, microsatellite instability] and *KRAS* (exon 2) and *BRAF*V600E mutational status in *in vitro* cultures; we correlated culture progression to the primary tumor features.
Results: 11 CRCs were collected. All tumors were successfully cultured as PDEs for 28 to 122 days. Culture duration was determined by the frequency of sampling along culture time to assure a minimum PDE concentration. PDEs ($N = 11/11$) retained their originals' architecture. There was always viable tumor for at least 28 days (~46 days, range 28–87 days) and for most cases ($N = 7/11$) viable stroma was retained for as long as the neoplastic cells. Capillaries were not preserved. PDEs ($N = 10/11$) considerably lost tumor architectural complexity, stroma cellularity and inflammatory cells, specifically TILs, at the first histological evaluation (days 7–11), but less significantly thereafter. After the first week of culture, PDE tumor cells progressively acquired a senescent phenotype. PDEs ($N = 10/11$) replicate the original tumors' immunohistochemical and genetic key features. One PDE showed a *KRAS* mutation undetected in the primary tumor, from day 0; p53 staining was also consistently different in the PDE. *KRAS* mutated clones seem to be positively selected in culture ($N = 3/5$).
Conclusion: PDE dynamic culture is an efficient method to culture human CRC. Overall the key pathological features of the primary tumors are retained over time, which supports the potential use in drug predictive assays. Divergent results may be due to intratumoral heterogeneity and optimization in tumor collection may be required to improve PDE representation of the primary tumor.

P0408 HDAC6 SELECTIVE INHIBITOR, ACY1215, INHIBIT CELL GROWTH OF COLON CANCER CELL LINE HCT116

Y Tan, S Zhang, J Huo, D Liu
The Second Xiangya Hospital, Central South University, Gastroenterology, Changsha, China

Contact E-Mail Address: tanyuyong@csu.edu.cn

Introduction: Colorectal cancer is the third leading cause of cancer death around the world, and 5-FU is the most common used chemotheraputic drugs for colorectal cancer, however chemoresistence do occur. HDAC6 is a unique member of HDACs, and is involved in regulating diverse key biological processes including cell motility, cell division, protein trafficking, and apoptosis, thus playing important role in carcinogenesis. HDAC6 inhibitors have emerged as promising agents for the treatment of various forms of cancer, and ACY1215, the first oral HDAC6 inhibitor, has showed promising results for treatment of multiple myeloma in phase I and II clinical trials, however little is known about its role in colorectal cancer.

Aims and Methods: We aimed to explore the effect of Rocilinostat (ACY1215), a specific HDAC6 inhibitor, on the cell growth, migration and apoptosis of HCT116 cells, as well as its influence on the chemotheraputic effect of 5-Fluoracil (5-FU) on colon cancer.

Treating HCT116 cells with different concentration of ACY1215, and explore its effect on cell viability, cell proliferation, cell migration and apoptosis, and explore the potential mechanism of ACY1215 via detecting some cell signal related protein by western blot. And them explore the influence of ACY1215 treatment on the chemotheraputic effect of 5-FU.

Results: 1. After treating HCT116 cells with ACY1215, the cell viability, colony formation, wound closure and migrated cell numbers were significantly reduced with the increasing concentration of ACY1215, and the propotion of apoptosis cells were significantly increased with the increased concentration of ACY1215 ($p<0.05$), as well as the expression of apoptosis-related protein (PARP and Cleaved-Caspase 3). After treating HCT116 cells with ACY1215, the expression of p-MEK and p-ERK were decreased, while no obvious changes were noticed regarding the expression of MEK and ERK. Treating HCT116 cells with ACY1215 and/or 5-FU, we found that the cell viability, colony formation, wound closure and migrated cell numbers were significantly reduced when comparing control with single drug, or comparing single drug with combined drugs ($p<0.05$). The same tendency was noticed in regarding to the expression of apoptosis related protein (PARP and Cleaved-Caspase 3).

Conclusion: HDAC6 specific inhibitor, ACY1215, could inhibit the cell growth, proliferation and migration, and promote apoptosis of HCT116 colon cancer cells. ACY1215 exibits its tumor suppression role via inhibition of the MEK/ERK signal pathway. ACY1215 may enhance the chemotheraputic effect of 5-FU on colon cancer cells.

Introduction: Colorectal cancer (CRC) is extremely rare in pediatric patients. A poor outcome has been reported in parallel with unfavorable prognostic factors.

Aims and Methods: We aimed to characterize at clinical, pathological and molecular level a group of pediatric CRC patients (< 18 years) - and evaluate overall and disease-free survival.

Included pediatric CRC patients diagnosed from January 2002 to January 2016. Clinical data, tumor features, and survival were evaluated.

Microsatellite instability (MSI) status, loss of heterozygosity for the dinucleotide Bethesda microsatellite markers and expression of the DNA mismatch repair (MMR) proteins were analyzed. Germline mutation analysis was performed for a multigene panel of 94 genes associated to increased cancer risk (including genes associated to CRC hereditary syndromes), using next generation sequencing and MLPA.

Results: 5 patients were included, 3 of them males, mean age at diagnosis 14.2 years (9–17 years). 4 out of 5 had family history of cancer in 2nd degree relatives: 2/4 corresponded to CRC (in 1/2 the parents had consanguinity), whereas the remaining 2 corresponded to other cancers. 4 out of 5 CRC were located in the right colon. Regarding histology subtype, 2/5 (40%) were mucinous with signet ring cells, 1 had signet ring cells, and 2 had no other specification (NOS). Lymphovascular invasion was present in 4/5 (80%) and perineural invasion in 3/5 (60%) of them. "*Crohn-like*" lymphoid reaction and tumor budding was not observed. All tumors were ≥ pT3N2.

Patients had a mean follow-up of 5.6 years (10 months to 14 years). 1 patient recurred after 15 months and 2 (40%) died after 24 and 10 months. A likely pathogenic germline mutation was identified in only 1/5 patients (heterozygous *MSH2* mutation), although not explaining by itself the diagnosis of CRC at pediatric age.

All CRC analyzed (n = 4) were microsatellite stable (MSS) and/or expressed all MMR proteins. Three CRC were analyzed for Bethesda microsatellite markers and one showed LOH for the 3 dinucleotide markers (chromosomes 2p, 5q and 17p), suggesting the presence of chromosomal instability. This 4 corresponded to the patient diagnosed at an earlier age (9 years), without any family history of cancer, presenting a NOS tumor.

Conclusion: Pediatric CRC presented with advanced disease and had a poor prognosis, however, its molecular cause(s) need yet to be clarified. These CRCs had distinct histological and molecular presentations, resembling features from different carcinogenic pathways, thus suggesting a heterogeneous nature.

Disclosure: Nothing to disclose

P0410 CANCER-ASSOCIATED FIBROBLASTS PROMOTES COLORECTAL CANCER THROUGH SECREATION OF TNFSF4 AND IGF2

Introduction: As an essential part in stromal cells, cancer-associated fibroblast (CAF) plays an important role in the tumor microenvironment and exerts promoting effect in colorectal neoplastic progression. However, the detailed molecular mechanism is elusive.

Aims and Methods: In this study, we proposed to reveal the oncogenic role of CAF in colorectal cancer (CRC) progression. The primary culture was employed for isolation of CAF and adjacent normal fibroblast (NF). The CRC cells were treated with conditional medium (CM) from NF and CAF for the assessment of cell proliferation rate and invasion ability. RNA-Seq analysis was applied to identify the differentially expressed genes in 3 paired NF and CAF samples. The candidate genes were validated by qRT-PCR in 18 paired primary samples and 2 top genes, TNFSF4 and IGF2, were selected for functional studies.

Results: In primary culture, CAF-produced CM exhibited oncogenic function through promoting CRC cell proliferation and invasion. TNFSF4 and IGF2 were screened out showing the highest expression in CAFs compared with NFs with 14 and 12-time upregulation respectively. qRT-PCR confirmed the abundance of TNFSF4 ($p < 0.001$) and IGF2 ($p = 0.006$) in CAF. Immunohistochemistry staining on the tissue microarray demonstrated that TNFSF4 was predominantly expressed in fibroblasts but IGF2 was located both in the cancer cells and fibroblasts. Their receptors, OX40 and IGF1R were expressed in immune cells and cancer cells respectively. In the functional studies, both rhIGF2 and IGF2 CM promotes CRC cell proliferation and invasion *in vitro*.

Conclusion: In colorectal CAF, TNFSF4 and IGF2 are abundantly expressed, whose secretion plays oncogenic role through promoting CRC growth. CAF enhances CRC progression via immune suppression and direct influence on tumor cells. Our study not only revealed novel mechanisms for the CAF in tumorigenesis but also provided a rational therapeutic strategy.

Introduction: Serrated adenocarcinoma (SAC) is one of several end-points of the serrated neoplasia pathway progression pattern. Although SAC prognosis is not widely recognized, the serrated pathway-associated subtype consistently exhibits unfavorable prognosis in genetic studies.

Aims and Methods: The aim of this study was to classify molecularly distinct subtypes for serrated carcinomas and clarify their associated clinicopathological characteristics and genetic changes.

We examined 38 early-stage colorectal SACs from 1142 consecutive patients (895 with Tis and 247 with T1 carcinoma) who were treated at Hiroshima University Hospital between January 2009 and January 2016. Of these, 24 were classified into 3 molecularly distinct groups by colon cancer subtyping (CCS) (De Sousa de Melo et al., Nat Med 19, 2013). Clinicopathologic characteristics, Ki 67 labeling index (LI), and SAC epithelial serration were assessed. DNA from carcinomas and normal tissue/adenoma was extracted using laser microdissection, sequenced by next generation sequencing, and mutation number and pattern for a 15-oncogene panel were determined.

Results: CCS groups included CCS1: CDX (+) and MSI-L/MSS (14 cases), CCS2: MSI-H (5 cases), and CCS3: CDX (−) and MSI-L/MSS (5 cases). Invasive cancer was significantly higher in CCS3 than CCS1 (CCS1:CCS3, 3/14:5/5, $p = 0.0048$). Ki67 LI and epithelial serration were higher in CCS3 than in CCS1 (CCS1:CCS3, 65.4 ± 4.0: 83.0 ± 5.8, 3/14:5/5, $p = 0.0048$, 0.031). CCS2 showed the highest mutation number, whereas *KRAS* and/or *BRAF* mutation number were higher in CCS3 than CCS1 (2/14 vs. 4/5, $p = 0.038$).
Conclusion: Early-stage SACs can be classified into 3 molecularly distinct subtypes with different clinicopathological and genetic characteristics.

P0412 MBD2 AND EZH2 REGULATE SFRP1 EXPRESSION WITHOUT AFFECTING ITS HYPERMETHYLATION IN COLORECTAL CANCER CELL LINE

J Qi, J Yu
Zhongnan Hospital of Wuhan University, Wuhan, China

Contact E-Mail Address: qiqidelizi@163.com
Introduction: The Secreted frizzled related proteins 1 (SFRP1) as extracellular inhibitors of Wnt signaling is downregulated by high frequency of promoter hypermethylation in the early stage of colorectal tumorigenesis. PCG proteins and MBD proteins important for gene epigenetic regulation have the ability to regulate gene expression. We aim to figure out the role of the specified PCG and MBD proteins in the regulation of SFRP1 gene expression.
Aims and Methods: The methylation status and mRNA expression of SFRP1 in CRC cell lines and human embryo intestinal mucosa cell CCC-HIE-2 are analyzed by Methylation-specific PCR (MSP) and real-time qPCR. The combination of PCG proteins, MBD proteins with SFRP1 gene is studied and the related proteins are screened by chromatin immunoprecipitation (ChIP). We knock down related genes by RNA interference to clear its role in the regulation of SFRP1 gene expression and the effect on proliferation of colorectal tumor cells.
Results: The promoter of SFRP1 was completely methylated in CRC cell lines, and partly methylated in normal cell line CCC-HIE-2. The mRNA expression level of SFRP1 was down-regulated significantly in CRC cell lines compared to CCC-HIE-2 ($p < 0.05$). SFRP1 promoter region was enriched with EZH2 in CCC-HIE-2 ($p < 0.05$) and it was enriched with EZH2 and MBD2 in SW480 ($p < 0.05$), but none of BMI1, EZH2 and MBD2 proteins bound to SFRP1 in HCT116 ($p > 0.05$). The expression of SFRP1 is reactivated by MBD2 siRNA ($p < 0.05$), but not by EZH2 siRNA in SW480 ($p > 0.05$). However, knockdown the MBD2 and EZH2 together can restore SFRP1 gene expression more effectively and inhibit the proliferation of SW480. All of those inhibitions cannot change the status of SFRP1 promoter methylation.
Conclusion: MBD2 and EZH2 regulate SRPF1 expression without affecting the hypermethylation of SFRP1 in colorectal cancer cell line, they may regulate the SFRP1 expression through other mechanisms system which need further research.

P0413 IDENTIFICATION OF NOVEL THERAPEUTIC TARGETS IN THE TUMOR MICROENVIRONMENT OF COLORECTAL CANCER

E Yamamoto, A Yorozu, H Aoki, H Suzuki
Sapporo Medical University, Dept. of Molecular Biology, Sapporo, Japan

Contact E-Mail Address: eiichiro@xa3.so-net.ne.jp
Introduction: Cancer microenvironment, including tumor endothelial cells (TECs) and cancer associated fibroblasts (CAFs), plays an important role in the pathogenesis of cancer and is considered as a potential therapeutic target.
Aims and Methods: We aimed to understand the molecular mechanism of microenvironment of colorectal cancer (CRC) and to identify novel therapeutic targets. To this end, we isolated stromal cells in primary CRC and performed transcriptome analysis. Stromal cells and epithelial cells from surgically resected primary CRC ($n = 14$) and corresponding normal colonic tissues ($n = 14$) by using CD146 and EpCAM as markers. RNA sequencing (RNA-seq) was performed in 3 pairs of normal and tumor stromal cells. Expression of the gene was validated by quantitative RT-PCR (qRT-PCR) and immunohistochemistry. To analyze the gene function, human umbilical vein endothelial cells (HUVECs) and culturedCAFs were transfected with specific siRNAs after which cell viability assay and gene expression microarray were performed.
Results: RNA-seq analysis identified a series of 18 genes upregulated in tumor stromal cells isolated from primary CRC tissues. Through validating the results by qRT-PCR and immunohistochemistry, we identified AEBP1, as a novel candidate of CRC stroma-related gene. AEBP1 is expressed in TECs and CAFsin CRC tissues, and that the expression was higher in the invasive front. The Cancer Genome Atlas (TCGA) datasets revealed that higher expression of AEBP1 is associated with worse overall survival of CRC patients. Expression of AEBP1 was also upregulated in HUVECs treated with TCM obtained from CRC cell lines. Knockdown of AEBP1 in HUVECs suppressed *in vitro* tube formation. Knockdown of AEBP1 in HUVECs and CAFs suppressed cell proliferation and induced G1 cell cycle arrest. Microarray analysis revealed that knockdown of AEBP1 in HUVECs significantly affected the expression signature of angiogenesis-related genes including AQP1 and POSTN1. To confirm our findings *in vivo*, we co-transplanted CRC cells with HUVECs into nude mice. We found that knockdown of AEBP1 in HUVECs resulted in reduced micro vessel formations in the xenograft tissues. Moreover, we found that injection of siRNAs targeting mouse AEBP1 suppressed *in vivo* tumor growth.
Conclusion: Our results suggest that AEBP1 may play an important role in the microenvironment in CRC, and that it could be a potential therapeutic target.

Introduction: The quantitative fecal immunochemical test (FIT) is a non-invasive biomarker for the early detection of colorectal cancer (CRC). Recently, the National Institute for Health and Care Excellence (NICE) has recommended the adoption of FIT in primary care to guide referral for suspected colorectal cancer in people without rectal bleeding who have unexplained symptoms but do not meet the criteria for a suspected cancer pathway referral (1).
Aims and Methods: Our goal is to assess the diagnostic accuracy of FIT for CRC detection in symptomatic patients.
2 searchers independently reviewed online databases including MEDLINE, EMBASE expanding the search to bibliography and authors of relevant studies. All studies evaluating the diagnostic accuracy of quantitative FIT for CRC in symptomatic patients until May 2017 were included.
Studies were classified by FIT threshold, brand, percentage of symptoms and CRC prevalence. Quality of studies was evaluated, and global sensitivity and specificity were estimated in addition to the ROC curve (sROC) taking the area under the curve (AUC) as a global precision estimator in those subgroups formed by at least three studies, using a random effect model. Heterogeneity was determined by means of the Q statistic of Cochran. Threshold effect was examined by calculating Spearman's rank correlation.
Results: 13 studies were included in our review accumulating a sample of 12,584 patients (52% women). Data from 7 cohorts were obtained for patients scheduled consecutively to undergo elective colonoscopy due to several indications, with their CRC prevalence ranging from 0.4 to 7.1%. The remaining 6 were carried out on purely symptomatic patients with CRC prevalence ranging from 2.3 to 16.8%.
The pooled sensitivity for CRC detection of OC-Sensor® at the 0, 10 and 20 μg/g of feces was 98% (95% confidence interval CI 96–99%), 91% (95% CI 88–93%) and 90% (95% CI 87–93%), respectively. Conversely, pooled specificity at the same thresholds was 36% (95% CI, 34–37%), 80% (95% CI 79–81) and 83% (95% CI 83–84%). At the threshold with the best discriminatory ability (20 μg/g of feces) the AUC was 0.93 (95% CI, 0.91–0.96).
The number of available studies performed with the OC-Sensor® allowed for the conduct of a subgroup analysis based on the prevalence of CRC and the percentage of symptoms at the 10 μg/g cut-off. Pooled sensitivities were higher in the studies reporting a CRC prevalence ≥3% (92%, 95% CI; 89–94%) and in those performed only on a symptomatic population (94%, 95% CI, 91–97%); Conversely, the test's specificity in those subgroups was 70% (5% CI; 68–71%) and 66% (95% CI; 64–67%) respectively.
3 studies using OC-Sensor® with the same threshold identified 79% (95% CI; 76–81%) of patients with significative colonic lesions (SCL), with a 70% (95% CI; 68–72%) specificity, respectively.
Only 3 studies evaluated HM-Jack® at different thresholds. The AUC was 0.88 (95% CI, 0.77–0.98). There was substantial heterogeneity between studies specially in the pooled specificity estimates.
Conclusion: The quantitative FIT is highly sensitive for CRC detection in symptomatic patients. However, its global accuracy may depend on the prevalence of another SCL. Caution is recommended when using it to rule out CRC in this setting.
Disclosure: The work described in this abstract has been previously presented as an oral presentation at a spanish scientific meeting (Asociación Española de Gastroenterología) in Madrid in March 2018.

Introduction: The quantitative immunochemical fecal occult blood test (FIT) has proved its worth on both CRC screening and in the timely assessment of patients with symptoms of lower bowel disease (1). However, its use in routine clinical practice remains unknown, as does its accuracy to detect CRC in this setting.

Aims and Methods: Our purpose is to describe the use of FIT in 2 Spanish regions and estimate its accuracy in real practice, in order to consider whether or not it is comparable to theoretical values.

Retrospective observational study with long-term follow-up. We included all subjects from the metropolitan area of San Sebastian (SS) and the province of Ourense (Ou) who had been performed a FIT determination (OC-Sensor®) requested at their primary care center between January 2009 and May 2015. CRC diagnosis was determined in the following 2 years using discharge information obtained from the national surveillance system for hospital data, Conjunto Mínimo Básico de Datos (CMBD), provided by the Ministry of Health. Global accuracy for detecting CRC was assessed by means of the receiver operating characteristics (ROC) curve and its area under the curve (AUC). Sensitivity and specificity were calculated using 10 and 20 μg/g feces as thresholds. Subgroup analysis were conducted using 10 μg/g cut-off to assess differences between center, age, sex and test indication (CRC screening / symptom evaluation).

Results: During the studied period, at least 1 FIT determination was requested to 22,819 patients (54.1% women). 5,265 people were from SS and 17,554 from Ou with significant differences with regard to age (SS = 60.4±16.3, Ou = 64.9±16.1; $p < 0.001$) and CRC prevalence (SS = 1.1%, Ou = 2.1%; $p < 0.001$). The reason for requesting the test was available for SS subjects (53.9% symptom evaluation). Overall, the AUC of FIT to detect CRC was 0.85 (CI 95% 0.84–0.87). Sensitivity and specificity at the 10 and 20 μg/g cut-offs were 91% (CI 95% 87.6–93.5) vs 88% (CI 95% 84.3–90.9) and 77.8% (CI 95% 77.2–78.4) vs 85.2% (CI 95% 84.7–85.8) respectively.

With regard to subgroup analysis, no differences were found in sensitivity between regions (SS 85.0, CI 95% 73.9–91.9, Ou 91%, CI 95% 87.6–93.5; $p = 0.15$), sex (men 90.5%, CI 95% 86.5–93.5, women 89.5% CI 95% 83.6–93.4; $p = 0.72$), age ('< 50y' 85.0%, CI 95% 64.0–94.8, '50–79y' 91.2%, CI 95% 87.3–94.0, '>79y' 88.7%, CI 95% 82.2–93.0; $p = 0.53$) or test indication (symptom evaluation 85.7%, CI 95%70.6–93.7, screening CRC 81.8%, CI 95% 61.5–92.7; $p = 0.70$).

Specificity was different between all analyzed subgroups except for test indication (SS 89.6%, CI 95% 88.8–90.4, Ou 77.8%, CI 95% 77.2–78.4; $p < 0.01$); (men 79.0%, CI 95% 78.2–79.8, women 81.9%, CI 95% 81.2–82.5; $p < 0.01$); ('< 50y' 87.6%, CI 95% 86.6–88.5, '50–79y' 80.5, CI 95% 79.9–81.2, '>79y' 71.7%, CI 95% 70.3–73.2; $p < 0.01$); (symptom evaluation 89.5%, CI 95% 88.3–90.6, CRC screening 89.7%, CI 95% 88.3–90.9; $p = 0.84$).

Conclusion: This analysis confirms the high diagnostic accuracy of FIT for the detection of CRC in routine clinical practice for both studied areas, no matter of age, sex nor the test indication.

Disclosure: The work described in this abstract has been previously presented as an oral presentation at a spanish scientific meeting (Asociación Española de Gastroenterología) in Madrid in March 2018.

Introduction: Effective colonoscopy requires successful bowel preparation. 'Adequate' preparation allows detection of lesions >5mm and has been defined as a Boston Bowel Preparation Scale (BBPS) score of ≥2 per segment. This post hoc analysis determined the relationship between BBPS scores and adenoma and polyp detection rates in patients who had identical scores in each of the 3 colon segments, using pooled data from 3 identically designed Phase 3, multicentre, randomised trials.

Aims and Methods: Analysed patients had: treatment-blinded central reader assessed BBPS scores where the BBPS score was identical in each segment; and recorded polyp and adenoma counts. Patients were stratified to assess the relationship between low-quality cleansing (BBPS of 1+1+1), adequate cleansing (BBPS of 2+2+2) or high-quality cleansing (BBPS of 3+3+3), and ADR and PDR. A logistic regression (LR) model was fitted to assess whether ≥1 polyps and, separately, ≥1 adenomas, were detected including the BBPS score group and study as fixed effects.

Results: 1170 patients were analysed (Table 1). For low, adequate and high-quality cleansing, the PDRs were: 40.7%, 41.7%, 54.8%, and the ADRs were: 27.8%, 26.0% and 42.8%. The odds ratio (OR) for detection were significantly higher with high-quality versus adequate cleansing (PDR OR: 1.60, 95% confidence interval [CI] 1.14–2.24, $p = 0.0067$; ADR OR: 1.97, 95% CI 1.39–2.80, $p = 0.0001$). LR analysis revealed a significant correlation between BBPS score and PDR ($p = 0.0239$) and ADR ($p = 0.0006$).

Conclusion: In patients who had uniform low, adequate or high-quality cleansing in each respective colon segment, there was a strong correlation between higher cleansing scores and increased PDR and ADR.

[Table 1. PDR and ADR by uniform BBPS score]

Introduction: Effective colonoscopy requires successful bowel cleansing. The bowel preparation NER1006 was assessed in 3 identically designed randomised phase 3 clinical trials. These trials used validated cleansing scales and treatment-blinded central readers for a standardised cleansing quality assessment. This post hoc analysis assessed the relationship between colon cleansing quality using the Harefield Cleansing Scale (HCS), and overall colon detection rates for adenomas (ADR) and polyps (PDR).

Abstract No: P0416

Overall colon lesion detection rates	High-Quality (N = 166)	Adequate (N = 950)	Low-Quality (N = 54)	Odds ratio High-Quality: Adequate (95% CI) [P-value]	Odds ratio Adequate: Low-Quality (95% CI) [P-value]
PDR, n (%)	91 (54.8)	396 (41.7)	22 (40.7)	1.60 (1.14–2.24) [0.0067]	0.90 (0.50–1.60) [0.7104]
ADR, n (%)	71 (42.8)	247 (26.0)	15 (27.8)	1.97 (1.39–2.80) [0.0001]	0.75 (0.39–1.43) [0.3829]
LR Analysis of Association between Uniform BBPS Score Group and PDR, P-value	0.0239				
LR Analysis of Association between Uniform BBPS Score Group and ADR, P-value	0.0006				

Abstract No: P0417: Table 1. Uniform segmental HCS scores vs lesion detection rates

	0/0/0/0/0 N = 4	1/1/1/1/1 N = 10	2/2/2/2/2 N = 379	3/3/3/3/3 N = 37	4/4/4/4/4 N = 39
ADR, n (%)	0	1 (10.0)	97 (25.6)	12 (32.4)	21 (53.8)
PDR, n (%)	0	3 (30.0)	164 (43.3)	19 (51.4)	24 (61.5)
Logistic regression analysis of the trend for uniform HCS scores vs ADR: Odds ratio (95% CI) [P-value]	1.61 (1.182–2.199) [0.0026]				
Logistic regression analysis of the trend for uniform HCS scores vs PDR: Odds ratio (95% CI) [P-value]	1.38 (1.021–1.863) [0.0361]				

Aims and Methods: Patients aged 18–85 years were included if they had fully reported HCS scores, adenoma and polyp counts, and also identical segmental HCS scores (range 0–4) in all 5 HCS colon segments. A logistic regression analysis examined the odds ratio (OR), 95% confidence interval (CI) and p-value (p) for the resulting trend in lesion detection, when segmental HCS scores increased incrementally from 0 to 4.
Results: 469 patients were included in this analysis (Table 1). When uniform segmental HCS scores were increased from 0, 1, 2, 3, and 4, the resulting ADRs increased continuously (0%, 10.0%, 25.6%, 32.4% and 53.8%) as did the PDRs (0%, 30%, 43.3%, 51.4%, and 61.5%). The corresponding OR (CI) and [P] were, for ADR 1.61 (1.182–2.199) [0.0026], and for PDR 1.38 (1.021–1.863) [0.0361].
Conclusion: ADR and PDR increased continuously with improved colon cleansing quality. There was a strong association between uniform segmental HCS scores and both ADR and PDR.

Introduction: Colorectal cancer (CRC) is the third main cause of cancer mortality. Around 75% of CRC are sporadic and they usually develop without symptomatology. Therefore, some countries are implementing CRC national screening politics in order to detect lesions at an early stage by using non-invasive tools. One of the most common tools is the faecal immunochemical test (FIT). Despite affordability, FIT shows a low sensitivity for precancerous lesions (29%) and a low positive predictive value (8%), which produces a high rate of false positive results. Hence, CRC-screening organizations are demanding new, non-invasive tools, capable of decreasing false positive rates, thus reducing the number of unnecessary colonoscopies. The aim of this study was to develop a new, non-invasive CRC screening tool based on bacterial faecal markers, which in combination with FIT (hereby named RAID-CRC), could reduce the false-positive rate.
Aims and Methods: We performed the FIT analysis (OC-Sensor® Kit) and the bacterial markers analysis (CRC1-CRC10) in stool samples from individuals with normal colonoscopy (167), non-advanced adenomas (88), advanced adenomas (30) and CRC (48). All participants showed CRC-associated symptoms. The RAID-CRC algorithm was designed using machine learning technology.
Results: Performance of FIT for advanced neoplasia (i.e. advanced adenoma and CRC) was determined by using the cut-off value established in Catalonia (OC-Sensor®, 20 μg Haemoglobin/g of faeces) for a population-based screening approach. Sensitivity and specificity values of 83% and 80%, respectively, and positive and negative predictive values of 56% and 94%, respectively, were obtained. When RAID-CRC was used, the corresponding values were 80% and 90% for sensitivity and specificity, respectively, and 70% and 94% for positive and negative predictive values, respectively, resulting in a 50% reduction of the false-positive rate.
Conclusion: RAID-CRC is a promising tool for CRC screening because of its non-invasiveness, its low cost and its capacity for lowering the number of false-positive results associated with the use of FIT. Therefore, RAID-CRC use would lead to a reduction up to 30% of unnecessary colonoscopies and their derived costs. However, since our study was performed in symptomatic individuals, this new approach warrants to be validated in a screening scenario.

P0419 CLINICAL AND PATHOLOGICAL OVERLAP AMONG THE HAMARTOMATOUS POLYPOSIS SYNDROMES CAN RESULT IN ERRONEOUS DIAGNOSIS

O Gilad, G Rozner, S Aharon-Kaspi, N Fliss -Isakov, N Gluck, R Kariv
Tel Aviv Sourasky Medical Center, Tel Aviv, Israel

Contact E-Mail Address: ophir.gilad@gmail.com
Introduction: Hamartomatous polyposis-syndromes (HPS) are a group of rare autosomal-dominant syndromes, associated with hamartomatous polyps and gastrointestinal (GI) tract malignancies, including- Juvenile polyposis (JPS), Peutz-Jeghers syndrome (PJS) and Cowden disease (CD). There is a known clinical and histological overlap between syndromes. Appropriate diagnosis dictates cancer preventing surveillance for the proband and family carriers. Yet, more than 50% of clinically diagnosed cases have no genetic diagnosis.
Aims and Methods: We aimed to describe phenotype, genotype, histology and outcomes of individuals/families with HPS, study overlap between syndromes and erroneous diagnosis according to genetic findings.
Retrospective cohort-study of consecutive HPS patients. Demographic, clinico-pathological and genetic data were obtained from computerized-medical-records.
Results: 52 individuals from 34 families were included. Phenotypic, oncologic and genetic findings of the 3 syndromes are described in Table 1.
Clinical manifestations included mainly rectal bleeding (40% JPS, 23% PJS, 25% CD) and bowel obstruction (46.15% PJS, 11.4% JPS). Pathological report varied widely, with 75% of JPS, 61% of PJS and 50% of CD having a polyp diagnosis different from the syndrome hallmark, with some patients having up to 6 different types of polyps. Overall 22/52 (42.3%) of patients had a histological diagnosis of adenoma during follow up (48.5% of JPS, 38.4% of PJS and 25% of CD). 4 patients had an initial incorrect diagnosis, with subsequent review of pathology and genetic testing unveiling the correct syndrome. Gastrointestinal cancer history was positive in 65%, 40% and 50% of JPS, PJS and CD families, respectively. 5 patients developed cancers (2 gastrointestinal, 1 thyroid, 1 breast and 1 with both breast cancer and liposarcoma of the chest). 18 (34.6%) patients tested positive for mutations in either STK11, PTEN, SMAD4 or BMPR1A. 2 additional patients were found to harbour novel gene mutations in AKT1 and TM7SF3. Sanger sequencing had a positive detection rate of 45.4% while next generation sequencing (NGS) had a 100% detection rate.
Conclusion: HPS present versatile phenotypes with apparent redundancy in histological diagnosis, requiring pathology review. Cancer rates are low at this cohort, potentially due to the young mean age. The NGS era should shed light on further candidate-genes and genetic alterations in order to better understand cancer related mechanisms and prevent malignancy.

P0420 ERCC6L PROMOTES CELL GROWTH AND INVASION IN HUMAN COLORECTAL CANCER

Y Xie, J Yu, F Wang, M Li, Y Liu, **J Qi**
Zhongnan Hospital of Wuhan University, Gastroenterology, Wuhan, China

Contact E-Mail Address: qijian@whu.edu.cn
Introduction: Excision repair cross-complementation group 6 like (ERCC6L), a newly discovered DNA helicase, has been discoverd highly expressed in diverse human cancers. However, the precise role of ERCC6L in colorectal cancer (CRC) remains unclear.
Aims and Methods: This study aimed to explore the potential role of ERCC6L in the development and progression of CRC. Real-time quantitative polymerase chain reaction (qRT-PCR) and western blot were used to detect the expression of ERCC6L in 30 colorectal cancer patients. 9 pairs of CRC tissues were examed

Abstract No: P0420: Table 1. Phenotypic, oncologic and genetic findings of HPS carriers

	JPS	PJS	CD	Total
Number of families	20	10	4	34
Number of patients	35	13	4	52
Mean age at diagnosis	23.9	24.6	42.6	25.3
Main polyp location	Colon and rectum	Small intestine	Stomach, small intestine and colon	
Cumulative polyp number - dozens	15 (42.8%)	7 (53.8%)	2 (50%)	25 (46.1%)
Cumulative polyp number - hundreds	3 (8.5%)	2 (15.3%)	0	5 (9.6%)
Patients with max polyp size <1 cm	8 (22.8%)	1 (7.69%)	2 (50%)	11 (21.1%)
Patients with max polyp size >4 cm	8 (22.8%)	4 (30.7%)	0	12 (23.07%)
Mutations found (no. of patients/families)	11/7	6/4	3/3	20/14

by immunohistochemistry. The function of ERCC6L in cell proliferation, cycle, apoptosis, invasion and colony-forming ability was examined in CRC cell lines.
Results: ERCC6L was highly expressed in CRC tissues and CRC cell lines. The expression of ERCC6L was related to tumor size, but not to other clinical features such as age, gender, differentiation and clinical stage. we found that silencing of ERCC6L by small interfering RNA (siRNA) remarkably inhibited the proliferation rate and colony-forming ability of CRC cell lines. Flow cytometry analysis shown that knockdown of ERCC6L in CRC cells blocked the cell cycle progression and more cells were delayed in G0/G1 phase without affecting apoptosis. Moreover, knockdown of ERCC6L remarkably decreased the invaded number of CRC cells compared with the cells treated with negative control.
Conclusion: Our results suggest that ERCC6L can stimulate cancer cell proliferation by promoting cell cycle progression, and it may be a potential target for cancer therapy.

Introduction: A simple, low invasive test with high sensitivity for both colorectal cancer and advanced precancerous lesions might increase uptake and adherence rates, which could improve clinical outcomes. Thanks to the technological advances, these days metabolomics technology offers a powerful tool for biomarker discovery.
Aims and Methods: In this study we have performed a targeted ultra-performance liquid chromatography/time-of-flight mass spectrometry (UPLC-(TOF) MS)-based metabolomics approach to identify faecal biomarkers for the detection of patients with advanced neoplasia. A cohort of 80 patients with advanced neoplasia (40 advanced adenomas and 40 cancers) and 49 healthy subjects were analyzed in the study. We evaluated the faecal levels of 105 metabolites including glycerolipids, glycerophospholipids, sterol lipids and sphingolipids.
Results: We found a panel of 18 metabolites that were significantly altered in patients with advanced neoplasia compared to healthy controls. Combinations of seven of these metabolites including ChoE(18:1), ChoE(18:2), ChoE(20:4), PE (16:0/18:1), SM(d18:1/23:0), SM(42:3) and TG(54:1) were employed to construct a predictive model that provide an area under the curve (AUC) value of 0.821. Furthermore, the levels of the cholesteryl esters correlated positively with the faecal haemoglobin concentration and its inclusion in the metabolomics signature improved the predictive model to an AUC of 0.885.
Conclusion: Faecal levels of ChoE(18:1), ChoE(18:2), ChoE(20:4), PE (16:0/18:1), SM(d18:1/23:0), SM(42:3) and TG(54:1) discriminated advanced neoplasia patients from healthy controls. Our data highlight the potential clinical use of these molecular signatures for low invasive screening of patients with colorectal neoplasia.

P0422 CLINICOPATHOLOGICAL STUDY OF SERRATED LESIONS OF THE COLORECTUM

M Sugimura, M Iwabuchi, Y Mano, K Ukai
Sendai Medical Center Dept. of Gastroenterology, Gastroenterology, Sendai, Japan

Contact E-Mail Address: msugimura@snh.go.jp
Introduction: Serrated lesions of the colorectum are the precursors of microsatellite unstable carcinomas. However, their clinical and pathologic features are still unclear and need further exploration.
Aims and Methods: The aims of this study was to clarify the clinicopathological features of colorectal serrated lesions. We reviewed clinical charts and pathology files of 6243 endoscopically resected specimens performed during January 2007 and December 2017 in our hospital. A total of 559 serrated lesions (9.0%) resected were classified into 3 categories: HP (hyperplastic polyp), SSA/P (sessile serrated adenomas/ polyps), and TSA (traditional serrated adenoma), according to the WHO criteria. We examined the features of these cases and evaluate the morphologic characteristics by using immunochemical staining for Ki-67 and the expression of MUCs (MUC2, MUC5AC and MUC6) in differentiating serrated lesions.
Results: Of these 559 lesions, a total of 291 (52.0%) were HP, 137 (24.5%) SSA/P, and 131 (23.5%) TSA. Male to female ratio (M/F) was 2.36 for HP, 0.98 for SSA/P, and 2.18 for TSA. Mean size of SSA/Ps (13.3mm) and TSAs (10.5mm) were significantly larger than that of HP (8.1mm) ($p < 0.005$, respectively). SSA/Ps were located predominantly in the proximal colon, whereas HP and TSA were mainly located in the sigmoid colon and rectum. 82% of SSA/Ps were flat in macroscopic appearance. SSA/Ps and HPs were whitish or almost the same as adjacent mucosa in color, whereas TSAs had a tendency to be reddish. Magnified colonoscopy showed Type II open pit pattern as characteristic of SSA/Ps, whereas pinecone-shaped pit pattern as that of TSAs. Incidences of concomitant carcinomas in HP, SSA/P, and TSA were 0% (0 out of 291), 2.9% (4 out of 137), and 3.8% (5 out of 131), respectively. Ki-67 positive cells in HP showed regular, symmetric distribution, and those in SSA/P did irregular asymmetrical pattern, whereas most of those cells in TSA distributed in the so-called ectopic crypts. Expression levels of MUC2, MUC5AC and MUC6 were significantly different between serrated lesions, SSA/Ps and HPs were positive for MUC5AC in comparison with TSAs.
Conclusion: Our studies showed the 3 types of serrated lesions have their own distinct features and could be helpful to distinguish between them. SSA/P and TSA are premalignant lesions of colorectum and we should detect these lesions and completely remove endoscopically.

Introduction: Large-scale comparison studies of pedunculated versus non-pedunculated T1 colorectal cancer (CRC) have not been performed and current risk stratification for adverse events such as lymph node metastasis is based on histology only.
Aims and Methods: We aimed to compare adverse oncologic outcomes of pedunculated versus non-pedunculated T1 CRCs. Patients diagnosed with T1 CRC between 2000 and 2014 in 14 Dutch hospitals were included. We evaluated the association between morphology and the primary composite endpoint adverse oncologic outcome adjusted for clinical variables, histological variables and treatment approach. Adverse oncologic outcome was defined as lymph node metastasis, distant metastasis, local recurrence or residual tissue. Secondary endpoints were metastasis, recurrence and incomplete resection.
Results: In total, 1,656 patients with T1 CRC with a median follow-up time of 42.5 months (IQR 18.5-77.5) were included. Adverse oncologic outcomes were observed in 9.3% (67/723) of pedunculated T1 CRCs vs 16.6% (155/933) of non-pedunculated T1 CRCs. Pedunculated morphology was independently associated with a decreased risk for adverse oncologic outcomes (adjusted OR 0.61; 95% CI 0.43–0.86; $p = 0.005$). Metastasis, incomplete resection and recurrence were observed in 8.5%, 6.5% and 5.4% of patients, respectively. Pedunculated morphology was also independently associated with a reduced risk for metastasis (adjusted OR 0.62; 95% CI 0.41–0.95; $p = 0.03$), incomplete resection (adjusted OR 0.60; 95% CI 0.38–0.98, $p = 0.03$) and recurrence (adjusted HR 0.51; 95% CI 0.32–0.84; $p = 0.007$).
Conclusion: Pedunculated morphology is independently associated with a better oncologic outcome in patients with T1 CRC. Incorporating morphology in future risk assessment is therefore likely to refine risk prediction in T1 CRC, thereby improving patient selection for surgery.
Disclosure: Nothing to disclose

P0424 LONG-TERM ONCOLOGIC OUTCOMES OF SELF-EXPANDING METALLIC STENTS AS A BRIDGE TO SURGERY IN MALIGNANT LEFT-SIDED COLON OBSTRUCTION COMPARED WITH EMERGENCY SURGERY

S.Y Oh
Ajou University School of Medicine, Suwon, Korea (Republic of)

Contact E-Mail Address: kgsosy@gmail.com
Introduction: Self-expandable metallic stents (SEMS) are used as a bridge to surgery in malignant left-sided large bowel obstruction (MLLO). However, the oncologic outcome after endoscopic stenting remains to be assessed.
Aims and Methods: The aim of this study is to compare the oncologic outcomes of SEMS with those of emergency surgery for MLLO. A database of MLLO between January 2001 and December 2012 were reviewed. They were divided into those who underwent bridge-to-surgery with SEMS and those who underwent emergency surgery (ES). The 2 groups were compared in terms of disease-free survival (DFS) and overall survival (OS).
Results: 93 patients underwent SEMS and 41 patients underwent ES. Clinicopathological features did not differ significantly between the SEMS and ES groups. 28 (30.1%) patients suffered recurrence in SEMS group and 14 (34.1%) patients suffered recurrence in ES group. There were no differences in 5-year DFS (67.6%vs. 64.6%; $p = 0.761$) and OS rates (71.0% vs. 64.9%; $p = 0.554$) between the 2 groups.
Conclusion: The SEMS as a bridge to surgery is equivalent to emergency surgery for MLLO with regards to oncologic safety.
Disclosure: Nothing to disclose

P0425 HIGH PRETREATMENT PLASMA D-DIMER LEVELS ARE ASSOCIATED WITH POOR SURVIVAL AFTER CURATIVE RESECTION IN PATIENTS WITH COLON CANCER

H Anzai, S Kazama, Y Kawashima, H Sakamoto
Saitama Cancer Center, Department of Gastroenterological Surgery, Ina-city, Japan

Contact E-Mail Address: anzaih-sur@h.u-tokyo.ac.jp
Introduction: Coagulation pathways are activated in patients with malignancies. Previous studies showed association between coagulation parameters (platelet count and plasma fibrinogen levels) and poor prognosis in patients with colon cancer. D-dimer is a stable end product of fibrin degradation. Here we investigated the association of the pretreatment plasma D-dimer levels and clinical characteristics or pathological features in patients with colon cancer.
Aims and Methods: We evaluated the medical records of 378 patients who underwent curative resection for colorectal cancer in our institution from 2013 to 2015. Information about all clinical parameters, complete follow-up, and pretreatment plasma D-dimer measurements was available for 207 patients. The normal cut-off level of 1.0 mg/L was used for distinguishing the negative from the positive D-dimer results. We retrospectively investigated the association between preoperative plasma D-dimer levels on clinicopathologic parameters and the 3-year overall survival (OS) rate in patients after curative resection of colorectal cancer.
Results: High preoperative plasma D-dimer levels were positively correlated with age at surgery and tumor depth. There were no statistically significant differences between the D-dimer normal group and D-dimer high group in terms of sex, tumor location (left colon or right colon), and histologic grade. A univariate 3-year survival analysis showed that lymph node metastasis (N factor) and high preoperative D-dimer levels were independent prognostic factors. The multivariate survival analysis using Cox regression model showed that the preoperative plasma D-dimer level was an independent prognostic factor with an odds ratio [95% confidence interval] of 4.04 (1.24–15.5). In stage III colon cancer, high pretreatment D-dimer levels were associated with a poor 3-year OS rate.
Conclusion: Elevated pretreatment plasma D-dimer levels in patients with colon cancer are associated with lower OS; patients with stage III colon cancer with high pretreatment D-dimer levels showed extremely poor OS. Preoperative D-dimer levels may be useful as a predictor of survival after curative surgery in patients with colon cancer.

P0426 ARE ADDITIONAL TREATMENTS REALLY NEEDED AFTER ENDOSCOPIC RESECTION FOR RECTAL SMALL NEUROENDOCRINE TUMORS?

D.H Jung[1], H.J Lee[2]
[1]Yonsei University College of Medicine, Seoul, Korea (Republic of)
[2]Seoul National University College of Medicine, Seoul, Korea (Republic of)

Contact E-Mail Address: leah1004@yuhs.ac
Introduction: Little is known about the long-term outcomes of endoscopically resected rectal neuroendocrine tumors (NETs).
Aims and Methods: The present study aimed to investigate treatment strategies determining additional treatment after endoscopic resection (ER) of rectal NETs and long-term outcomes of endoscopically resected rectal NETs. We analyzed medical records of patients who underwent ER for rectal NETs from January 2005 to December 2016. The clinicopathological characteristics of these lesions were analyzed and long-term outcomes were evaluated.
Results: A total of 322 patients were studied. The complete and curative resection rate were 76.4% and 55.9%, respectively. Rectal NETs initially resected as polyps and treated with conventional EMR were observed more frequently in the non-curative group ($p = 0.041$ and $p = 0.012$, respectively). After ER, only 44 of the 142 patients (31.0%) who did not meet the criteria for curative resection received additional salvage treatment. In multivariate analysis, lesions diagnosed via biopsies (OR, 0.096; $p = 0.002$) or suspected as NETs initially (OR, 0.04; $p = 0.001$) were less likely to undergo additional treatment. Positive lymphovascular invasion (OR 61.971; $p < 0.001$), positive (OR 75.993; $p < 0.001$), or indeterminate (OR 13.203; $p = 0.001$) resection margins were more likely to undergo additional treatment. Although lymph node metastasis was found in 6 patients, none experienced local or metastatic tumor recurrence during the median follow-up of 40.49 months.
Conclusion: Long-term outcomes after ER for rectal NETs were excellent. The prognosis showed favorable outcomes regardless of whether patients receive additional salvage treatments.
Disclosure: Nothing to disclose

P0427 IMPACT OF PRIMARY TUMOR LOCATION AS A PREDICTIVE FACTOR IN CYTOTOXIC ANTI-CANCER AGENT FOR COLORECTAL CANCER (CRC) BASED ON COLLAGEN GEL DROPLET-EMBEDDED DRUG SENSITIVITY TEST (CD-DST)

T Ochiai[1], Y Abe[1], K Kishine[1], T Sato[1], N Sakuyama[1], K Nagayasu[1], A Nakatani[1], M Kitajima[1], T Watanabe[1], K Nishimura[1], I Nagaoka[2]
[1]Tobu Chiiki Hospital Dept. of Surgery, Dept. of Surgery, Tokyo, Japan
[2]Juntendo University School of Medicine, Host Defense and Biochemical Research, Tokyo, Japan

Contact E-Mail Address: takumi_ochiai@tokyo-hmt.jp
Introduction: We have reported the usefulness of CD-DST for the individualization of first-line treatment in CRC (UEGW: 2014; P1538, 2015; P1681, 2016; P0929, 2017; P0466).
In recent years, primary tumor location in CRC as a predictive factor has attracted attention. Several reports have recently addressed the predictive impact of primary tumor location in CRC. A better outcome for left-sided colon cancer (CC) compared with right-sided CC has been reported. However, in those reports, the chemotherapy regimens always included molecularly-targeted agents. To the best of our knowledge, the impact of primary tumor location as a predictive factor in cytotoxic anti-cancer agent alone (FOLFOX/FOLFIRI without molecularly-targeted agents) remains to be explained.
Aims and Methods: The purpose of this study was to clarify the impact of primary tumor location as a predictive factor in cytotoxic anti-cancer agent using CD-DST. Between Mar. 2008 and Apr. 2017, we obtained tumor specimens from 133 CRC patients (CC; n:87, Rectal Cancer; n:46) without preoperative chemotherapy. Written informed consent for measurement of individual chemosensitivity was obtained from all patients. Approval for the present study was obtained from the Tobu Chiiki Hospital Institutional Review Board (No: 02.03.29. #1).

CD-DST was performed and the growth inhibition rate (IR) was determined by incubation for 24 h with 5-FU and l-OHP (6.0 and 3.0 μg/ml, respectively) and 5-FU and SN-38 (6.0 and 0.2 μg/ml, respectively). The IR values under each condition and the relationship between the tumor side and the IR values were evaluated using linear regression analysis and the t-test, respectively. Cancers proximal or distal of the splenic flexure were classified as right-side or left-side, respectively.

Results: There was a strong correlation between the IRs (%) of the FOLFOX and FOLFIRI regimens ($y = 0.88x+14.98$, $R^2 = 0.74$) using linear regression analysis. The median of the IRs (%) with the FOLFOX and FOLFIRI regimen were 58.2 and 66.2, respectively.

Among all patients, there was no significant difference in the IRs (%) of the FOLFOX and FOLFIRI regimens for right-sided vs left-sided tumors. In the FOLFOX regimen, the IRs (%) of right-sided and left-sided tumors were 57.4 ± 2.5 and 58.5 ± 1.8, respectively ($p = 0.72$). In the FOLFIRI regimen, the IRs (%) of right-sided and left-sided tumors were 67.0 ± 2.3 and 65.8 ± 1.9, respectively ($p = 0.69$).

Moreover, in 87 CC patients, there was also no significant difference in the IRs (%) of the FOLFOX and FOLFIRI regimens for right-sided vs left-sided tumors. In the FOLFOX regimen, the IRs (%) of right-sided and left-sided tumors were 57.4 ± 2.5 and 61.6 ± 2.4, respectively ($p = 0.23$). In the FOLFIRI regimen, the IRs (%) of right-sided and left-sided tumors were 67.0 ± 2.3 and 69.1 ± 2.4, respectively ($p = 0.53$).

Of the133 patients, 42 patients received palliative chemotherapy after surgery. From the 42 patients, the same results were also obtained.

Conclusion: In this study, there was no impact of primary tumor location in cytotoxic anti-cancer agent regimens for CRC. In contrast, as previously reported, a better outcome for left-sided CC compared with right-sided CC depended on molecular tumor biology, especially when using molecularly-targeted agent regimens.

As such, our findings underscore the fact that molecularly-targeted agents rather than cytotoxic anti-cancer agents may result in a better outcome for left-sided tumors.

P0428 RANDOMIZED COMPARISON OF SURVEILLANCE AFTER COLONOSCOPIC REMOVAL OF ADENOMATOUS POLYPS: ENDOCUFF-ASSISTED COLONOSCOPY VERSUS THE STANDARD COLONOSCOPY

Y Wada[1,2], M Wada[1], M Fukuda[2], K Ohtsuka[2], Y Wada[1], K Wada[1], Y Fukuma[1]

Contact E-Mail Address: w-yoshi@mtj.biglobe.ne.jp

Introduction: Endocuff-assisted colonoscopy (EAC) not only enabled a higher adenoma detection rate (ADR), but also increased the mean number of adenomas detected per patient (MAP)[1)]. According to the National Polyp Study (NPS)[2)], an interval of at least 3 years is recommended before follow-up examination after colonoscopic removal of newly diagnosed adenomatous polyps. However, only few reports have described follow-up surveillance for patients who underwent EAC and complete endoscopic removal of all adenomas.

Aims and Methods: The aim of this study was to compare the performance of EAC and standard colonoscopy (SC) as surveillance colonoscopy techniques after complete adenoma removal during EAC. For this study, 134 patients who underwent total EAC and removal of all adenomas between March and September 2014 were enrolled, and they prospectively underwent follow-up colonoscopy at 3 years in accordance with the recommendation of the NPS. They were randomly assigned to undergo follow-up EAC ($n = 66$) and SC ($n = 67$). The primary end point was the detection of index lesions (defined as those ≥10 mm in diameter and/or with villous component of >20%, and/or high-grade adenoma or invasive cancer). The secondary end point was the detection of any adenoma.

Results: The detection rates of index lesions were 3.0% (2/66) in EAC and 3.0% (2/67) in SC. There was no significant difference found between the two in both groups. The polyp detection rates and ADRs were higher in the patients who underwent EAC than in those who underwent SC, but these differences were not statistically significant (60.6% vs. 47.8% [$p = 0.14$] and 57.6% vs. 44.8% [$p = 0.14$]). The mean number of polyps detected per patient and MAP were also higher in the patients who underwent EAC, but these differences were not statistically significant (1.21 ± 1.45 vs. 0.85 ± 1.15 [$p = 0.15$] and 1.06 ± 1.30 vs. 0.82 ± 1.06 [$p = 0.31$]). There was no adenocarcinoma in both groups. No significant differences were found in detected polyp size, morphology, and distribution were found in between the both groups. No major complication occurred.

Conclusion: Both EAC and SC detected adenomas with advanced pathological features and adenomas in equal proportions in when they were used for follow-up surveillance after 3 years for patients who underwent EAC and were complete adenoma removaled all adenomas detected adenomas with advanced pathological features and adenomas in equal proportion. Further studies are required to confirm the current present results.

Introduction: We aimed to determine the cause of and risk factors for post-colonoscopy colorectal cancer (pcCRC) in patients who underwent endoscopic resection of a polyp with intramucosal carcinoma (IMC).

Aims and Methods: Patients diagnosed with IMC in the period 1995–2005 were selected from the Netherlands Cancer Registry (NCR). Patients with a surgical resection of intramucosal carcinoma or hereditary CRC were excluded. pcCRC was defined as CRC diagnosed between 6 and 60 months after endoscopic resection of IMC. Additional data were collected in 31 hospitals from all pcCRC cases and a sample of 367 controls. Multivariate logistic regression analysis was performed to identify risk factors for pcCRC.

Results: Among 1,979 patients who underwent endoscopic resection of IMC, 48 (2.4%) were diagnosed with a pcCRC according to the NCR. Manual review of the available medical records confirmed pcCRC diagnosis in 27 patients, discarded pcCRC diagnosis in 9 patients and identified 2 additional pcCRC cases among a sample of controls. Of these 29 pcCRC patients, 14 (48%) were attributed to an incomplete endoscopic resection, 9 (31%) to inadequate colonoscopy, 4 (14%) to a missed lesion and 2 (7%) were new CRCs. Recurrence of IMC (OR 10.65 95% CI 4.48–25.30; $p < 0.01$) and a personal history of CRC (OR 5.82 95% CI 1.23- 27.45; $p = 0.03$) were independent risk factors for pcCRC.

Conclusion: The majority of pcCRCs after endoscopic resection of polyps with IMC can be attributed to incomplete resections, with recurrence of IMC and personal history of CRC as most important risk factors. This suggests that en-bloc resection of polyps suspected to contain IMC is justified to limit the risk of invasive recurrence.

Introduction: Initial colonoscopies for screening or diagnostic colonoscopy and follow-up colonocopies for surveillance were frequently performed in the daily practice. There have been few studies regarding the clinicopathological comparison between colorectal neoplasms detected at first-time colonoscopy and those detected at subsequent colonoscopies. We tried to compare the characteristics of colorectal neoplasms detected at initial and follow-up colonoscopies.

Aims and Methods: A total of 3345 patients (group A) were included in this study who underwent an initial colonoscopy (1232 asymptomatic patients for first screening, 1173 for positive fecal occult blood test of first round, and 940 symptomatic patients for diagnostic colonoscopy). Another total of 2092 patients (group B) were also included who underwent follow-up colonoscopies for surveillance (1014 with no polyps or diminutive polyps at baseline, 690 with adenoma and/or intramucosal cancer resected at baseline, and 388 with invasive cancer resected at baseline). Detected colorectal neoplasms more than 5mm in size between group A and B were compared with each other regarding their prevalences and the characteristics.

Results: The prevalences of patients with low-grade adenoma, those with high-grade adenoma or intramucosal cancer, and those with invasive cancer between group A and B were 14.0% (467/3345) and 17.0% (355/2092), 4.5% (152/3345) and 5.0% (104/2092), and 5.6% (187/3345) and 1.3% (28/2092), respectively. The prevalence of patients with invasive cancer was significantly lower in group B than that in group A ($p < 0.0001$), although the prevalence of those with low-grade adenoma was significantly higher in group B than that in group A ($p < 0.005$). There was no difference of the prevalence of patients with high-grade adenoma or intramucosal cancer between group A and B. 793 and 952 low-grade adenomas, and 184 and 116 high-grade adenomas or intramucosal cancers were detected in group A and B, and total of 977 and 1068 mucosal lesions between group A and B were compared with each other. The prevalences of the lesions between group A and B with regard to the clinicopathological factors were as follows. The locations of the lesions were in the right colon 40.4%, 52.6%, left colon and lectum 59.6%, 47.4%, the numbers of the lesions were single or double 83.5%, 59.0%, triple or more 16.5%, 41.0%, the sizes of the lesions were less than 10mm 63.5%, 82.2%, 10mm or more than 10mm 36.5%, 17.8%, the configulations of the lesions were polypoid 87.2%, 83.7%, non-polypoid 12.8%, 16.3%, and the histologies of the lesions were low-grade adenoma 81.2%, 89.1%, high-grade adenoma or intramucosal cancer 18.8%,

10.9%, respectively. The lesions detected in group A were characterized by their left-sided location ($p < 0.0001$), no multiplicity ($p < 0.0001$), larger size ($p < 0.0001$), polypoid appearance ($p < 0.05$), and more-advanced histology ($p < 0.0001$). In contrast the lesions detected in group B were characterized by their right-sided location, multiplicity, smaller size, non-polypoid appearance, and less-advanced histology.

Conclusion: The prevalence of patients with invasive cancer was significantly lower in those at follow-up colonoscopies than those at initial colonoscopy. In contrast the prevalence of patients with low-grade adenoma was significantly higher in those at follow-up colonoscopies than those at initial colonoscopy. Adenomas and intramucosal cancers detected between an initial and follow-up colonoscopies disclosed clearly different characters as to the location, number, size, configulation, and histology.

Introduction: Lynch syndrome carriers' surveillance is performed through endoscopic examinations and with intervals of no more than 2 years. Colonoscopy allows direct visualization of the entire colon but requires bowel preparation, sedation, there is risk of intestinal perforation, it is time consuming and it has high associated costs. These are some of the reasons for which there is low surveillance acceptance among patients.

Aims and Methods: The aims of this work were to compare a specific faecal bacterial signature of sporadic colorectal cancer patients (CRC) and inflammatory bowel disease patients (IBD) with Lynch carriers and develop a non-invasive tool, hereby named RAID-LS, based on these bacterial signatures, which enabled the detection of neoplasia in Lynch population.

A cohort consisting of 66 Lynch syndrome carriers who underwent a surveillance colonoscopy were recruited. A second cohort consisting of 301 control individuals was recruited through the regional CRC screening program or for presenting CRC compatible symptomatology. We performed the analysis of 9 CRC-specific bacterial markers (CRC1, 2, 3, 4, 5, 6, 7, 9, 10) and 4 associated to IBD (IBD1, 2, 3, 4) in stool samples. The RAID-LS was eventually defined using 3 of the analysed biomarkers.

Results: Comparison between those Lynch syndrome carriers who had had CRC and those with no CRC personal background did not show significant differences in the abundance of any of the analysed bacterial markers.

When Lynch with a normal colonoscopy (NC) were compared to control subjects with NC, non-advanced adenomas and advanced adenomas, significant differences were found in the abundance of 4 (CRC1, $p = 0.014$; CRC5, $p < 0.001$; CRC6, $p < 0.001$; CRC7, $p = 0.03$), 7 (CRC2, $p = 0.043$; CRC3, $p < 0.001$; CRC5, $p < 0.001$; CRC6, $p < 0.001$; IBD2, $p = 0.013$; IBD3, $p = 0.012$, IBD4, $p = 0.003$) and 9 bacterial markers (CRC2, $p = 0.010$; CRC3, $p < 0.001$; CRC5, $p < 0.001$; CRC6, $p < 0.001$; CRC7, $p < 0.001$; IBD1, $p = 0.013$; IBD2, $p = 0.046$; IBD3, $p = 0.003$; IBD4, $p = 0.005$), respectively. Interestingly, only CRC3 showed significant differences when NC Lynch were compared to control subjects with CRC ($p = 0.034$).

We designed the RAID-LS algorithm combining CRC1, CRC3 and IBD2 bacterial markers. This combination allowed the detection of neoplastic lesions in Lynch syndrome carriers with sensitivity, specificity, true and negative predictive values of 100%, 72%, 42% and 100%, respectively (AUC = 0.859, 95% CI (0.754–0.964)). These results leaded to a false-positive rate of only a 23%, reducing by 60% the number of colonoscopies.

Conclusion: Healthy Lynch syndrome carriers show a similar microbiota to that of patients with tumour lesions, suggesting that there is an inflammatory basal gut environment in Lynch similar to that of CRC.

RAID-LS efficiently detects precancerous lesions in Lynch carriers. The use of this tool would suppose a breakthrough for Lynch carriers, who will significantly improve their quality of life by expanding the intervals between colonoscopic surveillance.

Introduction: Several node staging schemes have been proposed for colorectal cancer (CRC) and multiple studies have been conducted to whether number-based scheme (pN), ratio-based scheme (rN) or log odds of positive lymph nodes scheme (LODDS) was associated with CRC survival. However, to the best of our knowledge, there was no study investigate which kind of node staging schemes predicted CRC survival to the best using predicting capacity and the optimal system remains controversial.

Aims and Methods: This study aims to compare 3 node staging schemes in predicting survival outcome in patients with colorectal cancer. Patients with CRC were identified from the Surveillance, Epidemiology, and End Results (SEER) database, and a Chinese multicenter cohort was used for independent validation. The prognostic performance of 3 node staging schemes predicating CRC casue-specific survival (CSS) was compared, involving pN, rN and LODDS. Prediction performance were assessed for overall performance using R^2, discriminatory capacity using Harrell's C statistic, time-dependent receiver operating characteristic (tdROC) at 1, 3, 5, 7, 10 year survival and clinical utility using decision curve analysis (DCA) at 1, 3, 5, 7, 10 year survival. Sensitivity analyses were performed when competing risk was considered or when overall survival (OS) was used. R^2 and Harrell's C statistic was assessed for each multivariate model after including sex, race, age, tumor location, T stage, M stage, grade, histology and size. Comparison in predicting OS was also performed in Chinese multicenter cohort using R^2, Harrell's C statistic and tdROC.

Results: There were 240,898 patients in the SEER database and 1316 in the Chinese multicenter cohort. LODDS scheme performed better in overall performance R^2 (LODDS vs. rN vs. pN: 19.4% vs. 17.6% vs. 9.4%), predictive accuracy with Harrell's C statistic (LODDS vs. rN vs. pN: 0.727 vs. 0.719 vs. 0.712) and ROC (LODDS vs. rN vs. pN, 1year: 74.6 vs. 76.1 vs. 77.3; 3year: 75.5 vs. 76.5 vs. 77.4; 1year: 74.9 vs. 75.6 vs. 76.4; 7year: 74.4 vs. 74.9 vs. 75.2; 1year: 73.6 vs. 73.9 vs. 73.9) than either pN or rN, for patients with colorectal cancer in SEER database. DCA also showed LODDS scheme had higher net benefit than either pN or rN (LODDS vs. rN vs. pN, 1year: 0.019 vs. 0.019 vs. 0.007; 3year: 0.116 vs. 0.118 vs. 0.052; 5year: 0.171 vs. 0.139 vs. 0.139; 7year: 0.200 vs. 0.184 vs. 0.184; 1year: 0.226 vs. 0.219 vs. 0.219) when threshold probability was set at 20%. Similar results could be attained in the sensitivity analysis, multivariate cox model and independent Chinese multicenter cohort.

Conclusion: LODDS performed better than rN, and pN in predicting CRC survival.

Disclosure: Nothing to disclose

Abstract No: P0432: Overall prognostic performance of node staging schemes for colorectal cancer using different analytic strategy

Analysis	R2	HarrelÍs C index	ROC at 1 year	ROC at 3 year	ROC at 5 year	ROC at 7 year	ROC at 10 year

Introduction: We previously reported the risk for local recurrence was significantly higher in patients with rectal cancer than with colon cancer when treated with only endoscopic resection (ER) for pT1 colorectal cancer having high risk of lymph node metastasis. Especially, patients with high-risk pT1 rectal cancer should be recommended additional surgery after ER to prevent recurrence. However, some patients with high-risk pT1 rectal cancer refused additional surgery because of highly invasiveness including permanent stomas. Recently, we have experimentally performed adjuvant chemoradiotherapy (adj CRT) for only patients who had rejected additional surgery after local resection including ER or transanal local excision for pT1 rectal cancer in the rectum.

Aims and Methods: Our aim is to clarify long-term outcomes of local resection followed by adj CRT for patients with high-risk pT1 rectal cancer.

We retrospectively collected all data on patients with high-risk pT1 rectal cancer treated from January 2000 to December 2016 in our hospital. Patients were classified into 3 groups: patients undergoing only local resection (group A), patients undergoing initial or additional surgical resection with lymph node dissection (group B), and patients undergoing adj CRT after local resection for pT1 rectal cancer (group C). Adj CRT consisted of continuous infusion of 5-fluorouracil or oral administration of capecitabine, and concurrent radiation of 45Gy in total. We assessed to compare the recurrence rate (RR), 5-year disease-free survival (DFS), and 5-year overall survival (OS) between each groups.

Results: A total of 237 patients with pT1 rectal cancer were enrolled. Median follow-up period was 52.7 months (range, 12.2–180.2 months). Group A, B, and, C were 29, 169, and, 39 cases. RR in group A, B, and C was 20.7% (6 cases), 4.7% (8 cases), and 0%, respectively. In Group A, 3 cases developed local recurrence and the other 3 cases developed distant metastasis. In Group B, 2 cases developed local recurrence and the other 6 cases developed distant metastasis. RR in group A was significantly higher than group B and C ($p < 0.05$). 5-year DFS in group B (95.3%) and group C (96.3%) were significantly better comparing group A (70.8%) (A vs B, A vs C, $p < 0.05$). 5-year OS in group B (97.2%) and group C (96.2%) was also better comparing with group A (88.7%), however the difference was not significant among 3 groups. And, there were not significantly differences between group B and C in RR, DFS, and OS.

Conclusion: Long-term outcomes of adj CRT after local resection for patients with high-risk pT1 rectal cancer were similar to those of surgical resection. Adj CRT may be a treatment option if patients with high risk pT1 rectal cancer reject additional surgery.

Introduction: Approximately 40–60% of T1 colorectal carcinomas (T1 CRCs) are not recognized as such during endoscopy and often inadequately resected. This results in unclear resection margins at histology. Adjuvant surgery is often carried out, but residual malignancy is only found in 6–14% of cases. Biopsies from the polypectomy site are variably used in clinical practice to provide additional evidence for a local radical excision if they are negative for residual cancer. However, sensitivity of scar biopsies for residual cancer after polypectomy is unknown.

Aims and Methods: We aimed to evaluate the sensitivity of endoscopic biopsies < 6 weeks from the endoscopic polypectomy site for residual tumor. This concerns an interim report of an ongoing multicenter prospective cohort study since May 2016. Patients with 1) an endoscopically removed T1 CRC with unclear resection margins, or a resection margin less than 1 mm at histology, and 2) absence of additional conventional risk factors such as lymphovascular invasion, tumor budding, second tumor or oncological treatment were included. If patients were scheduled for adjuvant surgery or rescue endoscopic full thickness resection, patients were enrolled for protocol biopsies from the polypectomy site just before or during this procedure. The results of the biopsies were compared to findings of the resection specimen.

Results: In total, 81 patients have been prospectively included (mean age 66.9 years, 34% female). The T1 CRC was located in the recto-sigmoid in 67/81 (82%) of cases. Major segmental bowel resection was performed in 56 (69%) patients and bowel wall full thickness resection in 25 (31%) patients. In 68 (84%) patients the T1 CRC was not recognized as such during endoscopy. The reason for additional surgery was a positive resection margin (R1, $n = 34$ (42%)), a resection margin that was impossible to assess (Rx, $n = 32$ (40%)), and a tumor-free margin < 1 mm (R0 $<$ 1mm, $n = 15$ (19%)). At second look, visible tumor or adenomatous remnant was noticed in 3 and 6 patients respectively. 3 of them had malignancy in biopsies, two of them in the resection specimen. 4 patients without visible lesion still had tumor in the bowel wall in the resection specimen. In none of the patients with an endoscopically clean polypectomy site (scar or benign postpolypectomy ulcer only), tumor was found in biopsies. The resection specimen showed remaining cancer cells at the polypectomy site in 6/81 (7.4%) of these cases. This was located deeper in the bowel wall in 5/6 (83%) patients. In total 2 of 6 patients were detected by biopsies. This yielded a sensitivity of 33.3% (95% CI −4.4%–71.0%) and a specificity of 98.67% (95% CI 98.63%–98.70%). As all of these patients had visible remnants, the sensitivity of random biopsies from a scar of postpolypectomy ulcer without tumorous or adenomatous remnants was 0%.

Conclusion: The sensitivity of biopsies from the polypectomy site within 6 weeks is too low to safely exclude residual cancer. These biopsies should not be used to decide to refrain from additional surgery. As we did not find any residual cancer cells within the group of R0 resection but a margin < 1 mm, this argues against the value of this 1mm cut-off to predict local recurrence of cancer.

Disclosure: Nothing to disclose

P0436 ALCOHOL CONSUMPTION IS ASSOCIATED WITH THE RISK OF DEVELOPING COLORECTAL NEOPLASIA: PROPENSITY SCORE MATCHING ANALYSIS

Y.J Yang, C.S Bang, G.H Baik
Hallym University College of Medicine, Chuncheon, Korea, Gastroenterology, Chuncheon, Korea (Republic of)

Contact E-Mail Address: outopiar@naver.com

Introduction: Despite the well-known association between alcohol consumption and the development of colorectal neoplasm (CRN), the cumulative effect of alcohol consumption at the time of surveillance colonoscopy has not been investigated, and alcohol consumption was not included in the risk factors for the determination of the time interval of surveillance colonoscopy.

Aims and Methods: This study aimed to determine if alcohol consumption is associated with the development of CRN at the time of surveillance colonoscopy taking consideration with risk stratification of index colonoscopy. We retrospectively identified 1,448 patients who underwent index and subsequent surveillance colonoscopy during the study period. The association between significant alcohol consumption (males $>$ 30g/day, females $>$ 20g/day) and the cumulative occurrence of overall and advanced CRN at the time of surveillance colonoscopy was analyzed using propensity score matching (PSM) analysis.

Results: In the PSM analysis with 210 matched-pairs, the cumulative rate of overall CRN at 5 years after index colonoscopy was higher in the significant alcohol consumption group than in the control group (40% vs. 27.6%, $p = 0.004$). Significant alcohol consumption (adjusted hazard ratio [aHR]: 1.86, 95% CI:1.28–2.70, $p = 0.001$) was associated with the occurrence of overall CRN at surveillance colonoscopy with male (aHR:2.73, 95% CI:1.14–6.52, $p = 0.02$), hypertension (aHR:2.05, 95% CI:1.38–3.04, $p < 0.001$), and high-risk findings at index colonoscopy (aHR:2.26, 95% CI:1.38–3.72, $p = 0.001$). In subgroup analyses based on the risk categories of index colonoscopic findings, significant alcohol consumption was associated with the overall CRN occurrence at the time of surveillance colonoscopy in the normal (aHR:1.90, 95% CI:1.16–3.13, $p = 0.01$) and low-risk groups (aHR:2.13, 95% CI:0.98–4.62, $p = 0.06$). Moreover, Significant alcohol consumption was a risk factor for CRN occurrence at the distal colorectum (aHR: 2.01, 95% CI: 1.10–3.66, $p = 0.02$) and appeared to increase the risk of multiple CRNs (≥ 3) occurrence at surveillance colonoscopy with marginal significance in male (aHR: 2.64, 95% CI: 0.93–7.52, $p = 0.07$). However, there was no association between significant alcohol consumption and the development of advanced CRN on surveillance colonoscopy.

Conclusion: Significant alcohol consumption is associated with the risk of overall CRN occurrence, especially in patients in the normal or low-risk categories at index colonoscopy. In addition, significant alcohol consumption was associated with overall CRN occurrence in the distal colorectum and with more than 3 CRNs occurrence at surveillance colonoscopy. Alcohol consumption habits might be reflected in the determination of optimized time intervals for surveillance colonoscopy.

P0437 LONG-TERM OUTCOMES AFTER ENDOSCOPIC VERSUS SURGICAL RESECTION OF T1 COLORECTAL CARCINOMA

H.H Lee, Y.-S Cho, H.-H Lee, C.-H Lim, J Kim, B.-I Lee, M.-G Choi
Seoul St. Mary's Hospital, The Catholic University Of Korea, Department of Internal Medicine, Seoul, Korea (Republic of)

Contact E-Mail Address: lhh2002@hanmail.net

Introduction: The gold standard for treatment of T1 carcinoma used to be an oncological surgical resection including resection of draining lymph nodes. The number of endoscopic resections of T1 carcinoma will continue to increase in line with the increased detection. Increasing evidence showed that endoscopic resection is adequate for T1 carcinoma with a low risk for LMN. Long-term outcomes of patients with T1 colorectal carcinoma (CRC) treated by endoscopic resection (ER) or surgical resection have not been well established in Korea.

Aims and Methods: The aim of this study was to evaluate the long-term outcomes among patients with T1 CRC. This retrospective study included 386 patients with T1 CRC with initial endoscopy (n = 188) or surgery (n = 198) between 2000 and 2015 at Seoul St. Mary's Hospital. Patients who did not meet the curative criteria in the Japanese Society for Cancer of the Colon and Rectum guidelines (negative resection margin, no lymphovascular invasion, submucosal invasion depth < 1000 μm, well/moderately differentiated adenocarcinoma, grade 3 tumor budding) were defined as 'high risk', and were subdivided into 4 groups: ER with low risk (Group A: 71 patients), ER with high risk (Group B: 117 patients), surgery with low risk (Group A: 65 patients), surgery with high risk (Group B: 133 patients).

Results: During follow-up period, local recurrence or distant metastasis was developed in 8 (1.98%) patients (Group A: 0, Group B: 4, Group C: 0, Group D: 4). 5-year recurrence free survival rate was significantly lower in Group B (Group A: 100%, Group B: 85.0%, Group C: 98.5%, Group D: 95.6%, p = 0.02). However, there was no statistically significant difference in the 5-year overall survival rate among treatment methods (Group A: 100%, Group B: 94.2, Group C: 98.5%, Group D: 98.1%, p = 0.233). Among patients (n = 285) who underwent surgery, lymph node metastasis (LNM) was observed in 33 (11.6%) patients. In the multivariate analysis, lymphatic invasion and depth of submucosal invasion were independent risk factors of LNM.

Conclusion: Endoscopic resection of T1 CRC in patients with low risk is safe. ER for T1 CRC did not worsen the clinical outcomes of patients who required additional surgical resection.

Disclosure: Nothing to disclose

P0438 QUALITY OF LIFE AND WORRY ABOUT CANCER RECURRENCE IN T1 COLORECTAL CANCER PATIENTS TREATED WITH ENDOSCOPIC OR SURGICAL TUMOUR RESECTION

H Dang[1], W.H De Vos Tot Nederveen Cappel[2], S.M.S van der Zwaan[1], M.E van den Akker-van Marle[3], E Van Westreenen[4], Y Backes[5], L.M.G Moons[5], F.A Holman[6], K.C.M.J Peeters[6], J van der Kraan[1], A.M.J Langers[1], W.M Lijfering[7], J.C.H Hardwick[1], J.J Boonstra[1]

Introduction: To optimise therapeutic decision-making in T1 colorectal cancer (T1 CRC) patients, it is important to elicit the patient's perspective next to considering medical outcomes. Because empirical data on patient-reported impact of different treatment options are lacking, we evaluated patients' quality of life, perceived time to recovery and worry about cancer recurrence after endoscopic or surgical treatment for T1 CRC.

Aims and Methods: In this cross-sectional study, we selected patients with histologically confirmed T1 CRC, who had participated in the Dutch Bowel Cancer Screening Programme and received endoscopic or surgical treatment between January 2014 and July 2017. Quality of life was measured using the EORTC QLQ-C30 and the EQ-5D-5L questionnaire. We used the Cancer Worry Scale to evaluate patients' worry about cancer recurrence. A question on perceived time to recovery after treatment was also included in the set of questionnaires sent to the patient.

Results: Of all 119 eligible patients, 92.4% responded to the questionnaire (endoscopy group: 55/62, surgery group: 55/57). Compared to the surgery group, perceived time to recovery was on average 3 months faster in endoscopically treated patients after adjustment for confounders (p = 0.001). The 2 treatment groups did not show any significant difference in global quality of life, functioning domains as well as symptom severity. Moreover, patients in the endoscopy group did not report significantly more worries about cancer recurrence than those in the surgery group.

Conclusion: From the patient's perspective, endoscopic treatment provides a quicker recovery than surgery, without provoking more cancer recurrence worries or any deterioration in quality of life. These results contribute to the shared therapeutic decision-making process of clinicians and T1 CRC patients.

Introduction: The aim of the study was to describe the results of 3-dimensional high-resolution anorectal manometry (3DHRAM) in a large cohort of patients with functional anorectal disorders.

Aims and Methods: In this single-centre retrospective study, all consecutive patients referred for investigation of faecal incontinence (FI) or dyssynergic defecation (DD) underwent 3DHRAM. The parameters analysed were usual manometric data, repartition of dyssynergic patterns, and the prevalence of a new 'muscular subtype classification' underlying dyssynergia, of anal sphincter defects and of pelvic floor disorders.

Results: Final analyses were performed in 1477 patients of mean age 54 ± 16 years; 825 were suffering from DD and 652 from FI. Among the patients, 86% met dyssynergia diagnostic criteria. Dyssynergic pattern II was the most frequently observed (56%) in women and in men suffering from FI, as well as in women with DD. Type I was the most frequently observed in men with DD (49%). Regarding the muscle type subgroups, combined puborectalis muscle involvement with external anal sphincter profile was the most frequently observed. The global prevalence of rectal intussusception and of excessive perineal descent were 13% and 21%, respectively. The type III dyssynergic pattern was more frequently associated with pelvic floor disorders than were other types ($p < 0.001$).

Conclusion: This large cohort study provides reference values of 3DHRAM in patients with functional anorectal disorders. Further studies will be necessary to assess the prevalence of pelvic floor disorders in healthy volunteers and to develop new scores and classifications including all of these new parameters.

Disclosure: VV, MB and CA have conflicts of interests. They previously have worked for Given Imaging as experts in order to teach 3DHRAM to other practitioners.

P0440 THREE-DIMENSIONAL HIGH-RESOLUTION ANORECTAL MANOMETRY CAN PREDICT RESPONSE TO BIOFEEDBACK THERAPY IN DEFECATION DISORDERS

C Andrianjafy[1], C Bazin[2], L Luciano[3], A Loundou[4], M Bouvier[2], V Vitton[5]

Contact E-Mail Address: charlotte.andrianjafy@gmail.com

Introduction: Biofeedback therapy (BT) is a simple and effective technique for managing outlet constipation and faecal incontinence. Several clinical factors are known to predict BT response, but a 50% failure rate persists. Better selection of BT responsive patients is required. We aimed to determine whether the defecation disorder type per high-resolution manometry (HRM) was predictive of BT response.

Aims and Methods: We analyzed clinical, manometric and ultrasound endoscopic data from patients who underwent BT in our department between January 2015 and January 2016. Patients were classified into 4 groups per the following defecation disorder classification criteria: rectal pressure > 40 mmHg and anal paradoxical contraction (type I); rectal pressure < 40 mmHg and anal paradoxical contraction (type II); rectal pressure > 40 mmHg and incomplete anal relaxation (type III); and rectal pressure < 40 mmHg and incomplete anal relaxation (type IV). An experienced single operator conducted 10 weekly 20-minute sessions. Efficacy was evaluated with the visual analog scale.

Results: Of 92 patients, 47 (50.5%) responded to BT. Type IV and type II defecation disorders were predictive of success (p = 0.03) (OR = 5.03 [1.02; 24.92]) and failure (p = 0.05) (OR = 0.41 [0.17; 0.99]), respectively. The KESS score severity before BT (p = 0.03) (OR = 0.9 [0.81; 0.99]) was also predictive of failure.

Conclusion: The manometry types identified according to the defecation disorder classification criteria were predictive of BT response. Our data confirm the role of 3-dimensional HRM in the therapeutic management of anorectal functional disorders.

Disclosure: VV, MB and CA have conflicts of interests. They previously have worked for Medtronic as experts in order to teach 3DHRAM to other practitioners.

P0441 WHOLE AND REGIONAL ASSESSMENT OF CONTRACTILITY, TEMPERATURE AND PH PROFILE IN PATIENTS WITH FUNCTIONAL CONSTIPATION, IRRITABLE BOWEL SYNDROME WITH CONSTIPATION AND HEALTHY VOLUNTEERS USING WIRELESS MOTILITY CAPSULE

Contact E-Mail Address: enriquecossmd@gmail.com

Introduction: Constipation is a very common disorder with a wide spectrum, from functional constipation (FC) to irritable bowel syndrome with constipation (IBS-C). There are similitudes and differences between FC and IBS-C including changes in gut microbiota compared to healthy volunteers (HV). The wireless motility capsule (WMC) incorporates measurements of pressure, temperature and pH along the gastrointestinal (GI) tract. Whole and regional transit times, pressure pattern and pH have been described in several populations.

Aims and Methods: Aim: to describe whole and regional temperature, pressure pattern and pH profile values in patients with FC, IBS-C, and HV.

Methods: This is a prospective study conducted at 2 GI Motility Labs, in the INCMNSZ and IIMB-UV. We included patients fulfilling ROME III criteria for FC and IBS-C. HV were asymptomatic, no major comorbidities, no previous GI surgery. After a 12-hour fast, WMC was administered without having consumed antibiotics in the previous month, no bowel preparation and no fiber supplement administration were allowed 7 days before study. Subjects were instructed to wear a receiver and kept a diary until WMC was expulsed or for up to 120 hrs. Whole and regional transit time, pressure pattern and pH profile were evaluated. For detailed analysis, small bowel (SB) and colon were divided into quartiles (Q1-Q4) using specialized software (GIMS data viewer, Buffalo, NY). The variables are summarized with medians, frequencies and percentages. Non-parametric tests were used for comparisons.

Results: 52 subjects were included, 17 HV, median age 39 yo (25–54, 25th–75th), BMI 26.3 kg/m^2 (24–27.5), 8 IBS-C, median age 29.5 yo (24–41.5), BMI 25.9 kg/m^2 (21.2–28.7) and 27 FC median age, 41 yo (31–56), BMI 26.8 kg/m^2 (23.5–29.2). There was no difference in age distribution ($p = 0.35$) or BMI ($p = 0.52$). No changes were shown in whole and regional transit times and pressure pattern between groups ($p > 0.05$) (Table). FC had a lower SB pH profile, 6.66 (6.42–6.88, $p = 0.039$) compared to HV 6.87 (6.7–7.03) and IBS-C 7.03 (6.97–7.10) (Figure). Similarly, at ileum (distal quartile in SB), pH was lower in FC 7.18 (7.08–7.42, $p = 0.023$) vs HV 7.44 (7.19–7.66) and IBS-C 7.54 (7.47–7.66). At cecum (1st quartile at colon) FC had lower pH profile 6.02 (5.74–6.24) compared to IBS-C 6.31 (6.14–6.82; $p = 0.024$) but not different to HV.

Conclusion: FC presents a more acidic profile in the SB, ileum and cecum. This leads to the hypothesis that changes in pH may be due to differences in microbiota composition between study populations. It is necessary to evaluate these findings when comparing microbiota with intraluminal pH and symptom profile.

Disclosure: Nothing to disclose

P0442 LONG-TERM LINK BETWEEN THE SEVERITY OF FAECAL INCONTINENCE AND THE EXTENT OF THE OBSTETRICAL ANAL SPHINCTER DISRUPTION

L Luciano[1], **C Andrianjafy**[2], K Baumstarck[3], M Bouvier[4], V Vitton[5]

[5]*Aix Marseille Universite, Gastroenterology, Marseille, France*

Contact E-Mail Address: charlotte.andrianjafy@gmail.com

Introduction: Anal sphincter disruption, mainly from obstetrical origin, is frequent in patients suffering from fecal incontinence (FI). However, the link between the extent of the disruption and the severity of FI is not clear according to the time between the anal sphincter disruption and the apparition of FI. Our main objective was to assess, in the long term, the link between the anal sphincter disruption and the severity of FI.

Aims and Methods: In this retrospective study, all patients referred to our center for investigation of FI including an endo-anal ultrasonography (EUS) and a 3D High Resolution Anorectal Manometry were eligible. Clinical, manometric and EUS data were recorded, the Wexner score being assessed for the severity of FI.

Results: 250 patients (243 women), of mean age 59.97±14 years, were included. The mean duration of symptoms was 61.37±86.10 months. The repartition of anal sphincter disruption was as follows: isolated IAS disruption 30.4%, isolated EAS disruption in 8.4%, both IAS and EAS disruption in 60%. Considering manometric data, the voluntary contraction was lower in patients with EAS disruption and resting pressure was lower when an IAS was identified.

No significant link was observed between the extent of anal sphincter disruption and the severity of FI assessed by the Wexner score. BMI and urinary symptoms were not either linked to the severity of FI.

In our study, in multivariate analysis, menopause was the only independent factor linked to the FI severity.

Conclusion: In the long term, no link was identified between the extent of the disruption and the severity of FI, menopause being the only independent risk factor for the severity of FI.

These data confirm that, as suggested by the literature, the role of the extent of sphincter rupture occurs only in the immediate postpartum period. In the long term, this role is reduced due to the multifactorial nature of FI.

Disclosure: VV and CA have conflicts of interest. They previously have worked for Medtronic as experts in order to teach 3-dimensional high-resolution manometry to other practitioners.

P0443 POLYETHYLENE GLYCOL 3350 PLUS ELECTROLYTES FOR CHRONIC CONSTIPATION: A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED MEDIUM-TERM STUDY WITH AN EXTENSIONAL 52 WEEKS OPEN-LABEL, LONG-TERM STUDY

A Nakajima[1], K Shinbo[2], A Ota[2], Y Kinoshita[3]

Introduction: Although polyethylene glycol 3350 plus electrolytes (PEG3350+E) is the most popular osmotic laxative in Europe, prospective long term (over 6 months) safety and efficacy clinical data has not been available to date. In Japan, the current standard cure of chronic constipation is magnesium oxide, PEG3350+E has not previously been used as treatment for chronic constipation.

Aims and Methods: We aimed to determine the efficacy and safety of PEG3350+E for the treatment of chronic constipation with an extensional long term study in Japan. We report a Phase 3 trial; a randomized, double-blind, placebo-controlled medium-term study (Confirmatory phase) with an extensional open-label, long-term (52 weeks) study (Extensional phase) in patients with chronic constipation (who satisfied Rome III criteria for functional constipation). In the Confirmatory phase, 156 patients were randomized to receive PEG3350+E (80) or placebo (76) orally for 2 weeks. In the Extensional phase, 153 patients moved from the Confirmatory phase and received PEG3350+E orally. Starting dose was 13.7g/day dissolved in 125mL of water; dose titration was allowed in both phases within the range of 13.7–41.4g/day, according to the patient's bowel condition. We monitored bowel function (including number of bowel movements, stool consistency) and adverse events. The primary end point of the Confirmatory phase was the increase from baseline (last week of run-in period: Week -1) in spontaneous bowel movements (SBMs) per week during Week 2 of treatment. Secondary endpoints included frequency of complete spontaneous bowel movements (CSBMs), proportion of responders (defined as 3 or more SBMs/CSBMs per week with an increase from baseline of at least 1 SBM/CSBM per week), the median day to first SBM, stool consistency.

Results: In the Confirmatory phase, the difference from baseline in frequency of SBMs in Week 2 was significantly increased with PEG3350+E (4.3 ± 2.9 [Mean ± SD]) compared with placebo (1.6 ± 2.0, $p < 0.001$). Similarly, the frequency of CSBMs and proportion of responders were significantly improved with PEG3350+E compared to placebo.

In the Extensional phase, PEG3350+E showed sustained improvement in bowel function. The difference from baseline in frequency of SBMs in Week 1 and Week 2 were 2.98 ± 2.27 and 4.34 ± 2.89 respectively. Thus, it showed an increasing trend until Week 2 and remained stable at 3.89–4.82 times from Week 2 through Week 52. The frequency of SBMs from Week 1 to Week 52 was significantly increased compared with baseline. The SBMs proportion of responders was 78.4% (95% CI: 71.26%–84.21%) in Week 1 and remained stable at 78.4%–94.0% from Week 1 to Week 52.

In the Confirmatory phase, the incidence of adverse events (AEs) of placebo and PEG3350+E were 19.7% (15/76 patients) and 20.0% (16/80 patients) in the PEG3350+E group, respectively. The incidence of adverse drug reactions (ADRs) of placebo and PEG3350+E were 5.3% (4/76 patients) and 7.5% (6/80 patients), respectively.

In the whole phase 3 trial, the incidence of AEs was 78.8 % (123/156 patients) and the incidence of ADRs was 21.2 % (33/156 patients). The most common ADRs were gastrointestinal disorders (abdominal pain: 4.5%, diarrhea: 3.8%, nausea: 3.2% and abdominal distension: 2.6%). The incidence of AEs did not increase through the whole phase 3 trial.

Conclusion: PEG3350+E resolves constipation compared to placebo in the medium term, is well tolerated and improves bowel functions when administered for 52 weeks in Japanese patients with chronic constipation.

Contact E-Mail Address: amir.mari@hotmail.com
Introduction: Patients with faecal incontinence (FI) who are refractory to Loperamide and biofeedback may respond to neuromodulation. Previous data suggests a possible benefit of Cholestyramine, an anion exchange resin, binds to bile in the gastrointestinal tract, for FI management. We report a single center experience of Cholestyramine in the treatment of FI.
Aims and Methods: We report 44 patients with FI refractory to lifestyle modification, Loperamide and biofeedback therapy. All patients had organic disorders excluded by serology and endoscopy, and also had intact anal sphincters on endoanal ultrasound. *Group A* patients received Cholestyramine (median dose 4.9g per day) along with Percutaneous tibial nerve stimulation (PTNS) for 12 weeks and *Group B* received PTNS alone. Bristol stool form scale (BSFS), weekly incontinence episodes, weekly stool frequency, median St Mark's faecal incontinence score and days per week with abdominal pain were assessed at baseline and 12 weeks after therapy. SeHCAT studies were undertaken in some patients during PTNS.
Results: Data is shown in the Table with group A patients showing greater improvement in stool form, bowel frequency, episodes of incontinence and incontinence score compared to Group B. Only Group A patients had reduced abdominal pain. A responder analysis (>50% episodes reduction) was greater in Group A than B (73% vs 48%). In total, 26 patients underwent SeHCAT testing, 13 in each group: in Group A 7/13 were positive of whom 6 responded to cholestyramine + PTNS, in Group B 5/13 were positive, none of whom responded to PTNS alone.
Conclusion: Cholestyramine is efficient adjunctive therapy to PTNS for FI management. A positive SeHCAT was seen in 46% of patients, and associated with an excellent response to Cholestyramine.

Contact E-Mail Address: gridin_8@hotmail.com
Introduction: Previous studies have shown that green kiwifruit is a fiber-rich fruit that enhances colonic transit and may be effective for treatment of constipation in humans. However, non-soluble fibers are fermented by colonic bacteria increasing intestinal gas production and thereby may produce bloating and abdominal distension, a common complain of patients with functional gut disorders.
Aims and Methods: Our aim was to determine the effect of kiwifruit intake on gas production, transit, and tolerance to intestinal gas.
In 10 healthy individuals, transit and tolerance to intestinal gas was studied using a previously developed model of gas retention induced by lipids. A mixture of non-absorbable gases was infused into the jejunum at 12 mL/min for 2 h (total volume 1440 ml) with simultaneous duodenal lipid infusion (Intralipid 1 kcal/min). Intestinal gas clearance was continuously measured using a rectal cannula connected to a barostat. Abdominal symptoms, by a 0–6 score questionnaire and abdominal distension, by a metric tape, were measured at 10-min intervals during the gas infusion period. In each participant, 2 gas transit studies were performed in separate days and random order: 1) after 2 weeks on a low flatulogenic diet and daily intake of 2 kiwifruits (Green Kiwifruit, Zespri, New Zeland) and 2) after 2 weeks on the same low flatulogenic diet but without intake of kiwifruits. During the 2 weeks on low flatulogenic diet prior to the gas transit test, the number and consistency of stools, and abdominal symptoms were daily registered using specific diaries.
Results: During the 2 weeks with daily intake of 2 kiwifruits, participants reported a greater number of bowel movements (1.8±0.1) and a looser consistency of the stools (Bristol score 3.3±0.2) than during the 2 weeks off-kiwifruit (1.5±0.1 bowel movements/day; $p = 0.0009$ vs on-kiwifruit, and Bristol score 2.8±0.1; $p = 0.0716$ vs off-kiwifruit), without differences in the referred abdominal symptoms (abdominal pain score 0.1±0.1 and bloating score 0.1±0.0 on-kiwifruit; pain score 0.0±0.0 and bloating score 0.1±0.0 off-kiwifruit). During the gas transit studies, there were no differences in the volume of gas evacuated (1238±254 ml and 1172±290 ml on-kiwi and off-kiwi, respectively; $p = 0.4355$), in the subjective abdominal perception of symptoms (score 1.2±0.2 and 1.3±0.3 respectively; $p = 0.2367$) or in objective abdominal distension (girth increment 17±7 mm and 17±6 mm respectively; $p = 0.4704$).
Conclusion: Green kiwifruit increases the number of bowel movements and reduces the consistency of stools without increasing gas production or transit and tolerance to intestinal gas.
Disclosure: Nothing to disclose

P0446 CHANGES IN PSYCHOLOGICAL PROCESSES THROUGHOUT ANORECTAL BIOFEEDBACK THERAPY: CORRELATIONS WITH DYSSENERGIC DEFECATION AND FAECAL INCONTINENCE OUTCOMES

Introduction: Anorectal biofeedback (BF) therapy has established efficacy for both fecal incontinence and dyssynergic defecation. The BF program involves education and advice on toileting behaviour and positioning, diaphragmatic breathing, manometric-based biofeedback aimed at normalising anorectal physiology, sensory retraining and balloon expulsion retraining. In addition to pretreatment clinical state [1], some psychological characteristics of patients have shown to predict BF efficacy [2]. Although psychological mechanisms must be involved in this learning process, there is little information on the psychological changes that occur through anorectal BF.
Aims and Methods: Our aims were to determine (1) what psychological traits change as a result of BF, and (2) whether changes in psychological traits correlate with changes in patient symptoms and quality of life, in order to better understand their role in treatment efficacy. 67 patients ($M_{age} = 57$, $SD = 17$, 93% female) presenting to the Neurogastroenterology Unit at the Royal North Shore Hospital (Sydney, Australia) with fecal incontinence (FI) ($n = 39$) or dyssenergic defecation ($n = 28$) underwent a 6-visit instrumented anorectal BF program. Measures of executive function, cognitive flexibility, perceived stress, emotion regulation and self-efficacy were recorded prior to and at the end of therapy. Patient reported outcomes were symptom severity (Fecal Incontinence Severity Index and Constipation Score) and quality of life (Fecal Incontinence QOL and Patient Assessment of Constipation QOL) for FI and dyssenergic defecation patients as appropriate. Spearman's correlations above 0.3 were considered clinically meaningful (and bolded in the Table).
Results: Patients' perceived stress, executive function, cognitive flexibility, self-efficacy, and adaptive health-focused emotion regulation significantly improved throughout BF (all $Zs \geq 2.13$, all $ps < 0.05$. Change in psychological traits correlated more strongly with changes in QoL, as opposed to symptom severity (see Table). Improvement in constipation QoL was moderately correlated with greater decrease in stress and executive function impairment; improvement in FI QoL correlated with greater reduction in self-blame and catastrophizing, and increases in cognitive flexibility and self-efficacy.
Conclusion: Psychological traits of emotion regulation, cognitive functioning and stress improve through BF and correlate with improvements in PRO. While we cannot conclude causal direction of the relationships, our results open the possibility of potential mechanisms in BF efficacy, with potentially different mechanisms for dyssenergic defecation and FI.

Table. Spearman's correlations between change in psychological traits with change in BF PROs. + $p < 0.10$ * $p < 0.05$ ** $p < 0.01$

Change in:	Fecal Incontinence Severity Index	Constipation Score	Fecal Incontinence QOL	Constipation QOL
Perceived stress	0.177	**0.428***	−0.119	**0.391**$^{+}$
Executive function impairment	0.201	−0.007	0.246	**0.366**$^{+}$
Cognitive flexibility	−0.297^{+}	0.031	**0.531****	−0.244
Emotion regulation: self-blame	**0.349***	−0.117	**−0.383***	0.093
Emotion regulation: acceptance	0.206	0.253	**−0.386***	0.166
Emotion regulation: positive refocus	−0.016	−0.138	0.256	**−0.404**$^{+}$
Emotion regulation: planning	−0.069	−0.124	0.002	**−0.391**$^{+}$
Emotion regulation: putting into perspective	0.007	−0.126	0.283	**−0.532****
Emotion regulation: catastrophizing	0.153	0.084	**−0.351**$^{+}$	0.306

Introduction: Treatment of chronic idiopathic constipation is empiric, based on step-wise approach. If first-line conservative treatment (lifestyle advice and laxatives) do not relieve symptoms, secondary approaches with prokinetic or secretagogue drugs are used before considering hospital-based care (biofeedback, psychosocial support, transanal irrigation (TAI), surgery). Nevertheless, patients are often unsatisfied with care and fail to progress to adequate levels of therapy. The 5-point Failure to Provide Adequate Relief (F-PAR) scale was developed to facilitate the recognition of when to move from each step to the next. The aim of this study was to validate F-PAR in a tertiary clinic setting.
Aims and Methods: We studied 403 consecutive consultations of 331 patients (262 women, mean age 41) in our specialist clinic. All fulfilled Rome III/IV diagnostic criteria for chronic constipation. Immediately prior to clinical assessment by 1 of 2 experienced physicians, participants completed the F-PAR scale; patients were seen blind to the F-PAR result. Standard clinic assessment was undertaken to identify efficacy of the current management as the gold standard.
Results: Total of 403 consultations were accomplished, in 200 of which clinical assessment identified inadequate relief with current therapy (laxatives 81 patients, enema 22 patients, prucalopride 42 patients, lubiprostone 12 patients, transanal irrigation 20 patients, biofeedback 97 patients, surgery 3 patints or combination 127 patients). Neither duration nor type of treatment was correlated with relief. All the individual items of the F-PAR had specificity >96% but poor sensitivity (15–67%). Cumulatively, none of the subjects with 4 or more of 5 positive responses on the F-PAR had adequate relief with their current treatment.
Conclusion: We have shown that the F-PAR has excellent specificity, suggesting it is a useful confirmatory tests to confirm a clinical suspicion of inadequate relief. Good sensitivity is only seen if there are no positive F-PAR replies implying the F-PAR is only of screening value when there is high likelihood of treatment satisfaction. As such, the F-PAR may have a role in confirming efficacy of treatments in future trials of therapy for chronic constipation.

P0448 RISK OF COLONIC DIVERTICULAR REBLEEDING ACCORDING TO ENDOSCOPIC APPEARANCE

K Kawanishi, M Kitano
Wakayama Medical University, Second Department Of Internal Medicine, Wakayama City, Japan

Contact E-Mail Address: amurosyaa218@yahoo.co.jp

Introduction: Re-commencement of bleeding (rebleeding) of colonic diverticula after endoscopic hemostasis is a clinical problem.
Aims and Methods: This study aimed to examine whether endoscopic visibility of colonic diverticular bleeding affects the risk of rebleeding after endoscopic hemostasis. We performed a retrospective review of endoscopic images and medical charts of patients with colonic diverticular bleeding who underwent endoscopic hemostasis. Endoscopic visibility was classified into 2 types according to visibility of the source of bleeding; source invisibility due to bleeding or attached hematin (type 1), or endoscopically visible responsive vessels (type 2). Rebleeding rates within 1 year after initial hemostasis were examined.
Results: Of 93 patients with successful endoscopic hemostasis, 38 (41%) showed type 1 visibility, while the remaining presented type 2. All patients received hemostasis with clipping, rebleeding developed in 20 patients (22%). Type 1 visibility was more likely to be observed in patients with rebleeding (65% vs. 34%, $p = 0.013$). Multivariate analysis revealed that after endoscopic hemostasis, type 1 visibility (invisible source) was the only independent risk factor for colonic diverticular rebleeding (odds ratio, 3.05; 95% confidence interval, 1.03–9.59, $p = 0.044$). Kaplan-Meier curve showed the cumulative incidence of rebleeding was significantly higher in patients with type 1 visibility than those with type 2 visibility ($p = 0.0033$, log-rank test)
Conclusion: Hemostasis by clipping for colonic diverticular bleeding without definite observation of the source of bleeding may not be sufficiently effective. Other hemostatic methods, including band ligation, should be considered when the source of bleeding is unclear.
Disclosure: Nothing to disclose

Introduction: A validated endoscopic classification of Diverticular disease (DD) of the colon, called DICA (Diverticular Inflammation and Complication Assessment), is currently available.
Aims and Methods: Our aim was to assess the agreement on this classification among an endoscopists community setting.
The DICA score for DD resulted in the sum of the scores for extension of diverticulosis, number of diverticula per district, presence and type of inflammation, and presence and type of complications: DICA 1 (up to 3 points); DICA 2 (from 4 to 7 points); DICA 3 (over 7 points). A total of 55 endoscopists,

subdivided between expert (31 raters, namely endoscopists using this classification in their practice) and not expert about DICA classification (24 raters), independently scored a set of DD endoscopic videos using DICA classification. The percentages of overall agreement on DICA score and a free-marginal multirater kappa (κ) coefficient were reported as statistical measures of inter-rater agreement.
Results: .1375 visualizations were performed. The overall agreement levels among the total group of raters were: DICA 1, 70.2%; DICA 2, 70.5%; DICA 3, 81.3%. The inter-rater agreement between the 55 evaluators varied as follows: DICA, 1 free-marginal $\kappa = 0.553$; DICA 2, free-marginal $\kappa = 0.558$; DICA 3, free-marginal $\kappa = 0.719$.
The overall agreement levels among the expert group of raters were: DICA 1, 78.8%; DICA 2, 80.2%; DICA 3, 88.5%. The inter-rater agreement between the 31 expert evaluators varied as follows: DICA 1, free-marginal $\kappa = 0.682$; DICA 2, free-marginal $\kappa = 0.712$; DICA, 3 free-marginal $\kappa = 0.828$
Conclusion: DICA score is a simple, reproducible, and easy-to-use endoscopic scoring system for diverticular disease of the colon. The inter-rater agreement in this study was strong with a significant improvement in the expert subgroup of raters.

Contact E-Mail Address: francesco.dimario@unipr.it
Introduction: Symptomatic Uncomplicated Diverticular Disease (SUDD) affects about 20% of patients having diverticulosis. However, there is no consensus about the best treatment in treating this disease and in preventing the disease's complications. Rifaximin, a not absorbable antibiotic, is currently advised as effective treatment in controlling symptoms and in preventing complications, but no long-term data are available.
Aims and Methods: Our aim was to assess the outcome of a cohort of SUDD patients treated with rifaximin during a retrospective follow-up study. The study group (group A) included 346 SUDD patients with a median (range) age of 61(49–83) years, of whom 216 (62.4%) were females. Patients were treated with rifaximin 800 mg/day for 7 days/month. The control group (group B) included 470 patients SUDD taking spasmolithics when needed, with a median (range) age of 59 (47–81) years, of whom 288 (61.3%) were females. Diagnosis of SUDD was performed by colonoscopy and by clinical accepted criteria. Follow-up visit was performed every 12 months or whenever patients consider it necessary. At each control visit, symptoms were assessed by the Global Symptomatic Score (GSS), assessing 4 main variables (left lower abdominal pain, bloating, diarrhea, constipation) graded as 0 = no symptom; 1 = mild, symptoms easily tolerated; 2 = moderate, symptoms sufficient to cause interference with usual daily activities; and 3 = severe, incapacitating symptoms with inability to perform normal activities).
Results: At baseline global symptomatic score (interquartile range) was 7 (5–8) in the study group and 6 (4–8) in the control one ($p = 0.243$). Either abdominal pain or bloating or bowel alteration were comparable between the 2 groups. At a median (range) follow-up of 8 (5–12) years global symptomatic score (interquartile range) was 3 (1–4) in the study group and 5 (3–7) in the control group ($p = 0.002$). With exception of abdominal pain, either bloating or bowel alteration were significantly reduced in the study group with respect to the control group.
The number of visit/patient/year were 2.4 patient/year in group A and 4.2 patients/year in group B ($p = 0.02$). Acute diverticulitis occurred in 9 patients (2.60%) in group A and in 21 patients (4.46%) in group B ($p = 0.01$). Surgery due to complication of the disease occurred in 4 patients (1.16%) in group A and 9 (1.91%) in group B ($p = 0.06$). Deaths due to disease were 0 in group A and 2 (0.42%) in group B ($p = 0.303$).
Conclusion: Rifaximin is effective in the symptomatic relief of symptomatic uncomplicated diverticular disease of the colon. In particular, symptomatic relief was due to a significant reduction in bloating and bowel alteration symptomatic score. Finally, rifaximin seems to be also effective in reducing the risk of disease's complications.

Introduction: Although diverticular disease is an extremely common condition, its effective treatment represents a difficult task in daily clinical practice. We have used the Italian national 'Registro Malattia Diverticolare' (REMAD) registry, an ongoing 5-year prospective, observational, multicenter, cohort study in 1206 consecutive patients with diverticular disease, to assess the prevalence of treatment use in the different clinical entities of this disorder and the demographic and clinical factors associated.
Aims and Methods: At the entry in the REMAD registry, patients were categorized in subgroups according to different clinical entities: diverticulosis, symptomatic uncomplicated diverticular disease (SUDD), previous diverticulitis (PD). Demographic, clinical and lifestyle factors and quality of life were registered (Carabotti et al., *UEG Journal* 2018 in press) as well as the use of 1 or more treatments for diverticular disease (including poorly absorbed antibiotics, like rifaximin, mesalazine, probiotics, prebiotics, fibers, and antispasmodics) in the last year. Logistic regression analysis was used to assess the association between demographic and clinical factors with treatment assumption.
Results: 500 of the 1206 subjects (41.5%) included in the study have taken at least 1 treatment for diverticular disease in the last year. Of these subjects, 166 belong to diverticulosis group (of a total of 702 subjects with diverticulosis, 23.6%), 165 to SUDD group (of a total of 295 subjects with SUDD, 55.9%), and 169 to PD group (of a total of 209 subjects with PD, 80.9%) ($p < 0.0001$ for all). In all groups, poorly absorbed antibiotics, particularly rifaximin, were the most common treatment, accounting for 87.3% in diverticulosis, 84.8% in SUDD and 75.7% in PD. In a multivariate analysis, the following factors resulted to be significantly associated with treatment use: female gender (OR = 1.6; 95% CI, 1.2–2.2), family history of colonic diverticula (OR = 1.5; 95% CI, 1.1–2.1), gastrointestinal comorbidity (OR = 1.9; 95% CI, 1.4–2.5) and impairment of quality of life, particularly the physical component summary (PCS) score (OR = 1.6; 95% CI, 1.2–2.2). Interestingly, older age (OR = 2.04; 95% CI, 1.1–3.7) and gastrointestinal comorbidity (OR = 2.1; 95% CI, 1.4–3.2) were the most relevant factors associated with the use of treatments in diverticulosis, while first-degree family history for colonic cancer (OR = 2.4; 95% CI, 1.0–5.7) and for diverticula (OR = 2.3; 95% CI, 1.1–4.9), the presence of gastrointestinal comorbidity (OR = 2.3; 95% CI, 1.3–4.3) and the impairment of PCS score (OR = 2.2; 95% CI, 1.2–4.2) were significantly associated with treatment use in SUDD.
Conclusion: Pharmacological approaches targeting enteric bacteria (with poorly absorbed antibiotics, like rifaximin) were the most common therapies in diverticular disease, due to their ability of controlling symptoms and also preventing complications. In addition, this nationwide registry study identified different demographic and clinical features associated with the use of pharmacological treatments in the distinct clinical entities of diverticular disease. The optimal regimen of therapy must be established in *ad hoc* studies. ClinicalTrial.gov Identifier: NCT03325829.

P0452 ACUTE COLON DIVERTICULITIS HOSPITALIZATION TRENDS IN VENETO REGION (NORTHEAST ITALY)

D Caroli[1], M Saia[2], E Rosa-Rizzotto[3], F De Lazzari[4]
[1]*St Antonius Hospital, Dept. of Gastroenterology, Padova, Italy*
[2]*Veneto Region, Padova, Italy*
[3]*St. Anthony Hospital Gastroenterology Unit Dept. of Medicine, Dipto. di Gastroenterologia, Padova, Italy*
[4]*Gastroenterology Unit, St Anthony Hospital, Padova, Italy*

Contact E-Mail Address: d.caroli@libero.it
Introduction: Diverticular disease (DD) of the colon represents a common clinical condition affecting with high rate the population in developed countries. Several epidemiological studies have clearly shown that in the last decades the rates of hospital admissions for Acute Colon Diverticolitis (ACD), the most important complication of DD, is progressively increased.
Aims and Methods: Describe the hospitalization trend for ACD in Veneto region (North East Italy), including in-hospital mortality, and evaluate the impact of specialistic admission hospital units as Gastroenterologic (GE) units.
Data were obtained from the Veneto Region anonymous Hospital Discharge Record database from 2000 to 2017, in which diverticulitis of colon [ICD-9-CM code 562.11 and 562.13 (diverticulitis with and without mention of haemorrhage)] was the primary diagnosis.
Standardized Hospitalization Rate (SHR) per 5-year group (ref. pop. Veneto 2009) was calculated and expressed per 100,000 population.
To evaluate the impact of admission hospital units on the outcome of ACD management we analyzed in-hospital mortality, need for surgery (NFS) and lenght of stay (LOS).

Results: From 2000 to 2017 a total of 33,249 hospitalization for AD were registered with an increasing rate from 0.30 to 0.46 for 1,000 inhabitants (X^2 trend: 514.182 $p < 0.001$; mean increase of 2.6% per year, $p < 0.001$).
Mean age was 66.1±28.4, higher in female (70.1±29.8 vs. 60.5±24.9; $p < 0.05$) and the higher hospitalization rate (overall mean: 0.39) was in female (0.43 vs. 0.34; OR: 1.30; 95% CI:1.27–1.32; $p < 0.001$). SHR increased with age reaching the higher value in patients ≥85 years (162.43) with an increase of hospitalization over the study period for all class ages ($p < 0.001$).
Women showed an higher prevalence of hospitalization compared to men (OR: 1.30; 95% CI: 1.27–1.32; $p < 0.001$), and both genders presented an increasing trend, with a mean increase per year of 1.9% and 3.8% respectively ($p < 0.001$).
NFS was substantially stable (19.4%) while overall in-hospital mortality rate showed an important increase from 0.37 to 0.98 ($p = 0.037$). Also LOS decreased significantly (−18%) from 9.8 to 8 days ($p < 0.001$).
73% of patients were overall admitted by surgical units with a steady increase for admission in medical ones from 22% to 34% and in particular in GE units where admission rose from 7% to 22% of overall admission of Medical Area.
From the comparison between GE units and other medical area admissions, emerged that patients admitted in GE units do not have a significantly lower ($p > 0.05$) NFS rate (3.5% vs. 4.1%) and in-hospital mortality (0.3% vs. 1.4%), showing a significative lower LOS (7.1±2.2 vs. 11±3.6; $p < 0.001$).
Conclusion: Results suggest that ACD is an emerging heath-care problem related to the rising of age.
Through the years the NFS rate was stable with an increase of mortality.
In this scenary GE units seem to be more efficiently obtaining a significative reduction of the cost management of ACD.

Introduction: Colonic diverticulosis is one of the most common gastroenterological disorders. Although diverticulosis is commonly benign, many individuals develop diverticulitis or other complications of diverticular disease. Diverticular disease is caused by a complex interaction of environmental and genetic factors. A recent genome wide study (Sigurdsson et al. *Nat Commun* 2017) identified gene variation in the Family with sequence similarity 155A (*FAM155A)*, Collagen-like tail subunit of asymmetric acetylcholinesterase (*COLQ)* and Rho GTPase-activating protein 15 (*ARGHGAP15)* genes, but was derived from population based-data, and the cohorts were not stratified into diverticulosis and diverticulitis.
Aims and Methods: The aim of our present study was to assess the effects of the detected risk variants in an endoscopically characterized cohort containing 1,275 patients referred for colonoscopy to 3 academic medical centers in Germany (Homburg and Köln) and Lithuania (Kaunas), and specifically dissect the association with the distinct phenotypes diverticulosis and diverticulitis. Presence of diverticulosis was assessed with colonoscopy in all patients, and diverticulitis additionally confirmed with ultrasound and/or computed tomography. Risk variants in *ARHGAP15* (rs4662344-T), *COLQ* (rs7609897-T) and *FAM155A* (rs67153654-A) were genotyped using Taqman assays in 778 patients with diverticulosis, 169 patients with diverticulitis and 462 controls of Caucasian descent and free of diverticulosis (as confirmed by colonoscopy). The associations of the risk variants with (i) colonoscopy-proven diverticulosis as compared to controls free of diverticulosis and (ii) patients with prior diverticulitis as compared to patients with diverticulosis and no prior diverticulitis were assessed in multivariate models including the established environmental risk factors age and body-mass index (BMI) (diverticulosis), as well as age, BMI, intake of nonsteroidal-antiinflammatory drugs (NSAIDs), smoking, and daily alcohol intake (diverticulitis).
Results: Median age of our patients was 64 years (interquartile range [IQR] 55–72). Overall, 47% ($n = 598$) were male. The variant in *COLQ* (rs7609897) deviated from Hardy-Weinberg equilibrium in controls and could not be included in the analysis. Median body mass index (BMI) was 27.6 kg/m^2 (IQR 24.8–31.2). In univariate analysis for diverticulosis age ($p < 0.001$) and BMI ($p < 0.001$) were significantly associated, and the presence of a risk variant in *ARHGAP15* was borderline significant ($p = 0.06$). Neither the risk variant *FAM155A* nor sex were associated with diverticulosis. In multivariate logistic regression analysis, age and BMI remained significant. In univariate analysis for diverticulitis, frequent NSAID intake ($p < 0.001$), age ($p < 0.001$), BMI ($p = 0.02$) and the risk variant in *FAM155A* ($p = 0.037$) where associated with diverticulitis, whereas daily alcohol intake, smoking and the risk variant in *ARHGAP15* were not. In multivariate logistic regression analysis, BMI ($p = 0.017$) and NSAID ($p < 0.001$) remained significant, and there was a trend for the *FAM155A* risk variant ($p = 0.10$).
Conclusion: A complex network of risk factors modulates diverticulosis and the development of diverticulitis. In addition to confirming previously known environmental risk factors in our cohort, a risk variant in *FAM155A* (rs67153654) might be associated with diverticulitis, but not diverticulosis.
Disclosure: Nothing to disclose

P0454 EVALUATION OF HIGH-RESOLUTION ANOSCOPY AS A SCREENING TOOL FOR ANAL INTRAEPITHELIAL NEOPLASIA (AIN): A COMPARISON TO THE GOLD STANDARD ANAL MAPPING BIOPSIES

Contact E-Mail Address: jan.borovicka@kssg.ch
Introduction: Human papillomavirus-associated anal intraepithelial neoplasia (AIN) is a precursor of invasive anal carcinoma. High-resolution anoscopy (HRA) is recommended as a screening tool for AIN (1). However, the diagnostic accuracy of this method is unclear. In contrast, anal mapping biopsies (AMB) are not routinely performed and are not mentioned in the current guidelines. Whether they bring additional diagnostic benefit is unclear. To our knowledge, HRA has never been compared with systematic anal mapping biopsies before.
Aims and Methods: We aimed to evaluate HRA as a screening tool for AIN in comparison to anal mapping biopsies as the gold standard.
Retrospective analysis of a cohort of consecutive patients at risk for AIN, in whom both HRA and anal mapping biopsies had been performed. Histological findings of anal mapping biopsies performed on suspected HPV-associated lesions were compared with HRA findings. The comparison of HRA with mapping biopsies was carried out by inspection and description of lesions as a whole (lesion-based analysis) and for each field (field-based analysis). For the field-based analysis, the anal region of each patient was divided into 28 fields, which were assessed (HRA) and biopsied separately.
Results: 29 patients (20 male, 9 female) with anal mapping were analysed during 2 years. Of the 20 male patients, 11 were HIV positive and 14 practiced men sex with men (MSM). All women were HIV negative. HRA identified 23 lesions suspicious for AIN. 22 lesions (96%) were histologically confirmed as AIN. Anal mapping detected 27 AIN lesions. In HRA, the 22 confirmed lesions spread over 49 fields and 60 additional fields were detected by mapping biopsies (+122%). HRA shows in the lesion-based analysis a sensitivity of 84.6%, a specificity of 87.5%, a PPV of 95.7% and a NPV of 63.6%. For field-based analysis, HRA shows a sensitivity of 45%, a specificity of 98.6%, a PPV of 83.1% and a NPV of 92%.
Conclusion: This study shows that, although most AIN are detected with HRA, their extent is underestimated by 120%. It can be assumed that the repeatedly observed high recurrence rate (up to 60% in 2 years) after highgrade-AIN therapy is not only caused by overlooked lesions or due to their biological properties but also by underestimating their extent (2,3). This is relevant for therapy, especially when therapeutic interventions without resection and histological evaluation of the margins such as cryotherapy, CO_2 laser ablation, or RFA are used. In summary, the results of this study imply that anal mapping biopsies should be considered prior to local therapy, at least in high-risk patients with positive results in the HRA study.
Disclosure: Grant by Olympus, comperative study HRA vs. endoscopy for AIN diagnsotics

Introduction: The diagnosis of Hirschsprung's disease (HD) relies on anorectal manometry, barium enema and rectal biopsy. The role of endoscopic biopsy is not well-known for the diagnosis of HD in children.
Aims and Methods: In this study, we evaluated the safety and adequacy of biopsies procured by endoscopic mucosal resection (EMR) for the diagnosis of HD. All the children with suspected HD underwent anorectal manometry and barium enema. Children with absence of recto-anal inhibitory reflex and/ or radiological images suggestive of HD were included in the study. EMR was performed using the standard band ligation device at a distance of about 3 cm from dentate line along posterior wall of rectum. Submucosal lifting injection (saline + indigocarmine dye) was done in children < 3 years of age. All samples were assessed macroscopically and microscopically. Adequate sample was defined as - measuring >3 mm and including adequate submucosa for identification of ganglion cells.
Results: 6 children (median age, 5 years) underwent EMR using the band ligating device for the evaluation of HD. EMR was performed with and without submucosal lifting injection in 2 and 4 children, respectively. All the samples were adequate macroscopically (>3 mm). The mean volume of biopsy specimen was 0.11 ± 0.07 $cm^3$with inclusion of submucosa in all children. Ganglion cells were identified in 3 children and thereby, excluding the diagnosis of HD. There were no immediate or delayed complications.
Conclusion: Rectal biopsy using EMR with a band ligating device is feasible and provides adequate sample for the evaluation of HD in children.

Introduction: Persistent symptomatic hemorrhoidal disease after general counseling measures requires instrumental intervention. The benefit of the association of phlebotonics is uncertain.
Aims and Methods: Comparative study on the efficacy and safety of 4 instrumental non-surgical modalities for treatment of prolapsed internal hemorrhoids (IH).
Prospective (2016–2018) randomized non-blinded sequential trial with four intervention arms: Rubber band ligation (B) vs. Sclerotherapy with foam Polidocanol (PLDf) vs. [Ligation + phlebotonics (B+P)] vs. [PLDf + P]. Inclusion of adult patients with IH (grade II-III) diagnosis with no previous instrumental treatment, after signed written consent. Demographic and clinical characterization. Assessment of outcomes: Safety (adverse events after intervention); efficacy (complete, partial or absent response) at week 4–8 (short-term) and weeks 12–24 and 44–52 (long-term). Reintervention if indicated, at the same timepoints. Statistics: Oneway ANOVA, Welsh and Levéne test; chi-square.
Results: 68 patients were included (37 males, mean age 54 ± 12.8 years) and distributed among the 4 treatment groups (19 vs.19 vs.17 vs.13), adjusted for age ($p = 0.92$) and gender ($p = 0, 86$).
Short-term analysis - all patients were evaluated for this analysis. 3 cases of self-limited pain only, were documentes. Efficacy was superior for B group [no case of lack of response and 12/19 cases of complete response ($p = 0.006$)].
Long-term analysis - 46 patients were assessed (5 dropouts, 17 still incomplete follow-ups). 100% and 43% re-interventions were preformed on the 2nd and 3rd timepoints without reported adverse events In this long-term evaluation there is no difference between the treatment modality and the efficacy, time made the outcomes similar between treatment groups: The efficacy of each treatment is provided in 75% complete response and 25% partial response, with numerical superiority for the PLDf + P group (87.5% and 12.5%, respectively).
Conclusion: Non-surgical instrumental IH therapy is safe and globally effective. B showed to have superior efficacy at week 4 to 8, after a single intervention. Efficacy over time and after re-interventions is similar for B and PLDf. Combined PLDf + P therapy seems to enhance sustained efficacy over time.

Introduction: Human immunodeficiency virus (HIV) infection contributes to the occurrence of anal cancer in men who have sex with men (MSM), leading to a 30–100 fold higher anal carcinoma incidence in this patient group. Therefore convenient screening tools are mandatory to identify anal intraepithelial neoplasia (AIN) at early stages, which allow an early curative intervention.
Aims and Methods: In this pilot study we screened for anal carcinoma in HIV positive MSM, receiving stable antiretroviral therapy. Endoscopic high-intensity contrast (HIC) and the most recently introduced Blue Light Imaging technology (BLI) with optical magnification were applied during high-resolution anoscopy. The HIC/BLI equipped endoscope was advanced into the anal region of interest via a pre-inserted standard rectoscope. Conventional imaging in combination with aceto-enhancement, anal swaps as well as directed biopsies served as reference methods to identify AIN.
Results: Following preliminary inclusion of consecutive HIV patients, median (range) age 49.5 (37–61) years, CD4-count 633 (298–1076) cells/µl and HIV-RNA 0 (0–34) copies/ml, we were able to identify 1 patient with *condyloma acuminata* and low-grade AIN. HIC/BLI as well as aceto-enhancement both resulted in consistent findings and lead to the diagnosis of AIN. In addition magnified HIC/BLI revealed irregular superficial vascular network pattern within the identified AIN and condyloma lesions. In contrast, anal swaps and cytology, showing inconclusive results (PAP IIb) in 20% (1/5) and normal cytology in 80% (4/5), were not able to identify AIN in these patients.
Conclusion: HIC/BLI enhanced anoscopy provides an additional time-sparing method for the screening of anal carcinoma in HIV infected patients. High-definition imaging with the BLI technology also allows for identification of vascular patterns, which might help to characterize dysplastic anal lesions and might therefore allow for more targeted diagnosis and treatment.

Contact E-Mail Address: jregula@coi.waw.pl
Introduction: Oral Trisulphate Solution (OTS) is a low-volume bowel cleansing solution administered as 2 x 500 ml saline sulphate solution followed by 2 x 1 l water or clear liquids (for hydration). The aim of this study was to: assess misuse (defined as non-compliance with hydration); describe the safety profile overall and in case of misuse; and identify any immediate/acute adverse events (AEs) in special populations (the elderly and patients at risk of electrolyte shifts).
Aims and Methods: This was a prospective, non-interventional, multicentre, European Post Authorisation Safety Study (PASS) in patients receiving OTS in routine clinical practice (NCT02630680), requested by the European Medical Agency. Inclusion began on 12 October 2015 and ended on 20 January 2017. Consecutive patients who went for colonoscopy and were eligible for OTS were included at each participating centre, to achieve a target enrolment of 76 patients per site. Patients were instructed to record compliance and AEs on a leaflet. Compliance to hydration was calculated as a ratio of actual volume taken versus prescription 2 l. Non-compliance was defined as having taken $< 75\%$ of hydration. Missing volumes were imputed as not taken. Investigators assessed colon cleansing level on a 4-point scale.
Results: 1281 patients were recruited in 16 centres in the Czech Republic, Germany, the Netherlands and Poland. 1206 patients took OTS and provided safety information (safety population). 1177 patients reported their level of compliance (registry population). The most frequent indications for colonoscopy were screening (33%), a history of polyp or neoplasm (21.7%), and abdominal pain (13.2%). 94.5% of patients were compliant to hydration guidelines; 86.8% of patients were 100% compliant (Table). Compliance to osmotic OTS solution was 96.8%. Subgroup analyses (age, gender, dosing regimen) revealed no differences in compliance. Reported colon cleansing level was excellent-to-good in 1048/1196 patients (87.6%). 329 patients (27.3%) experienced 758 related treatment-emergent AEs (TEAEs), mostly gastrointestinal (82.9%). Most TEAEs were considered mild or moderate in intensity. TEAEs were similar in compliant versus non-compliant patients, and in elderly versus younger patients; however, significantly more TEAEs were noted in female than male patients. TEAEs were not associated with lower compliance. No AEs suggestive of dehydration were

noted in non-compliant patients. No acute AEs were observed in special populations. TEAEs did not differ in nature and intensity from the known safety profile overall and in special populations.
Conclusion: In this non-interventional study, treatment compliance to hydration guidelines was excellent or good in 94.5% of patients. The safety profile of OTS was good and similar to previous reports overall and in special populations.

Compliance to hydration guidelines: registry population (N = 1177)	n (%)
Compliant patients (volume taken ≥75%)	1112 (94.5)
Excellent (100%)	1022 (86.8)
Good (<100 and ≥75%)	90 (7.6)
Compliant patients to hydration guidelines by subgroups	**n (%) [95% CI]**
<65 years (n = 720)	689 (95.7) [93.9; 97.1]
≥65 years (n = 457)	423 (92.6) [89.8; 94.8]
Male (n = 606)	576 (95.0) [93.0; 96.6]
Female (n = 571)	536 (93.9) [91.6; 95.7]
Related TEAEs: safety population (N = 1206)	**n (%)**
Any related TEAEs [number of occurrences]	329 (27.3) [758]
Compliant patients (n = 1120)[95% CI]	304 (27.1) [24.6; 29.8]
Non-compliant patients (n = 86)[95% CI]	25 (29.1) [19.8; 39.9]
Male (n = 618) [95% CI]	110 (17.8) [14.9; 21.0]
Female (n = 588) [95% CI]	219 (37.2) [33.3; 41.3]

[Table: Patient compliance, and treatment-emergent adverse events]

Introduction: Colonic bubbles are common and obscure the colonic mucosa during colonoscopy with polyethylene glycol plus ascorbic acid (PEG-Asc). Antifoaming agent, simethicone was known to enhance colonic visualization during colonoscopy.
Aims and Methods: The aim of this study was to determine the optimal timing to add simethicone for improving bowel preparation during colonoscopy using PEG- Asc. This single-center, prospective, double-blind, randomized study enrolled the patients undergoing elective colonoscopy between January 2017 and January 2018. All patients were taken polyethylene glycol plus ascorbic acid (PEG-Asc) for bowel preparation. They were randomly assigned to 3 groups; received only PEG-Asc (Control) or adding simethicone in the morning on the day of colonoscopy (PEG-S1) or adding simethicone in the evening a day before colonoscopy (PEG-S2). The primary outcome measure colon cleansing quality using air bubble grades in 5 colonic segments (cecum, ascending, transverse, descending and rectosigmoid colon). The secondary outcomes were adenoma detection rates (ADR), polyp detection rates (PDR) and diminutive adenoma/polyp detection rates (diminutive ADR/PDR).
Results: 240 patients were randomly allocated to the 3 groups; 6 patients were withdrawn. Of 234 patients evaluated, 78 patients were control group, 79 patients were PEG-S1group and 77 patients were PEG-S2 group. Air bubble grades of all colonic segments were most significantly lowest in PEG-S2 group. There was no significant difference in the ADR and PDR among the 3 groups. However, diminutive PDR was significantly higher in PEG-S2 group compared with other 2 groups (Control: 11.5% vs PEG-S1: 8.9% vs PEG-S2: 23.4%, p = 0.038).
Conclusion: Bowel preparation with PEG-Asc plus simethicone eliminates air bubble effectively. Furthermore, adding simethicone at the optimal time could improve the quality of bowel preparation, especially enhancing diminutive PDR.

P0460 PUBLIC ATTITUDES TO COLONOSCOPY: HOW MUCH BOWEL PREPARATION LIQUID MUST BE DRUNK BEFORE A COLONOSCOPY?

B Amlani[1], F Radaelli[2], P Bhandari[3]
[1]*Norgine Ltd., Medical Affairs, Harefield, Uxbridge, United Kingdom*
[2]*Valduce Hospita, Chief, Endoscopy Unit, Department of Gastroenterology, Como, Italy*
[3]*Portsmouth University Hospital, Dept. of Gastroenterology, Portsmouth, United Kingdom*

Contact E-Mail Address: bamlani@norgine.com
Introduction: In European countries, public beliefs and attitudes to bowel preparation before colonoscopy are poorly understood. A survey was conducted to address the issue.
Aims and Methods: An online survey was conducted in 5 large European countries (UK, Germany, France, Spain, and Italy), among members of the general public who had not had a colonoscopy. 1 of 10 questions asked: Before a colonoscopy can be undertaken, the colon must be cleaned by the patient drinking a bowel preparation solution. How much of the bowel preparation liquid do you think a patient needs to drink prior to the procedure? The survey targeted 500 people aged 18–70 years from each country, and aimed to balance respondent groups for region, gender, age and occupation.
Results: Among 53,795 invited persons, 18,650 (35%) responded to the survey and 2,500 (5%) completed the survey who had never had a colonoscopy before across the 5 assessed EU countries. Among these, 13% respondents believed they had to drink maximally 1 half-litre bowel preparation liquid. 16 percent believed they must drink between 1 half and 1 litre, while 38% thought they must drink 1 whole litre. Fewer, 22%, expected to drink 2 litres, and only 12% believed they must drink more than 2 litres. Taken together, nearly 9 out of 10 potential colonoscopy patients expected to drink maximally 2 litres of bowel preparation liquid to accomplish their colon cleansing. The national levels were comparable except for Germany, where only 8 out of 10 respondents expected to drink maximally 2 litres.
Conclusion: The vast majority of people in UK, Germany, France, Spain, and Italy expect to drink 2 litres or less of a bowel preparation liquid before a colonoscopy. Such widespread public beliefs could potentially collide with clinical reality where patients must often drink 3 litres or more to adequately prepare their bowels. The new availability in Europe of highly effective low-volume bowel preparations such as the 1 L polyethylene glycol NER1006 can help close this perceptual gap whilst ensuring reliable cleansing success at a reduced fluid volume intake.

[5]*Imperial College London, Family Cancer of Bowel Cancer Clinic, Isleworth, United Kingdom*

Contact E-Mail Address: ibrahim.al-bakir@doctors.org.uk
Introduction: Genomics and personalised medicine are increasingly relevant for patients with gastroenterological conditions. In the United Kingdom, the higher training curricula of other specialities (e.g. cardiology and oncology) have been revised with the addition of modular training in genomics. We aim to capture the current state of genomics training in gastroenterology in the UK to review current understanding, clinical experience and long-term training needs of trainees, and to assess their preparedness for future consultant practice.
Aims and Methods: A web-based nationwide survey of all UK Gastroenterology specialty trainees was carried out in November and December 2017, supported by the British Society of Gastroenterology national training committee.
Results: 100 trainees (representing 15.2% of the 658 UK gastroenterology trainees) across 17 of 18 regions responded to this survey, representing a full range of gastroenterology registrar training levels.
Only 9% and 16% of trainees believe that their local training programme adequately prepares them for future clinical practice utilising genomic medicine and personalised medicine respectively. Barriers identified (with percentage agreeing or strongly agreeing in parentheses) include the need for greater education of trainees (95%), inadequate clinical guidance to base interventions on the results of genomic testing (53%), concerns over misinterpretation by patients (43%) and overuse/misuse of testing by clinicians (34%).
When assessing current mainstream genetic and personalised tests, trainees felt prepared to perform *HFE* genotyping (98%), assess TPMT status (97%), and

interpret HLA subtyping for suspected coeliac disease (85%). However, only a minority of trainees felt prepared to perform the following investigations: polyposis screening (34%), hereditary pancreatitis screening (30%), testing for Lynch Syndrome (33%), and *KRAS* testing for colorectal cancer (20%). For their future clinical practice, 76% of trainees did not know what mainstreaming of genomics would entail, with only 6% of trainees having recruited patients for the UK 100,000 genomes project.

Most trainees would support having dedicated training days on genomic medicine (83%), formal training provisions for the mainstreaming of genomic testing (64%), an update to both the UK gastroenterology specialty training curriculum as well as the specialty examinations (57%), and better-defined pathways for referral to local genomic services (91%).

Conclusion: Most British gastroenterology trainees feel ill-equipped to practise genomic and personalised medicine as consultants, at a time of progressive mainstreaming of genomic practice in our specialty. We propose that the UK gastroenterology specialty curriculum requires specific revision to prepare trainees for genomics in their future clinical practice, and recommend that other European gastroenterology training programmes also assess their local genomics training requirements.

Introduction: Up to 25% of fecal occult blood test (FOBT)-positive participants of colorectal cancer (CRC) screening programs fail to show up for colonoscopy. For many of them, the main obstacle is not lack of information, oppositional personality or denial, but rather a fear of finding out that they have cancer. The fear paralyzes their ability to start the work up. At the same time, they are completely aware of and frightened of the potential consequences of not undergoing the test. This unresolved emotional stress leads to feelings of anxiety and guilt, and often result in coping by self-explanations as to why the need for the test may not apply in their case, doing repeated FOBTs in the hope the results will be normal, and procrastination - the practice of performing less urgent tasks in preference to more urgent ones, to transfer attention away from it. Physicians often mistake coping mechanisms as patient resistance.

Motivational interview (MI) is a psychological intervention technique designed to facilitate a patient's awareness of the barriers, and aimed to challenge the patient to take steps toward the desired action. Our goal was to examine the efficacy of a brief MI-style telephone intervention in assisting patients to overcome this barrier.

Aims and Methods: Our study comprised 50 consecutive participants of the National CRC screening program who were reported FOBT-positive, and failed to show up for colonoscopy. Patients who completed colonoscopy within 48 months prior to FOBT were excluded.

Participants were randomized 3:1 to an intervention group (a single 5–10 minute telephone call session delivered by a medical psychologist specially trained in MI and problem-solving techniques), and a control group (control for attention; received a telephone call from administrator offering assistance in scheduling the test). The primary outcome was documentation of a colonoscopy, obtained by the 3-month follow-up chart review.

Results: 50 consecutive average CRC-risk patients aged 50–75 years were enrolled. 37 were enrolled for intervention and 13 for control.

The reported barriers for colonoscopy were (no. of patients):

Lack of information, 2
Denial, 1
Oppositional personality, 3
Fear of cancer-related stress, 31
Of these,
Repeated FOBT came back normal, 6
I have an alternative explanation for the result, 5
Would not fight the destiny, 5
Procastination, 15

14 of the 37 patients (38%) approached by the MI agreed to, and underwent colonoscopy. Advanced adenomata were found in 2 (14%), and multiple diminutive adenomata in 1 (7%).

Additional 10 patients (27%) agreed to schedule colonoscopy yet failed to complete the test within the study time-lines. 5 patients expressed significant emotional stress: 3 patients scheduled then cancelled the test, and another 2 stated that they have no emotional strength to fight the destiny.

13 patients (37%) persisted in their refusal for colonoscopy; 5 (38%) stated that their initial stress was relieved by a repeated FOBT and 3 (28%) replied that they would not fight the destiny.

None of the 13 patients in the control group agreed, neither completed colonoscopy within the study period.

Using Fisher's exact test for difference in colonoscopy completion ratio we found that patients approached by MI had a significantly higher probability to complete colonoscopy ($p = 0.007$).

Conclusion: Fear-of-cancer-related psychological barriers are an important obstacle to completion of work-up in FOBT-positive patients. MI is an efficient and valuable tool, and in our cohort helped 38% of patients to overcome this barrier.

Introduction: As of 2009, 19 out of 27 EU countries had a program for colorectal cancer (CRC) screening, with at least 3 countries currently using flexible sigmoidoscopy (FS). FS is the only cancer screening test proven to reduce all-cause mortality in randomized controlled trials. We hypothesize that this unique all-cause mortality reduction is attributable to colorectal cancer prevention rather than early detection.

Aims and Methods: Exploration of the relationship between mortality reduction and CRC prevention in randomized controlled trials of CRC screening. Study Design: Random effects meta-analysis with correlation of study outcomes using Pearson correlation coefficient followed by linear regression for statistically

Heterogeneity: Tau 2 = < 0.0001; Chi2 = 2.33, df = 3 (p = 0.51); I2 = 0% Test for overall effect: Z = 0.22 (p = 0.83)						

significant correlations. Setting or Dataset: Randomized controlled trials specified in the U.S. Preventive Services Task Force 2016 Evidence Report for Colorectal Cancer Screening. Patients: 786,769 normal risk males and females age 45 to 80 years. Interventions: CRC screening with FS or fecal occult blood test (FOBT). Main and Secondary Outcome Measures: All-cause mortality, CRC incidence, mortality attributed to CRC, quantitative comparison of these outcomes for different tests, and correlations of these outcomes.
Results: FS reduces all-cause mortality (relative risk [RR], 0.975; 95% CI, 0.958–0.992) and reduces CRC incidence (RR, 0.79; 95% CI, 0.74–0.84) at 10.5–11.9 years of follow-up, with an all-cause mortality reduction which shows a strong linear correlation with CRC incidence reduction (R, 0.95; 95% CI 0.42–0.99). FOBT does not reduce all-cause mortality (RR, 1.001; 95% CI, 0.992–1.010) nor CRC incidence (RR, 0.96; 95% CI, 0.89–1.02) but does reduce mortality attributed to CRC (RR, 0.84; 95% CI, 0.78–0.91) at 15.6–30.0 years.
Conclusion: All-cause mortality reduction displays a dose-response relationship with CRC prevention and regression analysis indicates that CRC prevention is the sole mechanism of action effecting all-cause mortality in these trials. Early detection of CRC does not appear to reduce all-cause mortality. These findings should inform updated recommendations for effective CRC screening in populations.*[All-Cause Mortality for Randomized Controlled Trials of Flexible Sigmoidoscopy and Fecal Occult Blood Test]*

Introduction: The presence of lymphovascular invasion (LVI) is the most influential risk factor for lymph node metastasis (LNM) and has been recognized as a potential prognostic factor in patients with early gastric cancer. There is accumulating evidence that immunohistochemical (IHC) and elastin stains markedly increase the detection of LVI, and LVI detected by these ancillary stains has stronger correlation with LNM than that by hematoxylin-eosin (HE) stain alone [1]. However, interobserver variability of assessment for LVI could be expected [2], and little is known about that in gastric cancer.
Aims and Methods: The aim of this study was to investigate the interobserver agreement and detection of LVI between 2 pathologists by adding IHC and elastin stain to HE stain.
A total of 60 lesions were randomly selected from lesions which were resected using endoscopic submucosal dissection (ESD) and pathologically diagnosed as submucosal invasive cancer between April 2014 and December 2016. 2 pathologists (A: expert, B: trainee) who were blinded to the clinicopathological information reviewed the specimens. First, they independently assessed lymphatic vessel invasion (LI) and venous vessel invasion (VI) with HE slide alone. Second, they reviewed corresponding slides of IHC stain (D2-40) and elastin stain (Elastica van Gieson; EVG). Interobserver agreement of LI and VI was evaluated using κ coefficients, respectively.
Results: Interobserver agreement of LI and VI in HE slides was poor ($\kappa = 0.35$ for LI; $\kappa = 0.35$ for VI). After reviewing D2-40 and EVG slides, interobserver agreement was improved to good ($\kappa = 0.64$ for LI, and $\kappa = 0.64$ for VI). The detection rate of LI was 23.3% for pathologist A and 18.3% for pathologist B in HE slides. By adding D2-40 slides, the detection rate of LI elevated to 36.7% and 36.7%, respectively. The detection rate of VI was 10% and 6.7% in HE slides. The observation of EVG slides improved the detection rate to 25% and 25%, respectively. Among 40 patients who underwent additional gastrectomy with lymph node dissection after ESD, 3 patients had lymph node metastasis. Although 2 of 3 cases were assessed as LI negative by both 2 pathologists in HE slide, LI was detected in D2-40 slide.

	Staining	κ-Value
Lymphatic vessel invasion	HE	0.346
	D2-40	0.641
Venous vessel invasion	HE	0.348
	EVG	0.644

[Interobserver agreement of lymphatic and venous vessel invasion]
Conclusion: Additional D2-40 and EVG stains improved interobserver agreement between expert and trainee in the histological LVI diagnosis in early gastric cancer. Furthermore, trainee's detection rate increased similarly to the level of the expert.

Introduction: Lymphovascular invasion (LVI) in gastric cancer is the most intensive risk factor of lymph node metastasis and has the greatest influence in determining whether to perform radical gastrectomy with lymph node dissection. [1] Although the interobserver variability of judgment for LVI could be expected even among expert pathologists [2], little is known about the degree of the diagnostic agreement in gastric cancer. Our hypothesis is that the agreement on examination of the hematoxylin and eosin (HE) slides is poor, however the use of ancillary immunohistochemical and histochemical stains improve the interobserver agreement.
Aims and Methods: The aim of this study was to investigate the interobserver agreement in the diagnosis of LVI in gastric cancer among expert pathologists. We randomly selected a total of 60 patients with a postoperative diagnosis of submucosal invasive gastric cancer who underwent endoscopic submucosal dissection (ESD) at Shizuoka Cancer Center Hospital between April 2014 and December 2016. 2 experienced gastrointestinal pathologists (pathologist A and B) who were masked to clinical information independently reviewed the HE slides (one slide from each case). The ancillary staining (D2-40 and EVG) on the corresponding section were then examined. D2-40 was applied for the detection of lymphatic invasion and EVG was used for the detection of venous invasion. The diagnostic agreement was evaluated using κ statistics between 2 pathologists.
Results: The interobserver agreement was 0.59 (95% CI: 0.34–0.84; moderate) in HE and 0.89 (95% CI: 0.77–1.00; excellent) in HE + D2-40. The detection rate of lymphatic invasion in HE was 23.3% for pathologist A and 25.0% for pathologist B. After reviewing D2-40 slides, the detection rate of lymphatic invasion increased in both examiners (A, 36.7%; B, 35.0%). Regarding venous invasion, the interobserver agreement was 0.21 (95% CI: 0.00–0.81; poor) in HE and 0.67 (95% CI: 0.44–0.90; good) in HE + EVG. The detection rate of venous invasion was 10.0% for pathologist A and 3.3% for pathologist B in HE staining. However, the detection rate was also raised to 25% for pathologist A and 20% for pathologist B by adding EVG to HE slides. Among 40 patients who underwent additional surgical resection with lymph node dissection, there were ten cases which were diagnosed as negative for LVI in HE slides and positive for LVI in D2-40 and/or EVG. Lymph node metastasis was histologically confirmed in the dissected specimens in 2 of these 10 patients.
Conclusion: The ancillary staining (D2-40 and EVG) dramatically improved the interobserver agreement among expert pathologists in gastric cancer. The higher detection rate with D2-40 and EVG could lead efficient identification of high-risk patient of lymph node metastasis.
Disclosure: Nothing to disclose

P0466 IDENTIFYING FGF18 AS A POTENTIAL ONCOGENE AND MIR-590-5P TARGET IN GASTRIC TUMORIGENESIS

J Zhang[1], Y Zhou[1], T Huang[1], F Wu[1], H Li[1], J Yu[2], W Kang[1], K.F To[1]

Introduction: Fibroblast growth factors (FGFs) and their receptors are significant components in signal transduction cascade and associated with fundamental cellular processes. FGF18 plays distinctively in modulating the activity of both tumor cells and tumor microenvironment.
Aims and Methods: This study aims to comprehensively investigate the expression and functional role of FGF18 in gastric cancer (GC) and elucidate its regulatory mechanisms. The expression of FGFs and FGFRs were detected among GC cell lines by expression microarray. The clinical relevance of FGF18 in GC was acquired and analyzed from online databases. To identify the biological function of FGF18 in GC cells, siRNAs against FGF18 were applied in the functional assays including cell proliferation, monolayer colony formation, cell invasion, cell-cycle distribution, and anti-tumor drug sensitivity. Expression Microarray was then employed in siFGF18 transfected cells and negative controls to identify the associated signaling pathways. The expression of the key factors in these pathways were validated by qRT-PCR, and the activities of related effectors were examined by Western blot and immunofluorescence. The miRNA that potentially binds to the 3'UTR of FGF18 was predicted by the miRNA database miRDB. The regulation of FGF18 by putative miRNA was confirmed by qRT-

PCR, Western blot, and dual luciferase activity assays. The *in vivo* functional roles of FGF18 and miRNA were demonstrated by the xenograft formation assay.
Results: FGF18 showed higher mRNA level than that of other FGF members in GC cell lines. The relative mRNA expression of FGF18 was upregulated in 7 out of 9 (77.8%) GC cell lines. In primary GC samples, FGF18 was overexpressed in genomically stable and chromosomal instability subtypes of GC and its overexpression was associated with poor survival in GC patients. FGF18 shows gene amplification in some primary samples but the increased copy number changes did not positively correlate with its mRNA upregulation. Knocking down FGF18 led to inhibition of cell proliferation, monolayer colony formation, and cell invasion ability. In addition, siFGF18 induced G1 phase cell-cycle arrest and increased anti-cancer drug sensitivity. The MEK-ERK signaling was suppressed in the siFGF18 transfectants. Expression microarray profiling analysis revealed that silencing FGF18 activated ATM pathway but quenched TGF-β signaling pathway. In ATM signaling, ATM, CTBP1 and TP53BP1 were upregulated in siFGF18 transfected cells. In TGF-β signaling pathway, TGFBR1, TGFBR2, ARRB2 and BAMB1 were downregulated in siFGF18 transfectants. After siFGF18 transfection, the phosphorylated ATM and downstream factor γH2AX were activated, while phosphorylated Smad2 and Smad3 were decreased. FGF18 was further confirmed to be a direct target of miR-590-5p. Their expressions showed a negative correlation in primary GC samples ($r = -0.278$, $p < 0.001$, $n = 367$). miR-590-5p suppressed the tumorigenic properties of GC cells. Re-overexpression of FGF18 partly reversed the tumor-suppressive effect of miR-590-5p.
Conclusion: FGF18 is overexpressed and plays a tumorigenic role in gastric carcinogenesis. The activation of FGF18 in GC is partly due to the silence of a tumor-suppressive miRNA, miR-590-5p. These findings comprehensively deciphered the regulatory mechanism between FGF18 signaling and miR-590-5p, which might imply a constructive therapeutic intervention in GC.

Introduction: Gastric cancer remains a cancer of high incidence and poor long-term survival in Taiwan, despite of the effort to eradicate *H. pylori* infection. Helios belongs to Ikaros family proteins, which perform as tumor suppressors because many studies reported that abnormal expressions of these proteins. Helios can express in regulatory T (Treg) cells and expression of Helios enhanced the suppressive function of Treg. Except the expression in T cells, in our previous study showed that higher expression of Helios in gastric cancer cells with better survival. These tumor suppressive pathways regulated by Helios shall be further examined.
Aims and Methods: To elucidate the Helios function in gastric cancer cells, we used IKZF2-targeting CRISPR-Cas9 system to knock-out Helios expression in AGS cell line. The CCK8-dependent proliferation assay, wound healing assay and invasion assay were performed. We further analyzed the genes expression between AGS and AGS-KO cells by next generation sequencing (NGS), and finally validated the gene expression in AGS and AGS-KO cells by QRT-PCR.
Results: The proliferation was inhibited, while the mobility and invasiveness were increased in Helios knockdown AGS cells compared to parental cells. The data of NGS indicated an increase of SPP1 expression upon depletion of Helios, and SPP1 mRNA was significantly higher expression in knockdown AGS cells. SPP1 has been shown to promote cancer progression and may be a therapeutic target.
Conclusion: Together, our finding illustrates the molecular pathway controlling SPP1 expression and the protective role of Helios in gastric cancer.

Introduction: Gastric cancer is one of the second leading cause of cancer worldwide. Our previous studies showed that aberrant activation of JAK/STAT3 signaling confer epigenetic silencing of its target genes in gastric cancer. However, the clinical significance of aberrant epigenetic silencing of STAT3 targets in gastric cancer is not fully understood.
Aims and Methods: To identify STAT3 targets that are epigenetically silenced by activation of STAT3 in gastric cancer, Illumina 850K methylation microarray was performed in AGS gastric cancer cells and cells depleted with STAT3. Bisulphite pyrosequencing or methylation-specific PCR (MSP) was also performed to examine promoter methylation of the identified targets in tissue or serum/plasma samples from patients with gastric cancer ($n = 53$), IM ($n = 8$), gastritis ($n = 12$) and a panel of gastric epithelial cells including cancer cell lines. While epigenetic drug treatment by DNMT inhibitor together with qRT-PCR was used to examine the role of DNA methylation in the expression of the identified targets.
Results: Integrative methylation microarray and computational analysis identifies SPG20 as one of the STAT3 targets that showed promoter hypomethylation in STAT3 depleted AGS cells. To confirm our results, bisulphite pyrosequencing found that promoter region of SPG20 was hypermethylated in a panel of gastric cancer cell lines including AGS cells but not in GES immortalized gastric epithelial cells. As expected, SPG20 was downregulated in a panel of gastric cancer cell lines in which the expression can be restored by the treatment of DNMT inhibitor thus suggesting that SPG20 is epigenetically silenced by promoter methylation. To determine the clinical significance of SPG20 methylation in gastric cancer, we examined promoter methylation of SPG20 in 53 paired of gastric cancer patient samples, 8 samples of intestinal metaplasia (IM) and 12 samples of gastritis by bisulphite pyrosequencing. Interestingly, promoter methylation of SPG20 is significantly higher in cancer tissues than that of gastritis ($p < 0.01$) and adjacent normal ($p < 0.01$). Unexpectedly, there is no association between SPG20 methylation and tumor grade, stage and patient's survival suggesting that methylation of SPG20 may be an early event. To confirm this hypothesis, we performed methylation specific PCR (MSP) in cfDNA isolated from serum samples of gastric cancer ($n = 53$), IM ($n = 3$) and gastritis ($n = 9$). Interestingly, SPG20 methylation showed a progressive increase in tumor progression (SPG20 methylation% in gastritis = 37.5%, IM = 66.7%, cancer = 91.7%, $p < 0.05$).
Conclusion: Taken together, SPG20, a potential STAT3 target, is frequently hypermethylated in gastric cancer. Methylation of SPG20 may be a novel non-invasive biomarker for early detection of gastric cancer.

Introduction: Gastric cancer is among the most treatment-refractory epithelial malignancies. Aberrant activation of Wnt/β-catenin signaling has been implicated in a variety of human cancers, including gastric cancer.
Aims and Methods: The purpose of this study is to develop optimized strategies for the use of Wnt/β-catenin signaling inhibitors to treat gastric adenocarcinomas. In this study, we tested the efficacy of 2,4-diamino-quinazoline for selective antagonistic effect on Wnt/β-catenin signaling response in gastric cancer cells
Results: Here we first found that the elevated lymphoid enhancer factor 1 (Lef1) expression was associated with TNM (tumor-node-metastasis) stage of gastric cancer. Then we screened for small-molecule compounds that acted against Wnt/β-catenin pathway and consequently suppressed the growth of gastric cancer cells. We identified a selective inhibitor of Wnt/β-catenin signaling, 2,4-diamino-quinazoline, which decreased the expression of Wnt/β-catenin target genes such as Axin2, Myc, and Lgr5, and resulted in the inhibition of gastric cancer cell proliferation through the apoptotic pathway. Additionally, 2,4-diamino-quinazoline also exhibited an inhibitory effect on the migration/invasion of gastric cancer cells. *In vivo* xenograft assay also showed that 2,4-diamino-quinazoline inhibited the growth of the grafted tumor when compared to the control.
Conclusion: Taken together, 2,4-diamino-quinazoline could have significant therapeutic activity against gastric cancer via suppressing Wnt/β-catenin signaling pathway.

Introduction: Hyperthermal intraperitoneal chemotherapy (HIPEC) is a treatment method to cure intraperitoneally spread gastric and ovarian cancer. Although a number of clinical trials report satisfactory results, data remains controversary. Heat shock proteins are known being responsible for cellular resistance to temperature. HO-1 is a heat shock protein, which is induced by hyperthermia.

Aims and Methods: The aim of our *in vitro* study was to clarify the response of gastric and ovarian cancer cells to hyperthermia and cisplatin, following the modulation of HO-1 expression.
AGS (gastric adenocarcinoma), OVCAR-3 (ovarian adenocarcinoma) cells were treated with different temperature regimens (normothermia: 37°C; and hyperthermia: 43^0C) either in isolation or combined with IC_{50} of cisplatin for one hour. Prior the treatment experimental groups of cells were HO-1 silenced by siRNA transfection. MTT was used to evaluate cells viability. Apoptosis was assessed by flow cytometry, using Annexin V-PE and 7ADD. Real-time cell analyzer was used to evaluate the changes of viable cell rates in real time manner. HO-1 expression was detected by QRT PCR and Western blot.
Results: Cisplatin increased *HO-1* expression by 3.73-fold in normothermia and 2.4-fold in hyperthermia for OVCAR-3 cells. Hyperthermia stimulated the increase of *HO-1* expression unsignificantly by 1.34-fold. *HO-1* expression was not affected neither by temperature, nor by cisplatin in AGS cells. In OVCAR-3 protein level, HO-1 expression was increased similarly as for RNA - by cisplatin and temperature. In AGS cells, temperature was the only trigger, increasing the level of HO-1 protein. The exposure of OVCAR-3 cells to cisplatin and temperature at 43°C resulted in drop of cells viability by 36% and *HO-1* silencing enhanced this effect by additional 20%. In AGS cells, HO-1 silencing reduced the viability by 16% at 37°C. HO-1 silencing in normothermia increased apoptosis rates in cisplatin treated OVCAR-3 and AGS cells by 2.07-fold and 2.63-fold. Silencing HO-1 in hyperthermia and treating with cisplatin, increased apoptosis rates by 3.09-fold and 6.84-fold in OVCAR-3 and AGS cells respectively. Real time cell analysis showed that exposure to cisplatin gradually decreased cell index of OVCAR-3 and AGS (HO-1 silenced) cells in normothermia. Hyperthermia enhanced this effect in OVCAR-3 cells, while AGS cell index stayed similar
Conclusion: Cytoprotective protein HO-1 is induced in cancer cells by different stressors in variable manner. In tumors with highly inducible *HO-1*, prior silencing of this gene could improve the cell response to hyperthermia and cisplatin.
Disclosure: Nothing to disclose

P0471 HEALTHY CHILDREN FROM 4 TO 12 YEARS OF AGE: FECAL CALPROTECTIN AND EOSINOPHIL-DERIVED NEUROTOXIN LEVELS

M Roca[1], A Rodriguez Varela[2], E Donat[1,3], F Cano[2], A Armisen[2], M.J Vaya[2], H Ekoff[4], D Hervas[1], N Rydell[4], E Masip[1,3], B Polo[1,3], **C Ribes Koninckx**[1,3]

[3]*Hospital La Fe Gastroenterology Unit, Valencia, Spain*
[4]*ThermoFisher Scientific, Uppsala, Sweden*

Contact E-Mail Address: maria_roca@iislafe.es
Introduction: We have previously reported that young infants have higher concentrations of fecal Calprotectin (fCP) and Eosinophil-Derived Neurotoxin (fEDN) compared to adults. The highest concentrations for both biomarkers were found in infants less than 4 years of age. There was also a large variation in fCP and fEDN concentrations between individual children in the 0 to 4 years age group, which stabilized from 4 years of age onwards.
Aims and Methods: The objective of the current study was to investigate fCP and fEDN levels in healthy children 4 to 12 years of age.
Prospective study including 153 healthy children, 4 to 12 years old, from the general population. Fecal samples (n = 153) were collected, sent to the laboratory no later than 7 days after collection and stored at −20°C until analysis. The extraction procedure was performed with the *Faecal sample preparation kit* (Roche Diagnostics). Fecal CP and fEDN levels in the fecal samples were measured by EliA Calprotectin 2 and an EDN research assay developed on the ImmunoCAP platform, respectively (Thermo Fisher Scientific).
Results: The median (50th percentile) of fCP and fEDN concentrations in the 153 children were 20.31 mg/kg and 0.3 mg/kg respectively. The 95th Percentile of fCP and fEDN concentrations were 104.85 mg/kg and 2.01 mg/kg. We did not find a statistically significant association between the median fCP concentration and age ($p = 0.31$) or gender ($p = 0.97$), or for the median fEDN concentration and age ($p = 0.08$) or gender ($p = 0.059$). However we found a statistically significant association between the 95th percentile of fCP and fEDN concentrations with age ($p < 0.001$), and this association was stronger at younger ages and decreased at around 80 months of age. We developed a nomogram showing that the lower 95th percentile of fCP and fEDN concentrations were 108.5 and 1.7 mg/kg, respectively, in the age group 4 to ≤6 years, and 66.2 and 1.1 mg/kg, respectively, in the age group >6 to 12 years.
Although the median concentrations for fCP were lower than the 50 mg/kg cutoff value proposed for adults, there was a percentage (21%) of children with fCP concentrations above 50 mg/kg. Therefore, the 95th percentiles of fCP concentrations for the age range of 4 to 12 years were higher than the cutoff value for adults. However, in agreement with our previous study, the fCP concentrations were lower, and showed less variability, in the age group of 4 to 12 years compared to the fCP concentrations in children below the age of 4 years (*JPGN* 2017 Oct;65(4):394–398).
Conclusion: Based on the results and a developed nomogram, 2 different age groups for evaluation of fCP and fEDN in children aged 4 to 12 years are suggested: from 4 to ≤6 years, and from >6 to 12 years. We also suggest reference values for fCP and fEDN representing the lower value of the 95th percentile for each age group: 108.5 and 1.7 mg/kg, respectively, in the age group 4 to ≤6 years, and 66.2 and 1.1 mg/kg, respectively, in the age group >6 to 12 years. For fCP, the suggested reference values are higher than the 50 mg/kg cutoff value proposed for adults.

P0472 EFFECTIVENESS OF REBAMIPIDE IN THE PREVENTION OF ESOPHAGEAL STRICTURE FORMATION IN ADVANCED CORROSIVE ESOPHAGITIS: A PROSPECTIVE RANDOMIZED CONTROL STUDY

M.L Sy, R.J Prieto, A Pang, M.A Chu, L Gatchalian, jr. F Domingo, M Naval
East Avenue Medical Center, Section of Gastroenterology, Quezon City, Philippines

Contact E-Mail Address: marky_lester_sy@yahoo.com
Introduction: Corrosive esophagitis causes significant morbidity with grades 2b and 3 esophagitis developing strictures in 70–100% of cases. According to the Philippine National Poison Management and Control Center 2009 report, each year 23% of 500 poisoned patients referred to them are due to caustic ingestion (1). While information on the effect and outcome of esophageal corrosive injury have been well documented, there is no clear evidence on the management of caustic esophageal injury, in particular, the prevention of esophageal stricture. However, animal studies show that suppressing inflammation and fibrosis can prevent stricture formation (2). Rebamipide, an anti-ulcer agent, has been shown to stimulate prostaglandin generation, increases epidermal growth factor expression, increases blood flow, and scavenges active oxygen radicals thereby reducing inflammation (3). Moreover, based on animal studies rebamipide has been shown to reduce the inflammation and decrease the mucosal permeability associated with acute reflux esophagitis (4-5).
Aims and Methods: This study aims to determine the effectiveness of rebamipide in preventing stricture formation in advanced corrosive esophagitis.
We conducted a prospective, assessor-blinded, randomized control study. Proper approval from the Institutional Review Board and written informed consent from the patients were obtained. 37 adult patients with grades 2B to 3B corrosive esophagitis admitted in our institution were included. They were randomly allocated into 2 groups. First group (n = 18) received conventional proton pump inhibitor (PPI) therapy with rebamipide (PPI+rebamipide group) while second group (n = 19) received only conventional PPI therapy (PPI group), both for 3 weeks duration. Endoscopists blinded to group allocations and damage severity before treatment performed upper endoscopy (EGD) on Days 21 and 60. Presence of dysphagia, number, length and stricture location were recorded. Descriptive statistics, Independent sample T-test, Mann-Whitney U test and Chi-square test were the analysis used. Null hypothesis was rejected at 0.05 α-level of significance. STATA 15.0 was used for data analysis.
Results: 34 patients were included in the final analysis. Dysphagia and esophageal stricture at Day 60 were significantly greater with PPI group versus PPI+rebamipide group (47% vs 5.88%, $p = 0.017$). Although the median length of esophageal stricture in the PPI group vs PPI+Rebamipide group at Day 60 is significantly shorter (5 cm vs 8 cm; $p = 0.034$), there were still significantly more patients with stricture formation in the PPI group (8 vs 1; $p = 0.017$). Presence of gastric stricture was not significantly different between the 2 groups both at Day 21 (23.53% vs 17.65%; $p = 1.00$) and Day 60 (29.41% vs 35.29%; $p = 0.714$). For both dysphagia and esophageal strictures, our data suggests that our number needed to treat to prevent 1 incident of these are at 3.40 patients at day 21 and 2.43 at Day 60.
Conclusion: PPI with rebamipide is effective in preventing dysphagia and esophageal stricture formation among patients with advanced corrosive esophagitis compared to PPI alone. However, this was not effective in preventing gastric stricture formation.
Disclosure: Nothing to disclose

Introduction: MyD88 is a key signaling adaptor for TLRs and involved in intestinal microbiota-host interaction associated innate and adaptive immune. This study aims at investigating the effect of MyD88 on colonic inflammation and gut flora.
Aims and Methods: MyD88 knockout mice and their wild-type littermates were kept under the same environment except for treated with normal drinking water (WT and MyD88 KO groups) or 3% DSS solution (WT-DSS and MyD88-DSS groups) for 7 days. Disease activity index (DAI) and histological score of colitis (HS) inflammatory cytokines were evaluated to determine the colonic inflammation severity. TGF-β1, EGF, COX-2 and tight-junction (T-J) protein mRNA was measured by qPCR to access epithelial restoration. NF-κB activation was evaluated by Western-blotting and measured by Grey-scale value. Proximal colonic mucosa was used to analyze gut mucosal flora using high-throughput sequencing analysis targeting V4-V5 regions of the bacterial 16S rRNA gene. Statistical analysis was performed using one-way ANOVA analysis and the Post Hoc LSD test or Tamhane's T2 test.
Results: Colonic NF-κB activation was significantly inhibited in MyD88-DSS group as compared to WT-DSS group, suggesting the inhibitory effect of MyD88 deletion on NF-κB activation. However, deletion of MyD88 failed to improve DAI and HS in DSS-colitis mice as compared to WT-DSS group. Besides, the difference of colonic IL-1β,TNF α and IFN γ mRNA expression didn't reach significance in MyD88 deficient mice with or without DSS challenge. TGF-β1, EGF, COX-2 and T-J protein mRNA was not significantly different among 4 groups, suggesting relatively normal epithelial reconstruction ability in WT-DSS, MyD88 KO and MyD88-DSS groups as compared to WT group. Colonic mucosal microbiome analysis shown that the alpha diversity was not significantly different among 4 groups in terms of diversity index (Shannon and inverse Simpson) and bacterial culture abundance (Chao). At phylum level, the proportion of *Proteobacteria* dramatically elevated to 41.9% in MyD88 KO mice as compared to WT, WT-DSS and MyD88-DSS groups (7.0%, 16.1% and 22.3%, respectively), within which pathegenic bacteria such as *Pseudomonadales*, *Burkholderiales* and *Enterobacteriales* were predominantly increased at order level in MyD88 KO mice. The percentage of probiotics such as *Lactobacillales* was decreased in MyD88 KO group (31.5%) and further dropped to 11.2% and 4.1% in WT-DSS or MyD88-DSS groups as compared to WT (55.5%).
Conclusion: Deficiency of MyD88 inhibited NF-κB activation but not colonic inflammation in mice with colitis possibly due to MyD88 deletion associated pathegenic-riched and probiotics-exhauseted gut microbiota.

P0475 PILOT STUDY ON THE EFFECTIVENESS OF THE COMBINATION OF HYALURONIC ACID, COINDRITIN SULFATE AND POLOXAMER 407 IN SCAR HEALING AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION OF THE ESOPHAGUS IN PORCINE IN-VIVO MODEL

Introduction: Hyaluronic acid + chondroitin sulfate + poloxamer 407 (HA+CS) has shown efficacy in the repair of microscopically-damaged esophageal epithelium caused by gastroesophageal reflux (GER). However, there are no studies that show efficacy in the repair of macroscopic damage of the mucosa and/or submucosa.
Aims and Methods: Primary Objective: To assess the efficacy of HA+CS in healing scar due to deep submucosal injury after endoscopic submucosal dissection (ESD) of the esophagus in porcine models.
Secondary Objective: To evaluate the efficacy of HA+CS in the prevention of esophageal stenosis secondary to ESD. This was a randomized, experimental, endoscopist- and pathologist-blinded pilot study. Dissection of ¾ of the middle-distal esophagus circumference was performed on 6 anesthetized pigs (female Landrace-Large Whites). In 3 pigs (C1, C4 and C5) 10 ml of HA+CS (1 sachet) was injected on the surface of the eschar, infiltrating it with a syringe on the submucosa of the eschar edges. This was followed by treatment with HA+CS 3 sachets per day + Omeprazole 20 mg/12h po). The other 3 pigs received only the standard treatment, Omeprazole 20 mg/12h po, to avoid potential additional damage from GER. The pigs were kept on a liquid diet for the first 24 hours and then started on a regular diet. After 15 days, an endoscopic evaluation was conducted to assess the degree of stenosis and healing grade using the modified Manchester scale for the clinical evaluation of scars. Finally, histological analysis was conducted by 2 pathologists, following necropsy.
Results: The average weight at the beginning of the study for the HA+CS group vs control group was 44.63 kg and 44.43 kg respectively, and 36.48 kg vs 41.80 kg respectively at the end of the treatment.
There were no differences in the mean size of eschars (9.9 mm in the HA+CS group vs 8.82 mm in control group) or in their location (15.66 mm from the gastroesophageal junction in the HA+CS group vs 11.66 mm in the control group). All the eschars covered more than 50% of the circumference. Stenosis presented in 100% of the cases. In 2 (33.3%) cases, the endoscope could be passed through the stricture (C2 and C6). The score on the modified Manchester scale was 4.3 for the HA+CS group and 3.3 for the control group. Complications: perforation with paraesophageal collection in C4. Histological analysis: Higher inflammatory infiltrate with predominance of neutrophils, lymphocytes, macrophages (acute inflammatory reaction) in the control pigs vs. the pigs treated with HA+CS, in which chronic inflammatory infiltrate (lymphocytes) predominated. In the control group, neovascularization consisted of small to medium vessels and the reorganization of the connective tissue process was in its beginning phase, whereas in the HA+CS group the blood vessels were large and vertically arranged and reorganization of the connective tissue was more advanced, as evidenced by the presence of fibroblasts well organized in parallel lines. 1 of the HA+CS-treated pigs showed re-epithelialization on 1 border (C1).
Conclusion: The histological results suggest that HA+CS promotes the repair of esophageal mucosa after ESD, although a clinically significant difference to control treatment was not shown, as all the pigs developed stenosis. More studies are required, with a larger sample size, to evaluate the efficacy of HA+CS in the repair of macroscopic damage of the mucosa.

P0476 PANCOLITIS INCREASES THE MORTALITY RISK OF CYTOMEGALOVIRUS COLITIS IN PATIENTS WITHOUT INFLAMMATORY BOWEL DISEASE: A RETROSPECTIVE COHORT STUDY

P.-H Le[1,2], C.-T Chiu[1,2]
[1]*Linkou Chang Gung Memorial Hospital, Department of Gastroenterology and Hepatology, Taoyuan City, Taiwan*
[2]*Taiwan Association of the Study of Small Intestinal Disease, Taoyuan City, Taiwan*

Contact E-Mail Address: puohsien@gmail.com
Introduction: Cytomegalovirus (CMV) colitis typically presents in immunocompromised and inflammatory bowel disease (IBD) patients. Several studies have been conducted on the endoscopic findings of CMV colitis in IBD patients; however, those of CMV colitis in non-IBD patients and their relationship with in-hospital mortality are unclear.
Aims and Methods: We aimed to describe the endoscopic presentation in these patients and to determine the endoscopic predictor of in-hospital mortality. Patients with CMV colitis diagnosed using histology between April 2002 and December 2016 at the Linkou Chang Gung Memorial Hospital, Taiwan, were retrospectively enrolled. Patients diagnosed with IBD during follow-up were excluded. Patient data, including underlying diseases, endoscopic presentation, laboratory data, clinical course, complications and clinical outcomes were collected. The independent risk factors for in-hospital mortality were analysed with logistic regression. The difference of overall survival was compared with Kaplan-Meier survival curve and log rank test. All statistical calculations were performed using SPSS software, version 21 (IBM, Armonk, New York).
Results: 69 patients were enrolled, and 8 IBD patients were excluded. Within the 61 non-IBD patients, 31 were diagnosed by colonoscopy and others by sigmoidoscopy. Ulceration (77%) was the most common endoscopic finding, followed by a cobble stone appearance (19.7%), colitis with/without erosions (9.8%), pseudomembrane (9.8%) and tumour/polyp-like lesions (8.2%). Among the patients who underwent full-length colonoscopy, 35.3% presented with right-sided colitis, 23.5% with left-sided colitis and 32.4% with pancolitis. Pancolitis was identified as a negative predictor of in-hospital mortality (odds ratio, 6.8; 95% confidence interval, 1.233-37.497; $p = 0.028$) and overall survival (log rank $p = 0.018$).
Conclusion: Colonoscopy is recommended for precise CMV colitis diagnosis and outcome prediction in non-IBD patients.

P0477 CLOSTRIDIUM DIFFICILE ISOLATION AND CHARACTERISATION - RESULTS OF A PILOT STUDY

Pintar[1], M Rupnik[1], **P Skok**[1,2]
[1]*University Maribor, Maribor, Slovenia*
[2]*University Clinical Centre Maribor, Maribor, Slovenia*

Contact E-Mail Address: pavel.skok@ukc-mb.si
Introduction: *Clostridum difficile* (CD) infection can lead to severe infectious colitis. Different bacterial toxins and diminished host immune response contribute to symptomatic disease. Inflammatory bowel diseases (IBD), ulcerative colitis, and Crohn's disease are chronic diseases causing a prolonged inflammation of gastrointestinal tract. In these patients colonisation with CD is often confirmed but its role is inconclusive.
Aims and Methods: The aim of the study was to compare CD colonization and selected inflammatory parameters in patients with IBD and other diseases in

hospitalized patients. We obtained fecal samples from 161 randomly selected patients, hospitalized at Department of Gastroenterology during the period between 1/12/2015 - 1/5/2016. Total DNA was isolated from feces and CD was detected using the real time PCR amplification of specific 16S RNA gene and toxigenic strains were confirmed by the amplification of *tcd*B gene. After collecting patient's basic information, inflammatory parameters (neutrophil granulocytes, leukocytes, CRP, erythrocyte sedimentation, albumins, ferritin, and iron) and therapy (pre-and hospital antibiotics, corticosteroids, biological therapy) we divided isolates in 2 groups: IBD group and control group.
Results: The final analysis included 151 samples, (male 75, female 76), 48 (31.8%) from IBD patients and 103 (68.2 %) from control group. In IBD group 23/48 samples (47.9%) were positive for CD; 7 of which (7/48, 14.6%) were *TcdB*+. In the control group 42/103 (40.8%) were positive for CD, 11 of which (11/103, 10.7%) were *TcdB*+. Between the 2 groups, significant differences were confirmed only in the use of corticosteroids and biological therapy prior to hospitalization, $p < 0.001$. Regarding the use of antibiotics prior to hospitalization, differences between the 2 groups were not confirmed, $p = 0.72$. There were no significant differences observed in inflammatory parameters within IBD patients (CD positive compared to CD negative).
Conclusion: The results of our study suggest that IBD patients and patients from the control group were colonized with CD in comparable proportions. The majority of strains were nontoxigenic, which will not cause CD infections, but could be regarded as a marker for disturbed gut microbiota.
Disclosure: Nothing to disclose

P0478 UNIVERSAL ANTIBIOTIC PROPHYLAXIS MAY BE UNNECESSARY IN ACUTE VARICEAL BLEEDING: A SINGLE-CENTER RETROSPECTIVE STUDY

M Ueno, T Kayahara, H Takabatake, Y Morimoto, M Mizuno
Kurashiki Central Hospital, Department of Gastroenterology and Hepatology, Kurashiki, Japan

Contact E-Mail Address: mu13951@kchnet.or.jp

Introduction: Randomized controlled trials conducted from the 1990s to early 2000s showed efficacy of antibiotic prophylaxis in acute variceal bleeding. Over the past decades, however, endoscopic and systemic therapy for variceal bleeding has improved remarkably, and the necessity of antibiotic prophylaxis could have decreased.
Aims and Methods: In this study, we aimed to evaluate the efficacy of antibiotic prophylaxis with our most recent data. We retrospectively studied clinical characteristics, treatment and outcomes of 150 patients (116 men, median age: 62 years) with acute variceal bleeding, who were admitted to our hospital between January 2012 and December 2016. Those who had obvious infection or aspiration pneumonia at admission were excluded. Patients were classified into 2 groups according to presence or absence of antibiotic prophylaxis. Rates of obvious bacterial infection, suspicious infection, in-hospital mortality, in-hospital rebleeding, and readmission within 30 days were compared between the 2 groups. Multivariate analysis was also performed to evaluate the efficacy of antibiotic prophylaxis.
Results: The median Child-Pugh score was 8. Immediate endoscopy was performed in 148 patients, and active bleeding was observed in 60 patients. Endoscopic variceal ligation was performed in 111 patients. Hemostasis was achieved in 148 patients. 2 patients died of uncontrolled bleeding (1 with and 1 without endoscopy). 46 patients (30.7%) received antibiotic prophylaxis. The rates of obvious bacterial infection, suspicious infection, in-hospital mortality, in-hospital rebleeding, and readmission within 30 days were not different significantly between the 2 groups. In the multivariate analyses, antibiotic prophylaxis was not associated with any of these outcomes. Instead, high serum creatinine levels at admission (greater than 1.2 mg/dL) were significantly associated with obvious bacterial infection (adjusted odds ratio 12.5, 95% CI 1.24–126), and higher Child-Pugh score (per point) was associated with mortality (adjusted odds ratio 3.57, 95% CI 1.25–10.2).
Conclusion: Universal antibiotic prophylaxis may be unnecessary in acute variceal bleeding. Impaired renal function at admission was a risk factor for bacterial infection and might be applied to a risk stratification approach for antibiotic prophylaxis.

P0479 AIMS65 IS THE MOST ACCURATE RISK-SCORING SYSTEM FOR PREDICTING PROGNOSIS OF PATIENTS WITH DUODENAL ULCER BLEEDING

R Hirai, Y Shimodate, S Ishikawa, T Kanatani, M Minami, A Doi, N Nishimura, H Mouri, K Matsueda, H Yamamoto, M Mizuno
Kurashiki Central Hospital, Gastroenterology and Hepatology, Kurashiki, Japan

Contact E-Mail Address: me20070@s.okayama-u.ac.jp

Introduction: In spite of the advance of endoscopic hemostasis for upper gastrointestinal bleeding, treating duodenal ulcer bleeding is sometimes difficult and does not yield good prognosis.
Aims and Methods: In this study, we evaluated and compared various risk-scoring systems for upper gastrointestinal bleeding to predict outcomes of patients who underwent endoscopic treatment for duodenal ulcer bleeding.
Bleeding from peptic ulcer was diagnosed in 1,147 patients (892 patients with gastric and 255 with duodenal ulcer) among 7,106 patients who underwent emergent esophagogastroduodenoscopy for upper gastrointestinal bleeding at our hospital from July 2007 to June 2017. We retrospectively reviewed clinical records of the 1,147 patients and compared their prognosis after endoscopic therapy between gastric and duodenal ulcer patients. In the 255 patients with duodenal ulcer, we evaluated the following risk-scoring system; Glasgow Blatchford, AIMS65, admission Rockall and full Rockall scores, to predict in-hospital mortality by analyzing their area under the receiver operating characteristic curve (AUROC).
Results: The mortality rate of patients with duodenal ulcer bleeding was 6.7% (17/255), which were significantly higher than that of those with gastric ulcer bleeding (0.67%, 6/892) ($p < 0.001$). In the duodenal ulcer patients, risk scores were significantly higher in patients with in-hospital mortality than those without in all of the scoring systems, and AUROC of AIMS65 (0.83) was highest among them (Table).
With more than 2 points of AIMS65 score as a cut-off value, sensitivity and specificity to predict in-hospital mortality of patients with duodenal ulcer bleeding were 0.882 and 0.597, respectively.
Conclusion: The prognosis of patients with duodenal ulcer bleeding was poorer than that of patients with gastric ulcer. The AIMS65 score may be useful to predict the outcome after endoscopic treatment for duodenal ulcer bleeding, especially in the situation at deciding the indication of endoscopic hemostasis because this scoring system can be calculated without endoscopic findings.

Scoring system	AUROC (95%CI)	Cut-off score	Sensitivity (%)	Specificity (%)
Glasgow Blatchford	0.74 (0.61–0.86)	≧13	64.7	71.0
AIMS65	0.83 (0.74–0.92)	≧2	88.2	59.7
Admission Rockall	0.76 (0.66–0.87)	≧3	82.4	55.5
Full Rockall	0.82 (0.74–0.91)	≧6	82.4	66.0

[AUROC and sensitivity and specificity of each risk-scoring system to predict in-hospital mortality in patients with duodenal ulcer bleeding.]

Introduction: Guidelines recommend resuming aspirin soon after control of bleeding in patients with cardiovascular disease who develop non-variceal upper gastrointestinal bleeding (NVUGIB).
Aims and Methods: Our primary aim was to synthesize the evidence comparing mortality and re-bleeding rates in patients who resume aspirin compared to those who do not after NVUGIB. Our secondary aim was to determine whether being on aspirin upon presentation with NVUGIB is associated with worse outcomes compared to not being on it.
We conducted a systematic review of randomized controlled trials (RCTs) and prospective observational studies. We ran a comprehensive sensitive search covering major electronic databases, clinical trial registries and grey literature. 2 teams of 2 reviewers screened titles and abstracts of identified citations independently and in duplicate for eligibility using pre-selected criteria. We retrieved full texts of citations judged potentially eligible by at least 1 reviewer. The 2 teams screened full texts independently and in duplicate, resolved disagreements, abstracted clinical characteristics of included studies and assessed their risk of bias using standardized forms. We used meta-analysis to pool data for mortality and re-bleeding outcomes.
Results: Of 9827 citations, we assessed 254 full-texts for eligibility. 1 RCT and 3 observational studies address the primary question; all assess low dose aspirin, but timing of its resumption varied. None compare different timings of aspirin resumption. The RCT suggests that early aspirin resumption may reduce mortality; HR = 0.20; 95% CI [0.06–0.63]; moderate certainty of evidence.

Meta-analysis of 3 observational studies suggests that aspirin resumption may reduce mortality: pooled HR = 0.79; 95% CI [0.50–1.25]; very low certainty of evidence. We assessed if the relative effect of resuming aspirin is modified by whether people were using it for secondary or primary prophylaxis. In those on aspirin for secondary prophylaxis, resuming aspirin may reduce mortality to a larger extent (HR = 0.56; 95% CI [0.31–1.00]) compared to those taking it for primary prophylaxis (HR = 4.07; 95% CI [0.54–30.74]), but studies were characterized by high heterogeneity (p = 0.06 for subgroup effect). The RCT suggests that aspirin resumption may increase re-bleeding; HR = 1.90; 95% CI [0.60–6.00]; moderate certainty of evidence, while meta-analysis of 2 observational studies suggests it may reduce re-bleeding: pooled HR = 0.82; 95% CI [0.35–1.91]; very low certainty of evidence.
7 observational studies address the secondary question. Meta-analysis of 5 studies suggests that being on aspirin upon NVUGIB admission is not associated with all-cause mortality: pooled HR = 1.02; 95% CI [0.70–1.51]; very low certainty of evidence. Meta-analysis of 2 studies shows no increased re-bleeding risk: pooled HR = 1.23; 95% CI [0.44–3.42]; very low certainty of evidence.
Conclusion: Evidence supporting a protective effect for aspirin resumption soon after NVUGIB is of very low certainty based on observational studies and moderate certainty based on 1 RCT. The available evidence is not informative as to the optimal timing of aspirin resumption. High quality RCTs are needed to address the best timing of aspirin resumption in patients with NVUGIB.

Contact E-Mail Address: huhcw@catholic.ac.kr
Introduction: Current guidelines recommend endoscopic therapy to be performed within 12 hours for acute variceal bleeding (AVB). However, the optimal timing of endoscopic therapy for AVB remains unclear.
Aims and Methods: The aim of this study was to examine the relationship between the endoscopy timing and clinical outcomes in AVB, with emphasis on liver function and endoscopy timing. From January 2010 to June 2017, cirrhotic patients with varices confirmed as the source of bleeding by endoscopy were evaluated. The primary outcome was a composite of 6-week rebleeding and mortality. We stratified patients according to the model for end-stage liver disease (MELD) score and analyzed the association between the endoscopy timing and primary composite outcome.
Results: In 411 patients, the overall composite outcome rate was 30.9% (n = 127) at 6 week. Patients who underwent urgent endoscopy (≤12 hours) had a significantly higher composite outcome than patients who underwent non-urgent endoscopy (>12 hours) (34.4% vs. 19.1%; p = 0.005). Low-risk patients who underwent urgent endoscopy were more likely to reach the composite outcome (adjusted OR, 0.84 per 4 hours; 95% CI, 0.73–0.98; p = 0.027). However, time to endoscopy was not a significant predictor of composite outcome in high-risk patients. These findings persisted even after adjustment for baseline characteristics between the urgent and non-urgent groups.
Conclusion: Urgent endoscopy is significantly associated with a poorer outcome in patients with AVB, especially in low-risk patients. Our result provides a treatment strategy according to the severity of underlying liver disease in patients with AVB.

P0482 FORREST CLASSIFICATION DOES NOT PROPERLY ASSESS REBLEDING RISK OR MORTALITY IN HIGH-RISK UPPER GI BLEEDING

E Redondo-Cerezo, R Jimenez-Rosales, F Vadillo-Calles, F Valverde López, M Lopez de Hierro, J Martínez-Cara
University Hospital 'Virgen de las Nieves', Gastroenterology and Hepatology Unit, Granada, Spain

Contact E-Mail Address: eredondoc@gmail.com
Introduction: Forrest classification has been the most endoscopic used 1 in upper GI bleeding. The 6 stages risk assessment establishes the higher risk in Forrest Ia patients, being the least Forrest III stage.
Aims and Methods: The aim of our research was to determine in a prospective upper GI bleeding patients whether this classification differentiates between patients with stage Forrest IIa and Forrest I, regarding rebleeding risk, because it has been previously suggested that a visible vessel might entail a higher risk of rebleeding.
Upper GI bleeding from Virgen de las Nieves University Hospital is a prospectively collected dadabase from January 2013. For this study, patients up to January 2017 were included. For every patient 150 clinical and biochemical variables are recorded. Variables were compared with SPSS 17 software (SPSS Inc. Chicago, ILL) by means of the Chi-square test.
Results: 414 patients were included (65.5% males) with non variceal upper GI bleeding. Mean age was 65.07 years (range 17–95).
The main upper GI bleeding etiologies were duodenal ulcer in 29%, gastric ulcer in 22%, acute gastric erosions in 13%, Mallory-Weiss and esophageal ulcers in 8%. 34 patients died (8.2%) and 69% had a relevant comorbidity. An endoscopic therapy with 2 methods (injection plus clipping or argon plasma coagulation) was applied to every patient.
Mortality did not significantly differ between Forrest Ib patients and Forrest IIa (19.6% vs. 20.8%). Regarding rebleeding, despite the proportion of rebleeding patients with Forrest IIa ulcers almost doubled Forrest Ib (20% vs. 10.9%), the statistic test did not reach statistical significance, neither did regarding the need for surgery (16% vs 6.5%, p = n.s.). Moreover, when mortality rates in patients with Forrest IIa and Ib were compared we found no significant differences, an a trend toward a higher mortality in Forrest IIa patients was higher (15.4% Ia vs. 21.7% IIa). A similar absence of statistical differences was observed for the rest of outcomes studied: rebleeding (23.1% Ia vs. 16.7% IIa) and need for surgery (23.1% Ia vs. 12.5% IIa).
Conclusion: Our study shows that that Forrest classification seems an inadequate predicting tool for rebleeding in its actual formulation. In view of our results, Forrest IIa patients should probably be considered of a higher risk than Forrest Ib, and closer to Forrest Ia. We might hypothesize that the presence of a visible vessel implies a higher risk than an oozing bleed, that usually originates in small capillaries, more easily coagulated through endoscopy and even natural mechanisms.

Contact E-Mail Address: ayayadejunya@yahoo.co.jp
Introduction: Although most of hemorrhagic gastroduodenal ulcers (HGU) can be safely treated with endoscopic procedures, some patients with HGU could have poor prognosis owing to comorbidities and medications for anticoagulation. In this study, risk factors of poor prognosis including mortality and impairment of activities of daily living (ADL) in patients with HGU were examined. In particular, prognosis of elderly HGU patients (≥ 75 years old) was evaluated in comparison to that of non-elderly (< 75 years old) patients.
Aims and Methods: The medical records of 589 patients with endoscopically confirmed HGU (430 men, 159 women; mean age 66.7 years; range 25–95 years) were retrospectively reviewed. Clinical backgrounds and outcomes were compared between patients < 75 years old (n = 394) and ≥ 75 years old (n = 195). The primary outcomes are overall mortality, mortality within 30 days after occurrence of hemorrhage, and impairment of ADL. Impairment of ADL was defined as admission to care facilities after hospital discharge or requirement of home modification for rehabilitation at home. Evaluated clinical factors were endoscopic features, need for interventional endoscopic procedures, comorbidities, symptoms, medications, vital signs, and blood test results.
Results: There were significant differences in overall mortality (3.8% vs. 7.6%), hospitalization period (16.2 ± 29.3 days vs. 22.8 ± 28.0 days), and impairment of ADL (1.3% vs. 6.7%) between patients < 75 years old and those ≥ 75 years old. Multivariate analysis revealed that independently significant risk factors for overall mortality were age (≥ 75 years) (odds ratio (OR) 2.25, 95% confidence interval (CI), 1.06–4.74), and renal disease (OR 3.38, 95% CI, 1.42–8.01). Risk factors of mortality within 30 days after hemorrhage were age (≥ 75 years) (OR 3.40, 95% CI, 1.21–9.56), need for interventional endoscopic procedures (OR 3.91, 95% CI, 1.08–14.1), and renal disease (OR 4.3, 95% CI, 1.40–13.2). Finally, risk factors of impairment of ADL were use of proton pump inhibitors prior to hemorrhage (OR 5.83, 95% CI, 2.1–16.2), heart disease (OR 3.06, 95% CI, 1.11–8.3), and age (≥ 75 years) (OR 5.07, 95% CI, 1.73–14.9).
Conclusion: High mortality and impairment of ADL were more likely to be observed in elderly HGU patients compared to non-elderly patients. In particular, concomitance of renal disease and heart disease was a risk of poor prognosis in those subjects. Prophylactic approaches for HGU and early improvement of ADL after HGU occurrence are particularly important in elderly patients with comorbidities.

Contact E-Mail Address: elshaarawy.omar@stadtmission-hd.de
Introduction: The albumin-bilirubin (ALBI) score eliminates the need for subjective variables required in the Child-Turcotte-Pugh (CTP) classification and has been validated as a prognostic indicator for patients with HCC. Incorporating platelet count to reflect portal hypertension in the PALBI score improved

validity in predicting outcome of patients with HCC undergoing resection and ablation.
Aims and Methods: We aimed to evaluate the PALBI score compared to the CTP class for predicting the outcome of acute variceal bleeding. Data of 1517 patients presenting with acute variceal bleeding were analyzed. The CTP class and PALBI score were calculated, and were correlated to mortality. PALBI score was calculated as = (2.02*Log10 bilirubin) +(−0.37*(Log10bilirubin)^2) +(−0.04*albumin) +(−3.48*Log10 platelets)+(1.01*(Log10 platelets)^2).[2] Areas under the receiving-operator characteristics curve (AUROC) were calculated for survival.
Results: Mean age was 52 years old; 77.5% were males. There were 69 CTP-A patients (4.5%), 434 (29.2%) CTP B and 1014 (66.8%) CTP C; 6 patients (0.39%), PALBI grade 1, 43 patients (2.8%) PALBI grade 2, 957 patients (63%) PALBI grade 3 and 542 patients (33.6%) PALBI grade 4. All CTP-A and PALBI-1 patients survived. 332 Patients died during the admission (21.9%). Bleeding related mortality occurred in 11% of CTP-B, 28% of CTP-C, and in 9.3% of PALBI-2, 14.1% of PALBI-3 and 35.6% of PALBI-4 patients. The AUROC for PALBI score was more significant in comparison to ALBI, MELD and CTP scores (0.871, 0.803, 0.689 and 0.668, respectively).
Conclusion: PALBI better predicts early mortality of patients with acute variceal bleeding than CTP score.
Disclosure: Nothing to disclose

P0485 UPPER GASTROINTESTINAL BLEEDING NOT ASSOCIATED TO PORTAL HYPERTENSION: ASPECTS OF EPIDEMIOLOGY AND MANAGEMENT IN A SOUTHERN SPANISH AREA

J.A Díaz Jiménez, J Leal Téllez, A.R Calle Gómez, F.J Correro Aguilar
Hospital Universitario Puerta del Mar, UGC Aparato Digestivo, Cádiz, Spain

Contact E-Mail Address: adiazjime@gmail.com
Introduction: The aim of the research was to evaluate different epidemiologic and management aspects of Upper Gastrointestinal Bleeding not associated to Portal Hypertension (UGBNPH) in Puerta del Mar Hospital, Cádiz (Andalucía, Spain).
Aims and Methods: Retrospective research including every patient admitted to Gastroenterology Department of Puerta del Mar Hospital (Cádiz), between January 2016 and December 2016, because of UGBNPH.
We analysed different variables: gender, age, cardiovascular risk factors such Arterial Hypertension (AHT), Diabetes Mellitus (DM) and Dyslipidemia (DLP); concomitant treatment with Proton Pump Inhibitors (PPIs), Antiplatelets, Antithrombotics, Nonsteroideal Anti-Inflammatory Drugs (NSAIDs) and Antidepressants; clinical and endoscopic findings; red blood cells and iron requirement, and *Helicobacter pylori* investigation. We also analysed short and medium term survival rates and recurrence rate in 1-year period.
Results: We included 75 patients admitted because of UGBNPH (56% men), with an average age of 69 years old (men 66, women 74).
We did not find significant differences by gender when analyzing AHT (53.3%), DM (28%) and DLP (34.7%), neither when analyzing PPIs treatament (men 33.3%; women 36.4%). The amount of patients with Antiplatelet (29.3%) and Antithrombotic (29.3%) concomitant treatment was similar. However, we found a higher quantity of UGBNPH events in men with Antiplatelet treatment (33.3%) and women with Antithrombotic treatment (36.4%). We also noticed more UGBNPH events in women who used NSAIDs (30.3%) and Antidepressant (24.2%), compared to men.
Clinical debut was predominantly as Melena (68%). Regarding Endoscopic findings, we found more frecuently Duodenal Ulcer among men (33.3%) and Gastric Ulcer among women (45.5%).
61.3% of patients needed red blood cell transfussion during their admission, with 4 packed red blood cells as average. We only began iron therapy in 22.7% of patients admitted. *Helicobacter pylori* investigation was made in 37.3% with high positivity rates (78.6%), especially among men (93.3%).
Short-term survival rate was similar (men 95.2%; women 94%), however medium-term survival rate (1 year after admission) was higher in men (88.1% vs women 78.8%). Recurrence rate in 1-year period was 14.1%, with no differences when analyzing genders or etiology of UGBNPH event.
Conclusion: Upper Gastrointestinal Bleeding not asocciated to Portal Hypertension is a frequent entity in our environment. Men using Antiplatelets and women using Antithrombotics are higher bleeding risk groups. In our experience, Duodenal Ulcer in men and Gastric Ulcer in women are more usual. Almost two-thirds of patients required red blood cells transfusion during admission, however we began iron therapy in a lower percentage. We did not investigate enough *Helicobacter pylori* infection. Finally, short-term prognosis was favorable, but recurrence is not unusual.
Disclosure: Nothing to disclose

P0486 UPPER GASTROINTESTINAL BLEEDING ASSOCIATED TO PORTAL HYPERTENSION: ASPECTS OF EPIDEMIOLOGY AND MANAGEMENT IN A SOUTHERN SPANISH AREA

J.A Díaz Jiménez, J Leal Téllez, A.R Calle Gómez, F.J Correro Aguilar
Hospital Universitario Puerta del Mar, UGC Aparato Digestivo, Cadiz, Spain

Contact E-Mail Address: adiazjime@gmail.com
Introduction: The aim of the research was to evaluate different epidemiologic and management aspects of Upper Gastrointestinal Bleeding associated to Portal Hypertension (UGBPH) in Puerta del Mar Hospital, Cádiz (Andalucía, Spain).
Aims and Methods: Retrospective research including every cirrhotic patient admitted to Gastroenterology Department of Puerta del Mar Hospital (Cádiz), between January 2016 and December 2016, because of UGBPH.
We analysed different variables: gender, age, cardiovascular risk factors such Arterial Hypertension (AHT), Diabetes Mellitus (DM) and Dyslipidemia (DLP); concomitant treatment with Proton Pump Inhibitors (PPIs), Antiplatelets, Antithrombotics, Nonsteroideal Anti-Inflammatory Drugs (NSAIDs) and Antidepressants; clinical and endoscopic findings; red blood cells and iron requirement. We also analysed short and medium term survival rates and recurrence rate in 1-year period.
Results: We included 30 patients admitted because of UGBPH (73.3% men), with a younger average age among men (men 54 years old, women 73). We did not find significant differences by gender when analyzing DM (33.3%), with higher frecuence of AHT among women (62.5% vs 27.3%) and DLP among men (22.7% vs 0%).
We did not find significant differences by gender when analyzing concomitant treatment with PPIs (43.3%), Antiplatelets (6.7%), Antithrombotics (3.3%), NSAIDs (0%) and Antidepressants (23.2%).
Clinical debut as Hematemesis (66.7%) and Melena (63.3%) was similar in frecuence. Regarding Endoscopic findings, in both genders, we found more usually Esophageal Variceal bleeding as etiology (70%) compared to Portal Hypertension Gastropathy bleeding (33.3%).
87.5% of admitted women needed red blood cell transfusion (vs 59.1% of admitted men), with 2.9 packed red blood cells as average (vs 4 packed red blood cells in men). We only began iron therapy in 20% of patients admitted.
Short-term survival rate was 90% (men 86.4%; women 100%) and medium-term survival rate (1 year after admission) was 80%. Bleeding recurrence rate in 1-year period was higher among women (50%) compared to men (36.8%) and related more often to Portal Hypertension Gastropathy (53.8%).
Conclusion: In our research, when analyzing Upper Gastrointestinal Bleeding associated to Portal Hypertension, cirrhotic men of medium age was the more commonly affected demographic group. Esophageal Variceal bleeding is the most usual etiology in both genders, however Portal Hypertension Gastropathy bleeding has the highest recurrence rate. Regarding high red blood cells transfusion requirement, we should consider the use of iron therapy in more cases. Finally, short-term prognosis is favorable in our population.

P0487 PREDICTOR OF MORTALITY IN UPPER GASTROINTESTINAL BLEEDING IN PATIENTS ALREADY HOSPITALIZED FOR ANOTHER CONDITION: A PROSPECTIVE STUDY

R Jiménez-Rosales, F Vadillo-Calles, E.J Ortega-Suazo, J.G Martinez Cara, E Redondo-Cerezo
Virgen de Las Nieves University Hospital, Granada, Spain

Contact E-Mail Address: ritajimenezrosales@gmail.com
Introduction: Upper gastrointestinal bleeding (UGIB) is one of the main causes of hospital admission and urgent endoscopy in Gastroenterology departments and represents a true emergency, associated with significant morbidity, mortality and healthcare costs. Several predictors of in-hospital mortality have been identified. 1 of these risk factors in patients with nonvariceal UGIB is a previous hospital admission because of a different medical problem, with reported mortality rates as high as 26% (1). Nonetheless, the reasons for increased mortality in this subgroup of patients have not been consistently identified. Recent data from Canada and Italy (2, 3) shed some light on the issue, showing that the mortality rate for in-patient (IP) bleeding was significantly higher than that of outpatient (OP) bleeding and identifying some predictors of outcomes. However, only 1 study is prospective and none includes patients with variceal bleeding.
Aims and Methods: The aim of our study is to compare outpatients (OPs) presenting with UGIB to those who started GI bleeding while IPs as well as to identify predictors of mayor outcomes: rebleeding and in-hospital mortality.
This was a prospective cohort study on consecutive patients with UGIB (variceal and non variceal) treated in "Virgen de las Nieves" University Hospital from 2013 to 2017 (from January 2013 to December 2017). All patients underwent upper endoscopy, and information regarding clinical and biochemical data, procedures, and outcomes for 6 months after admission were collected. Clinical outcomes documented were in-hospital mortality and rebleeding. Descriptive inferential and multivariate logistic regression models were carried out.
Results: 540 patients with a diagnosis of upper gastrointestinal bleeding were included, 481 IPs and 59 OPs. IPs differed from OPs in 30 days death rate (42.1% vs 7.8%; $p < 0.001$), rebleeding (29.3% vs. 15.3%; $p = 0.014$), AIMS65≥2 (25.6% vs. 13.7%;$p = 0.043$), ASA score (ASA disease acuity class of 3–4 86.4% vs. 65.5; $p = 0.001$), comorbidities (86.4% vs 73.6%; $p = 0.037$), antiplatelets drugs (39% vs. 21.4%; $p = 0.005$), active bleeding in endoscopy (55.9% vs. 26.4%; $p < 0.001$), endoscopic treatment (71.2% vs. 35.8%, $p < 0.001$), blood units transfusions (5.42 vs. 2.48; $p < 0.001$); days of hospital stay (23.69 vs. 6.91; $p > 0.001$), blood pressure (104.44 vs. 112.64; $p = 0.010$),

creatinine (1.44 vs. 1.19; p = 0.034) and albumin levels (2.76 vs. 3.22; p < 0.001). Independent predictors for mortality in IPs were ASA ≥3 (OR 7.8; 95% CI 2.089–29.143, p = 0.002) and need for endoscopic intervention (OR 2.00; 95% CI 1.063–3.746, p = 0.032).

Conclusion: In this study, we demonstrate that IPs have higher morbidity and mortality rates, and that ASA class is clearly a predictor of mortality in patients with UGIB (non-variceal and variceal). These results are in concordance with previous reports in non variceal bleeding population (2,3). More, we showed that those are also valuable for the whole group of bleeders. Guidelines on optimal management of IPs who develop UGIB have been derived essentially from studies on OPs bleeding, whereas few data are available that focus on in-hospital bleeding and its management. It is obvious that IPs have poorer outcomes, and better understanding of the reasons is essential to develop a specific management. More studies in this sense are needed.

P0488 RISKS OF UPPER GASTROINTESTINAL BLEEDING IN PATIENTS WHO FAILED INITIAL *HELICOBACTER PYLORI* ERADICATION THERAPY: A PROPENSITY SCORE MATCHING STUDY

C.-G Guo[1], K.S Cheung[1], L Chen[1], **W.K Leung**[1]

[1]*The University of Hong Kong, Department of Medicine, Hong Kong, Hong Kong, China (SAR)*

Contact E-Mail Address: waikleung@hku.hk

Introduction: Upper gastrointestinal bleeding (UGIB) is a leading cause of hospitalization which is still associated with significant mortality. Although *Helicobacter pylori* (HP) eradication and the use of gastroprotective agents could lower the risk of UGIB, the actual bleeding risk in patients who had received HP therapy remains unclear, particularly those who failed initial HP eradication.

Aims and Methods: This was a propensity score matched cohort study to determine the risk of UGIB in HP-infected patients who had received a course of clarithromycin-containing triple therapy for HP eradication between Jan 2003 and Dec 2012. Patients were identified from the territory-wide electronic health database of the Hong Kong Hospital Authority. The follow-up period commenced from 60 days after the HP therapy until the occurrence of UGIB, death or the end of the study (30 Jun 2016). The primary outcome was the occurrence of non-variceal UGIB. Failed initial HP eradication was identified by the need of repeat HP eradication therapy including repeated first-line therapy, a second-line or third-line therapy. Covariates included baseline characteristics, baseline medical conditions and concurrent medications. As medication usages could change over time, the follow-up period was split into intervals of 3-month and drug usage was defined in each interval as more than 7 days use. To reduce the indications bias for gastroprotective agents, the last 6-week before the index date of events or censoring were excluded when retrieving proton pump inhibitors (PPI) and histamine type-2 receptor antagonists (H2RA) prescription records. Propensity score (PS) matching was used to select controls for each failed eradication patient by the ratio of 1:5. Cox proportional hazards model was used to adjust the confounders, in which medications were included as time varying variables. Hazards ratios (HR) and corresponding 95% confidence intervals (CI) were presented.

Results: 70,869 patients who had received HP eradication therapy were included in PS matching, with 5,593 patients in the failed initial eradication group and 27,965 patients as controls. The median follow-up duration was 7.3 (interquartile range, 4.8–10.1) years. The overall incidence rate of non-variceal UGIB was 4.10 per 1000 person-year (failed group 5.48 vs successful group 3.90; log-rank test p < 0.001). Multivariate Cox regression analysis showed that patients in the failed group had higher risk of UGIB (HR 1.31; 95%CI 1.11–1.55, p = 0.001). Other risk factors for UGIB included older age, male sex, history of UGIB or ulcer, diabetes, cirrhosis, renal disease and stroke (Table). Concomitant use of aspirin, nonsteroidal anti-inflammatory drugs (NSAIDs), anticoagulants, corticosteroids, selective serotonin reuptake inhibitors (SSRI) also increased the UGIB risk but PPI and H2RA reduced the bleeding risk.

Conclusion: Patients who failed initial HP eradication still have higher UGIB risk, testifying the benefits of early HP eradication in preventing UGI complications. Both PPI and H2RA could further lower the risk of UGIB in HP eradicated subjects.

Variables	HR (95%CI)	P	Variables	HR (95%CI)	P
Age (in year)	1.06 (1.06–1.07)	< 0.001	PPI	0.74 (0.60–0.92)	0.006
Male	1.43 (1.26–1.63)	< 0.001	H2RA	0.57 (0.48–0.69)	< 0.001
Failed initial HP eradication	1.31 (1.11–1.55)	0.001	Aspirin	1.28 (1.03–1.60)	0.024

Introduction: Gastrointestinal bleeding (GIB) is among the top 10 reasons of gastroenterology referrals and is burdened by a high mortality rate. Little is known regarding GIB in elderly patients suffering from multimorbidity. We aimed to describe the prevalence, outcomes, and possible risk factors of GIB in a large cohort of elderly patients admitted in several internal medicine wards across Italy.

Aims and Methods: The REgistro POliterapie SIMI (REPOSI) is an Italian registry set up in 2008 with the aim of activating a network of internal medicine and geriatric wards in order to recruit, monitor, and prospectively study elderly patients, with particular regard to multimorbidity, polytherapy, and clinical outcomes. Data collection is still ongoing. A total of 101 internal medicine wards took part in the study. For the purpose of this study, we have identified all possible diagnoses of GIB (upper and lower), describing the length of stay (LOS), mortality rate, and possible risk factors of GIB, including drugs (i.e., anti-platelet agents, anticoagulants, selective serotonin reuptake inhibitors), smoking habit, alcohol abuse, obesity, index of comorbidity (through the Cumulative Illness Rating Scale [CIRS]), and common chronic diseases (i.e., diabetes mellitus, chronic heart failure, liver cirrhosis, and chronic obstructive pulmonary disease). Odds ratio, 95% confidence interval, and statistical significance were evaluated for all variables.

Results: The REPOSI registry includes 4486 (6-year time span). Among these, at least a diagnosis of GIB was reported in 120 patients (mean age 79±7, F:M 0.9:1), with a crude prevalence of 2.7%. Upper GIB occurred in 72 patients (mean age 79±7, F:M 0.8:1), lower GIB in 51 patients (mean age 79±7, F:M 0.9:1), and both upper/lower GIB in 3 patients. The pooled LOS of patients with GIB was 11.7±8.1 days. 4 patients with GIB died in hospital (3.3%) and eight died within the next 3 months (7.2%). Notably, the use of acetylsalicylic acid (ASA) and anticoagulants (either vitamin K antagonists and direct oral anticoagulants) was not associated with GIB (p = ns). Multivariate analysis for all the possible risk factors of GIB is shown in Table. Non-ASA anti-platelet agents (OR 2.77), CIRS index of comorbidity > 3 (OR 2.38), anaemia (OR 2.81), and liver cirrhosis (OR 5.87) were statistically associated with GIB (p < 0.01).

Conclusion: We here show for the first time that a high index of comorbidity (> 3) is associated with high odds for GIB. GIB carries both an in-hospital and 3-month high mortality rate. The use of non-ASA anti-platelet agents should be discussed and carefully evaluated in elderly patients.

P0490 MAST CELLS INFILTRATION AND SPACIAL RELATIONSHIP TO MUCOSAL AFFERENT NERVES IN PATIENTS WITH REFLUX DISEASE

K Nikaki[1], R Silva[2], J.L.S Ooi[1], F Grassi[1], C Lee[1], P Woodland[1], M Souza[2], D Sifrim[1]

Contact E-Mail Address: k.nikaki@qmul.ac.uk

Introduction: Oesophageal mucosal afferent nerve fibres lie more superficially in non-erosive reflux disease (NERD) patients, compared to erosive reflux disease (ERD) and Barrett's oesophagus [1]; possibly underlying the relative oesophageal hypersensitivity observed in NERD. A close spatial relationship between afferent nerves and mast cells (MCs) is implicated in colonic hypersensitivity observed in IBS patients [2].

Aims and Methods: This study aimed to quantify oesophageal mucosa MCs infiltration and their spacial relationship with afferent nerves in reflux disease patients.
Distal oesophageal biopsies from 10 patients with 'true' NERD and 11 patients with ERD were stained for CGRP and toluidine blue. The position of CGRP positive nerve fibres was determined as number of cell layers from the lumen. Similarly, the number of MCs per high power field (HPF: x50 magnification) and their position in the epithelium was recorded.
Results: The median age was 55.5 years (range: 28–75, 6M:4F) for NERD patients and 54 years (range: 31–73, 8M:3F) for ERD. The median density of MCs/HPF was 0.17 (CI: 0.08–0.5) for NERD vs 0.50 (CI: 0.5–0.8) for ERD ($p = 0.01$). There was no correlation between oesophageal acid exposure and density of MCs infiltration in NERD ($r = 0.09$). The MCs were more superficially located in NERD patients (17.5 cell layers) compared to ERD (23 cell layers), $p = 0.01$. There was no correlation between the position of the MCs and the nerve fibres amongst both groups ($r^2 = 0.2$, $p = 0.05$).
Conclusion: Although there are differences between the density of MCs infiltration and position of the MCs in the epithelium between NERD and ERD, we could not find a good correlation between the position of nerves and the position of the MCs. Therefore, the spacial relationship of the MCs and the mucosal afferent nerves in NERD appears to be different to IBS with possible pathophysiological implications.
Disclosure: Nothing to disclose

Introduction: Memantine, currently available for the treatment of Alzheimer's disease, is an uncompetitive antagonist of the N-methyl-D-aspartate type of glutamate receptors. Under normal physiologic conditions, these unstimulated receptor ion channels are blocked by magnesium ions, which are displaced after agonist-induced depolarization. In humans, memantine administration is associated with different gastrointestinal dysmotility side effects (vomiting, diarrhoea, constipation, motor-mediated abdominal pain), thus limiting its clinical use. Mechanism of these motility disorders has not been clarified yet. Pigs can be used in various preclinical experiments due to their relatively very similar gastrointestinal functions compared to humans.
Aims and Methods: The aim of this study was to evaluate the impact of a single and repeated doses of memantine on porcine gastric myoelectric activity evaluated by means of electrogastrography (EGG). 6 adult female experimental pigs (*Sus scrofa f. domestica*, mean weight 41.7±5.0 kg) entered the study for 2 times. The first EGG was recorded after a single intragastric dose of memantine (20 mg). In the second part, EGG was accomplished after 7-day intragastric administration (20 mg per day). All EGG recordings were performed under general anaesthesia. Basal (15 minutes) and study recordings (120 minutes) were accomplished using an EGG stand (MMS, Enschede, the Netherlands). Running spectral analysis based on Fourier transform was used. Results were expressed as dominant frequency of gastric slow waves (DF) and power analysis (areas of amplitudes).
Results: Single dose of memantine significantly increased DF, from basic values (1.65±1.05 cycles per min.) to 2.86 cpm after 30 min. ($p = 0.008$), lasting till 75 min. ($p = 0.014$). Basal power (median 452; inter-quartile range 280–1312 μV^2) raised after 15 min. (median 827; IQR 224–2769; $p = 0.386$; NS), lasting next 30 min. Repetitively administrated memantine caused important gastric arrhythmia. Basal DF after single and repeated administration was not different, however, a DF increase in the second part was more prominent (up to 3.18±2.16 after 15 and 30 min., $p < 0.001$). In comparison with a single dose, basal power was significantly higher after repetitively administrated memantine (median 3940; IQR 695–15023 μV^2; $p < 0.001$). Next dose of 20 mg memantine in the second part induced a prominent drop of power after 15 min. (median 541; IQR 328–2280 μV^2; $p < 0.001$), lasting till 120 min. ($p < 0.001$).
Conclusion: Both single and repeated doses of memantine increased DF. Severe gastric arrhythmia and long-lasting low power after repeated administration might explain possible gastric dysmotility side effects in the chronic use of memantine.

Introduction: It has been shown in severely abused 'non-patient' women population that a history of severe, combined physical and sexual abuse is associated with a higher number of GI symptoms (1).
Aims and Methods: To assess in healthy women, referring to lawyers for non-specific legal assistance excluding abuse (controls lawyers LC) compared to severely abused women (V) the prevalence of somatic symptoms and the association with the time of perpetration, type, and severity of abuse. 67 women, (18–58 yrs), receiving shelter in anti-violence associations and 46 lawyers controls (29–80 yrs) were invited to fill out an anonymous questionnaire with a medical and an abuse section. The severity of abuse was expressed as the 0–6 Abuse Severity Measure (ASM) (2). The association between abuse characteristics and the number of symptoms, was assessed by Poisson regression model.
Results: In controls lawyers (LC) 65% of woman suffered from physical and or sexual abuse in childhood and or adulthood vs 100% of severely abused women (V). Most women suffered from childhood and adulthood sexual and physical abuse. In 78% of LC the ASM was < 2 vs 36% of V (ASM$\geq$ 4 in 54%). Controls lawyers women reported a mean of 4.9 GI symptoms (median 4; IQR 2–8) vs 4.6 of severely abused women (median 4; IQR 2–7). Controls lawyers women with an ASM $\geq$2 reported significantly more GI symptoms (median 6.5; IQR 3–11 vs median 3; IQR 1–7) ($p = 0.002$ vs < 2). Severely abused women with an ASM $\geq$5 reported significantly more GI symptoms, than controls lawyers women (median 6; IQR 4–8 vs median 4.5; IQR 2–8 ($p = 0.000$). In both groups women having suffered from both sexual and physical abuse reported a higher number of GI symptoms than those reporting only one type of abuse.
Conclusion: Symptoms in abused 'non-patient' women mainly concern the abdomen and the GI tract. A history of severe, combined physical and sexual abuse, is associated with a higher number of GI symptoms

Introduction: Patients with Amyotrophic Lateral Sclerosis (ALS) may be affected by severe dysphagia, emerging in more than 80% of patients during the advanced phases of the disease and can affect all stages of swallowing with the need to resort to enteral nutrition via Percutaneous Endoscopic Gastrostomy. Previous studies have reported oro-pharyngeal dysfunction, but little is known about alterations of esophageal and gastric motor activity.
Aims and Methods: To assess motor function of esophagus and stomach, 12 ALS patients with bulbar or spinal presentation (6F; 63±12 yrs) underwent: (1) High Resolution Manometry with esophageal pressure topography, using a water-perfused catheter with 24 open tips 1 cm spaced (o.d.4.7mm) (EB Neuro S.p.A. Firenze), according to the Chicago III method and classification[1]; (2) evaluation of gastric emptying by ultrasonographic serial measurements of gastric antral volume in basal fasting conditions, and at the end and thereafter for 180 min from ingestion of a standardized 525 kcal solid-liquid meal. In 7 patients reporting dysphagia, the oropharyngeal stages of swallowing were evaluated by a fibrolaringoscopy procedure. The stage and progression of the disease were evaluated by ALS Functional Rating Scale (ALS FRS-R) and the Medical Research Council Score (MRC). The operators were blinded about the ALS clinical onset.
Results: Clinical presentation was bulbar in 5 patients (5F) and spinal in 7 patients (6M). The time interval between the onset of ALS symptoms and the enrollment was 23.2±18.8 months. The progression was slow in 8 cases and fast in 4 cases. ALS FRS was 39.6±5.1; the upper limbs MRC was 69.7±13.5, the lower limbs MRC was 59.8±20.4 and the total MRC was 129.4±26.5. Fibrolaryngoscopy identified dysphagia as oral, pharyngeal and mixed oropharyngeal respectively in 3, 1 and 3 patients. Resting pressure of the lower esophageal sphincter was normal in all patients except in 1 showing a reduced value; esophagel peristalsis was normal in 6 patients and ineffective in 8 patients (3/6 bulbar presentation; 5/7 spinal presentation). Delayed gastric emptying was detected in 2/5 bulbar presenting patients and in 4/7 spinal presenting patients. The oropharyngeal dysphagia was not related to manometric pattern, delayed gastric emptying was present in 4/7 of the dysphagic patients.
Conclusion: Statistical analysis cannot be performed because of the small study group, however these data suggest that patients with ALS may have defects in the esophageal peristalsis and delayed gastric emptying, and probably these defects are more frequent in spinal presentation than in bulbar one. The frequent association between oral and/or pharyngeal dysphagia with delayed gastric emptying suggests a possible involvement of the vagus nerve in these patients, as reported in a recent study.[2]

P0494 DOPAMINE ANTAGONISM DOES NOT MODULATE ESOPHAGEAL SENSITIVITY IN HEALTH

A Pauwels[1], C Broers[1], H Geysen[1], J Tack[2]
[1]*KU Leuven, TARGID, Leuven, Belgium*
[2]*University of Leuven, University Hospital Gasthuisberg, Gastroenterology, Leuven, Belgium*

Contact E-Mail Address: ans.pauwels@med.kuleuven.be

Introduction: Dopamine, a predominant catecholamine neurotransmitter, controls a wide range of functions such as emotion, cognition and positive reinforcement. Dopamine also plays an important role in the regulation of food intake and the gastrointestinal function. In animal models, dopamine-2 (D2) receptors have been implicated in the pathogenesis of visceral hypersensitivity (Nozu, NMO 2016) and itopride, a D2-antagonist and cholinesterase inhibitor, is able to decrease esophageal acid exposure and to improve reflux symptoms (Kim, *WJG* 2005; Scarpellini *APT* 2011). However, the role of dopamine in the control of esophageal sensitivity in man has not been studied.

Aims and Methods: We hypothesize that chlorpromazine, a D2-antagonist, decreases esophageal sensitivity in healthy volunteers (HV).

After IV administration of chlorpromazine (IV infusion 10mg) and placebo (0.9% NaCl), esophageal multimodal sensitivity was quantified in 13 HV (7m/6f, age 25y [19–40]) in a single-blind, randomized, cross-over study. After an overnight fast, a custom made probe with a balloon was positioned in the distal esophagus. Thermal, mechanical, electrical and chemical sensitivity were tested, in that order. Perception scores were evaluated using Visual Analogue Scales (VAS) and stimulus intensities were evaluated for first perception, pain perception threshold (PPT) and pain toleration threshold (PTT). General mood was assessed by the Positive and Negative Affect Schedule (PANAS) and the State-Trait Anxiety Inventory (STAI-state) questionnaires before and after the stimulations. Results were analyzed using two-tailed paired t-tests or Wilcoxon matched-pairs signed-rank test. A p-value of < 0.05 was considered significant.

Results: There was no difference in esophageal sensitivity to either 1 of the stimulations when comparing placebo to chlorpromazine. STAI scores were similar in both conditions and no differences were found between placebo and chlorpromazine after the stimulation. We did however find significantly lower positive affect scores after the stimulations in the chlorpromazine condition compared to before the stimulations (23.00 [19.50–28.50] vs. 29.00 [25.00–34.00], $p = 0.0002$). Positive affect was also significantly lower in the chlorpromazine condition compared to the placebo condition after the stimulations (23.00 [19.50–28.50] vs. 28.00 [25.00–33.00], $p = 0.004$).

Conclusion: Although positive affect scores after the stimulation procedure were lower when chlorpromazine was administered, chlorpromazine did not affect esophageal sensitivity to thermal, mechanical, electrical and chemical stimulation in HV. Therefore, we conclude that antagonism of the D2-receptor is not likely to be a therapeutic target for the modulation of esophageal pain perception.

P0495 ANALYSIS OF FULL-LAYER MUCOSAL HISTOLOGY IN ACHALASIA

H Sato[1,2], K Takahashi[1], K.-I Mizuno[1], S Hashimoto[1], S Ikarashi[1], K Hayashi[1], J Yokoyama[1], S Terai[1]
[1]*Niigata University Medical and Dental Hospital, Division of Gastroenterology, Niigata, Japan*
[2]*Saiseikai Niigata Daini Hospital, Department of Gastroenterology, Niigata, Japan*

Contact E-Mail Address: pyloki@yahoo.co.jp

Introduction: The mucosal histology in achalasia has only been investigated using superficial biopsy or surgically resected esophageal specimens in end-stage cases.

Aims and Methods: The present study aims to elucidate mucosal histological findings of achalasia and to determine if in fact these changes occur in the early stage of the disease. Endoscopy was performed to determine the pinstripe pattern (PSP) (an early achalasia indicator), dilation and thickening of the mucosa (advanced achalasia indicators). Peroral endoscopic myotomy was then performed, and the mucosal entry site was created using cap-fitted endoscopic mucosal resection to access the full-layer mucosa and the submucosa.

Results: Mucosal histology was compared between 35 patients with achalasia and 15 controls. Histological esophagitis with findings of inflammatory cell infiltration and dilated intercellular spaces was far more frequently observed in patients with achalasia than in controls (82.9% vs. 13.3%, $p < 0.001$; 77.1% vs. 46.7%, $p = 0.049$). Atrophy of muscularis mucosae (MM) and epithelial waves were only observed in achalasia (39.4% vs. 0%, $p = 0.004$; 25.7% vs. 0%, $p = 0.043$). Fibrosis was more common in achalasia, but without statistical significance (34.3% vs. 20.0%, $p = 0.502$). In achalasia with endoscopic dilation and thickening of the mucosa, atrophy of MM was observed histologically, and in patients involving endoscopic PSP, the histological epithelial waves were visible.

Conclusion: Histological findings of esophagitis were observed both in early and advanced achalasia. PSP corresponds to the epithelial waves observed histologically in achalasia, whereas endoscopic findings in advanced achalasia correspond to the atrophy of MM. Appropriate management is necessary during the early stage of achalasia to prevent progression to advanced achalasia with severe histological changes.

Introduction: The Chicago Classification (CC) for oesophageal motility disorders is based on ten 5mLs single water swallows (SWS). The addition of a solid test meal (STM) was shown to improve diagnostic sensitivity for patients with oesophageal symptoms and a normal gastroscopy in a European cohort. We further validate the feasibility and tolerability of an adjunctive STM in the routine evaluation of patients presenting with oesophageal symptoms in a multiracial Asian cohort.

Aims and Methods: Prospective study of patients referred for esophageal HRM between October 2014 to April 2018 after a normal gastroscopy. Single water swallows (SWS) based on 10 5mLs water and STM studies with 200g plain rice were performed in the upright seated position. Diagnosis of major and minor esophageal motility disorders were based on CC version 3.0 for SWS and modified for STM as appropriate. Symptoms reported during HRM were analyzed for concomitant esophageal manometric abnormalities. A positive symptom associated dysfunction [SAD] referred to a symptom event occurring within 10seconds of concomitant esophageal dysmotility on HRM.

Results: 363 patients (163 [45%] male; mean age 50.5 ± 17.0 years; 244 [67.2%] Chinese; 66 [18.2%] Malays; 27 [7.4%] Indians; 26 [7.2%] others) underwent HRM with SWS. 2 patients with achalasia were evaluated with SWS only. 361 patients (dysphagia [n = 154 (42.7%)], reflux [n = 145 (40.2%)] and atypical chest pain [n = 62 (17.2%)] were evaluated with SWS and STM. More patients were

Abstract No: P0496: Overview of manometry findings on single water swallows (SWS) and solid test meal (STM)

	Group 1 Dysphagia (SWS n = 156/STM N = 154)	Group 2 Reflux (n = 145)	Group 3 Atypical chest pain (n = 62)	Total (SWS[n = 363], STM[n = 361])
Age (mean,SD)	53.3±18.0	46.9±15.6	50.9±15.6	50.3±16.9
Achalasia/Esophaogastric junction outflow obtruction on SWS. N (%)	33 (21.1)	2 (1.4)	2 (3.2)	37 (10.2)
Achalasia/Esophagogastric junction outflow obstruction on STM. N (%)	37 (24.0)	4 (2.8)	3 (4.8)	44 (12.2) p = 0.41 compared with SWS
Oesophageal spasm on SWS	2 (1.3)	1 (0.7)	0 (0)	3 (0.8)
Oesophageal spasm on STM	4 (2.6)	6 (4.1)	1 (1.6)	11 (3.0) p = 0.03 compared with SWS
Jackhammer oesophagus on SWS	1 (0.6)	2 (1.4)	5 (8.1)	8 (2.2)
Jackhammer oesophagus on STM	17 (11.0)	3 (2.1)	9 (14.5)	29 (8.0) p < 0.005 compared with SWS
Ineffective oesophageal motility on SWS	27 (17.3)	33 (22.8)	6 (9.7)	66 (18.2)
Ineffective oesophageal motility on STM	12 (7.8)	5 (3.4)	4 (6.5)	21 (5.8) p < 0.005 compared to SWS

diagnosed with esophageal spasm during STM (n = 11 [3.0%] compared to SWS (n = 3 [0.8%], p = 0.03) and jackhammer esophagus (n = 29 [8.0%]) during STM compared to SWS (n = 8 [2.2%], p = 0.0003). Similarly, more patients were diagnosed with esophagogastric-junction outflow obstruction (EGJOO) during STM (n = 15 [4.2%]) compared with SWS (n = 9 [2.5%], p = 0.22) Diagnostic sensitivity of HRM with inclusion of STM was improved, with a higher overall prevalence of a major motility disorder with STM (n = 91/361 [25.2%]) compared to SWS (n = 63/363 (17.4%) [p = 0.0141]. Conversely, more patients were diagnosed with a minor motility disorder on SWS (n = 66 (18.2%) compared to STM (n = 21 [5.8%], p < 0.0001). None of the patients experienced symptoms during SWS compared to 69 [19.1%] patients who had a positive SAD with STM (p < 0.0001). The STM was tolerated by all subjects.
Conclusion: Addition of STM to routine esophageal manometry was well tolerated in Asians. STM improved diagnostic sensitivity and specificity of clinically relevant esophageal dysfunction and symptom reproducibility in a multiracial Asian cohort.

Introduction: The relationship between esophageal chemical clearance and abnormal high-resolution manometry (HRM) findings in GERD patients has not been fully investigated in terms of both EGJ barrier and motility function.
Aims and Methods: The main aim of this study was to determine the effect of EGJ barrier and peristaltic dysfunction on esophageal clearance in patients with GERD. 53 patients with PPI-refractory GERD symptoms who underwent both HRM and MII-pH tests were recruited. 2 cases of EGJ outflow obstruction were excluded, 51 remaining cases including 4 cases of major motility disorders, 20 cases of minor motility disorders and 27 cases of normal motility were included. Esophageal chemical clearance was evaluated by post reflux swallow-induced peristaltic wave (PSPW) index and mean acid clearance time (MACT) in MII-pH test and compared among different groups of peristalsis and EGJ morphology on HRM. Prediction models were developed to assess the strength of esophageal clearance parameters in GERD diagnosis by calculating the area under the curve (AUC) at receiver-operating-characteristic (ROC) analysis.
Results: The median values of PSPW index for major disorder of peristalsis, minor disorder of peristalsis, and normal peristalsis were 9.4 (1.9–14.7)%, 12.7 (8.6–20.0)% and 16.7 (7.7–30.2)%, respectively. The median values of MACT were 172.5 (145.0–1268.8) seconds, 78.5 (22.7–165.5) seconds, and 46.0 (22.0–132.0) seconds, respectively. The MACT in the major disorder group was significantly higher than in the minor disorder group and the normal motility group (p < 0.05) while PSPW index did not show any significant difference among groups. On the other hand, there was no difference in PSPW index and MACT among 3 EGJ morphology types. At ROC analysis, median MACT and mean nocturnal baseline impedanc (MNBI) showed good prediction of GERD with AUC being 0.78 (p = 0.001) and 0.84 (p < 0.001), respectively.
Conclusion: Major disorder of peristalsis is a cause of chemical clearance dysfunction while minor disorder of peristalsis and EGJ morphology type do not play an important role. MACT could be used as a promising index to evaluate chemical clearance in GERD.

P0498 LONG-TERM OUTCOMES OF PER ORAL ENDOSCOPIC MYOTOMY IN CHILDREN

Z Nabi, M Ramchandani, R Chavan, D.N Reddy
Asian Institute of Gastroenterology, Gastroenterology, Hyderabad, India

Contact E-Mail Address: zaheernabi1978@gmail.com
Introduction: Achalasia cardia (AC) is rare in children and optimum endoscopic management options are not known. Per oral endoscopic myotomy (POEM) is a novel treatment modality for AC with excellent results in adult patients. However, the long-term outcomes of POEM and incidence of gastroesophageal reflux disease (GERD) have not been evaluated in children.
Aims and Methods: In this study, we aim to evaluate the outcomes of POEM in children and adolescents with AC.
We analyzed the data of all the children (≤ 18 years) with AC who presented to our hospital from September, 2013 to January 2018. The following outcome parameters were assessed- technical success, clinical success and adverse events. GERD was assessed with 24-hour pH-impedance study and esophagogastroduodenoscopy.
Results: A total of 43 children (boys-22, girls-21) with mean age, 14.5 ± 3.41 years (4–18) underwent POEM during the study period. The subtypes of achalasia according to Chicago classification were - type I- 11, type II- 29, III- 2 and unclassified-1. 18 children (41.9%) had history of prior treatment including - pneumatic dilatation (15), laparoscopic Heller's myotomy (1) and both dilatation and Heller's myotomy (2). POEM was successfully performed in all the children. Mean total length of myotomy was 10.09 ± 2.53 cm (5–15). Median procedure time was 48 minutes (18–240). Operative time was significantly less in cases where new triangular knife with water jet was used as compared to those in whom old triangular knife was used (mean, 42.72±14.92 vs 97.05±47.30 min, p < 0.05). Intra-operative adverse events occurred in 11 (25.6%) children including retroperitoneal CO2 7, capnoperitoneum 3 and mucosal injury 1. At a median follow-up of 540 days (66–1594), the clinical success was 95.3% (39/41). Clinical success at 1, 2, 3, and 4-years follow-up was 96.42% (27/28), 100% (18/18), 92.3% (12/13), and 83.3% (5/6) respectively. GERD was evident in 55% (11/20) and 53.8% (7/13) children as assessed by endoscopy and 24-hour pH study, respectively.
Conclusion: POEM is safe and effective for the management of achalasia in children. However, GERD is a potential concern and evident in over half of the children. Randomized comparison with Heller's myotomy combined with fundoplication is warranted in future trials.

Introduction: Asian populations have relatively lower prevalence and singular symptom presentation of gastroesophageal reflux disease (GERD) in comparison with those of Western descent. Increased gastric retention as a result of slower gastric emptying (GE) is a pathophysiological factor of GERD. In Asia, previous study suggested elderly have slower GE compared with younger subjects. However, there are scant studies ascertaining potential relation between gastroduodenal motor function and GERD in the Asian countries.
Aims and Methods: Our aim is to examine the relevant implication of slower GE in GERD by the design of a hospital-based, single institution, cross-sectional survey in Taiwan. We recruited 152 patients (87 men, range: 18~69 years old, mean age: 40.4 ± 12.4 years) of GERD, diagnosed by symptom presentations and endoscopy examinations. They completed the scintigraphic measurement of solid phase GE. The presence of dyspetic and/or atypical GERD symptoms, psychological stress including Spielberger Trait Anxiety Inventory (TAI), Beck's Depression Inventory (BDI), and Social Readjustment Rating Scale (SSRS) are recorded by self-report questionnaire. The status of *Helicobacter pylori* infection, blood level of pepsinogen I and I/II ratio are assessed.
Results: 47% and 28 % of the patients have slower GE rate, depending on the defined cut-off values with half emptying time ($t_{1/2}$) ≥ mean plus 2 standard deviation (SD) and 3 SD, respectively. Multiple logistic regression analysis indicates that older age (adjusted OR = 1.037, p < 0.05) and BDI score (adjusted OR = 1.052, p < 0.05) are independently related to slower GE. Subgroup analysis according to the status of GE discloses that patients with slower GE and higher BDI score tend to present with non-erosive reflux disease (NERD) whereas higher BMI level and male gender in patients with normal GE predict the presence of erosive reflux disease (ERD). Severe ERD (Grade C & D, n = 12) tend to be older among the 88 ERD patients (p = 0.054).
Conclusion: A subset of Asian patients with GERD have slower GE and that are associated with aging and higher psychological stress. The presence of slower GE specifies distinctive clinical implications of the GERD.

Introduction: Laparoscopic Heller's myotomy (LHM) is a technically difficult procedure in obese achalasia patients with sub-optimal outcomes and increased rates of gastro-oesophageal reflux disease (GERD). Per oral endoscopic myotomy (POEM) is emerging as a less invasive alternative to LHM in such patients. The impact of obesity on the outcomes and post-treatment GERD after POEM are not well known. Hence our study aims were to compare the outcomes and rates of abnormal oesophageal acid exposure after POEM in obese versus non-obese patients with achalasia.

Aims and Methods: Records of achalasia patients who underwent POEM between April 2014 and June 2017 were reviewed. Patients who underwent pre-treatment timed barium oesophagram (TBE), high-resolution oesophageal manometry (HREM) along with 2 month post-treatment TBE, HREM and a 24-hour oesophageal pH study were included. Patients were categorized into 2 groups, obese (BMI≥30 kg/m2) or non-obese (BMI < 30 kg/m2). Patient demographics, type of achalasia, prior interventions, pre-treatment and 2 month post-treatment TBE, HREM, Eckardt's scores and pH study findings were compared between the 2 groups. Eckhardt's symptom score of < 3 was considered as successful palliation of symptoms.

Results: Among a total of 134 patients who underwent POEM, 100 patients (Obese = 46; Non-obese = 54) met the study criteria. There were no significant differences in the age, gender, ASA class, achalasia subtype, prior interventions, procedure time, length of stay (LOS) and complication rates between the 2 groups. Post treatment Eckardt's scores, HREM parameters and TBE parameters improved significantly in both groups. Eckardt's scores improved from an average of 7 to 0 ($p < 0.001$) in both the groups. However there was no significant difference in pre-post change in values of these parameters between the 2 groups. DeMeester score was abnormal in 57.5% in non-obese versus 43.9% in obese group ($p = 0.22$). Similarly there was no difference in number of patients who reported having GERD symptoms in non-obese versus obese patients (15.8% vs. 21.1%, $p = 0.55$).

Conclusion: POEM is an equally safe and effective treatment option for both obese and non-obese achalasia patients. Interestingly, POEM does not lead to increased GERD in obese as compared to non-obese patients. POEM might emerge as the preferred approach for myotomy in obese achalasia patients as compared to LHM in future.*[Pre and Post POEM findings in Eckhardt's score, HREM, TBE and 24-hr oesophageal Ph study findings.]*

Disclosure: This Abstract is accepted to be presented at Digestive Disease week (DDW) meeting in Washington DC, USA in June/2018.

P0501 ROLE OF HIGH-RESOLUTION MANOMETRY IN THE DIAGNOSTIC AND THERAPEUTIC APPROACH OF POST FUNDOPLICATION DYSPHAGIA

Introduction: Laparoscopic fundoplication is the gold standard of non-pharmacological treatment of gastroesophageal reflux disease (GERD). Despite good symptomatic control, a significant percentage of patients develop dysphagia at follow-up. High-resolution manometry (HRM) is indicated in the evaluation of these patients, but its impact is not well established.

Aims and Methods: We performed a retrospective study evaluating GERD patients who developed persistent post fundoplication dysphagia. Demographic, clinical and HRM data were evaluated whenever possible in the pre and postoperative period. The analysis of HRM data was performed according to the Chicago III classification.

Results: We included 27 patients, 63% women, with a median age of 58 years (range: 46–64). Nissen fundoplication was the most frequently performed surgical procedure (85%). Patients presented with dysphagia after a median period of 7 months (range: 1–43), more frequently for solid food (59%). 12 patients (44%) had preoperatively HRM, with abnormal findings in half of the cases (ineffective motility n = 4, hypercontractile esophagus n = 2). Significant manometric changes were observed in the postoperative HRM in 16 patients (59%). The main findings were esophagogastric junction outflow obstruction (n = 9, 33%) and absence of contractility (n = 3, 11%). Compared to the preoperative period, there was a significant increase in the resting pressure of the lower esophageal sphincter (8.1 mmHg vs. 20 mmHg, $p = 0.043$). There were no significant differences in the integrated relaxation pressure ($p = 0.686$) and in the distal contractile integral ($p = 0.109$). In patients with available pre and postoperative HRM, the manometric diagnosis was changed in 83% (10/12). In the follow-up, 15% of the patients were submitted to endoscopic dilatation and 41% underwent revision surgery, with clinical success of 25% and 75%, respectively.

Conclusion: HRM in post-fundoplication dysphagia is associated with relevant changes in a considerable percentage of patients, allowing a tailored management approach. Also, this study reflects the need for additional metrics to better identify patients at higher risk for postoperative dysphagia, and potentially benefiting from a different initial therapeutic strategy.

Introduction: The relative merits of endotherapy for refractory gastroparesis remain unclear.

We assessed the symptomatic response of patients undergoing non-surgical pyloric intervention at a specialist tertiary centre.

Aims and Methods: 57 patients (21 male, mean age 47, 16–81) with medical refractory gastroparesis (29 idiopathic, 5 diabetic, 23 post-gastric transposition) underwent 117 endoscopic treatments from Sep 2013-Sep 2017: either 100IU units of Botox injected into 4 quadrants of the pylorus (N = 66), balloon dilatation to 15–20 mm (EBD, N = 13) or combination therapy (N = 38). Patients with gastric malignancy, pyloric surgery or no follow-up were excluded. Symptoms were assessed immediately prior to each procedure and at first follow-up using a retrospective scoring system based on the presence (1 point) or absence (0 points) of Vomiting, Nausea, Bloating or Early satiety. This formulated a composite symptom score (SS) out of 4; positive response was defined by improvement in SS of at least 1. Statistical analysis was performed using Wilcoxon Signed-Rank Test and Fischer's Test.
Results: There were no immediate or late complications. Mean symptom score (SS) improved per-patient from 2.1 points at baseline to 1.2 post initial endotherapy ($p < 0.01$) at median follow up of 2.1 months. 20 patients required further endotherapy (median 2.5 treatments; range 2–12); mean SS was 1.0 at latest follow-up.
Per-procedure, mean reduction in SS was 0.8 points ($p < 0.01$) with overall positive response rate of 67%. By symptom, vomiting was most responsive to endotherapy (86% pre v 32% post). By treatment type, Botox alone (N = 66) had the highest overall response (78%) compared to EBD (38%, p = 0.02) or combination therapy (66%, p = 0.3). Response to Botox was greater in patients under 40 (83% v 61%, p = 0.04) and females (81% v 33%, p = 0.002). By indication, diabetic GP(N = 17) were most likely to respond (76%).
Sub-group analysis showed procedures for gastroparesis (diabetic/ idiopathic, N = 75) responded significantly more to Botox (mean SS reduction 1, $p < 0.01$) than EBD (mean SS reduction 0.2, $p > 0.1$) or combination therapy (mean SS reduction 0.44, p = 0.12). Procedures for gastric transposition (N = 42) showed significant SS reduction post combination therapy (2.1 v 1.2, p = 0.01) but not post EBD (1.9 v 1.6, $p > 0.1$) or Botox (1.7 v 1.1, p = 0.08).
Conclusion: Endotherapy is a safe and effective treatment for refractory gastroparesis. We found Botox monotherapy significantly improved symptoms in diabetic or idiopathic gastroparesis, especially younger females; conversely, combination therapy was preferable for delayed gastric emptying post gastric transposition. Careful patient selection may augment therapeutic response.

Introduction: Gastroesophageal reflux disesase is diagnozed based on the symptoms such as acid regurgitation or heartburn through transient lower esophageal sphincter (LES) relaxation. Non-erosive reflux disease (NERD) is recognized as hard to treat and less effective with proton pump inhibitor (PPI) compared with erosive reflux disease. Therefore, the diagnosis of NERD deserves functional testing as well as symptom association. The aim of the study was to evaluate the association between lower esophageal sphincter function and symptom and to assess the reponse to treatment with PPI.
Aims and Methods: A total of 80 patients with NERD were enrolled. All patients underwent esophageal manometry and symptom assessment using symptom index and symptom sensitivity index. All patients received a standard dose of PPI for 4 weeks, and then investigated symptom assessment by questionnaire.
Results: The patients were divided into 2 groups by LES function: normal LES relaxation group (LES relaxation % ≥90%) and abnormal LES relaxation group (LES relaxation % < 90%). Clinical and manometric findings were compared and investigated the reponse to PPI. 18 patients (22.5%) were included in the normal LES group whereas 62 patients (77.5%) in LES relaxation abnormality group. There was significant difference in sex (p = 0.007), major symptom (p = 0.024), symptom index (p = 0.032), symptom sensitivity index (p = 0.045), abnormal upper esophageal sphincter function (p = 0.032), and PPI response (p = 0.014) between the 2 groups. In a linear logistic regression model, only LES relaxation abnormality was associated with poor PPI response (p = 0.015).
Conclusion: LES relaxation abnormality was associated with patients' symptom, especially acid regurgitation. Furthermore, LES relaxation abnormality served as a predictor of poor PPI response.

Introduction: Heartburn is the most specific symptom of reflux disease, highly responsive to proton pump inhibitor (PPI) therapy. However, some patients do not respond to PPIs, but the mechanisms of refractoriness have not been fully elucidated. Impedance-pH monitoring, allowing a comprehensive off- and on-therapy assessment of reflux, represents a valuable test to investigate PPI-refractoriness.
Aims and Methods: We aimed to clarify the mechanisms of PPI-refractory reflux-related heartburn, as investigated with impedance-pH monitoring**.** In this prospective, multicenter, pathophysiological study, 64 patients complaining of heartburn with a negative upper gastrointestinal endoscopy, performed after 4-week PPI withdrawal, and with proven GERD at off-PPI impedance-pH monitoring, entered the study. 32 individuals had PPI-refractory heartburn (i.e. < 50% of symptom relief after 8-week high-dosage PPI therapy), and 32 had PPI-responsive heartburn. Mechanisms of heartburn refractoriness to high-dosage PPI were investigated by means of on-therapy impedance-pH monitoring and compared with off-PPI findings. Blindly and manually assessment of impedance-pH tracings comprised conventional reflux testing parameters, including esophageal acid exposure time (AET), number of reflux episodes and symptoms association analysis (symptom index, SI, and symptom association probability, SAP), and novel impedance-detected features, including the post-reflux swallow-induced peristaltic wave (PSPW) index and mean nocturnal baseline impedance (MNBI).
Results: The 2 groups were well comparable for gender, age, BMI, rates of hiatal hernia and of abnormal off-PPI impedance-pH variables (p = ns), as shown in the Table. On PPI, median esophageal AET did not differ between the 2 groups. Moreover, AET was abnormal in 6/32 (19%) of PPI-refractory patients. The total number of refluxes, weakly acidic refluxes and bolus exposure were significantly higher, while PSPW index and MNBI were significantly lower in PPI-refractory cases ($p < 0.05$). At multivariate logistic regression analysis, only PSPW index was an independent risk factor for PPI refractoriness (OR 1.082, 95% CI 1.022–1.146, p = 0.007). Comparing off- and on-PPI parameters, median PSPW index did not change in PPI-refractory patients (24% vs. 26%, p = 0.327), but increased significantly in PPI-responsive cases (29% vs. 46%, $p < 0.001$).
Conclusion: Lack of improvement of impaired chemical clearance represents a major biomarker of PPI-refractory reflux-related heartburn. Add-on therapies aimed to improve chemical clearance by stimulation of timely post-reflux salivary swallowing could benefit patients with PPI-refractory reflux-related heartburn.

	PPI-refractory N = 32	PPI-responsive N = 32	P value
Male Gender, n (%)	16/32 (50%)	18/32 (56%)	0.802
Age (years) (median) (IQR)	48 (44–56)	56 (47–62)	0.070
BMI (median) (IQR)	25 (23–27)	25 (24–27)	0.535
Endoscopic Hiatal Hernia, n (%)	24/32 (75%)	16/32 (50%)	0.071

Introduction: Prevalence of gastroesophageal reflux disease (GERD) ranges 18–46%. In the last few years, the esophageal microbiota has been suggested to have a role in esophageal diseases (1). Identifying microbiota in the esophagus offers new approaches to understanding bacterial roles as pathogenetic factors in GERD, Barrett's esophagus, and esophageal adenocarcinoma (2).
Aims and Methods: We aimed to compare the esophageal intraluminal microbiota of patients of GERD and healthy controls using the 16S ribosomal RNA (rRNA) sequencing. A total of 22 patients were enrolled in this study: 16 patients with GERD and 6 healthy controls. All patients were performed esophageal fluids collection procedure using the specially designed esophageal perfusion catheter equipped with 2 inflatable intraesophageal balloons. mRNA expression was

analyzed by qRT-PCR. Bacterial DNA was purified from the esophageal fluids samples and analysed by next generation sequencing - metagenomic analysis.
Results: We found that microbial communities of esophageal fluid samples are different in healthy volunteers and patients with GERD. *Bacteroidetes* (25.8%), *Firmicutes* (25.5%), *Actinobacteria* (15.4%), *Proteobacteria* (11.7%) *Fusobacterium* (8.8%) were the most prevalent phylum represented in healthy volunteers. In patient with GERD the most prevalent phylum also were *Bacteroidetes* (34.2%), *Firmicutes* (27.3%), *Actinobacteria* (15.4%), *Proteobacteria* (3.5%). However, relative abundance of *Proteobacteria* of esophageal fluid samples in healthy volunteers was greater in comparison with patients with GERD (11.7% vs 3.5, $p = 0.047$). Proportion Bacterial families *Acetobacteraceae, Bacillaceae, Bdellovibrionaceae, Clostridiales Insertae Sedis XI, Fusobacteriaceae, Moraxellaceae, Pasteurellaceae and Rhodocyclaceae* also was higher in healthy volunteers ($p < 0.05$).
Conclusion: Our study showed difference in the esophageal intraluminal microbiota between the patient with GERD and healthy controls. Phylum-level and family-level analysis of esophageal fluids samples revealed that the bacterial communities differed among groups. We found that in healthy controls *Proteobacteria* was present in greater numbers in comparison with patients with GERD. However, a study with larger sample size is needed to further explore difference of esophageal microbiota.
Disclosure: All authors have declared no conflicts of interest

P0507 MACROPHAGE FUNCTIONAL ACTIVITY CHANGES IN DIFFERENT CLINICAL VARIANTS OF GASTROESOPHAGEAL REFLUX DISEASE DEPENDING ON REFLUXATE PH VALUES

S Lyamina, O Kladovikova, S Kalish, I Maev, I Malyshev
Moscow State University of Medicine and Dentistry named after A.I. Evdokimov, Moscow, Russian Federation

Contact E-Mail Address: svlvs@mail.ru

Introduction: Esophageal exposure to gastric refluxate is a primary determinant of gastroesophageal reflux disease (GERD) disease severity. The refluxate provokes active esophageal mucosa inflammation with moderate immune cells infiltration, which includes macrophages. Considering the concept of macrophage functional activity changes depending on their phenotype (M1/M2) and its strong correlation with systemic Th1/Th2 immune response, macrophages greatly influence esophageal mucosa inflammation and affect GERD clinical variants.
Aims and Methods: Pooled analysis of macrophage and monocyte functional activity in exposure to different pH refluxates of patients with different clinical variants of GERD. Patients with non-erosive reflux disease (NERD; $n = 26$; 41.2±3.6 y.o.), erosive reflux disease (ERD; $n = 25$; 41.9±3.1 y.o.), and Barrett's esophagus (BE; $n = 19$; 43.7±4.2 y.o.) were included in the study. Macrophage functional activity was assessed cumulatively by *in vitro* model of local patients' refluxate exposure on macrophages and by monocyte/macrophage phenotype changes in systemic circulation. *In vitro* model included adding refluxates of patients ($n = 70$) with different pH (4.6–8.1) to peritoneal macrophages of C57/BL6 mice ($n = 70$) culturing in standard conditions for 36 hours. Monocytes were isolated from systemic circulation and derived to macrophages (MDM) in standard conditions. Assessment of macrophage and monocyte/MDM functionality included analysis of secretory activity (Th1/Th2 cytokine production in culture medium, Antigenix, USA), receptor characteristics - typical M1/M2 macrophage CD markers (CD25, CD80 and CD163, CD206, respectively) performed by flow cytometry (FC500, Beckman Coulter). Mean pH values of refluxates were assessed for all patients' groups.
Results: Upper range pH values were typical for ERD patients (6.53±0.41) vs 5.52±0.24 and 5.44±0.32 in BE and NERD, respectively. Analysis of cytokine production revealed the prevalence of Th1 and Th1/Th2 bivalent (IL-2, IL-6) cytokines as compared to Th2. The most significant changes in all patient groups were observed in such Th1 cytokines as IL-8, IL-12, INF-g; Th2 - IL-4, IL-5, IL-10. The production of IL-8 and IL-4 dominated in all groups. IL-8 level was 1.4-times increased in BE as compared to ERD (60.3±0.4 pg/ml vs 44.2±0.4 pg/ml, $p < 0.05$); IL-4 production was 2-fold elevated in BE as compared to NERD (13.3±0.7 pg/ml vs 6.8±0.6 pg/ml, $p < 0.05$). For pooled secretory function analysis Th1/Th2 cytokine production index was used. Th1/Th2 cytokine index varied among groups: 4.9 vs 5.7 vs 7.2 in ERD, BE and NERD, respectively. Expression analysis of surface M1/M2 macrophage receptors revealed the predominance of M1 macrophage phenotype in all groups and in all monocytes/MDM isolated from the patients' blood. The expression of CD25 (M1) and CD163 (M2) changed more significantly. The highest values of M1/M2 markers expression indices were noted in BE for both macrophages (2.96) and monocytes (2.56), the lowest - for ERD (2.08 for macrophages, 1.98 for monocytes). These data reflect the same trend as the analysis of macrophage secretory activity in the groups.
Conclusion: The pooled assessment of macrophage functional activity in different clinical variants of GERD, inclusive of pH of the refluxate, revealed characteristic changes of macrophage functional activity in groups. Progressive decrease of pooled Th1/Th2 cytokine production indices and M1/M2 surface CD markers expression indices on macrophages and monocytes are associated with higher pH refluxate values and are typical for ERD patients.

Introduction: At present the diagnosis of GERD uses syndrome-based diagnoses which often lacks specificity and are invasive. The disadvantage of endoscopy lies in its low detection rate, only 2.95% to 4.1% as NERD is the most frequent diagnosis. In recent years, Peptest™, a new non-invasive rapid diagnostic test, detecting and measuring pepsin in expectorated saliva as a marker of a prior reflux event, has been used in the western world to complement questionnaires and to assist office-based diagnosis. To validate the clinical benefits of Peptest™ in China; a multi-center clinical study involving a large number of patients and healthy controls has been conducted.
Aims and Methods: 1031 subjects aged between 18 to 75 years were recruited from 9 hospitals (2 Beijing and 7 Shanghai), including 323 asymptomatic healthy control subjects and 708 patients. According to their endoscopy results, patients were divided into 2 subtypes, Erosive Esophagitis (EE) and Non-Erosive Reflux Disease (NERD). All subjects were asked to provide 1 saliva sample 1 hour following the main meal of the day and patients were encouraged to provide an additional sample when their gastroesophageal reflux symptoms occurred, Table 1. All saliva samples were collected following the standard collection procedure in Peptest™ collection tubes and analysed for the presence of pepsin by lateral flow technology. A faint test line indicating a low pepsin concentration in the saliva of less than 75ng/ml was defined as weak positive and treated as negative, differentiating between physiological and pathological reflux (greater than 75ng/ml).
Results: Higher levels of pepsin were found in the EE and NERD patient groups with over 78% pepsin positivity (553 patients pepsin positive and 155 negative) compared to the control group with only 40% pepsin positivity. The overall sensitivity was 78% and specificity 60%. The positive predictive value (PPV), the fraction of those who were pepsin positive and actually have the disease was 81% and the negative predictive value (NPV) 55%. The likelihood ratio of positive patients presenting with reflux disease was 1.94 with an Observed Proportionate Agreement (accuracy) of 72.36%.
Conclusion: Pepsin a biomarker for reflux and Peptest™ which contains 2 unique anti-human pepsin monoclonal antibodies to detect and capture pepsin enables the rapid detection of pepsin in clinical samples. This easy-to-use non-invasive and rapid test improves the accuracy of reflux diagnosis complementing the use of questionnaires, invasive diagnostic tests and office based reflux diagnosis to better tailor appropriate treatments. The study also revealed that the prevalence of reflux disease in the Chinese population was much higher than previously reported.

P0509 EROSIVE ESOPHAGITIS - NEW APPROACHES TO DIAGNOSIS

D Danilov, A Shuleshova
Central State Medical Academy of Department of Presidential Affairs, Moscow, Russian Federation

Contact E-Mail Address: dvdy@mail.ru
Introduction: At present time, the spread of the gastroesophageal reflux disease and its morbidity is still on a considerably high level, which compels to searching for new approaches to diagnosis and treatment.
Aims and Methods: To study the incidence of the virus persistence of the herpes febrilis (HSV), cytomegalovirus (CMV) and human herpes virus type 4 (EBV) in the esophageal mucosa of patients with an erosive form of gastroesophageal reflux disease.
75 patients with erosive esophagitis (detected via esophagogastroduodenoscopy) were included in this research, the mean age of the patients: 53 ± 14.7 years, males - 55 years, females - 20 years. During the endoscopic examination all patients underwent a biopsy of the esophageal mucosa from the visual defect (2 cm from the gastro-esophageal junction) for immunohistological analysis (IHC test).
Results: According to the results of the IHC test, 32 patients (42.7%) had a virus infection. The degree of incidence of the virus infection in patients with an erosive esophagitis was the following: 21 patients (40.4%) had herpes febrilis (HSV), 19 patients (36.5%) had cytomegalovirus (CMV) and 12 (23%) patients had human herpes virus type 4 (EBV). 18 patients (56.3%) had a combination of several virus types, from 2 to 3 types simultaneously.
Conclusion: Chronic virus infection of the esophageal mucosa is widespread amongst patients with an erosive form of gastroesophageal reflux disease. In the majority of cases, several virus types are present.
Disclosure: Nothing to disclose

P0510 MOTOR ABNORMALITIES IN EROSIVE GASTROESOPHAGEAL REFLUX DISEASE

V Kaibysheva, E.D Fedorov, S Shapovaliantc
Pirogov Russian National Research Medical University (RNRMU), Moscow, Russian Federation

Contact E-Mail Address: valeryslove@mail.ru
Introduction: The Chicago Classification of esophageal motility disorders is not designed to evaluate motor function in gastroesophageal reflux disease (GERD)[1]. The aim of the study is to assess manometrical abnormalities in erosive GERD.
Aims and Methods: 127 patients (75 women, age 28–78 years) with esophagitis LA Grade B,C,D. Esophageal high resolution manometry (HRM), 24-h esophageal impedance-pH monitoring were performed in all patients after upper endoscopy. Esophagogastric junction contractile integral (EGJ-CI) was calculated during 3 respiratory cycles using the distal contractile integral (DCI) box. The calculated 'DCI' was then divided by the duration of the 3 respiratory cycles [2].
Results: According to esophageal impedance-pH monitoring pathological acid exposure time (AET > 6%) [2] was detected only in 115 (90.5%) patients, so the remaining 12 (9.5%) were excluded from further evaluation. Among 115 GERD-patients HRM revealed ineffective esophageal motility (IEM) in 44 (38.3%), absent contractility in 6 (5.2%), fragmented peristalsis in 2 (1.7%), normal esophageal motility in 63 (54.8%) patients. Esophageal manometry also assessed esophagogastric junction (EGJ) morphology [2]: type I was detected in 71 (62%), type II in 24 (20.7%), type III (≥3 cm separation between the LES and CD) in 20 (17.3%) patients. Basal LES pressure (median (5th–95th percentile)) in GERD patients was 10.7 (4.4–15.3) mm Hg, median EGJ-CI was 21.3 (10.4–38.6) mm Hg. Among 44 patients with IEM multiple rapid swallows revealed contraction reserve (post-MRS contraction has greater vigor than the preceding test swallows) in 12 (27.3%) patients, while 6 patients (100%) with absent contractility demonstrated absent post-MRS contraction.
Conclusion: Manometrical abnormalities in GERD include low basal LES pressure and low EGJ-CI (in comparison to normal values) [3], hiatal hernia, esophageal body hypomotility, absence of contraction reserve.
Disclosure: Nothing to disclose

P0511 HEALTH-RELATED QUALITY OF LIFE IMPACT AMONG GASTROESOPHAGEAL REFLUX DISEASE PHENOTYPES IN ECUADORIAN PROTON PUMP INHIBITOR NON-RESPONDERS: A PROSPECTIVE COHORT

R Oleas, H Pitanga-Lukashok, M Puga-Tejada, M Valero, M Sanchez-Carriel, J Ospina-Arboleda, H Alvarado-Escobar, M Soria-Alcivar, R Del Valle, C Robles-Medranda
Instituto Ecuatoriano de Enfermedades Digestivas (IECED), Guayaquil, Ecuador

Contact E-Mail Address: robertoleas@gmail.com
Introduction: More than 50% of Gastroesophageal Reflux Disease (GERD) patients do not respond to Proton Pump Inhibitor (PPI) therapy, remaining symptomatic. Yadlapati et al. described the impact on the Health-Related Quality Of Life (HRQOL) doesn't depend on the GERD phenotype. The Northwestern Esophageal Quality of Life survey (NEQOL), assesses the HRQOL impact across different chronic esophageal diseases (CED). It has previously validated in an Ecuadorian Spanish-speaking population (NEQOL-S). The HRQOL impact among different GERD phenotypes has not been assessed by the NEQOL, especially in a Hispanic population.
Aims and Methods: We aimed to describe the HRQOL impact using NEQOL-S among GERD phenotypes in Ecuadorians PPI non-responders. Prospective cohort study performed at a single medical center from Ecuador (Sept-2016 to Sept-2017). PPI non-responder patients who underwent 24-hour pH-impedance monitoring test and completed the NEQOL-S and SF-12 (a very used survey to assess general-HRQOL in South America). Acid exposure time (AET) and symptomreflux association (SRA) were recorded. Participants were classified into cohorts based on test results: GERD (+AET), reflux hypersensitivity (RHS) (-AET/+SRA) and functional heartburn (FH) (-AET/-SRA). The sample size for each group was estimated using known mean PROMIS Global quality of life reported by Yadlapati et al., with an 80% statistical power. The pH-impedance test outcomes and HRQOL results were contrasted between groups through ANOVA or Kruskal-Wallis test. The relationship between HRQOL (NEQOL-S) vs. AET was estimated through Spearman's rank correlation coefficient (rho). A confirmatory analysis was done using SF-12. A p-value < 0.01 was considered to be statistically significant. Analyses were performed using R v3.4.2 (R Foundation for Statistical Computing, Vienna, Austria).
Results: There were 85 cases with 24-hours pH-impedance monitoring test performed: 30 (35%) +AET, 14 (16%) -AET/+SRA, and 41 (48%) -AET/-SRA. Baseline characteristics and pH-impedance test outcomes are summarized on table 1. NEQOL median scores among groups were: 28.5, 25, 27; respectively ($p = 0.719$). SF-12 median scores among groups were: 40, 39, 39, respectively ($p = 0.977$). Relationship between acid exposure time and HRQOL, measured through NEQOL-S and SF-12 reached a rho = 9.0% ($p = 0.414$) and 7.3% ($p = 0.510$), respectively.
Conclusion: There is no statistical difference of HRQOL impact among GERD phenotypes, or relationship between HRQOL vs. AET. NEQOL-S results are

P0512 FIRST SPANISH VALIDATED TRANSLATION OF A SINGLE HEALTH-RELATED QUALITY OF LIFE SURVEY FOR BROAD USE ACROSS DIFFERENT CHRONIC ESOPHAGEAL DISEASES: A PSYCOMETRIC EVALUATION OF THE NEQOL SURVEY IN AN ECUADORIAN POPULATION

R Oleas, H Pitanga-Lukashok, M Puga-Tejada, M Valero, M Sanchez-Carriel, A Acosta-Crow, J Ospina-Arboleda, G Muñoz-Jurado, H Alvarado-Escobar, M Soria-Alcivar, R Del Valle, C Robles-Medranda
Instituto Ecuatoriano de Enfermedades Digestivas (IECED), Guayaquil, Ecuador

Contact E-Mail Address: robertoleas@gmail.com
Introduction: Chronic Esophageal Diseases (CED) are related to significant disease burden, disability, and cost. Health-related quality of life (HRQOL) is a multidimensional construct that captures physical, mental, social and emotional aspects of patients' lives and how health status is impacted. In 2016, Northwestern Esophageal Quality of Life survey (NEQOL) was developed as the first hybrid questionnaire that allows for broad use across different CED, keeping sensitivity to specific conditions. It is a 14-items scale, measured through a Likert Scale (0–4); with fewer points meaning more HRQOL impact. There is no validated translation of the NEQOL into Spanish.
Aims and Methods: We aimed to better understand how HRQOL can be affected by different CED in Ecuadorians, through the development of a validated translation of NEQOL for its use in Spanish-speaking patients. Observational, prospective cohort study (Oct-2016 - Oct-2017). The translation was based on Sperber recommendations. NEQOL-Spanish version (NEQOL-S) and general HRQOL SF-12 survey were prospectively applied to a clinic-based population. NEQOL-S was reapplied 7 days later. The sample size was calculated using estimating proportion formula (5% margin error). Selection criteria: >18 years old, able to complete the survey, CED diagnosis was based on clinic, endoscopy, biopsy, pH-impedance or manometry findings, no history of esophageal cancer or corrosive esophagitis. NEQOL-S Psychometric analysis included: Internal consistency (Cronbach's alpha, CA), construct validity (Kaiser-Meyer-Olkin Index, KMO), criterion validity against SF-12 (Spearman's rank correlation coefficient (rho) & linear regression, R2), and test-retest reliability (Intraclass Correlation Coefficient, ICC). NEQOL-S utility describing HRQOL by each CED was defined through median (Kruskal-Wallis test). p-value < 0.01 was regarded as statistically significant. Analyses were performed using R v3.4.2 (R Foundation for Statistical Computing, Vienna, Austria).
Results: After completing strict translation, any item was considered problematic. The sample size was calculated to be 385 patients, who were successful included: median age 48 (18–90) yo, 242 (63%) female, 24 months median length symptoms. Internal consistency was excellent (CA = 90%). Construct validity did not suggest to reduce survey number of items (KMO = 92%, $p < 0.01$). Criterion validity showed good coherence when correlated with the SF-12 survey (rho = 75%, $p < 0.01$) with an important impact of CED on general HRQOL (R2 = 57%, $p < 0.01$). Test-retest reliability showed very good correlation when repeating survey (ICC = 82%). Table 1 resumes how NEQOL-S results differed per CED ($p < 0.01$).

	NEQOL-S	SF-12
Achalasia	12 (0–49)	30 (12–52)
Barrett's esophagus	25 (0–50)	42 (19–55)
Gastroesophageal reflux disease (GERD)	27 (0–52)	40 (12–56)
Esophageal scleroderma	7 (1–17)	27.5 (27–35)
Reflux Esophagitis	23 (0–54)	40 (21–54)
Nonerosive Reflux Disease (NERD)	35 (9–50)	45 (9–50)

[Table 1. NEQOL-S and SF-12 survey results for each Chronic Esophageal Disease (CED) [median score (minimum - maximun range)]]
Conclusion: CED has a negative impact on HRQOL. NEQOL-S showed very good psychometric properties, which let us recommend it as a useful tool for measuring HRQOL in Spanish-speaking patients with CED.

P0513 DIAGNOSTIC VALUE OF HIGH-RESOLUTION MANOMETRY IN HIATAL HERNIA DETECTION

V Kaibysheva, E.D Fedorov, S Shapovaliantc
Pirogov Russian National Research Medical University (RNRMU), Moscow, Russian Federation

Contact E-Mail Address: valeryslove@mail.ru
Introduction: Detection of hiatal hernia (HH) is usually done with contrast-enhanced X-ray examination of the esophagus, upper gastrointestinal endoscopy. The aim of this study was to assess the diagnostic value of high-resolution manometry (HRM) in HH detection.
Aims and Methods: 95 patients (37 women, age 23–84 years) with typical symptoms of gastroesophageal reflux disease (GERD) were evaluated using upper gastrointestinal endoscopy, HRM in supine position (HRM). Endoscopic size of HH was measured between the distal margin of the esophageal palisade vessels and the diaphragm hiatus. Manometrical length of HH detected between the lower margin of the lower esophageal sphincter (LES) and pressure inversion point (PIP).
Results: Upper endoscopy revealed HH in 87 (91.6%) GERD patients, which were subdivided in 3 groups (depending on endoscopic HH size). Group I (the maximum HH length is 4–6 cm) included 20 (21%) patients. Group II (the maximum HH length is 2–3.9 cm) - 44 (46.3%) patients. Group III (0.5–1.9 cm) - 23 (23.7%). HRM detected separation between the LES and CD only in 44 patients (45.4%). Moreover HH (≥2 cm separation between the LES and CD) [1] was confirmed just in 20 (21%) patients (all patients from group I). Among the 44 patients from group II HRM revealed separation between the LES and CD < 2 cm in 24 cases (EGJ type II)[1]. In group III HRM did not detect HH.
Conclusion: Endoscopic detection of HH correlates with esophageal manometric diagnosis only in case of big HH (HH > 4 cm long). Using upper endoscopy as the only diagnostic tool may lead to overdiagnosis in 70.5% cases. HRM is the more accurate and specific test for detecting HH than upper endoscopy.
Disclosure: Nothing to disclose

Introduction: Hiatal hernia (HH) is common in obese patients. Classically, HH is detectedby upper gastrointestinal endoscopy (UGIE) or fluoroscopic upper gastrointestinal (UGI) xray series, however intraoperative diagnosis of HH is considered the gold standard. High resolution manometry (HRM) showed a higher sensitivity and specificity than the classical techniques in non-obese patients. There are no data in morbidly obese population.
Aims and Methods: We aimed to evaluate in a population of obese patients candidated to bariatric surgery the agreement in the detection of HH between HRM and intraoperative diagnosis.
52 consecutive morbidly obese patients were prospectively recruited from an outpatient clinic devoted to the surgical therapy of obesity and related disorders. All underwent a preoperative assessment including standardized GERD questionnaire, UGI xray, an UGIE and HRM. All the surgical procedures were performed by a single surgeon who was blinded to HH presence/absence. For both HRM and UGIE or UGI xray, the ability to diagnose hiatal hernia was assessed by means of receiver operating characteristic (ROC) analysis with calculation of area under the curve (AUC). Sensitivity, specificity, and positive and negative predictive values were determined
Results: There was a significant correlation between the 3 morphological types of EGJ assessed by HRM and the presence of HH at UGIE (R = 0.28, p = 0.044). 34/52 enrolled patients underwent bariatric surgery; in 9/34 patients HH was intraoperatively diagnosed. The sensitivity of UGI xray or UGIE in detecting intraoperative diagnosis of HH was 77.8 % and the specificity was 44%; the positive predictive value was 33.3% and the negative predictive value 84.6%. The AUC for UGI xray or UGIE in detecting intraoperative diagnosis of HH was 0.609 (0.40/0.82) with a 95% CI. The sensitivity of the HRM in detecting intraoperative diagnosis of HH was 88.9% with a 60% specificity rate and a positive predictive value of 44.4% and a negative predictive value of 93.75%. The AUC for HRM in detecting intraoperative diagnosis of HH was 0.74 (0.55/0.91) with a 95% CI, p = 0.039.
Conclusion: HRM is a useful tool in the preoperative work-up of bariatric patients, since it shows a better sensitivity and specificity compared to traditional techniques and correlates with the diagnostic gold standard.

Introduction: Endoscopic resection is the cornerstone in treatment of Barrett's esophagus (BE) related neoplasia. The optimal method for handling of endoscopic mucosal resection (EMR) specimens directly after the endoscopy however, remains unknown. As a result, practice varies widely around the world.
Aims and Methods: The aim of this study is to compare 3 different specimen handling methods (pinning on paraffin, the cassette technique, and direct fixation in formalin) for 1) enabling optimal evaluation of all clinically relevant histologic parameters and 2) required time for specimen handling. In this multicenter, randomized trial, EMR specimens of visible lesions in BE with no suspicion of submucosal invasion during endoscopy were randomized to 3 different specimen handling methods: pinning on paraffin, direct fixation in formalin and the newly introduced cassette technique. The cassette is a small box in which an EMR specimen can be enclosed after stretching it out on paper. By closing the cassette, gentle pressure is applied on the specimen during the process of formalin fixation to prevent curling of the lateral margins of the EMR specimen. The pinning method comprises smooth stretching of the EMR specimen and pinning it out on cork or paraffin. Direct fixation of the EMR specimen in formalin requires no handling at all. Primary outcome parameter was an overall optimal evaluation score of 5, on a 5 point Likert scale, for assessment of all relevant histologic parameters. Secondary outcome parameters were evaluation scores for all histopathologic parameters separately and the time required for specimen handling. The histopathological evaluation scores were assessed by 2 BE expert pathologists blinded for the specimen handling method.
Results: In total, 127 specimens of 42 patients were randomized (83% male, mean age of 68.5, median BE segment of C1M4). A median of 2 specimens (IQR 1–4) were included per patient. Of the 127 randomized EMR specimens, 45 were assigned to pinning on paraffin, 40 to the cassette technique, and 42 to direct fixation in formalin. The percentages of specimens with overall optimal histopathological evaluation scores were similar for the pinning method (96%) and for direct fixation in formalin (93%), but significantly lower for the cassette technique (64%, $p < 0.001$). Additional analysis per histologic parameter shows that this difference is caused by 1) the ability to discern lateral from vertical margin ($p = 0.001$); 2) the ability to assess the deep vertical margin ($p = 0.005$); and 3) the ability to assess the lateral margin ($p = 0.003$). Time required for specimen handling was shortest when the EMR specimen was directly fixated in formalin ($p < 0.001$ vs. pinning and Cassette). Needle artifacts were present in 25 of the specimens handled with the pinning method (57%).
Conclusion: EMR specimens can be directly fixated in formalin, provided that there is no suspicion of submucosal invasion during endoscopy and that the specimens will be evaluated by experienced BE pathologists. Direct fixation in formalin is the preferred handling method, since it results in a significantly shorter handling time without derogating the histopathological evaluation.

Contact E-Mail Address: wong.may.yw@gmail.com
Introduction: There are comparable strains of high-risk HPV present in a subset of Barrett's dysplasia and esophageal adenocarcinoma as in head and neck squamous cell carcinomas and the anatomical proximity of both lesions.
Aims and Methods: We hypothesized that oral sex may increase the risk of Barrett's dysplasia/ esophageal adenocarcinoma. Therefore, we compared the sexual behaviour of patients with Barrett's dysplasia / esophageal adenocarcinoma and controls (hospital, reflux and Barrett's metaplasia to explore a plausible mechanism of viral transmission to the lower esophagus. A hospital-based case-control study involving 36 Barrett's dysplasia / esophageal adenocarcinoma subjects and 55 controls with known HPV DNA status and markers of transcriptional activity i.e p16INK4A and E6/E7 mRNA of the esophageal epithelium was conducted to evaluate differences in sexual history (if any).
Results: Barrett's dysplasia / esophageal adenocarcinoma patients were more likely than controls to be positive for HPV DNA (18 of 36, 50% versus 6/55, 11%, p for trend < 0.0001), be male ($p = 0.001$) and in a relationship ($p = 0.02$). Viral genotypes identified were HPV 16 ($n = 14$), 18 ($n = 2$), 11 ($n = 1$) and 6 ($n = 1$). HPV exposure conferred a significantly higher risk for Barrett's dysplasia / esophageal adenocarcinoma as compared with hospital/reflux/Barrett's metaplasia controls (OR = 6.8, 95% CI: 2.1–23.1, adjusted $p = 0.002$). On univariate analysis, ≥6 lifetime oral sex partners was significantly associated with dysplastic Barrett's esophagus and adenocarcinoma (OR, 4.0; 95% CI: 1.2–13.7, $p = 0.046$). After adjustment for confounders, HPV exposure and men with ≥2 lifetime sexual partners were at significant risk for Barrett's dysplasia / esophageal adenocarcinoma.
Conclusion: If these initial findings can be confirmed in larger studies, it could lead to effective prevention strategies in combating some of the exponential increase in the incidence of esophageal adenocarcinoma in the West.
Disclosure: Nothing to disclose

Introduction: Early neoplasia in Barrett's esophagus (BE) is difficult to detect during surveillance endoscopies. This is partly because of its subtle appearance and partly because most endoscopists rarely encounter early BE neoplasia and therefore are unfamiliar with its endoscopic appearance. Computer-aided detection (CAD) systems might assist endoscopists in the recognition of early BE neoplasia, thereby improving efficacy of BE surveillance. Ideally, a CAD system is incorporated in the endoscopy system and would run real-time on the background during surveillance endoscopies. In case a visible lesion is present, the CAD system would red-flag the lesion on the endoscopy screen, enabling the endoscopist to take a targeted biopsy. Clinically-inspired CAD systems are trained with labelled data and predefined image features. These systems have therefore shown to be suitable for small and unbalanced databases. The aim of this study was to develop a clinically inspired CAD system using high-quality endoscopic images of BE neoplasia.
Aims and Methods: Endoscopic overview images of 40 subtle early neoplastic BE lesions and 20 non-dysplastic (ND)BE patients were prospectively collected in White Light Endoscopy (WLE) in 3 tertiary referral centers. Between September and November 2017, 6 international BE experts annotated all neoplastic images using a proprietary online delineation module specifically designed for this project.
The overlap area of ≥4 expert delineations was considered to have the highest suspicion of visible neoplasia and was labeled as *the sweet spot*. The area with ≥1 expert delineations was labelled as *the soft spot*. The CAD system was trained on local color and texture features (using Gabor filters) of the images, where positive features were taken from the sweet spot of the neoplastic images and negative features from the area outside the soft spot and from the NDBE images. No preprocessing of the expert delineations prior to input into the algorithm was performed at this stage. Performance was evaluated using a leave-one-out cross validation on a per image basis.
Outcome parameters: 1) Detection scores: diagnostic accuracy of the algorithm per image in terms of accuracy, sensitivity, specificity, NPV and PPV; 2) Localization scores: Percentage of recognized neoplastic images where the delineation of the algorithm detected the soft spot and sweet spot.
Results: Accuracy, sensitivity, specificity, NPV and PPV for detection were 88.3%, 92.5%, 80%, 84.2% and 90.2% respectively. The percentage of the soft- and sweet spot that was recognized was 94.6% and 89.2%, respectively.
Conclusion: This CAD system detected early neoplastic BE lesions on endoscopic WLE images with high accuracy, thereby showing feasibility of CAD systems as a red-flag detection technique and taking an important step towards real-time automated detection of early BE neoplasia. Future work will focus on further development of the algorithm towards video analyses and the development of a deep learning algorithm.

P0518 ARTIFICIAL INTELLIGENCE IDENTIFIES EARLY BARRETT'S NEOPLASIA IN *IN-VIVO* BIOPSY-CORRELATED VOLUMETRIC LASER ENDOMICROSCOPY IMAGES

M.R Struyvenberg[1], **J de Groof**[1], F van der Sommen[2], J van der Putten[2], E.J Schoon[3], S Zinger[2], P de With[2], W.L Curvers[3], J.J Bergman[1]

Introduction: Volumetric laser endomicroscopy (VLE) provides a circumferential near-microscopic scan of the superficial esophageal wall layers, and has potential

to improve the detection of early Barrett's esophagus (BE) neoplasia. However, the interpretation of numerous grey-shaded VLE images is complex and time-consuming. Artificial intelligence using novel machine and deep learning techniques may aid in this process. Recent studies have focused on neoplasia detection algorithms based on *ex-vivo* VLE images. Our study is the first to investigate the feasibility of *in-vivo* BE neoplasia detection using computer-aided detection of VLE images.

Aims and Methods: A prospective single-center study was conducted including 23 Barrett's patients with and without early neoplasia. High quality *in-vivo* VLE-histology correlation was provided by laser marking. Laser marked regions of interest consisted of non-dysplastic BE (88 NDBE), and high-grade dysplasia and/or esophageal adenocarcinoma (34 HGD/EAC). Conventional machine learning and recent deep learning techniques were evaluated for the analysis of these regions of interest and differentiate between non-dysplastic and neoplastic tissue. Tissue was first segmented with a pre-trained convolutional neural network (U-net) and clinically inspired features were used for classification between non-dysplastic tissue and neoplasia. Based on earlier findings, analysis was performed on the superficial esophageal wall layers (0.2–1.2 mm), as experiments have demonstrated this generated an optimal classification performance. The reproducibility of the results were independently validated by leave-one-out cross-validation.

Results: In total, 8 different machine learning methods were used for BE neoplasia detection resulting in area under the curves ranging from 0.82–0.90. The clinically derived feature layer histogram in combination with Naive Bayes Classifier demonstrated the most optimal performance. This *in-vivo* method resulted in an accuracy of 84.4% and an area under the curve of 0.90. Corresponding sensitivity was 73.5% and specificity was 88.6% for the differentiation between 88 NDBE and 34 HGD/EAC VLE images. Negative predictive value and positive predictive value were 89.7% and 71.4%, respectively. Average time for the computer algorithm to analyze a VLE image was 15 milliseconds.

Conclusion: Artificial intelligence, using both machine- and deep learning techniques, correctly identify *in-vivo* biopsy-correlated VLE images of early BE neoplasia. The clinically derived feature layer histogram shows high detection accuracy. This study shows feasibility of fast and objective computer aided detection, bringing real-time, red-flag identification 1 step closer.

Introduction: Detection and delineation of early neoplasia in Barrett's esophagus (BE) may be difficult. Blue Light Imaging (BLI; Fujifilm, Tokyo, Japan) is a new optical chromoscopy technique that may improve visualization of these lesions with White Light Endoscopy (WLE).

The aim of this study was to evaluate if BLI has additional value in the visualization of early Barrett's neoplasia.

Aims and Methods: In this multicenter prospective cohort study corresponding endoscopic WLE- and BLI images of 40 early neoplastic BE lesions in overview and magnification were obtained in three tertiary referral centers. A proprietary online scoring and delineation module, specifically for this project, was used by 6 international BE experts to assess images in three assessment rounds, each separated by a wash-out period of 2 weeks. Each assessment consisted of overview- and magnification images. Assessment 1: WLE images only; Assessment 2: BLI images only; Assessment 3: corresponding WLE- and BLI images in a side-to-side display. The order of images in each assessment round was randomized. During each assessment, the experts scored their appreciation of the macroscopic appearance and surface relief using visual analogue scales (VAS) and subsequently delineated each lesion using the proprietary software tool. Their delineation agreement was quantified by calculating the mean AND/OR ratio for each image in which the AND area was defined as the area delineated by $\geq$4 experts and the OR area as the area delineated by $\geq$1 experts.

Outcome parameters: 1) Experts' appreciation of macroscopic appearance and surface relief (VAS-scores); 2) Experts' ability to delineate the lesion (VAS-scores); 3) Experts' preferred technique for delineation (ordinal scores); 4) Experts' quantitative agreement on lesion delineations (AND/OR scores).

Results: Experts appreciated BLI images significantly better than WLE for visualization of macroscopic appearance (median 8.0 vs. 7.0, $p < 0.001$) and surface relief (8.0 vs. 6.0, $p < 0.001$). For both overview and magnification images, experts appreciated BLI significantly better than WLE for ability to delineate lesions (8.0 vs. 6.0, $p < 0.001$ and 8.0 vs 5.0, $p < 0.001$). There was no overall significant difference in AND/OR scores of WLE+BLI when compared to WLE, yet agreement increased significantly with WLE+BLI for cases with a low baseline AND/OR score on WLE, both in overview (mean difference 0.15, $p = 0.015$) and magnification (mean difference 0.10, $p = 0.01$).

Conclusion: This study demonstrates the additional value of BLI for the visualization of BE neoplasia. International BE experts appreciated BLI better than WLE for the different aspects of visualization of BE neoplasia and preferred BLI for delineation with the proprietary delineation tool. Their quantitative agreement for delineation increased significantly when BLI was offered next to WLE for lesions that were hard to delineate with WLE alone.

Disclosure: This study was supported by an unrestricted research grant from FUJIFILM Europe (FUJIFILM Europe GmbH®, Düsseldorf, Germany), which had no involvement in the design, recruitment, data collection, analysis or interpretation or writing of the abstract.

P0520 SELF-SIZING RADIOFREQUENCY ABLATION BALLOON FOR ERADICATION OF BARRETT'S ESOPHAGUS: RESULTS OF AN INTERNATIONAL MULTICENTER RANDOMIZED TRIAL COMPARING THREE DIFFERENT TREATMENT REGIMENS

Introduction: The 360 Express RFA balloon catheter (''360 Express'') for radiofrequency ablation (RFA) of Barrett's esophagus (BE) has the ability to self-adjust to the esophageal lumen ensuring optimal tissue contact during ablation.

Aims and Methods: Aim of this randomized clinical trial was to compare three different ablation regimens for treatment of BE using the 360 Express.

Patients with a 2–15 cm BE with low-grade dysplasia (LGD), high-grade dysplasia (HGD) or early cancer (EC) were included. Visible lesions were removed by endoscopic resection (ER) prior to RFA. Patients were randomly assigned on a 1:1:1 ratio to the standard (1×10J/cm2-clean-1×10J/cm2), simple-double (2×10J/cm2-no clean), or simple-single ablation regimen (1×10J/cm2-no clean). Sample size calculation showed that 36 patients would be necessary in

Abstract No: P0520: Table 1. Outcomes

Ablation regimen	Standard	Simple-single	Simple-double (arm early closed)
Number of patients	31	31	28
Median BE regression, % (IQR)	85 (75–94) 95% CI: 78%–92%	73 (48–90) 95% CI: 59%–85%	88 (81–93) 95% CI: 83%–92%
Patients with a poor regression response ($\leq$50% BE regression), n (%)	3 (10)	9 (29)	0 (0)
Median procedure duration, min (IQR)	31 (26–36)	17 (13–20)	17 (14–20)
Overall adverse event rate	5 (14)	5 (13)	7 (25)
Stricture requiring an intervention, n (%)	0 (0)	0 (0)	6 (21) Mild n = 1; Moderate n = 1, Severe n = 4
Minor laceration, n (%)	4 (11)	3 (8)	0 (0)
Other adverse events, n (%)	Unrelated death: 1 (3)	Minor bleeding: 1 (3) Pain and fever: 1 (3)	Near collapse: 1 (4)

each arm. Primary outcome: percentage of endoscopically visual surface regression of BE at 3 months as scored by 2 independent blinded endoscopists. Secondary outcomes: adverse events and procedure time.
Results: Inclusion started September 2015 and was completed by October 2017. A total of 103 patients (81 male, median 66 yrs, median C4M7 BE) were included. 43 patients underwent ER prior to RFA (EC, n = 22; HGD, n = 13; LGD, n = 6, non-dysplastic IM, n = 2). Worst histology prior to RFA: HGD, n = 42; LGD, n = 51; non-dysplastic IM, n = 10. In February 2017, after 28 patients were included in the simple-double arm, further inclusion in this arm was stopped because of an unexpected high risk of severe stenosis. 6 patients developed a stenosis (21%, 95% CI:10–39%) requiring a median of 6 dilations after simple-double ablation. The study was continued with the standard and simple-single arm. To date, a total of 90/103 patients have completed the study (standard, n = 31/37; simple-single, n = 31/38, simple-double, n = 28/28). Median BE regression was higher in the standard arm compared to the simple-single regimen: 85% (IQR 75–94), 95% CI:78–92% versus 73% (IQR 48–90), 95% CI:59–85% (p = 0.009). A poor response (defined as ≤50% regression) was found in 3/31 and in 9/31 patients in respectively the standard and simple-single arm (p0.05). The standard ablation procedure was significantly longer: median 31mins (IQR 26–36) versus 17mins (IQR 13–20), $p < 0.001$. Adverse events occurred in 5/37 patients in the standard arm (minor laceration n = 4, unrelated death n = 1) and in 5/38 patients in the simple-single arm (minor laceration n = 3, minor bleeding n = 1, pain and fever n = 1).
Conclusion: Results of this randomized controlled trial suggest that c-RFA with the 360 Express using the standard regimen results in significant better regression after one treatment session compared with the simple-single regimen. However, the procedure is longer when using the standard regimen. The simple-double ablation regimen is not advised given the unacceptable risk of severe stenosis.

P0521 CD147 EXPRESSION CORRELATED WITH TREATMENT RESPONSE AND SURVIVAL IN PATIENTS WITH ESOPHAGEAL CANCER RECEIVED CHEMORADIOTHERAPY

C.-T Lee[1], M.-H Hsu[1], H.-P Wang[2], **W.-L Wang**[1]

Introduction: Chemo-radiotherapy (CRT) play crucial roles in the management of esophageal squamous cell carcinoma (ESCC), but such an aggressive treatment may increase toxicity or even delay surgery in patients with poor CRT response. Therefore, we need a good biomarker to identify patients who may/may not benefit from CRT, and to choose the best therapy for patients. Previous studies had demonstrated CD147 plays important roles in inducing matrix metalloproteinases production, anti-apoptosis and induction of various multidrug transporters, we thus hypothesize the CD147 may participate in the CRT resistance and tumor progression.
Aims and Methods: We consecutively enrolled 100 patients with locally-advanced ESCC, who received CRT (51 pre-operative; 49 definitive) as initial treatment. All of the pre-treatment tumor tissues were tested for CD147 expression, defined into either low or high expression by immunohistochemistry. The CD147 levels were validated for the correlation to overall survival and response rate to CRT. In ESCC cell lines, CD147 expressions were determined by western blot. The migration ability of tumor cells was investigated by wound closure assay and transwell migration assay. Clonogenic assay and MTT cell viability assay evaluated the radiation and chemotherapy sensitivity.
Results: The overall clinical complete response rate after CRT was 55% and the pathological complete response rate in pre-operative CRT group was 39%. 42 subjects (42%) were defined to have high-CD147 tumors. The multivariate logistic regression model showed high-CD147 expression is an independent predictor for poor clinical CRT response (OR: **0.39**, 95% CI: 0.17–0.92) and poor pathological response (OR: **0.12**, 95% CI: 0.02–0.62). Patients with high-CD147 expression ESCC have poor survival than those with low-CD147 tumors (2-year survival: 35% vs. 60%; log-rank p = 0.007), both in definitive and pre-operative CRT groups. *In vitro*, we found high-CD147 expression cell lines (KYSE-150 and KYSE-510) constitute higher migration properties, and higher resistance to radiation and chemotherapy, compared to the low-CD147 cell lines (KYSE-50 and KYSE-70).
Conclusion: CD147 may participate in the tumor progression and the resistance to CRT in ESCCs. High-CD147 expression ESCCs are associated with a poor CRT response, and thus additional therapy, more aggressive surveillance shall be applied. CD147 inhibitor may be promising to enhance CRT response and inhibit tumor progression in the future.

Introduction: Endoscopic resection is regarded as the best treatment for patients with early-stage gastrointestinal cancer. However, argon plasma coagulation (APC) is often selected as a treatment for such patients because of the patient's general condition or status of the lesions. Recently, we reported good long-term outcomes for patients with esophageal squamous cell carcinoma who underwent APC (local recurrence rate of 3.6% and the 5-year cause-specific survival rate of 100%) in ESGE days 2018. We considered that submucosal injection prior to APC would result in uniform and sufficient coagulation and would contribute to a good outcome. Previously, Manner et al. reported the efficacy of APC with prior submucosal injection (hybrid APC) by using a resected porcine esophagus; however, there has been no study using an *in vivo* model. In this study, we evaluated the efficacy of hybrid APC for the esophagus by using an *in vivo* porcine model.
Aims and Methods: We performed hybrid APC and direct APC without submucosal injection (standard APC) in various settings. In study 1, we sacrificed the pigs immediately after APC. In study 2, we sacrificed the pigs 1 week after APC. Pathological evaluation of the depth of coagulation from the basal layer (study 1) and non-atrophic muscle zone (study 2) in the resected specimens was carried out. According to a report by Georg et al., superficial tissue damage of the tunica mucosa was classified as type A damage and an injury pattern limited to the tunica muscularis was classified as type B damage in study 1. The tissue sections were stained with anti-α-SMA antibody, anti-CD107a antibody, anti-CD31 antibody and anti-MPO antibody in study 2. 9 random submucosal fields from each pig were photographed (high-powered field [HPF], × 400) and the stained cells were counted in a blinded manner.
Results: We performed all APC methods using the forced APC mode.
Argon gas flow of 2.0 L/min, 3 seconds, at 60 watts (W): hybrid APC (types A and B damage) vs standard APC (types A and B damage); 3200 μm (longitudinal muscle layer [ML]) and 3090 μm (ML) vs 2750 μm (circular muscle layer) and 3340 μm (ML).
Gas flow of 1.0 L/min, 6 seconds, at 40 W: hybrid APC vs standard APC; 70 μm (lamina propria mucosa [LPM]) and 1440 μm (submucosa [SM]) vs 1300 μm (SM) and 2710 μm (ML).
Gas flow of 1.0 L/min, 4 seconds, at 40 W: hybrid APC vs standard APC; 80 μm (LPM) and 1370 μm (SM) vs 630 μm (muscularis mucosa [MM]) and 3010 μm (ML).
Gas flow of 1.0 L/min, 3 seconds, at 40 W: hybrid APC vs standard APC; 80 μm (LPM) and 870 μm (SM) vs 510 μm (MM) and 2360 μm (ML).
Results (study 2):
Gas flow of 2.0 L/min, 3 seconds, at 60 W: hybrid APC (2 lesions) vs standard APC (2 lesions), 23.8 and 2.9 mm^2 vs 4.5 and 0 mm^2.
Gas flow of 1.0 L/min, 3 seconds, at 40 W: hybrid APC (2 lesions) vs standard APC (2 lesions), 9.6 and 11.0 mm^2 vs 4.2 and 3.0 mm^2.
Gas flow of 1.0 L/min, 1 second, at 40 W: hybrid APC (2 lesions) vs standard APC (2 lesions), 13.9 and 15.6 mm^2 vs 6.4 and 7.6 mm^2.
Immunohistochemical analysis demonstrated that the numbers of activated myofibroblasts and infiltrating neutrophils and macrophages were decreased in the hybrid APC group.
Conclusion: Submucosal injection prior to APC contributes to safe and sufficient coagulation for esophageal lesions.
Disclosure: Nothing to disclose

P0523 PREVENTION OF ESOPHAGEAL STRICTURE AFTER COMPLETE CIRCULAR ENDOSCOPIC SUBMUCOSAL DISSECTION IN PIGS USING STENT WITH ACELLULAR PORCINE DERMAL MATRIX

Introduction: Circumferential endoscopic submucosal dissection (CESD) permits radical en-block removal of superficial esophageal neoplasms. However, CESD is regularly complicated by the development of esophageal stricture, often refractory to endoscopic treatment. Currently, an effective method for stricture

prevention is still missing. We hypothesized that a stent covered with acellular matrix of porcine dermis might lead to an earlier re-epithelisation and thus prevent the post-CESD stricture formation.
Aims and Methods: To assess the local effect of a metallic (SEMS) or biodegradable (BD) stent (with or without a acellular matrix) in preventing post-CESD esophageal stricture in pigs. The main outcome was the development of endoscopically non-passable stricture. Secondary outcomes were stricture severity and histopathological parameters. Methods: Pigs were randomized into 6 groups: A. control - CESD only (n = 6); B. CESD + systemic corticosteroids (SC, n = 6); C. SEMS (Wallflex) + SC (n = 8); D. SEMS + matrix + SC (n = 8); E. BD stent (ELLA-CS) + SC (n = 3); F. BD stent + matrix + SC (n = 2). CESD was performed by using a dual knife. The acellular matrix was attached to the outer surface of a stent prior to its deployment. SEMS were removed 21 days after CESD. Pigs were euthanatized if a significant stricture developed.
Results: A total of 33 pigs underwent CESD in the middle esophagus; the average length of the defect was 5.5 ± 0.3 cm. All pigs with BD stent experienced macroscopic inflammation, massive hypergranulation and food stagnation within the stent while stent biodegradation did not occur. Thus, we decided to stop using the BD stent prematurely and BD groups were excluded from the final analysis.
Significant strictures were developed in all pigs except 1 (group B - SC) after a mean of 12.9 ± 0.1 days from CESD (groups A and B) and in 13.9 ± 1.4 days after SEMS extraction (groups C and D). The longest stricture was observed in the group A (2.7 ± 1.3 cm) and the shortest in SEMS groups (C, D) (1.5 cm ± 0.8 cm and 1.6 ± 1.1 cm). The narrowest stricture occurred in groups A and C (8.5 ± 3.1 mm and 8.8 ± 3.7 mm) vs. groups B and D (14 ± 4.1 mm and 13.6 ± 7.7 mm), ($p < 0.05$).
Re-epithelization was present in 80% of animals in the group A, in all animals in the group B, in 42% of animals in the group C and in 71% of animals in group D. The widest re-epithelization layer (0.14 mm) was present in the group D.
Conclusion: None of the tested methods resulted in the effective prevention of post-CESD esophageal stricture. Coverage of SEMS using acellular matrix of porcine dermis resulted in a decrease in the severity of stenosis and improved healing quality. The BD stent is inappropriate in this indication.

Introduction: The link between inflammation and cancer is well established. Esophageal carcinogenesis is an ideal model to study the underlying mechanisms of inflammation induced tumor initiation: Chronic inflammation induces Barrett's Esophagus (BE) which later advances to esophageal adenocarcinoma (EAC). In particular, elevated levels of IL-6, a downstream target of NF-kB, have been identified as an important mediator of tumorigenesis in the IL-1b mouse models of EAC.[1] In the IL-1b mouse model of BE and EAC, IL-1b induces chronic inflammation and spontaneous carcinogenesis in an IL-6 dependent manner. This inflammatory milieu often contains apart from cancer cells and infiltrating immune cells, myofibroblasts (MF) that express αSMA and Vimentin. In the L2-IL-Ib mouse model increased inflammation correlates with increased MFs and an accelerated phenotype.
Aims and Methods: As it is still uncertain, however, if and how activated MFs are important in tumour initiation, answerable only in the context of carcinogenesis studies, we here analyze the effect of MFs in our mouse model of esophageal carcinogenesis (L2-IL-1b). To analyze the effect of Nfkb signaling in MFs, we crossed IL-1b mice to tamoxifen inducible Vim-Cre (Vim-Cre^{Tm}) mice and floxed p65 (p65$^{fl/fl}$) mice to eliminate NfKb signaling in fibroblast during carcinogenesis (IL-1b. Vim-Cre^{Tm}.p65$^{fl/fl}$). Furthermore, we analyzed the interaction of epithelial cells and stromal cells in 3D organotypic cultures of mouse and human BE organoids.
Results: Histological scoring of IL-1b. Vim-Cre^{Tm}.p65$^{fl/fl}$ mice showed a significantly attenuated phenotype compared to IL-1b mice, with mild inflammation, decreased levels of metaplasia and no dysplasia. This correlated with decreased proliferation and crypt fission and increased differentiation in the junctional region at the gastric cardia where metaplasia and dysplasia would arise in IL-1b. Vim-Cre^{Tm}.p65$^{fl/fl}$ compared to IL-1b mice. Finally we observed decreasing numbers of recruited immune cells and mesenchymal cells in the microenvironment of IL-1b. Vim-Cre^{Tm}.p65$^{fl/fl}$ compared to IL-1b mice by immunohistochemistry. The changes of cytokines in local microenvironment in IL-1b. Vim-Cre^{Tm}.p65$^{fl/fl}$ mice was investigated by cytokine array and qPCR analysis. To confirm the impact of MF on epithelial cell growth we co-cultured activated fibroblasts from mouse stomach with IL-1b mouse BE 3D organoids with and without NfKb inhibitors and observed a significant impact of Nfkb inhibition on the growth of BE organoids.
Conclusion: In summary, we here analysed the role of fibroblasts in an inflammatory environment and conclude that NFkB in the stromal cells is an important driver of esophageal carcinogenesis. This also suggests that inhibition of inflammation in general or NfkB specifically could be an important treatment strategy to prevent tumor progression during surveillance of BE patients.

Introduction: The esophageal gland duct may serve as a pathway for the spread of early esophageal squamous cell neoplasia (ESCN) to a deeper layer. However, the significance of ductal involvement (DI) in patients receiving complete endoscopic submucosal dissection (ESD) has yet to be investigated.
Aims and Methods: We consecutively enrolled patients with early ESCN who were treated with ESD. The resected specimens were retrospectively reviewed for the number, morphology, resected margin, distribution and extension level of DI, which were then correlated to clinical factors and survival.
Results: A total of 160 lesions were analyzed, with en bloc and R0 resection rates of 97.5% and 95.6%, respectively. A total of 317 DIs (median: 3, range 1–40 per-lesion) in 61 lesions (38.1%) were identified. Of these lesions, 14 have DIs maximally extended to the level of lamina propria mucosa, 17 to muscularis mucosae, and 30 to the submucosal layer. Multivariate logistic regression analysis showed that tumors located in the upper esophagus (OR = 2.93, 95% CI, 1.02–8.42), large tumor circumferential extension (OR = 5.39, 95% CI, 1.06–27.47), deep tumor invasion depth (OR = 4.12, 95% CI, 1.81–9.33) and numerous Lugol-voiding lesions in background esophageal mucosa (OR = 2.65, 95% CI, 1.10–6.37) were risk factors for esophageal DI. The maximally extended level and total number of ducts involved were significantly correlated with the depth of cancer invasion ($p < 0.05$). The patients with DI had worse overall survival (log-rank p = 0.015) and recurrence-free survival (log-rank p = 0.028) than those without DI after successful ESD.
Conclusion: DI is not uncommon in early ESCN. Our findings may guide clinical decision making with regards to endoscopic treatment and surveillance.

Introduction: Oesophageal squamous cell carcinoma (OSCC) is the dominant histological subtype of oesophageal cancer in Eastern countries and globally, and despite an increasing incidence of oesophageal adenocarcinoma in Western countries, OSCC remains a major type of oesophageal cancer also in these countries. In 2012, approximately 38,000 new cases of OSCC occurred in Europe, North America, and Oceania, accounting for around 60% of all cases of oesophageal cancer in these regions. OSCC is characterized by poor prognosis with a population-based overall 5-year survival rate of less than 20%, which has not improved much in recent years. Upper endoscopy for OSCC may be indicated to detect disease at curable stage, but universal endoscopic screening is not justified given the low absolute risk of OSCC in the population. A more feasible way may be to identify a limited group of individuals with high absolute risk of OSCC, who might benefit from tailored endoscopic screening and surveillance.
Aims and Methods: By combining readily identifiable risk factors, risk prediction modelling is a promising tool for selecting individuals with high absolute cancer risk. This study aimed to develop an OSCC risk prediction model for individuals. This was a nationwide Swedish population-based case-control study, including 167 new cases of OSCC and 820 randomly selected control participants. Associations between candidate predictors and risk of OSCC were assessed using multivariable unconditional logistic regression, producing odds ratios with 95% confidence intervals (CI). The discriminative accuracy of the model was assessed by the area under the receiver operating characteristic curve (AUC) with leave-one-out cross-validation. Models for projecting individuals' absolute 5-year risk of OSCC were developed by incorporating the age- and sex-specific incidence rates of OSCC and competing risk of death from other causes.
Results: A model including age, sex, tobacco smoking, alcohol overconsumption, education, duration of living with a partner, and place of residence during childhood generated an AUC of 0.81 (95% CI 0.77–0.84). A model based only on age, sex, tobacco smoking, and alcohol overconsumption reached a similar AUC (0.79, 95% CI 0.75–0.82). The estimated individuals' absolute 5-year risk of OSCC varied according to combinations of risk factors. Individuals' absolute risk assessment was available in an excel calculator.
Conclusion: To the best of our knowledge, this is the first study that developed a prediction model for the absolute risk of OSCC in a Western population. This

'easy-to-use' risk prediction model showed good discriminative accuracy and could identify individuals at high absolute risk of OSCC within the next 5 years. With further validation in independent populations, the model is potential for clinical use in identifying individuals at high absolute risk of OSCC who may benefit from tailored endoscopic surveillance for early tumour detection at a curable stage.

Introduction: Radiofrequency ablation (RFA) is an accepted treatment modality for early Barrett's neoplasia. Less is known about RFA for esophageal squamous cell neoplasia (ESCN). Our group has reported several prospective studies of RFA for ESCN in high-risk areas in China. Complete remission (CR) of ESCN was achieved in up to 87% of patients, but follow-up (FU) was restricted to 12 months[1,2].
Aims and Methods: We aimed to evaluate long-term 5 year outcomes after RFA for ESCN. Patients with flat type (Paris 0-IIb) unstained lesions (USLs) on Lugol's endoscopy, 3–12cm in length and with moderate or high grade intraepithelial neoplasia (MGIN/HGIN) or mucosal squamous cell cancer (ESCC-m) were treated with RFA every 3 months in the first year, until CR (defined as absence of MGIN or worse in biopsies) was established. All patients with CR at 12 months (CR12) were included in the current study extension, and underwent annual FU endoscopy with Lugol's and biopsies. Flat type USLs were treated with RFA; other lesions were treated per investigator's discretion. We also describe the clinical course of patients with persistent ESCN at 12 months (treatment failures), with treatment and FU per investigator's discretion.
Results: The 78 patients with CR12 were included in this extension. During a median FU of 48 months (IQR 48–48) with 5 endoscopies (IQR 4–6) after the first year, 67/78 patients (86%) sustained CR. Recurrence occurred in 7 pts (9%; MGIN:6, HGIN:1) and all were managed with RFA. CR was re-established in 4, and the other 3 were treated at the last FU endoscopy. 4 other pts (5%) had progression (non-flat HGIN:1; ESCC-sm:3) and were managed endoscopically with ESD. During FU, protocol violations (prolonged intervals, USLs left untreated or no adequate FU after retreatment) occurred in 46/78 patients (59%). Of the 12 treatment failures at 12 months, progression of ESCN occurred in 6 (50%), managed by endoscopic (1) or non-endoscopic (5) treatment. Overall, 2 patients developed subepithelial disease that was not clearly visible with Lugol's endoscopy. Post-hoc analysis on the 'pink-color sign' at baseline, showed that this reddish to pink color change after Lugol's staining significantly predicted recurrence or progression during FU as well as initial failure at 12 months (HR 4.0, 95% CI 1.8–9.2).
Conclusion: RFA is relatively easy to apply and can efficiently treat large areas with ESCN. Despite protocol violations that may have interfered with the efficacy of RFA treatment in 59% of patients, the great majority with CR12 had sustained CR during FU. However, some patients progressed to advanced disease and 2 patients developed subepithelial disease that was not visible with Lugol's. Based on currently available data, we advise to restrict the use of RFA for flat type MGIN and HGIN without pink-color sign on Lugol's chromoscopy.
Disclosure: This was a Medtronic, Inc. sponsor initiated study

P0528 CHEMORADIOTHERAPY FOR LYMPH NODES RECURRENCE AFTER ESOPHAGECTOMY FOR ESOPHAGEAL CANCER

S Matono, T Tanaka, N Mori, H Hino, K Saisho, Y Akagi
Kurume University School of Medicine, Dept. of Surgery, Kurume, Japan

Contact E-Mail Address: ms0805@med.kurume-u.ac.jp
Introduction: Recurrent esophageal cancer after esophagectomy has a poor prognosis, while we sometimes encounter patients with long-term survival. Lymph nodes recurrence is one of the common recurrence patterns after esophagectomy. Here we discuss the usefulness of chemoradiotherapy for lymph nodes recurrence after esophagectomy.
Aims and Methods: The aim of this study is to evaluate outcomes of chemoradiotherapy and prognostic factors for patients with only lymph nodes recurrence. Four hundred six patients underwent R0 esophagectomy for thoracic esophageal squamous cell carcinoma at our institution, between 1995 and 2014. Recurrence occurred in 148 patients (36%). Among these, 58 patients (39%) developed recurrence only in the lymph nodes. The median follow-up duration after recurrence was 13 months (range from 1 to 155 months). Post-recurrence survival was defined as the time between the first recurrence and death or most recent follow-up examination.
Results: The 58 patients with lymph node recurrence were 54 males and 4 females, with a median age of 64 years (range from 44 to 80 years). Of those, 16 (28 %) had pT1 cancer, 8 (14%) had pT2 cancer, 31 (53%) had pT3 cancer, and 3 (5%) had pT4 cancer. The number of patients at pN status (UICC 7th) N0/N1/N2/N3 was 16 (28%)/ 14 (24%)/ 19 (33%)/ 9 (16%), respectively. 11 patients (19%) had pM1 LYM. 3-field lymphadenectomy had been performed in 33 (58%) patients, and 2 or less-field lymphadenectomy was performed in 25 (42%) patients. The median time to recurrence after esophagectomy was 12.5 months (range from 1.8 to 47.5 months). M1 LYM recurrence occurred in 28 patients (48%) including 15 patients with both M1 LYM and regional lymph node recurrence, and 30 patients (52%) had only-regional lymph node recurrence. 34 patients (59%) had a single site of lymph node recurrence, and 24 patients (41%) had two or more recurrence sites. 43 patients (74%) had 1-field recurrence, and 15 patients (26%) had 2-field recurrence. Chemoradiotherapy was employed in 36 patients including 8 patients with surgery. The remaining 22 patients received other treatment; chemotherapy, radiotherapy, surgery, or best supportive care. The overall 1- and 3-year-survival rates in all patients after recurrence were 55% and 22%, respectively. By univariate analysis, the depth of tumor invasion (pT), the interval until recurrence, and the method of treatment were each found to be a factor affecting the survival ($p < 0.05$). The location and number of lymph nodes recurrence did not significantly affect survival. In multivariate analysis, the depth of tumor invasion (pT1,T2 vs. pT3,T4: hazard ratio 0.407; 95% confidence interval 0.212–0.754; $p = 0.0040$) and treatment (chemoradiotherapy vs. other treatment: hazard ratio 0.427; 95% confidence interval 0.234–0.786; $p = 0.0067$) were each found to be an independent prognostic factor. The 3-year-survival rate in patients with pT1,T2 was 36%, compared to 12% in those with pT3,T4 ($p = 0.0014$). The 3-year-survival rate in patients who received chemoradiotherapy was 29%, compared to 9% in those who received other therapy ($p = 0.0030$).
Conclusion: Our findings suggested that chemoradiotherapy could improve survival in those esophageal squamous cell carcinoma patients with only lymph nodes recurrence. The location and number of lymph nodes recurrence did not affect survival.

Contact E-Mail Address: s.n.vanmunster@amc.uva.nl
Introduction: Globally, 80% of all esophageal cancer cases are esophageal squamous cell cancer (ESCC), arising from esophageal squamous cell neoplasia (ESCN). Patients with ESCC have poor prognosis, but when diagnosed at the stage of ESCN, curative endoscopic treatment can be performed. ESCN mainly occurs in developing countries like Central and Eastern Asia and Eastern and

Southern Africa, often with limited endoscopic expertise and resources. Hence, an easy-to-use, low-cost treatment for ESCN would be of great value. Focal Cryoballoon Ablation therapy (FCBA) (*C2 Therapeutics Inc. Redwood City, CA, USA*) is a novel endoscopic ablation therapy that comprises a through-the-scope catheter with a conformable balloon that obviates the need for sizing, a handle, and a small disposable cryogen cartridge. The balloon is simultaneously inflated and cooled with nitrous oxide from the cartridge, resulting in ice patches of approximately 2cm.[2] FCBA is handheld, easy to use and requires no capital equipment. Although early studies for FCBA of Barrett's esophagus have shown promising results, limited data are available for its use in ESCN.

Aims and Methods: We aimed to assess the safety, tolerability and efficacy of FCBA in the eradication of ESCN. In this single-center prospective trial in China, patients with 1 flat type (Paris 0-IIb) unstained lesion (USL) on Lugol's chromoscopy, < 6cm in length and $< 50\%$ of the esophageal circumference, with a diagnosis of Moderate or High Grade Intraepithelial Neoplasia (MGIN/HGIN) were enrolled. At baseline, the entire USL was ablated with side-by-side ablations of 10 seconds and tattoos were placed to identify the treatment area (TA). Safety phone calls were performed at days 2, 7 and 30. A second treatment was repeated within 3 months in the case of persisting USLs. All patients underwent a 12-month endoscopy with biopsies from the TA. Outcomes included safety, tolerability (11-point visual analog scale (VAS) for pain); complete response (CR; absence of MGIN or worse in all TA biopsies) rates at 3 and 12 months; and adverse events.

Results: We enrolled 80 patients (59 MGIN, 21 HGIN) with a median USL length of 3 (IQR 3–4) cm. Median 5 (IQR 4–7) side-by-side ablations were performed per patient over a median ablation time of 8 (IQR 5–10) minutes. After a single treatment, 70/78 patients (90%, per protocol) exhibited CR. The other 8 patients had residual USL and were retreated; all had CR 3 months later (4 LGIN, 4 esophagitis). 2 patients were lost to follow-up. At 12 months, 76/78 patients (97%, per protocol) or 76/80 (95%, intention to treat) patients exhibited CR. AT 12 months, 2 patients, both with MGIN at baseline, were found to have a USL with MGIN. No strictures or serious adverse event had been noted. 3 patients developed self-limiting mucosal lacerations upon balloon inflation. Post-procedure median VAS was 1 (IQR 0–2) at day 2, and 0 (0–0) at days 7 and 30. Median dysphagia score was 0 (0–0) on all days.

Conclusion: Results of our prospective cohort study in China suggest that focal cryoballoon ablation of esophageal squamous cell neoplasia is safe, well-tolerated, and highly effective in inducing endoscopic and histological remission. FCBA is a promising, easy to use and low-cost modality for the treatment of ESCN.

Introduction: Because oesophageal squamous cell carcinoma (ESCC), confined to the muscularis mucosae (MM) or up to 200 μm of the submucosa (SM1), confers the risk for lymph node metastasis, it is defined as relative indication for endoscopic submucosal dissection (ESD) by the Japan Esophageal Society guidelines. Although additional surgical treatment after ESD is recommended, long-term outcomes of ESD compared with those of surgery have not been clarified.

Aims and Methods: This study aimed to evaluate the long-term outcomes of ESD and surgery for cN0M0 relative indication lesions of ESCC. Between 2006 and 2016, patients with relative indication lesions of ESCC who underwent ESD or surgery at eight participating hospitals were retrospectively examined. Using propensity-score matching, we evaluated the survival curves and hazard ratios for ESD compared with those for surgery.

Results: In total, 135 lesions in the ESD group and 87 lesions in the surgery group met the pathological criteria of relative indication for endoscopic resection. After matching, 51 matched pairs of patients who underwent ESD or surgery were selected. In the ESD group, 8 patients underwent additional chemoradiation and four underwent additional radiation. In the surgery group, four patients underwent additional chemotherapy. The 5-year overall survival rates were 88.5% [95% confidence interval (CI) 74.4–95.1] in the ESD group and 85.1% [95% CI 66.8–93.7] in the surgery group. The numbers of all-cause deaths were 9/51 in the ESD group and 6/51 in the surgery group. The Cox proportional hazard ratio of mortality for ESD compared with that for surgery was 1.16 (95% CI 0.41–3.27, $p = 0.78$). The 5-year recurrence-free survival rates were 89% [95% CI 73–95.8] in the ESD group and 89.3% [95% CI 73.9–95.9] in the surgery group. There were two cases of disease-specific deaths in each group. The 5-year disease-specific survival rates were 97.7% [95% CI 84.6–99.7] in the ESD group and 93.6% [95% CI 75.5–98.4] in the surgery group.

Conclusion: Compared with surgery, ESD does not compromise long-term outcomes. Further large-scale randomized controlled trials are necessary to confirm these results.

Introduction: Intraductal spread is one of the forms of tumor spread in esophageal squamous cell carcinoma (ESCC). The treatment of superficial ESCC is mainly EMR or ESD, and ductal involvement (DI) could be resected by EMR and ESD. However, DI may not be treated by radio frequency ablation (RFA), and it may cause local recurrence after RFA. However, the details of DI aren't well known.

The aim of this present study is to clarify the incidence and characteristics of DI using specimens obtained by ESD.

Aims and Methods: 40 patients who had T1a esophageal squamous cell carcinoma (ESCC), and consecutively undergone esophageal ESD at the Saku Central Hospital Advanced Care Center, Nagano, Japan between Jan 2017 and Feb 2018 were enrolled to this study. Local recurrent cases after chemo-radio therapy or endoscopic resection were excluded.

In this study, diagnostic criteria for DI were defined by the presence of ductal cancerization accompanied by non-neoplastic ductal epithelium lined by a single layer of cuboidal cells or mucinous cells in the center of and/or external to the cancerous nest.

The patients included 32 men and 7 women, aged 56–86 years (mean, 70.3 years). The location of ESCC was sub-classified to upper (Up), middle (Md) and lower (Lo). And the number of Up, Md and Lo was 6, 22 and 6, respectively. Invasion depth, EP, LPM and MM were 6, 30 and 4, respectively. Mean tumor size was 24.7 (4–71) mm.

The resected specimen was spread out, pinned on a flat rubber, and fixed in 10% formalin solution. Fixed materials were sectioned serially at 2mm intervals and stained with hematoxylin and eosin. Diagnostic criteria for DI were defined by the presence of ductal cancerization accompanied by non-neoplastic ductal epithelium lined by a single layer of cuboidal cells or mucinous cells in the center of and/or external to the cancerous nest.

The histological findings such as invasion depth, ductal involvement was diagnosed by hematoxylin eosin staining. Esophageal duct was sub-classified into mucosal(MD) and submucosal duct (SMD), and the distribution of MD, SMD and proper esophageal gland (EG) with or without SCC involvement was investigated by expert pathologist. And the number of MD, SMD and EG with DI was counted.

Results: 1. The total number of MD, SMD and EG in 40 lesions were 569, 1008 and 1087, respectively. The reason why the number of SMD and EG were higher than that of MD was thought that esophageal duct makes branch in deep mucosal layer.

2. The total number of MD, SMD and EG within SCC were 120, 463 and 419, respectively.

3. The total number of MD, SMD and EG within non- neoplastic epithelium were 322, 545 and 664, respectively. There was no significant difference between SCC and non-neoplastic area.

4. The ratio of DI positive in MD, SMD and EG were 74% (89/120), 11% (52/463) and 2% (10/419), respectively.

5. The ratio of DI positive in MD, SMD and EG per person were 55%(22/40), 15% (6/40) and 10% (4/40).

6. There was no significant difference between DI and Age, Gender, macroscopic findings and location.

Conclusion: Ductal involvement in MD, SMD and EG per person were 55%, 15% and 10%, respectively.

RFA has the possibility to complete DI in MD. However, DI in SMD and EG may remain after RFA, and will cause local recurrence. Our study suggests the local recurrence rate after RFA may be more than 10%.

P0532 CLINICOPATHOLOGIC CHARACTERISTICS OF SYNCHRONOUS MULTIPLE EARLY ESOPHAGEAL NEOPLASTIC LESIONS

X Zhu[1], J Wu, T Gan, J Yang
West China Hospital of Sichuan University, Department of Gastroenterology, Chengdu, China

Contact E-Mail Address: 2358856583@qq.com

Introduction: Some studies had clarified that multiple esophageal lesions develop more frequently in patients who have undergone endoscopic treatment. Related study reported 30% patients found recurrent neoplasia after endoscopic

resection. However, there is rarely published study investigating the clinicopathologic features of synchronous multiple early esophageal neoplastic lesions. Therefore, this study aimed to investigate the clinicopathologic characteristics of synchronous multiple early esophageal neoplastic lesions so that clinicians can make better decisions for the preserved esophagus after endoscopic treatment.
Aims and Methods: The clinical data of 37 patients with synchronous multiple early esophageal neoplastic lesions who meet the inclusion criteria between May 2013 to May 2017 were analyzed. According to postoperative pathological results, patients were divided into 2 groups: Group A: all the lesions had confirmed high-grade intraepithelial neoplasia (HGIN) or esophageal cancer; Group B: only 1 lesion had confirmed HGIN or esophageal cancer, while other lesions were high-grade intraepithelial neoplasia (HGIN). The clinicopathologic features were compared between the 2 groups by univariate analysis.
Results: There were 20 patients, 44 lesions in group A and 17 patients, 34 lesions in group B. No significant differences were observed between the 2 groups in terms of age, gender, body mass index (BMI), family esophageal cancer history, heavy drinking, heavy smoking, flush after drinking, while significant differences were observed between the 2 groups in Lugol-voiding lesions (LVLs) grade ($p = 0.001$), submucosal involvement on EUS ($p = 0.005$), circumferential extent ($p = 0.000$), R0 resection rate ($p = 0.007$), lesion size ($p = 0.000$) and pathological upgrade rate ($p = 0.043$).
Conclusion: The higher LVLs grade, larger lesion size, circumferential extent $\geq 1/2$, non-R0 resection, postoperative pathologic estimation upgrade, and an EUS finding of submucosa involvement are considered high-risk factors in patients with synchronous multiple esophageal neoplastic lesions. Therefore, clinicians must remain vigilant and perform careful observations and surveillance on patients with such characteristics during endoscopic examination.

Introduction: Acetylsalicylic acid (ASA) and clopidogrel in antiplatelet doses are effective in prevention of vessel crash connected to coronary heart disease. But development of erosive and ulcerative gastric lesions puts limitations to their administration.
Aims and Methods: To study morphologic characteristics of gastric mucosa lesions in rats under applying antiplatelets and pantoprasol equivalent to human doses.
White male rats with average body mass 150–180g were divided into 7 groups according to the treatment they received: ASA in dose 6.8 mg/kg of body weight (on conversion to 75 mg for an adult person); Clopidogrel 6.8 mg/kg of body weight (on conversion to 75 mg for an adult person); ASA 6.8 mg/kg of body weight + 6.8 mg/kg body weight of clopidogrel; ASA 6.8 mg/kg of body weight + pantoprasol 3.6 mg/kg (on conversion to 40mg for an adult person); Clopidogrel 6.8 mg/kg body weight + pantoprasol 3.6 mg/kg; ASA 6.8 mg/kg of body weight + Clopidogrel 6.8 mg/kg body weight + pantoprasol 3.6 mg/kg.
The drugs were introduced a 1-time per day during 14 days intragastrically. The following characteristics were analyzed: general histological parameters, apoptotic index (AI) and caspase-3 expression (CPP32).
Results: During a short time in ASA and clopidogrel groups the connective tissue of gastric mucosa became uncovered and microerosions appeared mostly in the antral region (in 94% of rats). Fundus was manifested by swollen connective tissue, subepithelial lamina propria with minute diapedetic extravasations and infiltration with the presence of single lymphocytes and plasmatic cells were revealed around the swollen area. Other groups didn't show erosions.
In ASA + clopidogrel group lesions of the basement membrane were found in 42% of rats vs 25% in ASA group and 10% in clopidogrel group and were not seen in other groups.
The expression of CPP32 in ASA group and ASA + clopidogrel group showed that the amount of positively stained cells was > 70%, and in control group - up to 10% ($p < 0.05$), which testifies to immaturity of epitheliocytes owing to their rapid death and renewal. In ASA + pantoprasol, clopidogrel + pantoprasol, ASA + clopidogrel + pantoprasol groups positively stained cells were 18%, 12% and 15% respectively ($p < 0.05$).
AI in control group was 2.9±0.32%, in clopidogrel group - 4.6±0.61%, in ASA group - 7.18±0.48%, in ASA + clopidogrel group −7.18±0.48%. The amount of apoptotic bodies in the form of unstructured roundish eosinophilic homogenous masses were increasing.
Comparing AI of control group with clopidogrel group - $p < 0.05$, ASA group - $p < 0.001$ and ASA + clopidogrel group - $p < 0.001$. In clopidogrel group AI was reliably lower ($p < 0.05$) comparing both ASA group and ASA + clopidogrel group, which can attest to less negative influence of clopidogrel on gastric mucosa comparing to ASA and ASA + clopidogrel combination.
In clopidogrel + pantoprasol, ASA + pantoprasol and ASA + clopidogrel + pantoprasol groups AI was 3.5±0.42%, 4.1±0.56% and 3.4±0.31% respectively. Differences in AI in clopidogrel + pantoprasol, ASA + pantoprasol and ASA + clopidogrel + pantoprasol groups were absent ($p > 0.05$).
Conclusion: Microerosion formation was the main morphologic feature of gastropathy which is not always revealed by macroscopic examination of gastric mucosa during application of ASA and clopidogrel. Pantoprasol use on the background of ASA and clopidogrel promotes to prevention of gastric mucosa necrosis due to stabilization of apoptotic activity of gastric epitheliocytes.

Introduction: Over 5 years have already passed since direct oral anticoagulants (DOACs) was released in Japan. It was not just known that DOACs have similar efficacy as vitamin K antagonists (VKA), but might be a more mucosal-friendly agent than VKA[(1)]. However, for reducing the incidence of mucosal injuries, we don't know what kind of agents is helpful to use concomitantly for patients taking DOACs as well as VKA.
Aims and Methods: The aim of this study is to explore whether proton pump inhibitors (PPI) play a protective roll for gastric mucosa in patients taking DOACs or VKA. To reveal the roll of PPI, we compared the severity of gastric mucosal injury between PPI users and nonusers in the subjects taking DOACs or VKA, individually. Data were extracted from the records of subjects who underwent upper gastrointestinal endoscopy at our department between April 2015 and December 2017. Of the 3,900 subjects analyzed, we focused on 203 subjects who took DOACs (Dabigatran, Edoxaban, Rivaroxaban, Apixaban) or VKA (Warfarin). After excluding subjects who took other type of antacid (histamine 2 receptor blockers or potassium competitive acid blockers) in each group, we divided subjects into 2 subgroups: those who were taking PPI, and those who were taking no antacids. Severity of gastric mucosal injury was evaluated endoscopically according to the modified LANZA score (MLS) [(2)]. Statistical analyses were performed by Fisher's exact test.
Results: This study included 88 subjects in DOACs users (62 men, 26 women; mean age 72.9 years; 58 PPI user, 30 nonuser) and 72 subjects in VKA users (45 men, 27 women; mean age 74.9 years; 49 PPI user, 23 nonuser). In patients taking DOACs, average MLS of PPI users and nonusers was, respectively, 0.24±0.76 and 0.63±1.45 ($p = 0.263$). In patients taking VKA, average MLS of PPI users and nonusers was, respectively, 0.59±1.38 and 1.91±2.25 ($p = 0.045$). In the subjects taking VKA, gastric mucosal injury was statistically significantly mild in PPI users, but not in the subjects taking DOACs.
Conclusion: PPI play a protective role in gastric mucosa in patients taking VKA but not in patients taking DOACs.
Disclosure: Nothing to disclose

Introduction: Among the reasons for proton pump inhibitor (PPI) resistance is different quality of enteric coatings, as a result of which PPIs acid degradation in the stomach leads to its release there. The influence of factors such as pathologic duodenogastric reflux (PDGR) with pH ≥ 7 followed by its decrease and the pH increasing ≥4 within multiple PPIs dosing in patients with gastro-esophageal reflux disease (GERD) on coatings and premature active compounds degradation has not been studied specifically. PDGR and pharmacological acid suppression can be reliably modeled with comparative dissolution testing (CDT). In PDGR, pH ≥ 7 exposure time for omeprazole and rabeprazole is 4 and 12 minutes, respectively. Omeprazole or rabeprazole detection in the pH 7 buffer after 4 or 12-minute exposure should be estimated as PPIs degradation in the stomach due to PDGR. The stability of PPIs in case of an inhibited gastric acid secretion can be confirmed by drug compounds absence in the pH 4 buffer.
Aims and Methods: CDT (pH 1.2±0.05; pH 4.0±0.05, pH 7.0±0.05) has been used to estimate influence of PDGR and pharmacological acid suppression on omeprazole and rabeprazole gastric release and degradation. The additional aliquots were taken from the pH 7.0±0.05 solution after 4 minutes for original omeprazole (OO) and generics (GO1, GO2, GO3) and 12 minutes for rabeprazole (OR, GR1, GR2). PDGR resistance for PPIs capsules and tablets was determined by active substances presence or absence.

Results: The drug release was not detected in the pH 1.2 buffer. Drugs were moved from solution with pH 1.2 ± 0.05 to pH 7.0 ± 0.05. The drug release in the pH 7.0±0.05 after 4-minute exposure was 4.7±0.7%, 0, 80.8±3.6%, 82.5±1.7% for OO, GO1, GO2, GO3, respectively. OR and generics were subjected to the same conditions during 12 minutes with only GR1 detected final release (5.4±0.4%). Therefore, PDGR model demonstrated poor reflux influence on OO and GR1, strong influence on GO2 and GO3 with the almost complete omeprazole release and its potential degradation after following pH decrease.
Any omeprazole was not detected in the pH 4.0±0.05. Pellet destructions were not registered for OO, GO1 and GO3 while GO2 pellets were totally degraded. Non-degraded pellets were moved to pH 7.0±0,05 where their release was determined. In the same dissolution conditions, rabeprazole amount from GR2 after 10; 15; 20; 30; 45; 60 minutes was 0; 0; 5.5±0.4%; 38.8±0.4%; 58.0±0.3%; 82.4±0.5%; 68.9±0.5%. No OR and GR1 release or visible tablets destruction were registered. Pharmacological acid suppression model had demonstrated OO, OR, GO1, GO3 and GR1 resistance while total GO2 and partial GR2 degradations were determined.
Conclusion: Omeprazole and rabeprazole generics with high-risk degradation under PDGR and multiple PPIs dosing were determined by CDT. Omeprazole was totally degraded in pH 4.0±0.05 but not rabeprazole.

P0536 COMPARISON OF SAFETY AND OUTCOMES BETWEEN ENDOSCOPIC AND SURGICAL RESECTIONS OF SMALL (≤ 5 CM) PRIMARY GASTRIC GASTROINTESTINAL STROMAL TUMORS

G Xu[1]
[1]*Affiliated Drum Tower Hospital of Nanjing University Medical School., Nangjing, China*

Contact E-Mail Address: 13852293376@163.com
Introduction: Endoscopic resection is increasingly performed for gastric gastrointestinal stromal tumors (GIST). However, the safety and outcomes remain elusive.
Aims and Methods: We aimed in this retrospective study to compareoperative complications and prognosis between endoscopically and surgically resected small (≤ 5 cm) GIST tumor groups. In this single-center retrospective study, we compared demographics and clinical outcomes including operative complications, postoperative courses, and the R0 resection rate between the endoscopy (n = 268) and surgery (n = 141)groups. Only GIST tumors in size of ≤ 5.0 cm were recruited for this comparison study.
Results: Overall, the mean age of patients was 59.0 years (range: 31.0–83.0). The male-female ratio was 0.68. The most common site of GIST was, in a descending order, the gastric fundus (55%), corpus (27.6%), cardia (10.8%), antrum (6.6%). Compared with the surgery group, GIST tumors in the endoscopy group was significantly smaller (1.69±0.9 cm, compared to 3.20±1.2 cm in the surgery group; $p < 0.001$) in size; postoperative hospital stay was significantly shorter (4.66±1.5 days, compared to 8.11±5.0; $p < 0.001$); post-resection time to first fluids diet was significantly shorter (1.94±1.1 days, compared to 4.63±2.6; $p < 0.001$); incidence of operative and post-operative complications was significantly fewer ($p < 0.05$), and hospital costswere significantly lower (20115.4±5113.5¥ compared to 43378.4±16795.7¥; P < 0 .001). The R0 resection rate was significantly lower in the endoscopy (93.3%) than in the surgery (99.3%) groups ($p < 0.01$). In the endoscopy group, 176 (65.7%), 69 (25.7%), 14 (5.2%) and 9 (3.4%) patients were found to be very low, low, intermediate, and high risk, respectively. In contrast, 27 (19.1%), 87 (61.7%), 14 (10.0%), 13 (9.2%) patients were found to be very low, low, intermediate, and high risk in the surgery group, respectively. The risk stratification was significantly different between the endoscopy and surgery groups ($p < 0.001$). Among 409 cases, 50 (12.2%) patients were found to be intermediate or high risk. Among 50 patients, only 20 patients received adjuvant therapy with imatinib after resection. 7 of the 20 patients took imatinib 1 to 3 months because of its side effects and high costs. However, during 33.5 months of follow-up, no local or distant tumor recurrence was observed and 2 patients were died of other disease in surgery group.
Conclusion: Endoscopic resection of selected gastric GISTs (≤5cm) is feasible and safe, and is associated with a better intraoperative outcome and an equal postoperative course compared with surgery group.

Introduction: Gastric cancer is still one of the leading causes of cancer-related death in Japan. Due to wide-spread use of endoscopic submucosal dissection (ESD), physicians are facing dilemma as to the indication for additional gastrectomy in elderlies treated by non-curative ESD. This is due to little information with regards to the long-term outcomes and prognostic factors of non-curative ESD for gastric cancer in elderly patients.
Aims and Methods: We aimed to clarify the long-term outcomes and prognostic factors of non-curative ESD for gastric cancer in elderly patients. Among 1,358 patients with early gastric cancer (EGC) treated by ESD at our institution during 2002–2012, we enrolled 87 patients with ages ≥75 yrs, who were treated by non-curative ESD. First, clinicopathological findings and long-term outcomes up to the end of 2017 were evaluated. Next, the prognostic factors were analyzed using the Kaplan-Meier methods and a Cox proportional hazards model.
Results: 27 of 87 patients died of any cause. However, only 1 patient died of gastric cancer. 3-year overall survival (OS) and 5-year OS were 89.7% and 79.3%, respectively. The univariate analyses revealed that patients who were in Eastern Cooperative Oncology performance status of 2 or 3, high Charlson comorbidity index (CCI) (≥3), high neutrophil to lymphocyte ratio (≥3.3), low prognostic nutritional index (< 44.8), antral location of EGC and depressed or completely flat configuration of EGC were factors associated with death. The high CCI (≥3) was found to be an independent prognostic factor associated with OS (hazard ratio: 2.79, 95%CI: 1.16–6.69, $p = 0.021$).
Conclusion: After non-curative ESD for gastric cancer in elderlies, CCI may be a clue for decision making of additional gastrectomy. Careful follow up without additional gastrectomy may be an acceptable strategy for elderly patients.

Introduction: In gastric mucosa-associated lymphoid tissue (MALT) lymphoma, the clinical significance of various endoscopic findings has not yet been determined. This study aimed to compare the time to complete remission (CR) and relapse-free survival (RFS) in gastric MALT lymphoma based on endoscopic findings.
Aims and Methods: In this single-center retrospective cohort study, the medical records of 122 consecutive adult patients with gastric MALT lymphoma were collected over a period of 12 years. CR was defined by the absence of macroscopic or microscopic features of lymphoma on 2 subsequent follow-ups. Relapse was clinically defined by a positive endoscopic biopsy after CR.
Results: The median time to CR did not differ significantly between treatment methods. However, it was significantly longer in the group with polypoid endoscopic appearance than in the groups with diffuse infiltration or ulceration (7.83, 3.43, and 3.10 months, respectively; $p = 0.003$). 6 patients relapsed after CR. Kaplan-Meier analysis showed that RFS differed significantly between groups based on Ann Arbor staging, treatment methods, and initial endoscopic findings.
Conclusion: In gastric MALT lymphoma, the endoscopically defined polypoid type was characterized by a longer duration to CR, with a higher likelihood of recurrence, compared to the endoscopically defined diffuse infiltration or ulceration types.

P0539 FLAP FORMATION TIME AS A NEW ENDPOINT OF TECHNICAL SUCCESS OF ESD FOR SUPERFICIAL DUODENAL EPITHELIAL TUMORS; A TIMELINE ANALYSIS

A Nakayama, M Kato, Y Ochiai, Y Kiguchi, T Akimoto, T Maehata, N Yahagi
Keio University, Division of Research and Development for Minimally Invasive Treatment, Cancer Center, Tokyo, Japan

Contact E-Mail Address: anakayama34@keio.jp
Introduction: Though ESD has been a standard treatment for superficial epithelial neoplasia of various gastrointestinal tracts, duodenal ESD has been still technically challenging due to anatomical features of duodenum. Procedure time has been recognized as a scale for technical difficulties of ESD; however, there have been few studies analyzing in what part of the procedure the time was consumed. At the beginning of ESD procedure, making a mucosal flap may be important step because we can obtain stable visual field by exposure of

submucosa using distal hood of the endoscope. We hypothesized time to flap formation would be a surrogate endpoint for technical success for duodenal ESD.
Aims and Methods: The aim of this study was to assess the feasibility of time to flap formation as endpoint for duodenal ESD. This was a retrospective observational study from a university hospital. A total of 102 cases that underwent ESD for duodenal superficial neoplasia from July 2013 to June 2017 were included in this study. ESD was performed using DualKnife J (Olympus medical systems, Tokyo, Japan) and short tip type transparent hood (ST hood, FUJIFILM Medical Co., Ltd. Tokyo, Japan). An endoscopist reviewed all movies of the procedures and measured time to flap formation and total procedure time. In this study, flap formation was defined as the timing when complete exposure of submucosa using upper rim of the hood was obtained. The distribution of total procedure time and time to flap formation was analyzed in addition to other short-term outcomes. Those were compared according to the skill level of endoscopists (expert: >100 duodenal ESD, and the others). Moreover, we analyzed the linear regression between total procedure time and time to flap formation and other clinical features of the lesion using least square methods.
Results: As for location of the lesion, 13.7% located in bulbs, 73.5% in descending part, 3.0% in horizontal part, and 9.8% located in superior duodenal angle (SDA) or inferior duodenal angle (IDA). The mean lesion diameter was 32.5 ± 16.5 mm. Resection in a single piece and R0 resection was 98.0% and 86.3%, respectively. Bleeding and perforation was found in 3.0% and 5.9% of patients, respectively. Mean procedure time was 55.8 ± 3.9 min and mean time to flap formation was 13.5 ± 1.1 min. It was significantly shorter by expert's hand (12.1 ± 1.1 min vs 24.0 ± 2.9 min, $p < 0.0001$). Multiple linear regression analysis revealed time to flap formation as well as lesion size, location, and endoscopists' skill were independently correlated with total procedure time (Table 1).
Conclusion: Time to flap formation reflected the skill level of the endoscopists and predicted total procedure time independently of the size and the location of the lesion. It could be a surrogate endpoint for technical success of duodenal ESD.

	β coefficient	t value	P value
Flap formation time	1.32	5.41	<0.0001
Lesion size	90.59	10.01	<0.0001
Location (SDA or IDA)	454.09	2.66	0.0092
Endoscopistś skill	788.18	3.27	0.0015

[The results for multiple linear regression analysis about total procedure time]

P0540 EFFECT OF THE DURATION TIME OF UPPER GASTROINTESTINAL ENDOSCOPY ON THE DETECTION RATE OF GASTRIC NEOPLASTIC LESIONS

Y Sato, H Yasuda, M Kato, H Kiyokawa, M Yamashita, Y Matsuo, H Yamamoto, F Itoh
St. Marianna University. School of Medicine, Gastroenterology and Hepatology, Kawasaki, Japan

Contact E-Mail Address: y2satou@marianna-u.ac.jp
Introduction: Early detection and prompt treatment using upper gastrointestinal endoscopy are important to reduce the mortality rates of gastric cancer. Previous reports on esophagogastroduodenoscopies (EGD) have stated that compared to observation cohorts of less than 7 minutes, the detection rates of high-risk gastric lesions are significantly higher in observation cohorts of 7 minutes or longer. Nevertheless, there are few reports assessing the relationship between EGD examination time and the detection rates of high-risk gastric lesions, and it remains unclear if longer observation times can increase the detection rate of lesions.
Aims and Methods: In this study, we examined whether a longer examination time increased the detection rate of gastric neoplastic lesions. From June 2017 to December 2017, we investigated 1019 patients (501 men and 518 women, mean age: 62.8±16 years) who underwent a first screening EGD at our hospital. Endoscopists were classified as fast or slow based on the mean amount of time it took them to perform a normal screening endoscopy. We used the histopathological tissue results of biopsies to retrospectively examine the detection rate of neoplastic lesions such as early-stage gastric cancers, gastric adenomas, lymphomas, by both fast and slow endoscopists. Furthermore, we also used multivariate analysis to examine the factors that contribute to the detection of gastric neoplastic lesions.
Results: Of normal 782 endoscopies, the median duration time was 6.85 minutes (range, 2–24). Based on the results, we used 7 minutes as the cut off time. The fast group was defined as 12 endoscopists with a mean duration time of 5.97 ± 2.03 min, and the slow group was defined as 12 endoscopists with a mean duration time of 9.59 ± 2.80 min. Screening endoscopies were performed for 596 cases (305 men and 291 women, mean age: 62.8 ± 16 years) in the fast group and for 423 cases (196 men and 227 women, mean age: 62.7 ± 16 years) in the slow group. Overall, biopsy was performed by 237 cases (23.2%) of screening endoscopy, 36 neoplastic lesions were diagnosed, of which 16 lesions (1.6%) were early gastric cancers, 9 lesions (0.9%) were adenomas, 8 lesions (0.8%) atypical lesion and 3 lesions (0.3%) were lymphoma. Compared to the slow group, the fast group had significantly higher rates of staff performing exams 327 (62.8%)/ 211 (49.8%) ($p < 0.001$), significantly lower rates of sedation 380 (63.8%)/ 332 (78.5%) ($p < 0.001$), significantly lower rates of biopsy implementation 124 (20.8%)/ 113 (26.7%) ($p = 0.027$). The detection rates of neoplastic lesions in the fast and slow groups were 23 (3.9%)/13 (3.1%), so no significant difference was observed.
In the multivariate analysis, men ($p = 0.012$; odds ratio 2.60, 95% CI 1.23–5.49), age≥60 ($p = 0.004$; odds ratio 4.03, 95% CI 1.55–10.52), and staff performing the examinations ($p = 0.035$; odds ratio 2.60, 95% CI 1.07–6.31) were independent factors that contributed to the detection of gastric neoplastic lesions.
Conclusion: In this study, a longer examination time did not increase the detection rate of gastric neoplastic lesions. In the multivariate analysis, the staff implementing the exams was an independent factor that contributed to the detection of gastric neoplastic lesions. In the EGD, it is thought that the detection of gastric neoplastic lesions is made possible using a short examination time and efficient biopsies due to the accumulation of experience.
Disclosure: Nothing to disclose

P0541 VALIDITY OF SUBMUCOSAL PATTERN ANALYSIS OF EUS FOR PREDICTING DEPTH OF INVASION IN ULCERATIVE EARLY GASTRIC CANCER

J.H Kim
Inje University Busan Paik Hospital, Busan, Korea (Republic of)

Contact E-Mail Address: zep2000@hanafos.com
Introduction: Accuracy of endoscopic ultrasonography (EUS) for predicting depth of invasion in early gastric cancer (EGC) accompanied with endoscopic ulcer or ulcer scar was lower than that without ulcer.
Aims and Methods: We tried to evaluate the validity of submucosal pattern analysis of EUS for predicting depth of invasion in ulcerative EGC. Demographic, endoscopic and EUS features of 176 consecutive endoscopically suspected EGC patients who underwent the EUS examination and the endoscopic treatment or surgery were retrospectively reviewed. The EUS findings were classified as the (1) no deformity type, (2) fan-shaped deformity type, and (3) arch-shaped or punch-shaped deformity type, according to submucosal layer change. The EUS findings also classified into 2 groups; submucosal fibrosis and no fibrosis groups.
Results: 73 among total 176 cases (41.5%) were accompanied with the active or healing staged endoscopic ulcer, whereas S1-staged ulcer was found in 62 cases (35.2%) and no ulcer group was 41 cases. The EUS fibrosis was combined in 71 cases (41%). Fan-shaped deformity and arch-shaped deformity in submucosal layer was noted in 88 cases and 48 cases, respectively. The histologic submucosal fibrosis was found more frequently in the EUS fibrosis group than no fibrosis group (51.6% vs 10.4%, p≤0.001). The Arch-shaped submucosal deformity was a significant independent predictive factor for presence of submucosal cancer invasion than Fan type or no SM deformity group.(80.9% vs 18.2% vs 19.5% odds ratio 11.83) ($p < 0.001$). With regard to the results of endoscopic resection, curative, and complete resection rate were significantly lower in EGCs with the arch-type submucosal deformity than those with no SM change or fan-type SM change groups ($p < 0.001$).
Conclusion: Pattern analysis of the submucosal deformity on EUS examinations can be an useful tool for predicting the presence of the histologic ulcers and cancer invasion in ulcerative EGC.

Contact E-Mail Address: leah1004@yuhs.ac
Introduction: Endoscopic submucosal dissection (ESD) is an accepted curative treatment option for gastric tumors with very low local recurrence. However, residual or locally recurrent tumors occur rarely after ESD. Although secondary (Redo) ESD is technically demanding, it can be applied to residual or recurrent tumors with scar and dense fibrotic submucosa. Here, we investigated the feasibility and safety of secondary ESD for gastric tumors.
Aims and Methods: Between 2010 and 2017, 1623 consecutive patients underwent ESD for gastric neoplasms at a single tertiary referral center. Among these, 28 patients underwent secondary ESD for a residual or locally recurrent tumor. Our analysis compared clinicopathologic factors between primary ESD and secondary ESD groups.
Results: The en-bloc resection and curative rate of resection of secondary ESD were 92.9% and 89.3%, respectively. The average procedure time of secondary ESD was significantly longer than primary ESD (78.2 vs. 55.1 minutes, $p = 0.004$) and the adverse events rate was slightly higher in secondary ESD group than primary ESD group without statistical significance (10.7 vs. 3.8%, $p = 0.095$).

Patients who received secondary ESD had favorable outcomes without severe adverse events. During a mean follow-up period, no local recurrence occurred in patients who received secondary ESD.
Conclusion: Although it requires greater technical efficiency and a longer procedure time, secondary ESD of residual or locally recurrent gastric tumors appears to be a feasible and curative treatment.

P0543 A NEW HISTOPATHOLOGICAL CLASSIFICATION OF GASTRIC ADENOCARCINOMA OF FUNDIC GLAND TYPE AND CLINICOPATHOLOGICAL FEATURES OF GASTRIC ADENOCARCINOMA OF FUNDIC GLAND MUCOSAL TYPE (A MULTICENTER STUDY OF 80 CASES)

H Ueyama[1], T Yao[2], A Ikeda[1], N Yatagai[1], Y Akazawa[1], H Komori[1], K Izumi[1], K Ueda[1], K Matsumoto[1], M Hojo[1], A Nagahara[1]

Contact E-Mail Address: psyro@juntendo.ac.jp
Introduction: Gastric adenocarcinoma of fundic gland type (GAFG) is newly added as a special type cancer in Japanese classification of gastric carcinoma, the 15th Edition 1). GAFG is an uncommon variant of gastric adenocarcinoma which has a distinct clinicopathological, immunohistochemical, and endoscopic features 2–4). GAFG is defined by positive immunohistochemical staining for pepsinogen-I (a marker of chief cells) and/or H+K+-ATPase (a marker of parietal cells) and is not associated with *H. pylori* infection. We suggested that a progression of GAFG might be associated with *GNAS* mutations 5). Histopathologically, GAFG is classified into pure GAFG and gastric adenocarcinoma of fundic gland mucosal type (GAFGM) which exhibited differentiation toward gastric foveolar epithelium in addition to fundic gland differentiation. However, the histopathological classification of GAFG including GAFGM have not been established, and clinicopathological features of GAFGM have not been well investigated.
Aims and Methods: The aim of this study was to establish a new histopathological classification of GAFG and clarify the clinicopathological features of GAFGM by comparisons with pure GAFG. A total of 80 GAFG cases from April 2004 to December 2017 were retrospectively collected from 27 institutions. We performed an immunohistochemical analysis using pepsinogen-I, H+K+-ATPase, MUC5AC (a marker of foveolar epithelial cells) and MUC6 (a marker of mucous neck cells) to classify these GAFG cases as pure GAFG (MUC5AC+, $< 10\% <$ MUC6+ < pepsinogen-I and/or H+K+-ATPase +, n = 57) or GAFGM (MUC5AC+, $\geq 10\% <$ MUC6+ < pepsinogen-I and/or H+K+-ATPase +, n = 23). In addition, GAFGM was classified to 3 subtypes, as follows; Type 1. Tissue construct of foveolar epithelium and fundic gland is maintained, and tumor is exposed on the surface (n = 9), Type 2. Tissue construct of foveolar epithelium and fundic gland is collapsed, and tumor is exposed on the surface (n = 10), Type 3. Tissue construct of foveolar epithelium and fundic gland is collapsed, and tumor is not exposed on the surface (n = 4). We then compared the pure GAFG and GAFGM cases, and 3 subtypes of GAFGM via a clinicopathological evaluation and the frequency of *GNAS* mutation.
Results: There were no significant differences between the 2 groups (pure GAFGs vs. GAFGMs) in the following findings: location of lesion, macroscopic type, method of treatment, depth of invasion, lymph node metastasis, proliferative activity, p53 protein overexpression, *H. pylori* infection, and activating mutations in *GNAS*. The average of tumor size (8.6mm vs. 21.3mm, $p < 0.01$) and depth of submucosal invasion (310μm vs. 1242μm, $p < 0.05$) were significantly greater in GAFGMs than in pure GAFGs. Furthermore, the rates of lymphatic and venous invasion were significantly higher in GAFGMs than in pure GAFGs (1.8% vs. 34.8%, $p < 0.01$). The average of tumor size (11mm vs. 31.8mm vs. 18.5mm, $p < 0.05$) was significantly greater and the rates of lymphatic invasion (0% vs. 60% vs. 0%, $p < 0.05$) was significantly higher in Type 2 than in Type 1 and 3.
Conclusion: This histopathological classification of GAFG is useful to estimate its malignant potential. GAFGM should be categorized as a new aggressive variant of GAFG that has high malignant potential and differ in malignancy by tissue construct of foveolar epithelium and fundic gland.
Disclosure: Nothing to disclose

Introduction: Endoscopic submucosal dissection (ESD) has become widely accepted as a standard treatment for gastric neoplasm. The safety of gastric ESD has been mostly established, Although, complication such post-operative bleeding and perforation remain problematic.
Since 2012, an endoscopic approach involving continued administration of low-dose aspirin (LDA) for patients at high risk of thromboembolism has been recommended in Japan. This approach is similar to the one stated in the guidelines of the European Society of Gastrointestinal Endoscopy; however, there is insufficient date to support this guideline in Japan.
Aims and Methods: The aim of this study was to identify risk factors for early and delayed post-operative bleeding after gastric ESD and to evaluate the relationship between the use of antithrombotic agents and post-operative bleeding. From January 2004 to December 2017, we analyzed 922 patients (673 men and 249 women, mean age: 72.7±14years) 961 gastric neoplasms who treated by ESD at our hospital. Traditionally, we have interrupted therapy 5–7 days before gastric ESD for patients using LDA. However, since January 2012, we have followed the above mentioned guidelines, thus performing ESD with continued LDA for patients at high risk of thromboembolism.
In this study, post-operative bleeding was defined as a decrease in the blood hemoglobin level of > 2g/dL accompanied by an occurrence of hematemesis or melena.
Bleeding within 6 days after ESD was defined as early post-operative bleeding, whereas bleeding on the sixth day or later post-operatively was defined as delayed post-operative bleeding.
Risk factors for early and delayed post-operative bleeding were retrospectively examined using univariate and multivariate analysis.
Results: The overall post-operative bleeding rate was 4.4%. The mean duration until post-operative bleeding was 6.2±4.6days. The post-operative bleeding rates for patients who continued LDA, discontinued antithrombotic agents, or received heparin replacement (HR) were 11.1%, 5.5%, and 13.1%, respectively. In the multivariate analysis, chronic kidney disease (CKD) requiring hemodialysis ($p < 0.005$; odds ratio 6.71, 95% CI 1.79–25.1), HR ($p < 0.001$; odds ratio 4.15, 95% CI 1.73–9.93) and a specimen size of ≥ 50mm ($p = 0.024$; odds ratio 2.27, 95% CI 1.11–4.62) were independent risk factors for post-operative bleeding.
Early post-operative bleeding rate was 1.9%. In the multivariate analysis, CKD requiring hemodialysis ($p < 0.002$; odds ratio 14.2, 95% CI 2.62–77.0), and a specimen size of ≥ 50 mm ($p = 0.023$; odds ratio 3.35, 95% CI 1.18–9.51) were independent risk factors for early post-operative bleeding.
Delayed post-operative bleeding rate was 2.5%. In the multivariate analysis, HR ($p < 0.002$; odds ratio 5.69, 95% CI 1.92–116.8) was independent risk factor for delayed post-operative bleeding.
Conclusion: Continued LDA was not risk factor for post-ESD bleeding. CKD requiring hemodialysis, and specimen sizes ≥50 mm are independent risk factors for early post-operative bleeding, whereas HR is an independent risk factor for delayed post-operative bleeding. The timing of post-operative bleeding differs with the factors. Careful observation is required for patients at high risk of post-operative bleeding.

Introduction: Gastroenteropancreatic neuroendocrine tumors (GEP-NETs) constitute a heterogeneous group of tumors with variable clinical presentations, different growth rates and unpredictable prognoses. In our study, we aimed to identify the independent prognostic markers for the patients in the whole GEP-NET group.
Aims and Methods: 93 patients who were diagnosed with GEP-NET within the specified period were included in this study. The data were retrospectively analysed. The relationship between all independent variables with 5-year survival status and calculated follow-up period (months) was assessed. In addition, the relationship between the independent variables was investigated.
Results: When we compared the 5 year survival rate, there was a statistically significant relationship between age at diagnosis, male gender, tumor size, tumor stage, liver and / or distant metastasis, tumor grade determined by Ki-67 level and mitotic count and the level of CRP that 1 of the biochemical data. The mean survival (OS) of the study group was 102.5 ± 6.3 (SD) months. The percentages of 1, 3 and 5-year survival were 90%, 72% and 61%, respectively. Of the 93 patients in the study, 63 had a Ki-67 and the mitotic count determined same grade. Ki-67 levels in 29 patients and mitotic count in only 1 patient were higher grade. Risk of death rising %4 by the every 1 increase in the age at

diagnosis, for male sex 2.0-fold, G3 according to mitosis count 3.0-fold, G3 according to Ki-67 level 3.7-fold, tumor stage 3 or 4 cases 12.7-fold, 1 cm increase in tumor size 9%, liver metastasis 6.1-fold, by every 1 mg/dl increase in CRP level 1.5%. There was a significant difference between the pancreas and stomach NETs in favor of stomach tumors in terms of survival.
Conclusion: As a result, it was observed that 1 of the biochemical parameters, CRP affected the course of the progression in the worst way (particularly if it is > 20 mg / dl). With the need for larger scale and prospective studies, it was suggested that CRP level might be a poor prognostic factor for the entire GEP-NET group.

Introduction: Indications for endoscopic submucosal dissection (ESD) of early gastric cancer (EGC) are expanding, but signet ring cell (SRC) carcinoma is still unclear because of its unclear lateral margin.
Aims and Methods: The purpose of this study was to compare pathologic size and endoscopic size in early gastric SRC and to find risk factors associated with tumor size underestimation. A retrospectively medical records reviewed of total 137 patients with diagnosed early gastric SRC between January 2009 and December 2016 at our tertiary hospital. According to pathologic and endoscopic tumor sizes, classified into correct estimation, underestimation and overestimation groups, and risk factors related to underestimation were analyzed.
Results: Among 137 patients with early gastric SRC, 77 patients (56.2%) had undergone correct estimation, 43 patients (31.4%) had underestimation and 17 patients (12.4%) had overestimation. Mean pathologic size (SD) was 20.1 (13.8) mm and mean endoscopic size (SD) was 17.9 (10.1) mm, the correlation coefficients were 0.919 ($p = 0.000$) and there was no significant difference between the two groups. Multivariate analysis showed that more than 20mm endoscopic tumor size (OR, 3.419; 95% CI, 1.271–9.194, $p = 0.015$) and atrophy (OR, 6.011; 95% CI, 2.311–15.633, $p = 0.001$) was a risk factor for tumor size underestimation.
Conclusion: There was no significant difference in pathologic and endoscopic size in early gastric SRC. Therefore ESD may be considered as a therapeutic option if the size of the tumor is less than 20 mm and atrophy is not present in the surrounding mucosa.

Introduction: Metachronous gastric neoplasm is the major concern after endoscopic resection (ER) for early gastric cancer (EGC). Several studies showed that patients with EGC with synchronous neoplasm had increased recurrence rate after ER than those with single EGC. However, the incidence and prognosis are not well-known in patients with synchronous neoplasm including adenoma.
Aims and Methods: In this study, we compared the outcome between patients with single neoplasm and synchronous neoplasm including adenoma after ER. We also compared the outcomes of synchronous neoplasm subgroup which were divided according to the diagnostic histology.
A total of 1569 patients who underwent ER for gastric neoplasm were divided into 2 groups: those with single neoplasm and with synchronous neoplasm which was detected at the initial evaluation or within 1 year follow-up period. The patients with synchronous neoplasm were further divided into 3 subgroups according to the diagnostic histology: subgroup 1 compromised the patients with cancers, subgroup 2 with cancer and adenoma, and subgroup 3 with adenomas. We compared the clinicopathologic characteristics and the incidence of metachronous neoplasm between the patients with and without synchronous gastric neoplasm. Furthermore, we also compared the outcomes of three synchronous neoplasm subgroups.
Results: Synchronous gastric neoplasms were found in 182 patients in a total of 1,569 patients (11.6%). There were no significant differences in gender, proportion of initial tumor pathology, location, and depth of invasion, the incidence of *Helicobacter pylori* infection, and duration of follow-up between the patients with single and synchronous neoplasm. The median follow-up period was 30 months (range, 1–161) in single neoplasm group and 25 months (range, 1–112) in synchronous group. In synchronous groups, multiple adenomas were most commonly found (n = 84, 46.1%), followed by a combination of adenoma and cancer (n = 68, 37.3%), and multiple cancers (n = 30, 16.4%). The risk of metachronous neoplasms was significantly higher in patients with synchronous neoplasm than those with single neoplasm [OR, 2.3 (95% CI, 1.53–3.36); $p < 0.001$]. There was no difference in the risk of metachronous neoplasm in 3 synchronous subgroups. However, cancer was more frequently found in subgroups including cancer than the group including only adenoma during the follow-up period ($p = 0.0026$). When the subgroups including cancer were combined into 1 group, the cancer risk was significantly higher in these patients than those with only adenomas [OR, 4.89 (95% CI, 1.32–31.51); $p < 0.001$].
Conclusion: Patients with synchronous gastric neoplasm including adenoma had increased risk of metachronous neoplasm than those with single lesion. There was no difference in the risk of metachronous neoplasm in three synchronous subgroups. However, the incidence of metachronous cancer was significantly higher in subgroups with cancer than subgroup with only adenomas. Therefore, we have to consider the strict follow-up strategy in the presence of synchronous neoplasm not only EGC but also adenoma.

Introduction: The phenomenon of active inflammatory crosstalk between tumor cells and the surrounding stroma has attracted more and more attention [1]. Some investigations have indicated that inflammation-related proteins, such as matrix metalloproteinases (MMPs), may facilitate the growth, proliferation, and migration of tumor cells, including GC [2–4]. This study was carried out to reveal and testify their significance as candidates for tumor markers of GC.
Aims and Methods: Plasma samples from 12 GC patients (3 cases for each clinical stage from I to IV) and 10 non-neoplastic gastric disease (NGD) patients (3 cases with chronic superficial gastritis, 4 cases with chronic atrophic gastritis and/or intestinal metaplasia and 3 cases with dysplasia) were collected from November 2016 to March 2017 as training set. Human MMP arrays (RayBiotech, Norcross, GA, USA) were used to quantitative measurement of 7 major MMPs (MMP-1, MMP-2, MMP-3 MMP-8, MMP-9, MMP-10, and MMP-13) and 3 their endogenous tissue inhibitors (TIMP-1, TIMP-2, and TIMP-4) simultaneously. Then the levels of them were compared between the GC and NGD groups and their diagnostic value was assessed by ROC curve. The candidate differential subtypes were validated by corresponding serum microchips in another group of patients, which included 40 GC patients and 38 NGD patients. Additionally, the levels of alpha fetoprotein (AFP), carcinoembryonic antigen (CEA), carcinoma antigen 125 (CA125), and carbohydrate antigen 19-9 (CA19-9) in plasma of the 52 GC patients were determined by electrochemiluminescence assay (Roche cobas e 601, Switzerland).
Results: Compared to the NGD group, except MMP-2, MMP-3 and MMP-13, other MMPs showed an increased trend in the GC group, but no significant difference in the training set. Only TIMP-4 increased significantly in the GC group than NGD group, $p < 0.05$. The area under the curve (AUC) of the MMPs were from 0.500 to 0.858, and combined AUC of them was 0.858 (95% CI, 0.699-1.000) for the diagnosis of GC. Particularly, TIMP-4, whose AUC was the highest, 0.858 (95% CI: 0.692–1.000). At the optimal cut-off value of 2438.3 pg/mL, its sensitivity, specificity and accuracy for the diagnosis of GC were 83.3%, 80.0% and 81.8%, respectively. In the validation set, the concentration of TIMP-4 in GC and NGD group were 1101.2 + 703.3 pg/mL and 890.1 + 454.7 pg/mL, respectively. Compared with the NGD group, the concentration of TIMP-4 increased in the GC group, but no statistical difference was found. Its AUC value for the diagnosis of GC was 0.574 (95% CI: 0.444–0.704). Furthermore, the positive rates of AFP, CEA, CA125 and CA19-9 in both sets for the diagnosis of GC and early gastric cancer (EGC), as shown in Table 1.
Conclusion: The diagnostic value of the conventional tumor markers is limited. However, MMP profiles may have potential value for the diagnosis and screening of GC. TIMP-4 is a promising biomarker for the auxiliary diagnosis of GC.

Variable	Training	set	Validation	set
	GC (n = 12)	EGC (n = 3)	GC (n = 40)	EGC (n = 10)
AFP	0	0	0	0
CEA	25.0	0	18.9	11.1
CA125	20.0	0	8.3	0
CA19-9	8.3	0	10.8	0
Combined	33.3	0	32.4	11.1

[Positive rates of traditional serological tumor markers for the diagnosis of GC and EGC (%).]

P0549 CLINICAL COURSE AFTER NON-CURATIVE ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY GASTRIC CANCER WITHOUT ADDITIONAL SURGERY

T Shimada, T Yamagata, T Ohira, Y Harada, Y Kanno, Y Koike, M Tanaka, K Ito

Sendai City Medical Center Dept. of Gastroenterology, Sendai, Japan

Contact E-Mail Address: soccerballshimashimada@yahoo.co.jp

Introduction: Even when early gastric cancer (EGC) is not curatively treated by endoscopic submucosal dissection (ESD), additional surgical gastrectomy is not performed for various reasons.

Aims and Methods: The aim of this study was to assess clinical courses for patients who did not undergo additional surgery for non-curative EGC after ESD. From January 2004 to July 2017, 2,156 patients underwent ESD for EGC at Sendai City Medical Center. Among patients defined as being not curative based on clinicopathological evaluation according to the Japanese Gastric Cancer Treatment Guidelines 2018, 109 patients who did not undergo additional intervention, such as surgery, were included in this study. After elimination of 18 patients who were alive during an insufficient follow-up period of < 3 years, risk factors for short survival (< 3 years) were evaluated by using univariate and multivariate analyses.

Results: Of the 109 patients, the median age was 75.8 years (range, 48–93 years) and 78% were male. The median Charlson Comorbidity Index (CCI) was 2.0 (range, 0–7). The ratio of the patients with low level activity of daily living (ADL), with which the patient could not go out by him/herself, was 13%. As to pathological outcomes, the depth of cancer invasion was M in 28% of the patients, SM1 in 28%, SM2 in 41%, and unclear in 3%. The median tumor size was 35 mm (range, 9–98 mm). The histological type was diagnosed as the differentiated type in 81%, undifferentiated type in 3%, mixed type in 14%, and others in 2%. Lymphatic and venous invasion were observed in 23% and 7%, respectively. The rates of lateral and vertical margin involvement were 3% and 8%. Ulcerative findings were observed in 31%. The risk of lymph node metastasis was defined as being high in 9%, intermediate in 49%, and low in 42% in the eCura system (Hatta et al. *Am J Gastroenterol* 2017). Procedure-related adverse events occurred in 10% (perforation, 3%; postoperative bleeding, 4%; and pneumonia, 3%). The 3- and 5-year overall survival rates (OS) were 87.7 and 81.7%, respectively. Both of the 3- and 5-year disease-specific survival rates (DSS) were 98.7% (median follow-up period, 68.5 months; range, 2.0–165.7 months). Among the 26 patients (23.9%) who died during clinical follow-up, the cause of death was gastric cancer in only 1 patient (37.6 months after ESD) and other causes in 25 patients (median survival period, 45.4 months [range, 4.3–94.8 months]). From univariate analyses, advanced age ($\geq$ 85 years) ($p = 0.043$), high CCI ≥ 3 ($p = 0.007$), low ADL level ($p < 0.001$), and low serum albumin level < 3.5 g/dl ($p = 0.043$) were significantly associated with short survival period. Multivariate analysis revealed that the high CCI (odds ratio [OR], 4.8; 95% confidence interval [CI], 1.1–21; $p = 0.036$] and low ADL level (OR, 6.2; 95% CI, 1.2–31; $p = 0.028$) were independent risk factors for the short survival period.

Conclusion: Given the relatively high OS and DSS, ESD without additional surgery for non-curative EGC was found to be an acceptable option for patients with poor surgical tolerance. Although the survival period was shorter in patients with some comorbidities and those with low ADL level, it is unclear whether additional surgical resection is appropriate or not because the cause of death was not gastric cancer for most of the patients.

Introduction: Early gastric cancer (EGC) is known to present low rate of lymph nodal metastasis (LNM). Gastrectomy with D2 lymphadenectomy is usually curative for EGC. Endoscopic submucosal dissection (ESD) is a well-accepted treatment modality for lesions that meet the classic criteria, a mucosal differentiated adenocarcinoma measuring 20 mm or less, without ulceration. Expanded criteria for ESD have been proposed based on null LNM metastasis rate from large gastrectomies series coming from Japan. The expanded criteria for ESD are as follows: intramucosal non-ulcerative well-differentiated tumor > 2 cm, intramucosal ulcerative differentiated tumor ≤ 3 cm, or intramucosal non-ulcerative undifferentiated tumor ≤ 2 cm or superficially submucosal (sm1) differentiated tumor ≤ 3 cm. Patients with positive LNM have been reported in western centers, creating a need for validation of expanded criteria.

Aims and Methods: Our aim was to assess the risk LNM in gastrectomy specimens of patients with EGC who met the expanded endoscopic treatment criteria for ESD.

Evaluation of gastrectomy specimens including LNM staging of patients submitted to gastrectomy for EGC in a 39-year retrospective cohort.

Results: A total of 389 surgical specimens were included. We identified 53 patients with lymph node metastases in our casuistic (13.6%). Patients with indication of surgical treatment (S) had higher incidence of lymph node metastases ($p < 0.001$). From the 135 patients which fulfilled criteria for endoscopic resection, none of the 31 patients with classic criteria had LNM. Of the 104 patients with expanded criteria, 3 had LNM ($n = 104$, 2.9% 95% CI 0.7–8.6%), all of them with undifferentiated tumors without ulceration and less than 20 mm.

Conclusion: There is a small risk of LNM in EGC when expanded criteria for ESD are met. Refinement of the expanded criteria for the risk of LNM metastasis may be desirable in West. Meanwhile the decision to complement the endoscopic treatment with gastrectomy will have to take into consideration the individual risk of perioperative morbidity and mortality.

Introduction: The comprehensive efficacy of various anti-ulcer medications after gastric endoscopic resection has not been fully evaluated. Recently, vonoprazan, a novel potassium-competitive acid blocker, has also been used in ulcer treatment after endoscopic resection.

Aims and Methods: We searched for all relevant randomized controlled trials examining the efficacy of anti-ulcer medications after gastric endoscopic resection, published through October 2017. Healing of iatrogenic ulcers was investigated at 4–8 weeks after the procedure. A network meta-analysis was performed to calculate the network estimates.

Results: 23 studies with 2137 patients were included in the meta-analysis. Concerning the comparative efficacy for ulcer healing at 4 weeks after the procedure, no network inconsistency was identified (Cochran's Q-test, $df = 12$, $p = 0.22$; $I^2 = 22\%$). A combination therapy of proton pump inhibitor (PPI) and mucoprotective agent was superior to all other regimens (risk ratio [RR] [95% confidence interval, CI]: vs. PPI, 1.69 [1.23–2.31]; vs. vonoprazan, 1.97 [1.09–3.56]; vs. H_2 receptor antagonist, 1.73 [1.02–2.93]; vs. mucoprotective agent, 1.68 [1.06–2.65]). Concerning the ulcer healing rate at 8 weeks after the procedure, however, vonoprazan was superior to PPI (RR [95% CI] = 1.27 [1.03–1.56]). Additionally, vonoprazan tended to be superior to the combination therapy of PPI and mucoprotective agent (RR [95% CI] = 1.20 [0.96–1.51]).

Conclusion: A combination therapy of PPI and mucoprotective agent was superior to other anti-ulcer drug regimens for ulcer healing at 4 weeks after endoscopic resection. However, vonoprazan tended to be superior to the combination therapy of PPI and mucoprotective agent for ulcer healing at 8 weeks after the procedure.

Introduction: The usefulness of pepsinogen (PG) I and I/II ratio as biomarker for screening gastric cancer (GC) has been well established in Japan. PG II is known to be a non-invasive marker of gastric inflammation, but clinical interest in diagnosis of GC was relatively low and its role has not been clearly established either. The purpose of this study is to investigate the role of PG II in the screening of GC.

Aims and Methods: Total of 2,956 subjects, including patients with GC (n = 1,136), gastric dysplasia (n = 346) and controls (n = 1,474) who underwent gastroscopy with well-defined biopsy sampling protocol, were enrolled in this study during 2006–2017. Serum tests of PG and Helicobacter pylori (HP) infection tests (Giemsa stain, CLOtest and culture) were performed. Each PG level were divided into 3 categories. The usefulness of PG levels to detect GC compared to controls was validated by using multivariate logistic regression. Odds ratios and 95% CIs were calculated.

Results: In the cross-sectional analysis, PG I, PG II and PG I/II ratio (especially PG I/II ratio) were associated with the presence of GC. When classified by histology, the prevalence of diffuse type GC was higher in high PG II levels group (OR = 2.20, $p < 0.001$). Furthermore, high PG II levels were strongly related with subgroup of below age 40 (OR = 4.77, $p < 0.001$) and female diffuse GC patients (OR = 6.77, $p < 0.001$). By combining PG II with PG I/II ratio, higher ORs were obtained when the young age group with PG II ≥22.1 ng/mL and PG I/II ratio < 3 was defined as high-risk group (OR = 18.77, p = 0.005).

Conclusion: High PG II levels are associated with the risk of diffuse type GC. Serum PG II ≥22.1 ng/mL and PG I/II ratio < 3 could be used to identify high risk individuals for diffuse type GC, particularly in young adults in Korea.

Introduction: The problem of adequate diagnostics and interpretation of chronic gastritis, as well as identical understanding of an essence of process, remains a stumbling block between pathologists, endoscopists and gastroenterologists. Attempts to compare an endoscopic picture with histologic have shown the prevailing importance of microscopy as in definition of a form and stage of gastritis, and risk of malignization on his background.

Aims and Methods: Justification of the uniform scheme of the endoscopic conclusion at chronic gastritis. Results of 59710 endoscopic conclusions and 38421 microscopic investigations of 3593 patients with chronic gastritis were studied in long dynamic observation from 2000 to 2016.

Results: The analysis of endoscopic signs in the descriptive picture of chronic gastritis, regardless of the prescription of the disease, revealed three main common indicators: diversity, roughness, focuses of atrophy of the gastric mucosa. The analysis of a microscopic picture has revealed similar atrophic - hyperplastic processes of different degree of varying severity with different forms of chronic gastritis (according to Current International Statistical Classification of Diseases and Related Health Problems (ICD-10) of classification of gastritis (K29 code)).

The correlation between frequencies of endoscopic signs is not found (Spearman R = −0.213057, p = 0.484630), but the frequency of endoscopic signs varied significantly depending on the severity of atrophy (Chi-Square = 15330.83 df = 12 $p < 0.000000$). A high degree of correlation between endoscopic and microscopic signs was found (Spearman Rank Order Correlations = 0.985610760609162; t (N-2) = 11.6619037896906; p = 0.000309). The scheme of a current and visual interpretation of chronic gastritis is offered.

The fact and quality of endoscopic diagnosis of chronic gastritis depends on the doctor's understanding of the phases of chronic gastritis. Accumulation of visual atrophic changes and community microscopic changes at the different area of atrophy of the gastric mucosa make the endoscopic conclusion 'chronic subatrophic gastritis' from an uneven mucous membrane without visible foci of atrophy right up to the appearance of a picture of atrophic gastritis.

Conclusion: The establishment of the fact of chronic subatrophic gastritis requires morphological verification of the degree of atrophy and the risk of carcinogenesis using the OLGA or OLGA-IM protocol.

Introduction: Gastric adenocarcinoma with enteroblastic differentiation (GAED) is a rare variant of gastric adenocarcinoma characterized by fetal gut-like structures with glycogen-rich clear cytoplasm and frequent expression of AFP, Glypican-3 (GPC3) and SALL4 [1–5]. Clinicopathologically, GAED shows aggressive behavior characterized by frequent vascular invasion, lymphatic invasion and, liver metastasis even in early cancer [6–7]. Last year, our group reported by comprehensively analysis using next generation sequence (NGS) that GAED had high frequency of *TP53* mutation associated with p53 overexpression. Furthermore, we also showed that *ERBB2* amplification and HER2 overexpression were observed as is seen in conventional gastric adenocarcinoma (CGA) and that Trastuzumab could be used as a therapeutic target therapy in this tumor.

Aims and Methods: This study aimed to further clarify the inactivation mechanism of *TP53* in GAED. In addition, the frequency and prognostic impact of *SMAD4* expression and loss of heterozygosity (LOH) of this gene were also assessed, because *SMAD4* was identified as one of the frequently deleted genes by copy number variation (CNV) analysis of NGS. We enrolled 51 cases (early:17, advanced:34) of GAED for this study. We performed sanger sequence for *ATM* mutation that were shown to be related to the inactivation of p53, and also evaluated the DNA promoter methylation status of *TP53* by methylation-specific PCR (MS-PCR) and LOH analysis of *TP53* locus. Furthermore, we evaluated LOH of *SMAD4* locus and *SMAD4* mutations. In addition, we performed immunohistochemistry for *SMAD4* and ten-eleven translation (TET)1 related to the methylation of the promoter and examined their clinicopathological correlations. Regarding the frequencies of the genetic alterations, obtained data were compared to those of CGA from TCGA [8].

Results: We found only 1 case of *ATM* mutation. The frequency of LOH at *TP53* locus was 39.2%, and the promoter methylation of *TP53* was detected in 20%. Among cases with promoter methylation of *TP53*, 40% (4/10) did not show p53 overexpression by immunohistochemistry. These findings suggest that p53 dysfunction in GAED is in part caused promoter methylation, in addition to *TP53* mutation/LOH. 14 cases harbored both LOH at *TP53* locus and either missense or nonsense mutation of *TP53*, however, p53 inactivation did not affect patients' prognosis in GAED. Reduced TET1 expression was found in 16 cases (32%), however, the reduced expression of TET1 was not associated with promoter methylation of *TP53*. LOH at *SMAD4* locus was found in 23 cases (45%) and was significantly higher in GAED compared to CGA. *SMAD4* mutation was not found in any case. Reduced *SMAD4* expression was found in 18 cases (36%) and was significantly associated with advanced stage of GAED. LOH at *SMAD4* locus was not associated with reduced *SMAD4* expression. LOH status of *SMAD4* locus did not affect patients' overall survival in GAED.

Conclusion: Inactivation mechanism of *TP53* other than gene mutations or LOH seemed to be rare in GAED. Frequent *TP53* mutation is one of the characteristics of GAED, however, does not contribute to the aggressive biological behavior in this tumor. In contrast, The LOH rate (45%) of *SMAD4* locus in GAED

was significantly higher than that of CGA, suggesting that this locus is one of the susceptibility genes in this tumor, although *SMAD4* mutation was not detected. Furthermore, dysfunction of *SMAD4* seemed to contribute to the acquisition of the aggressive behavior of GAED.

P0555 COMPREHENSIVE BIOINFORMATIC ANALYSIS OF ABERRANTLY EXPRESSED PROFILES OF MIRNAS AND LNCRNAS WITH THE ASSOCIATED CERNA NETWORK IN GASTRIC CANCER

X Zhou[1]
[1]*Jiangsu Province Hospital, Dept. of Gastroenterology, Nanjing, China*

Contact E-Mail Address: zhouxiaoying0926@sina.cn

Introduction: Increasing evidence has highlighted the critical roles of miRNAs as biomarkers and therapeutic targets for cancer. MiRNAs are also regarded as a major part of competing endogenous RNA (ceRNA) network due to its regulation on protein-coding gene expression by acting as sponges. However, functional roles of miRNA-mediated ceRNAs in gastric cancer (GC) remain unclear.
Aims and Methods: To clarify relevant potential mechanisms, we comprehensively compared the expression profiles of mRNAs, lncRNAs and miRNAs between 55 GC tissues and 55 non-tumor tissues, based on GEO databases. Then, we selected most relevant genes through GO and pathway analysis, together with target gene prediction. We also set up a ceRNA network through the certain algorithm.
Results: The flow chart of our study was shown in Figure 1. A total of 11 miRNAs, 299 lncRNAs and 1118 mRNAs were identified as aberrantly expressed in all of the four databases (GSE67354, GSE78775, GSE79973 and GSE19826). After screening by GO and pathway analysis, 364 significant mRNAs were selected ($p < 0.05$) and they had correlations with tumorigenesis and/or progression of GC. Further screening was performed using targeting gene prediction and 179 mRNAs were chosen. Then, a dysregulated miRNA-associated ceRNA network was successfully constructed, which inculdes 70 lncRNAs, 11 miRNAs and 112 mRNAs (Figure 2A). Finally, 2 out of the 11 dysregulated miRNAs functioned as prognostic biomarkers for GC patients according to the overall survival analysis, which is a higher expression of hsa-miR-125-5p and hsa-miR-130-3p represented a lower prognosis rate (P value = 0.0259 and 0.0236, respectively) (Figure 2B). We then examined the miRNAs' expression in our 30 GC tissues and 30 control tissues. MiR-125 and miR-130 were both decreased in GC tissues.
Conclusion: In summary, our study identified novel miRNAs as candidate prognostic biomarkers and potential therapeutic targets for GC, based on large-scale sample size. More importantly, the newly identified ceRNA network will be beneficial for improving the understanding of miRNA-mediated ceRNA regulatory mechanisms in the pathogenesis of GC.

P0556 ADIPOCYTES CAN INCREASE THE INVASIVE POTENTIAL OF PERITONEAL METASTASIS FORMATION IN GASTRIC CANCER

S Fushida, T Yamaguchi, J Kinoshita, T Ohta
Graduate School of Medical Science, Kanazawa University, Gastroenterological Surgery, Kanazawa, Japan

Contact E-Mail Address: fushida@staff.kanazawa-u.ac.jp

Introduction: According to the progression of gastric cancer (GC), released cancer cells from stomach surface attach to peritoneal mesothelial cells. As the result, peritoneal metastatic nodules occur in omentum and mesentery which contain rich adipocytes. However, the interaction between gastric cancer cells and adipocytes in the process of peritoneal metastasis has not sufficiently elucidated. In this study, we clarified adipocytes enhanced gastric cancer progression by transforming to juvenile phenotype.
Aims and Methods: Adiponectin which is one of adipokine in the omental fat tissue from resected specimen was measured using ELISA and western blot analysis. Matured adipocyte derived from progenitor adipocyte 3T3-L1 was co-cultured with gastric cancer cell MKN45 and OCUM-2MD3. After that, differential markers and cytokines from adipocyte were analyzed using quantitative RT-PCR and fluorescence immunostaining.
Results: Adiponectin in the fat tissue adjacent primary tumor revealed lower expression in the patients with high T stage than with low T stage. Adipocytes co-cultured with gastric cancer cell showed decreased expression of adiponectin. PPARg and C/EBPa as differential marker of adipocytes also decreased. On the other hand, expression of IL-6 and PAI-1 as SASP (Senescence-associated Secretory Phenotype) factors were increased in the co-cultured adipocytes. These cells also showed high expression of aSMA as EMT marker and FAP (fibroblast-activated protein) as CAFs (cancer-associated fibroblasts) marker.
Conclusion: These results suggest that transformed adipocytes in cancer microenvironment are induced expression of SASP factors, facilitating tumor growth and invasion. A part of adipocytes might differentiate to fibroblasts and involve formation of peritoneal metastasis in GC.

P0557 THE EXPRESSION OF WNT-SIGNALING PATHWAY COMPONENTS IN DIFFUSE GASTRIC CANCER

M Sremac[1], T Nikuseva Martic[2], N Rustemovic[1], Z Krznaric[1]
[1]*University Hospital Center Zagreb, Department of Gastroenterology and Hepatology, Zagreb, Croatia*
[2]*University of Zagreb, School of Medicine, Department of Medical Biology, Zagreb, Croatia*

Contact E-Mail Address: maja.sremac@gmail.com

Introduction: The Wnt genes encode a large family of secreted molecules that play important roles in controlling tissue patterning, cell fate and cell proliferation within a broad range of embryonic contexts, including the gastrointestinal tract. Dishevelled (DVL) proteins are the central mediators in this pathway which enable its fine regulation. The interactions of Wnt ligands and Frisbee receptors are modulated by the secreted Wnt antagonists, which can be divided into 2 functional classes: the soluble frizzled related protein (SFRP) and the dickkopf (Dkk) class. Wnt antagonists interact directly and indirectly to affect Wnt signalling and influence a wide variety of biological processes, including developmental cell fate, differentiation and tumorigenesis.
Aims and Methods: The aim of the study was to investigate the expression of components of the Wnt - signaling pathway SFRP1, SFRP3, DVL-2 and DVL-3 in diffuse gastric cancer and healthy gastric tissue samples. Samples of 60 diffuse gastric carcinoma and adjacent nontumoral tissues were collected from the Department of Pathology, University Hospital Center Zagreb, Croatia. The tumor tissues were formaline fixed, parrafin embedded**.** All tumors were studied by pathologists and classified as diffuse gastric carcinoma according to the WHO criteria. Immunohistochemistry was performed in order to establish the levels of expression (absent, poor, moderate, intense) and cellular localization (membrane, nucleus, cytoplasm) of SFRP1, SFRP3, DVL-2 and DVL-3. Statistical analyses were performed using GraphPad Prism 5.01 (GraphPad Software, Inc., San Diego, CA, USA) and Principal component analysis (PCA) was done using Matlab Software PLS Toolbox. The stereological data were evaluated by descriptive statistics.
Results: SFRP1 expression was observed in the cytoplasm. In gastric tissue SFRP1 expression was found in glandular cells. We found statistically significant difference in the number of SFRP1 positive cells between normal and tumor tissues ($p < 0.05$). The amount of SFRP1 protein expression in normal tissues was higher compared to the one observed in tumor tissue. Subcellular localization of SFRP3 protein in gastric tissue was observed in cytoplasmic and membranous glandular. We found statistically significant difference in the number of SFRP3 positive cells between normal and tumor tissues ($p < 0.05$). The amount of SFRP3 protein expression in normal tissues was higher compared to the one observed in tumor tissue. DVL-2 and DVL-3 expression was observed in the cytoplasm of glandular cells. We found statistically significant difference in number of DVL-2 positive cells between normal and tumor tissues ($p < 0.05$). The amount of DVL-2 protein expression in tumor tissues was higher compared to the one observed in normal tissue. There was no statistically significant difference in the number of DVL-3 positive cells between normal and tumor tissues, although the amount of DVL-3 expression was higher in tumor tissue.
Conclusion: Despite some recent advances, gastric cancer remains the third leading cause of cancer-associated death worldwide. This indicates the absence of therapeutic options, stemming from the limited understanding of the molecular mechanisms involved in carcinogenesis. According to our data there is a statistically significant difference in the expression of SFRP 1, SFRP3 and DVL-2 between normal gastric tissues and tumor tissues, thus indicating that the loss of Wnt inhibitors and overexpression of Wnt cell fate regulators in tumor tissues may play an important role in gastric carcinogenesis.

Introduction: Recent pilot studies ascertained the safety and feasibility of the Thulium/Erbium laser system (TELS) as a new therapeutic tool for endoscopic haemostasis, ablation and resection.

Aims and Methods: We investigated for the first time ever, the safety and efficacy of endoscopic treatment with TELS in patients with gastrointestinal bleeding due to vascular lesions. This single-centre, open-label study prospectively enrolled consecutive patients referring for chronic gastrointestinal bleeding plus moderate/severe anaemia due to vascular lesions at IRCCS Policlinico San Donato Hospital between March 2016 and April 2018. Data were collected retrospectively.

The primary endpoints were the safety and the technical success of TELS treatments. As secondary outcomes, we investigated the biological success comparing the lowest haemoglobin values ± 1month prior to and after treatment, along with the need of packed red blood cells (PRB) transfusions ± 6month prior to and after treatment. Patients requiring blood transfusions for major comorbidities or surgery not related to gastrointestinal bleeding were ruled out from the assessment of biological parameters. The symptoms and the endoscopic score proposed by Dray X et al.[1] were used to evaluate the clinical and endoscopic success in patients with radiation proctitis (RP). A new scoring system was developed to assess the severity and the endoscopic success of TELS in gastric antral vascular ectasia (GAVE; 1–3 points according to a relative mucosal involvement $< 30\%$, 30–50% or $> 50\%$, respectively plus 3 or 5 points for traces of blood or active bleeding). For each procedure, image/video documentations and TELS technical parameters (i.e., lasing time, power output and total energy employed) were recorded. The Wilcoxon signed rank test was employed to challenge the quantitative results obtained.

Results: 11 patients underwent 16 endoscopic treatments with the TELS according to the diagnosis of GAVE (4 pts and 8 procedures), angioectasias (4 pts and 4 procedures) and RP (3 pts and 4 procedures). All procedures resulted in a complication-free technical success, thereby succeeding the primary study endpoints. According to preliminary data available in April 2018, haemoglobin values showed a significant rise (Δ_{lowest}Hb±1month = +1.6 g/dl, 95%CI = 0.45–3.20, p-value = 0.008) along with a decreased need of PRB transfusions (Δ_{PRB} ± 6months = −5 units, 95CI% = 1–9; p-value = 0.046). Consistently, the median values of GAVE endoscopic severity and of RP-related symptoms improved (from 5 to 2 and from 3 to 1 respectively), while preliminary data on RP endoscopic severity showed no remarkable changes in terms of severity of residual lesions.

The median Thulium/Erbium power output adopted during treatments were 6/2W, 5/1W and 5/2W with a median lasing time equal to 5'33'', 1'50'' and 3'45'' accounting for a median total energy of 1676/414J, 675/193J and 1024/417J for GAVE, angioectasias and RP, respectively.

Conclusion: This pilot study conducted in real-life setting suggests the TELS as a safe and effective tool for the endoscopic luminal treatment of patients with gastrointestinal bleeding caused by various types of superficial vascular lesions. Our data further confirmed the manoeuvrability of this new therapeutic tool, which mostly enables a complete eradication of large vascular lesions within few endoscopic procedures. Randomized-controlled studies involving established endoscopic techniques for haemostasis and ablation of gastrointestinal vascular lesions in larger cluster of patients are now warranted.

Disclosure: Nothing to disclose

P0559 IS GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION FEASIBLE UNDER THE DIRECT ORAL ANTICOAGULANTS ADMINISTRATION?

R Nakahara, H Harada, T Ujihara, D Murakami, R Sagami, S Satoshi, Y Katsuyama, K Hayasaka, Y Amano
New Tokyo Hospital, Gastroenterology, Chiba, Japan

Contact E-Mail Address: pppryoutarou@yahoo.co.jp

Introduction: Several studies have reported that anticoagulant therapy on gastric endoscopic submucosal dissection (ESD) increases the risk of postoperative bleeding [1, 2]. Previously, we have reported that the continuous warfarin administration does not increase the bleeding risk after gastric ESD compared to intravenous heparin bridge therapy (HBT) [3]. Currently, direct oral anticoagulants (DOAC) have been frequently used for the prevention and treatment of cardiovascular diseases instead of warfarin. Therefore, we investigated the effect of DOAC for postoperative bleeding after gastric ESD in comparison with those of warfarin and HBT.

Aims and Methods: A total of 89 gastric neoplasms in patients with anticoagulant therapy were treated with ESD at New Tokyo Hospital between September 2008 and December 2017. 37 out of 89 patients underwent gastric ESD with continuous warfarin, 27 done with intravenous HBT, and 20 done with DOAC. In patients with continuous warfarin, the dose of warfarin was controlled to maintain the PT-INR under 3.0. Patients with DOAC were treated with interrupted DOAC on the day of ESD. We assessed the clinical findings and outcomes of gastric ESD with anticoagulant therapy.

Results: The rates of complete en bloc resection were 100% in the continuous warfarin group and the HBT group, and 95% in the DOAC group ($p = 0.238$). The rates of postoperative bleeding were 10.8% in the continuous warfarin group, 18.5% in the HBT group, and 15.0% in the DOAC group ($p = 0.672$). All bleeding events were successfully managed with endoscopic hemostasis. One patient in the HBT group developed a delayed perforation resultantly required for an emergency surgery. The period of hospitalization was higher in the HBT group than in the other 2 groups (median [IQR], 13 [11–16] days in HBT, 6 [5–7] days in continuous warfarin, 6 [5–8] days in DOAC; $p < 0.001$).

Conclusion: The bleeding rate was not statistically different in the 3 groups. Gastric ESD under the DOAC administration was considered to be feasible and acceptable.

Disclosure: Nothing to disclose

P0560 QUANTIFYING EXCESS CARDIO-RESPIRATORY EVENTS AND ADMISSIONS FOLLOWING DAY CASE DIAGNOSTIC GASTROSCOPY

C.J Crooks, J West, T.R Card
University of Nottingham, School of Medicine, Nottingham, United Kingdom

Contact E-Mail Address: colin.crooks@nottingham.ac.uk

Introduction: Age-stratified estimates of adverse events after endoscopy will inform clinical decisions about appropriate investigation in those at high risk. We have quantified the absolute risks of cardiovascular and respiratory events in both primary and secondary care following day case diagnostic gastroscopy.

Aims and Methods: Patients undergoing day case diagnostic gastroscopy were identified in the English population from the linked hospital data in the Clinical Practice Research Datalink, and frequency matched with replacement on decade of birth to 4 times as many controls from this population, who were alive and registered at the time of the endoscopies. Follow up was censored on the earliest of; diagnosis of cancer, subsequent interventional procedure, emergency hospital admission, transfer out the study population, or death.

The first acute event of cardiac, cerebrovascular, or respiratory disease was identified in the 30 days after either the endoscopy or matched index date,

Abstract No: P0559: Baseline characteristics and therapeutic outcomes in patients with anticoagulant therDOAC, direct oral anticoagulants; HBT, heparin bridge therapyapy

from linked primary care consultations, underlying cause on death certificates, or the main diagnosis from emergency hospital admissions.
The age-stratified risks following day case diagnostic gastroscopies were estimated from a Cox regression model adjusted for age, gender and pre-existing co-morbidity.[1] Then excess risks were calculated, adjusted for censored and competing events, by using cumulative incidence functions derived from this Cox model.
Results: 307,925 day-case diagnostic gastroscopies were identified (among 248,217 people) with 13,411 cardiovascular or respiratory events within 30 days, of which 1,644 were emergency admissions and 351 were deaths. 1,584,660 matched index dates were identified (among 1,074,214 unique controls) with 51,681 cardiovascular or respiratory events within 30 days, of which 4,769 were emergency admissions and 1,105 were deaths.
After adjusting for age, gender, co-morbidity, and competing events, the absolute predicted risk for a cardiovascular or respiratory event within 30 days of a gastroscopy procedure was 2.2% for those under 30 years and 8.5% for those 80 years and older (table 1). This translated to an absolute excess risk over the control population of 1.0% (< 30 years) to 2.5% (≥80 years) respectively. Having a day-case diagnostic gastroscopy was correspondingly associated with an overall 2.1-fold relative increase in risk of cardiovascular or respiratory admissions (95% confidence interval 2.0–2.2, adjusted for age and gender), which was reduced to 1.9-fold (1.8–2.0) after adjusting for pre-existing co-morbidity.
Conclusion: This study showed an important excess risk of acute cardiovascular and respiratory events in primary and secondary care following day-case diagnostic gastroscopy compared to the general population. The excess risk of such an event was 1 in 100 procedures for those under 30 years of age and 1 in 40 procedures for those aged 80 or over. Almost 1 in 50 of those over 80 experienced an additional event which required hospital admission. We believe this information will be of value to clinicians deciding on whether to request routine tests, and patients in the consent process.
[Cardio-respiratory events in primary care consultations or emergency hospital admissions, and excess compared to age matched population controls]

Introduction: Accreditation is one method of assuring quality and requires the setting of standards and the creation of a reliable process for assessing them. Accreditation is a well-established form of external peer review that can help in reducing medical errors, and in one study the improvement was found to be around a 50% reduction in medical administration errors (1). In 2014 the Italian Society For Digestive Endoscopy (SIED) launched a national program for accreditation of all endoscopy centres.
Aims and Methods: An 8-member group, endorsed by SIED, prepared standards for accreditation, developed from national and international guidelines and approved by SIED Central Committee. These standards were published on the SIED internet site, open to all SIED members. An independent third party certification body (Kiwacermet-Bologna-Italy) was chosen to provide assessment and certification. The working group prepared 295 quality indicators centered on patient experience, efficiency and operations, precedure-related endoscopy unit issues, safety and infection control, reprocessing. Reprocessing quality indicators were prepared in collaboration with the Italian Endoscopist Nurses Society (ANOTE). A group composed of 2 endoscopists, 1 nurse and a Kiwacermet representative tested the quality indicators during a one-day site-visit to endoscopy centres requiring accreditation. Expenses were covered by SIED and enrollment of endoscopy centres is free of charge.
Results: So far we have evaluated 23 centres scattered all over Italy. During the site-visits we have pointed out 162 critical issues, not in accordance with the SIED accreditation program. In all centres visited we found critical issues about targets and periodic evaluation of results. In the procedure-related domain, we have found 68 critical issues for gastroscopy, 75 for colonoscopy, 20 for percutaneous gastrostomy and 13 for retrograde colangio-pancreatography. In the reprocessing domain 46 critical issues have been discovered. In the post-polypectomy surveillance domain we have noticed 8 negative remarks. All these critical issues have been corrected by the 18 accreditated centres. To date 3 centres have not been granted by the SIED accreditation award and 2 centres are complying with the SIED requests. Eleven centres are waiting for a 2018 site-visit.
Conclusion: The SIED free accreditation program has the potential to identify and correct flaws responsible for suboptimal performance. Reprocessing and polyps surveillance are 2 of the greatest weaknesses of the Italian endoscopy services.
Disclosure: The Italian Accreditation program is entirely funded by an unrestricted grant of SIED-Italian Society for Digestive Endoscopy-Rome. M Capelli is part of the medical advisory board for Kiwacermet-Bologna-Italy. All other authors disclosed no financial relationships relevant to this work.

P0562 THE ROLE OF THE CLINIC AND OF THE ORGANIZATIONAL COMPLEXITY ON THE MORTALITY FROM ACUTE UPPER GASTROINTESTINAL BLEEDING

R Marmo[1], **M Soncini**[2], C Marmo[3]
[1]*ASL Salerno, Sant'Arsenio, Italy*
[2]*San Carlo Borromeo, Milan, Italy*
[3]*Catholic University of Rome, Naples, Italy*

Contact E-Mail Address: marco.soncini1@gmail.com
Introduction: The role of the Gastroenterologist and of the Department of Gastroenterology and Gastrointestinal Endoscopy is crucial for the management of patients with upper gastrointestinal bleeding, variceal, non-variceal and non-ulcer. With the Ministry of Health decree n.70 of April 2nd 2015, the Italian health system features hierarchical levels of healthcare complexity of hospitals. The emergency network is made up with hospitals with different healthcare complexity according to the model hub and spoke. D.E.A. hospitals of second level work as Hub and are institutionally referable to Hospital Agencies, University Hospitals and certain Healthcare Centers of Scientific Research (IRCCS).
Aims and Methods: Evaluate the impact of 1) patients' clinical conditions and 2) organizational and health care courses on mortality from upper gastrointestinal bleeding in hospitalized patients.
The analysis of the healthcare setting of upper gastrointestinal bleeding in Campania has been carried out processing the data from the hospital discharge reports of 2015. The level of healthcare complexity of hospital facilities has been evaluated taking into account two profiles: Regional Hospital Agencies (AO) and Local Healthcare Companies (ASL). The University Hospitals of Naples, the Institute of Cancer Research and the Pediatric Hospital have been excluded as not involved in the management of acute gastrointestinal bleeding. The mortality rate of 30 has been considered as the measure of clinical efficiency, the length of hospital stay has been considered as the measure of efficiency.
Results: 8707 hospital discharge reports were initially selected, which met the recruitment criteria; at the end of the exclusion process the data of 3368 patients were included in the analysis; considering that the average resident population in 2015 was 5,856,189, the rough rate of upper gastrointestinal bleeding in 2015 was 575 per 1,000,000 inhabitants. The patients discharged from local healthcare agencies were 2,192 (65.1%) with 1,980 males (58.8%), the average age was 65.4±DS 18.7. The non-variceal bleedings were 2,980 (88.5%).

The average age was slightly older in the ASL (65.9 ± DS vs AO 64.4 ± DS 19.6). The number of patients with variceal bleeding discharged from AO was higher: 199/1176 (16.9%) vs 198/2192 (8.6%) p < 0.000. The overall mortality rate in the two healthcare settings was similar: 8.0% in AO vs 6.7% in ASL Pr = 0.184. The overall mortality rate for patients discharged from Gastroenterology Units (regardless AO or ASL) was 4.7% vs 7.9% in other departments p < Pr = 0.002. Considering together the healthcare setting ASL or AO and the patients discharged from Gastroenterology Units (Table) we can see that those discharged from gastroenterology units show a lower mortality rate. This datum is less relevant in non-variceal bleedings but much more relevant in variceal ones. In the multi-varied analysis the mortality risk factors were: age over 79 OR 2.80 (95% CI 2.12 to 3.69) variceal bleeding OR 2.84 (95% CI 1.98 to 4.06), while protection factors were discharge from a Gastroenterology Unit OR 4.77 (95% CI 3.2 to 7.0) and hospitalization in AO and in Gastroenterology Unit OR 9.6 (95% CI 9.3 to 9.9).
Conclusion: AO hospital facilities present the same mortality rate as ASL ones. The hospital stay in Gastroenterology Units reduce all mortality cases and was similar in both AO and ASL. Mortality in non-gastroenterology unit both in AO and ASL is similar.

	AO No Gastro	AO Yes Gastro	ASL No Gastro	ASL Yes Gastro	p-value
Mortality Overall	11.2%	4.5%	6.9%	5.3%	<0.001
Mortality Non Variceal	9.4%	3.8%	6.5%	4.2%	<0.002

[Mortality rate by AO or ASL with patients discharged Yes or No from Gastroenterology Unit]

P0563 SIMPLE "PURE" ENDOSCOPIC TECHNIQUE OF PEG-J-PLACEMENT IN ADVANCED PARKINSON'S DISEASE- A RETROSPECTIVE SINGLE-CENTER STUDY

P Karagyozov, Z Georgieva, I Tishkov, I Boeva, V Koynarski, V Mitova
Acibadem City Clinic Tokuda Hospital, Department of Interventional Gastroenterology, Sofia, Bulgaria

Contact E-Mail Address: petko.karagyozov@gmail.com
Introduction: Levodopa is absorbed mainly in the upper intestine and is metabolized rapidly, consequently requiring frequent applications. Continuous levodopa/carbidopa infusion straight into the proximal jejunum via percutaneous endoscopic gastrostomy with jejunal extension tube (PEG-J) connected to a portable infusion pump has emerged as a promising tool in the treatment of Parkinson's disease (PD). [1–2]
Aims and Methods: We aim to assess effectiveness and safety of PEG-J placement under direct endoscopic control and with no additional imaging tools in patients with Parkinson's disease.
Study group includes 76 patients with advanced PD who underwent PEG-J placement in the period June 2014 - February 2018.
In all patients, a nasojejunal tube was inserted initially to assess levodopa-carbidopa efficacy and dosage. After a short period of time (4–7 days) a PEG-J (Freka® PEG CH15, and Freka® CH9 Intestinal Tube for CH15 PEG) was placed under i.v. propofol infusion. Peri interventional drug prophylaxis included antibiotic, proton pump inhibitor and analgetics.
All patients underwent placement of both PEG tube (via the pull method) and J-tube in a single procedure. J-tube placement technique used was grasping the tube tip with forceps and advancing it along with the endoscope into the distal duodenum. The scope was then slowly withdrawn into the stomach while the forceps is advanced blindly to hold the tip of the J-tube in place. Finally J-tube was advanced approximately 80–90 cm in the jejunum. No fluoroscopy, nor any other imaging tool was used to determine accurate J-tube position. Patient's clinical response to levodopa/carbidopa infusion indicated procedure effectiveness, instead.
Results: PEG-J was successfully placed in all patients, confirming high technical effectiveness of the PEG-J endoscopic guidance placement method.[3]
No single serious adverse event has been reported in 48-hours postrocedural clinical observation period. Additionally, there was no need of J-tube reposition in any of the patients. We registered 1.52% late complications (within one month after procedure): a case of mesenterial thrombosis and another one of *C. difficile* colitis, both requiring hospital admission. Both patients were successfully managed.
Conclusion: Endoscopic guided PEG-J placement with 'blind' jeunal extension insertion is a highly effective, fast and simple procedure with limited adverse events. Clinical response to levodopa/carbidopa is suitable and sufficient indicator for accurate jejunal position of the J-extension. Further, PEG-J placement followed by continuous levodopa/carbidopa infusion was associated with improvement in quality of life and clinical symptoms in PD patients with advanced disease.
Disclosure: Nothing to disclose

Introduction: For many gastrointestinal (GI) diseases the severity of the impairment of Quality of life (QoL) is a key driver for health care utilisation and health care costs. However, very little is known about the of the impact of specific GI symptoms on QoL in different patient cohorts.
Aims and Methods: We aimed to determine and compare the proportion of patients with severe or very severe impairment of QoL due to specific GI symptoms in patients with selected highly prevalent GI diseases in the outpatient setting of a tertiary hospital. From a cohort of 10,000 consecutive occasions of service (OOS) of patients presenting during a 12 month period at a tertiary teaching hospital in Brisbane we identified patients with Functional gastrointestinal diseases (FGIDs), inflammatory bowel diseases (IBD) including Crohn's disease (CD) and ulcerative colitis (UC) and celiac disease (CeD). In addition, we included patients with cured hepatitis C infection as 'controls'. The records of patients with one of the above primary diagnoses documented in the electronic medical record were reviewed and assessed. At each OOS the patients had completed the validated Structured Assessment of Gastrointestinal Symptoms (SAGIS) to capture the severity of symptoms. SAGIS assesses the severity of symptoms on a 5-point scale with the 2 most severe defined as 'severe:...influence daily activity...' and 'very severe symptoms: . . .markedly influence daily activities and/or require rest...'. Prevalence rates and the 95% confidence intervals for postprandial pain, epigastric pain, constipation, diarrhea and, pain and discomfort during defecation and bloating were determined.
Results: Out of the total of 10,000 OOS, we identified 1,157 patients with CD, 936 with UC, 999 with FGIDs, 173 with cured HCV, 150 with GI cancers, 136 with CeD and 173 with cured HCV. The proportion of OOS when patients reported severe or very severe symptoms was highest in FGID patients. Even for symptoms that were frequently observed in patients with IBD (e.g. diarrhea, pain or urgency during defecation), the proportion of patients with severe or very severe symptoms was substantially higher in FGID patients.
Conclusion: The disease burden as measured by the proportion of patients reporting severe or very severe impairment of QoL by specific GI symptoms is highest in patients with FGIDs. Overall the symptom 'bloating' was reported by 40% of FGID patients as severely impacting QoL. The burden by the symptom diarrhea

Abstract No: P0564: Baseline characteristics and therapeutic outcomes in patients with anticoagulant therDOAC, direct oral anticoagulants; HBT, heparin bridge therapyapy

	Cured HCV (n = 173) n (95% CI)	Cancer (n = 150) n (95% CI)	Celiac disease (n = 136) n (95% CI)	CD (n = 1157) n (95% CI)	UC (n = 936) n (95% CI)	FGIDs (n = 999) n (95% CI)
Post prandial pain	4.0 (1.6–8.2)	14.0 (5.5–15.2)	8.8 (4.6–14.9)	9.5 (3.6–19.5)	4.8 (3.5–6.4)	28.7 (25.9–31.6)

Introduction: In western populations, increase of body mass index (BMI) has been shown after successful eradication of *H. pylori* infection. However, influence of *H. pylori* eradication on nutritional intake has not been well studied. Since Japanese health insurance system approved eradication therapy for all infected patients, there has been significant increase in the number of subjects who receive eradication of *H. pylori* without dyspeptic symptoms. The aim of this study was to investigate the influence of *H. pylori* eradication on nutritional metabolism considering daily nutritional intake in a Japanese population.
Aims and Methods: Healthy adults who received health survey both in 2012 and 2014 were entered into the study. We measured *H. pylori* stool antigen (Testmate EIS) and titer of serum antibody to *H. pylori* (E-plate). Subjects were considered as *H. pylori*-infected when positive stool antigen test and/or serum antibody titer >10 U/mL were observed. Non-infected subjects were defined as negative stool antigen test, serum antibody titer of <3 U/mL and without past history of eradication therapy. Patients who received successful eradication after the survey in 2012 and diagnosed as non-infected in 2014 were considered as eradicated group. Patients were extracted adjusting sex and age from subjects who were diagnosed as infected in both 2012 and 2014, as control (persistent infection) group. Subjects who were taking PPI and/or had previous history of gastric surgery were excluded. Daily intake of lipid and carbohydrate during one month prior to the survey was calculated using a brief-type comprehensive self-administered diet history questionnaire. Change of daily intake of nutrients, BMI, serum level of lipid and HbA1c were compared for between eradicated group and control group.
Results: Daily intake of lipid and carbohydrate was not different between 2012 and 2014 in both male and female in 33 eradicated patients and 66 control subjects. In female eradicated patients, BMI was significantly increased from 22.1±3.3 to 22.4±3.3 ($p=0.022$) while serum level of HDL-C and LDL-C decreased from 75.9±13.7 to 71.0±15.0 mg/dL and 125.8±26.2 to 119.3±27.9 mg/dL, respectively ($p=0.003$ and $p=0.021$). In eradicated male and control subjects, no significant change were observed in BMI and serum levels of lipid. HbA1c was not changed in both male and female in both groups.
Conclusion: In female subjects without dyspeptic symptoms, increase of BMI and decrease of serum level of HDL-C and LDL-C were observed after eradication of *H. pylori* without corresponding changes of daily intake of lipid and carbohydrate.

P0566 RACK1 IS A NEW REGULATOR IN THE NF-κB SIGNALING PATHWAY INDUCED BY *HELICOBACTER PYLORI* INFECTION

Y Hu[1], J.-P Liu[2], X.-Y Li[1], Y Cai[1], C Xie[1], C He[1], Y Zhu[1], N.-H Lu[1]
[1]*The First Affiliated Hospital of Nanchang University, Department of Gastroenterology, Nanchang, China*
[2]*Karolinska Institute, Huddinge, Sweden*

Contact E-Mail Address: 360041934@qq.com
Introduction: The receptor of activated protein kinase C 1 (RACK1, GNB2L1) is a 36-kDa cytosolic protein involved in multiple physiology and pathology processes. Recent reports indicated RACK1 was an anti-oncogene in gastric cancer. Herein, we aimed to investigate investigated the relationship between *Helicobacter pylori* (*H. pylori*) infection, proinflammatory NF-κB activation and RACK1.
Aims and Methods: The study used *in vivo* and *in vitro* experiments. TCGA data base analysis, tissue microarrays, luciferase reporter, quantitative real-time PCR, Western Blot, immunofluorescence, chromatin immunoprecipitation sequence, *H. pylori* infection, and immunohistochemical assays were used.
Results: TCGA analysis of gastric cancer indicated RACK1 protein level was lower in the *H. pylori* positive gastric cancer group in comparison with *H. pylori* negative gastric cancer group**.** Our results indicated that *H. pylori* infection increased RACK1 mRNA expression and decreased RACK1 protein levels in gastric cancer cells, gastric mucosa of mice and gastric cancer tissues. *H. pylori* infection increased the activity of NF-κB reporter and p-NF-κB (Ser 536) protein level in vitro and in vivo. Moreover, the overexpression of RACK1 inhibited the activation of NF-κB signaling pathway induced by *H. pylori* infection, as determined by Western Blot, PCR, luciferase reporter assays. Immunohistochemistry analysis demonstrated a significant positive correlation between IκBα and RACK1 expression levels ($r^2=0.762$, $p<0.01$) and a significant negative correlation between NF-κB and RACK1 expression levels ($r^2=0.762$, $p<0.05$) in gastric mucosa of mice.
Conclusion: RACK1 is a new regulator in NF-κB signaling pathway induced by *H. pylori* infection. The decreased expression of RACK1 following *H. pylori* infection and activation of NF-κB provides a link between infection, inflammation and gastric tumourigenesis.

P0567 ENTEROENDOCRIN CELL COMPARTMENT SIZE DECREASES DURING H. PYLORI INFECTION IN PATIENTS WITH INTESTINAL METAPLASIA BUT IS RESTORED AFTER ERADICATION

M Mommersteeg, M.C.W Spaander, M.J Bruno, E.J Kuipers, M Peppelenbosch, G Fuhler

Introduction: Gastric cancer, the fifth leading cause of cancer, develops following Correa's cascade: well defined steps involving several premalignant lesions, the most common of which is intestinal metaplasia (IM). The mechanism by which these premalignant lesions develop and progression is driven is still largely unknown. The largest risk factor for development of both IM and gastric cancer is infection with the pathogen Helicobacter Pylori (HP). One of the theories is that HP-associated inflammation causes a disbalance of gastric hormone levels by causing destruction of the somastatin-producing D-cell compartment. This in turn would cause a relative increase of gastrin which has several proliferative and pro-oncogenic effects. In this study we determine the effect of both HP and eradication on the enteroendocrine cell compartments of the antral stomach in patients with intestinal metaplasia.
Aims and Methods: Antral gastric biopsies were taken systematically in a surveillance cohort of patients with IM or gastric atrophy (PROREGAL Cohort). HP positivity was determined by serology and histology. Patients were scored as having active infection when histology was positive, and negative when both histology and serology were negative. Presence or absence of IM was scored by trained pathologist. We included 24 HP-naïve patients and 23 biopsies from patients infected with HP. Of the HP infected patients, also biopsies were obtained 1 year after successful eradication of HP. Immunohistochemical staining of G-cells and D- cells was performed using anti-gastrin and anti-somatostatin antibodies respectively. The number of positive cells per high power field were counted and intensity of staining was scored. Means of 4 biopsies were represented using the Allred score. Significance was determined using students T-test.
Results: As expected, antral biopsies from IM patients show patches of IM as well as normal crypts. In IM both the G-cell ($p<0.0001$) and D-cell ($p=0.0002$) compartments are reduced as compared to non-IM crypts. In patients infected with HP, total D-cell numbers were significantly reduced as compared to patients without HP ($p=0.0001$), in line with findings described in literature. Unexpectedly however, we also observed a significant reduction of G-cells in in patients with active HP infection ($p=0.0008$). Interestingly, 1 year after HP eradication, this reduction in enteroendocrine cell compartment size was no longer apparent and both D-cell and G-cell levels were normalized to the levels seen in patients that have never been infected. Enteroendocrine cell compartment size is not associated with either progression or regression of gastric premalignant lesions in this cohort.
Conclusion: These results confirm previous studies showing that HP infection causes a reduction in the antral D-cell compartment in IM crypts. However, we further demonstrate that this reduction is not restricted to D-cells, but also affects antral G-cells. After eradication of HP, enteroendocrine cell compartments return to sizes comparable to non-infected patients even though the gastric premalignant lesions persist. These results suggest that antral G-cell compartment size is likely of minor importance in early gastric carcinogenesis.
Disclosure: Nothing to disclose

P0568 PEPSINOGEN I/II RATIO IS AN EXCELLENT BIOMARKER TO ESTIMATE THE GRADE OF GASTRIC ATROPHY IN BOTH HELICOBACTER PYLORI-INFECTED AND NONINFECTED SUBJECTS: OPTIMAL CUTOFF POINT TO IDENTIFY SEVERE ATROPHIC GASTRITIS

Introduction: Atrophic gastritis is one of the most important clinical manifestations of *Helicobacter pylori* (HP) infection. To know grade of atrophic gastritis is valuable for estimating not only gastric cancer risk but also gastric acid-related diseases. Pepsinogen I is secreted by chief and mucous neck cells in the fundic glands, whereas pepsinogen II is also secreted by cells in the pyloric and Brunner's glands. When atrophic changes develop to the corpus, the level of pepsinogen I decreases, whereas the level of pepsinogen II remains high or stable. Therefore, pepsinogen I/II ratio decreases in a stepwise manner. We

aimed to evaluate the adequacy of measuring pepsinogen I/II ratio as a non-invasive maker of grade of atrophic gastritis.
Aims and Methods: A total of 959 consecutive subjects who underwent esophagogastroduodenoscopy and measurement of serum pepsinogen level at the same day were enrolled. To avoid the influence to pepsinogen levels, the following subjects were excluded; (1) those who had received successful HP eradication therapy in the past, (2) those who had undergone gastrectomy, (3) those who were taking proton pump inhibitors for various reasons, and (4) those having renal failure (Creatinine > 3.0 mg/dl). HP infection status was determined by the titer of serum HP IgG (E plate). Endoscopic grades of atrophic gastritis were classified into three groups: none to mild (C-0 and C-1), moderate (C-2 and C-3), and severe (O-1, O-2, and O-3) using the Kimura-Takemoto Classification. The correlation of pepsinogen I/II ratio with endoscopic grade of atrophic gastritis was analyzed by Kruskal-Wallis test. Receiver operating characteristic (ROC) curves were constructed to evaluate the ability of pepsinogen I/II ratio for discriminating endoscopic severe atrophic gastritis (≥ O-1 atrophy) and to extract the corresponding cutoff value for severe atrophic gastritis (≥ O-1 atrophy).
Results: The 959 enrolled subjects comprised 466 males, with a mean age of 52. Of the enrolled subjects, 236 had HP IgG positive test results, whereas the remaining 723 had HP IgG negative test results. Significant correlation between pepsinogen I/II ratio and endoscopic grade of atrophic gastritis was found in both HP infected- and non-infected-subjects ($p < 0.001$ in both comparisons). ROC curves were used to assess the diagnostic accuracy of pepsinogen I/II ratio for discriminating endoscopic severe atrophic gastritis. The areas under the curve (95% confidence intervals) were 0.93 (0.91–0.96) in the entire cohort, 0.81 (0.75–0.86) in the HP infected subjects, and 0.88 (0.80–0.95) in the HP noninfected subjects, respectively. In the HP infected subjects, a pepsinogen I/II ratio of 2.3 was indicated to be best cutoff value for predicting severe atrophic gastritis, with a corresponding sensitivity of 81.6% and specificity of 67.6%. Meanwhile, in the HP noninfected subjects, a pepsinogen I/II ratio of 4.9 was indicated to be best cutoff value for predicting severe atrophic gastritis, with a corresponding sensitivity of 73.1% and specificity of 87.5%.
Conclusion: We confirmed the presence of a significant correlation between pepsinogen I/II ratio and endoscopic grade of atrophic gastritis. In ROC analysis, pepsinogen I/II ratio is indicated to be an excellent biomarker to estimate the grade of atrophic gastritis. Clinical use of pepsinogen I/II ratio as a surrogate marker of gastric atrophy may be valuable for not only estimating the grade of atrophic gastritis but also assessing longitudinal changes in gastric atrophy of each patient.
Disclosure: Nothing to disclose

P0569 APPLICATION OF CONVOLUTIONAL NEURAL NETWORKS IN THE DIAGNOSIS OF *HELICOBACTER PYLORI* INFECTION STATUS BASED ON ENDOSCOPIC IMAGES

Introduction: We recently reported the role of artificial intelligence in the diagnosis of *Helicobacter pylori (H. pylori)* gastritis based on endoscopic images, and showed that the ability of the convolutional neural network (CNN) was comparable to experienced endoscopists, and diagnostic time was considerably shorter (*EBioMedicine* 2017). However that study includes only *H. pylori*-positive and negative cases, and excluded eradicated cases.
Aims and Methods: In this study, we constructed CNN, and evaluated its ability to diagnose *H. pylori* infection status, that is *H. pylori* positive, negative, or eradicated. We performed standard esophagogastroduodenoscopy (EGD) and captured esophagogastroduodenal mucosal images. Clinical diagnosis of *H. pylori* as reference standard was performed by blood or urine anti-*H. pylori* IgG levels, fecal antigen test, rapid urease test, or urease breath test. Patients who tested positive on any of these assays were classified as *H. pylori*-positive. Among patients who tested negative for the assays, those who had never received eradication therapy in the past were classified as *H. pylori*-negative. Those who had succeeded in eradication therapy were classified as *H. pylori*-eradicated. A deep CNN was pre-trained and fine-tuned on a dataset of 98564 images from 5236 patients (17432 images of 742 *H. pylori*-positive patients, 64934 images of 3649 *H. pylori*-negative patients, and 16198 images of 845 *H. pylori*-eradicated patients) obtained from December 2015 to April 2017. The CNN was trained using these images classified according to 8 anatomical locations of the stomach (cardia, upper body, middle body, lesser curvature, angle, lower body, antrum, and pylorus). A separate test data set (23699 images from 847 patients (70 *H. pylori*-positive, 493 *H. pylori*-negative, and 284 *H. pylori*-eradicated) obtained from May to June 2017) was evaluated by the CNN.
Results: The trained CNN output a continuous number between 0 and 1 as the probability index for *H. pylori* infection status per image (Pp for *H. pylori*-positive, Pn for negative, and Pe for eradicated. (Pp + Pn + Pe = 1). Most probable (largest number of Pp, Pn, and Pe) of the 3 infectious status was selected as the 'diagnosis of the CNN'. Among 23699 images, the CNN diagnosed as positive for 418, negative for 23034, and eradicated for 247 images, respectively. Among the 655 cases the CNN diagnosed negative for all the images, 466 cases (71%) were negative for *H. pylori*. While among the remaining 192 cases the CNN diagnosed as positive or eradicated for at least 1 image, 165 cases (86%) were positive or eradicated for *H. pylori*. As for the 119 cases the CNN diagnosed as eradicated for at least 1 image, 83 (70%) were *H. pylori*-eradicated. Time needed to diagnose 23699 images was 261 seconds.
Conclusion: *H. pylori* infection could be diagnosed based on endoscopic images using CNN in a considerably short time. It was suggested that the CNN can be introduced to aid endoscopists in diagnosing *H. pylori* infectious status.

Introduction: We aimed to assess THD fecal test diagnostic accuracy for detecting *Helicobacter pylori*, using ^{13}C-urea breath test as the reference standard. We additionally explored bacterial antibiotic resistance.
Aims and Methods: We conducted a prospective two-center diagnostic test accuracy study. We enrolled consecutive people ≥18 years without previous diagnosis of infection, referred for dyspepsia between February and October 2017. At enrolment, all participants underwent ^{13}C-urea breath test. Participants aged over 50 years were scheduled to undergo upper endoscopy with histology. Participants collected stool samples 1–3 days after enrolment for THD fecal testing. The detection of bacterial 23S rRNA subunit gene indicated infection. We also used the index diagnostic test to examine mutations conferring resistance to clarithromycin and levofloxacin. Independent investigators analyzed index test and reference test standard results blinded to the other test findings. We estimated sensitivity, specificity, positive (PPV) and negative (NPV) predictive value, diagnostic accuracy, positive and negative likelihood ratio (LR), together with 95% confidence intervals (CI).
Results: We enrolled 294 consecutive participants (age: median 37.0 years, IQR 29.0–46.0 years; men: 39.8%). 95 (32.3%) participants had a positive^{13}C-urea breath test. 23 (7.8%) participants older than 50 years performed upper endoscopy with histology. There was full concordance between ^{13}C-urea breath test and histology in detecting *Helicobacter pylori* infection in these participants. THD fecal test sensitivity was 90.2% (CI:84.2%–96.3%), specificity 98.5% (CI:96.8%–100%), PPV 96.5% (CI:92.6%–100%), NPV 95.6% (CI:92.8%–98.4%), accuracy 95.9% (CI:93.6%–98.2%), positive LR 59.5 (CI:19.3–183.4), negative LR 0.10 (CI:0.05–0.18). Out of 83 infected participants identified with the THD fecal test, 34 (41.0%) had bacterial genotypic changes consistent with antibiotic-resistant *Helicobacter pylori* infection. Of these, 27 (32.5%) had bacterial strains resistant to clarithromycin, 3 (3.6%) to levofloxacin, and 4 (4.8%) to both antibiotics.
Conclusion: The THD fecal test has high performance fornon-invasive diagnosis of *Helicobacter pylori* infection while additionally enabling assessment of bacterial antibiotic resistances.
Disclosure: We thank THD Spa, Correggio (Italy), for providing free of charge THD fecal test for all participants included in the study.

P0571 ENDOSCOPIC DIAGNOSIS OF *HELICOBACTER PYLORI* BASED ON THE ARRANGEMENT OF COLLECTING VENULES IN A EUROPEAN POPULATION

Contact E-Mail Address: mgfernan@clinic.ub.es
Introduction: *Helicobacter pylori* (Hp) is the major cause of gastritis and gastritis-associated diseases. The development of high definition endoscopy in recent years has allowed a better characterization of the gastric mucosa and the identification of endoscopic findings that correlate with the diagnosis of Hp. One of the features that has shown better results is the detection of a regular arrangement of collecting venules (RAC) of the mucosa in the lower part of the gastric body. The presence of RAC has a sensitivity and negative predictive value (NPV) higher than 90% in Hp uninfected patients, but most of the studies have been conducted in Asian population and we do not know their reproducibility in our population.

Aims and Methods: The aim of the study was to evaluate the value of the arrangement of collecting venules as a diagnostic method of Hp infection in our population.
Secondary objective was to assess whether age, sex, concomitant antiplatelet therapy, anticoagulants or non-steroidal anti-inflammatory drugs, or history of Hp eradication modify the prevalence of the infection. Retrospective analysis of a prospectively collected database of patients who underwent upper gastrointestinal endoscopy from February 2017 to March 2018. The inclusion criteria were: age over 18 years, absence of treatment by proton pump inhibitors in the last 10 days and absence of a history of gastrectomy, gastric lymphoma or portal hypertension. We excluded those patients with presence of blood or food in gastric lumen that precluded an adequate exploration of the mucosa.
Explorations were performed with high-definition endoscopes by three expert endoscopists and under sedation by anesthesiologist. The RAC pattern was defined as the presence of starfish-like minute points regularly distributed throughout the lesser curvature of the gastric body. We considered significative endoscopic findings the presence of erosive gastroduodenal lesions, atrophic gastritis, intestinal metaplasia and gastric polyps. Pictures were taken during the procedure. The gold standard tests for Hp infection were the anatomopathological study and/or rapid urease test.
Results: 111 patients were included with an Hp infection rate of 29.73%. 37 of 111 patients (33.3%) presented a RAC pattern. No differences were observed in RAC prevalence regarding to sex, concomitant treatment or previous history of Hp eradication. In contrast, the mean age of patients with RAC pattern was lower (45 vs 53 years, $p = 0.01$) and had less significative endoscopic findings (43% vs 65%, $p = 0.03$).
None of the patients with Hp presented RAC pattern. Contrarily, the RAC pattern was observed in all uninfected patients. Performance characteristics endoscopic diagnosis of Hp based on the arrangement of collecting venules pattern were: sensitivity 100% (CI 87%–99,7%), specificity 47.4% (CI 36.1%–59%), negative predictive value 100% (CI 88.3%–99.7%) and positive predictive value 44.6% (CI 33.2%–56.6%).
Conclusion: Careful observation of the gastric mucosal pattern in lower curvature with high-definition endoscopy can accurately predict Hp uninfected cases when RAC is present, avoiding the obtention of biopsies.
Disclosure: Nothing to disclose

Introduction: According to current clinical guidelines, the stool antigen test (SAT) may be an alternative method to the urea breath test (UBT) to diagnose *Helicobacter pylori (H. pylori)* infection, provided a monoclonal laboratory test (ELISA) is used. Since 2015 the Monolab Test, which is not an ELISA test but an immunochromatographic monoclonal test, has been incorporated to our regional health system.
Aims and Methods: The aim of the present study was to compare the diagnostic accuracy of SAT Monolab Test and UBT, considering UBT the gold standard. A prospective multicentre study (Hospital Reina Sofia in Tudela -HRS- and Complejo Hospitalario de Navarra in Pamplona -CHN-) was performed in consecutive patients since November 2016 (HRS) and June 2017 (CHN) until October 2017. All patients who were submitted to gastroenterology outpatient clinic to perform a UBT according to standard clinical practice were enrolled and SAT Monolab was simultaneously determine. Sensitivity, specificity and negative and positive predictive values (NPV and PPV respectively) adjusted to prevalence were determined, and SAT accuracy was compared with UBT.
Results: 450 patients, 183 CHN and 267 HRS were included, with the features detailed in table 1. Both tests were performed for initial diagnosis of infection in 230 cases and to check the efficacy of eradication treatment in 220. The prevalence of *H. pylori* infection was 35% before treatment and 12% after eradication therapy. Concordance between AST Monolog and UBT was 78% (sensitivity 82%, specificity 77%), with a kappa index of 0.51 (moderate concordance). Before treatment, NPV was 66% and PPV 89%, whereas after eradication therapy PPV was of 34% and NPV 97%.
Conclusion: Compared with the diagnostic reference test, UBT, the AgH Monolab test differs in the diagnosis of *H. pylori* infection in up to 22% of patients. There is a striking amount of false positives, which is increased especially in patients evaluated after eradication treatment.

	Hospital Reina Sofia	Complejo Hospitalario de Navarra	Total

P0573 PHOTOMETRY OF RAPID UREASE TEST FOR DIAGNOSTICS OF *HELICOBACTER PYLORI* IN PATIENTS WITH DYSPEPTIC SYMPTOMS

B Starostin[1]
[1]*Sun Pharmaceutical Industries Ltd., Clinic, Gastroenterology, St.-Petersburg, Russian Federation*

Contact E-Mail Address: starostinbd@mail.ru

Introduction: Eradication of *H. pylori* significantly reduces the risk of stomach cancer and prevents the development of rebleeding. Rapid urease test allows well-timed and adequate diagnosis of *H. pylori* in patients with dyspeptic symptoms to be performed achieving correct evaluation of the results of the eradication after treatment. There is now the digital rapid urease test with photometry available that excludes possible errors of the visual evaluation of the test results.
Aims and Methods: The diagnostics by the new rapid urease test photometer that allows to trace kinetics of the enzyme activity through multiple readings of the test-slides was compared with the validated visual-evaluation rapid urease test. The two-center study with the total of 585 patients (female 344 and male 241, age 55.1±13.3 years) having symptoms of dyspepsia was performed. All of the patients underwent endoscopy of the upper gastrointestinal tract and histological examination in accordance with the OLGA classification. In cases of discrepancy, the results of the histological examination, stool-PCR test and ^{13}C UBT were used as a reference. 2 biopsy samples of the same localization were taken to perform the 2 rapid urease tests: 1 for AMA RUT Expert with AMA RUT Reader, AMA Co Ltd. and 1 for *Helicobacter Pylori* Quick Test, Biohit Oyj.
Results: *H. pylori* was detected in 204 patients - 34.9%. In the group of patients ($n = 283$), who haven't had anti-helicobacter therapy (naive), 52% of patients ($n = 147$) showed positive results for *H. pylori*, as detected by AMA RUT Expert. In the group of patients ($n = 302$), previously subject to various forms of eradication therapy, *H. pylori* was detected in 21% of patients (63 patients). In all cases of discrepancy where the Quick Test showed positive and AMA RUT Expert showed negative, the results of the 3 reference methods confirmed absence of *H. pylori*. In 23 cases where AMA RUT Expert was positive and the Quick Test negative, the reference methods of histology and stool-PCR proved the presence of the infection in 21 patients. Histologically *H. pylori* was detected in 237 patients, of which AMA RUT Expert revealed the presence of *H. pylori* urease activity in 234 patients. The sensitivity of AMA RUT Expert was 98.7% and the specificity was 100%, the accuracy was 99.4%. Thus our study revealed higher sensitivity and specificity of AMA RUT Expert compared to the Quick Test (98.4% vs 93.6% and 100% vs 87.8%). Meta-analysis of studies evaluating the sensitivity and specificity of various visual-evaluated rapid urease tests has shown their sensitivity ranging from 56.3 to 97.4%, with an average of 89.9%. The specificity of different rapid urease tests ranged from 70 to 100%, with an average of 94.4%. Differences for sensitivity and specificity were statistically significant at $p < 0.001$.
Conclusion: The results obtained by the AMA RUT Expert test-slides with the AMA RUT Reader showed higher values of diagnostic sensitivity and specificity than those in the visual-evaluated rapid urease tests, both in our study and in the data of meta-analysis. To achieve the most accurate diagnostics of *H. pylori* in patients with dyspeptic symptoms it is recommended to routinely use the photometry of the enzymatic reaction. Nothing to disclose

P0574 MEDICATION DIARY CARD ON THE ERADICATION RATE AND SYMPTOM REMISSION OF PATIENTS INFECTED BY *HELICOBACTER PYLORI*

M Shen, J Li, L.-N Meng, B Lv
The First Affiliated Hospital of Zhejiang Chinese Medical University, Gastroenterology, Hangzhou, China

Contact E-Mail Address: s167725@163.com

Introduction: *H.pylori* is closely related to the genesis of diseases such as chronic active gastritis, peptic ulcer and gastric cancer [1–2]. Typically, about $< 1\%$ of patients infected by *H.pylori* will finally develop into intestinal-type gastric cancer [3–4]. Guideline emphasizes that, the major objective of eradicating *H.pylori* is to reduce the incidence risk of gastric cancer [5]. Therefore, eradicating *H.pylori* is the important measure for preventing intestinal-type gastric cancer. Moreover, the rates of *H.pylori* resistance to drugs are increasing in recent years, the eradication rate of standard triple therapy is lower than 80% [6]. Additionally, relaxed mastering of clinical eradication indications, irregular therapeutic scheme and patient compliance difference have added to the difficulties in eradication. Consequently, informing the patients of *H.pylori* eradication guidance in the manners of the medication method, time and filling in the medication diary card can increase patient understanding to *H.pylori* therapeutic scheme, then improve compliance, raising the *H.pylori* eradication rate and relieving the clinical symptoms.

Aims and Methods: We aimed to explore the influence of eradication rate of *Helicobacter pylori* (*H.pylori*) and symptom remission by means of distributing medication diary cards and giving medication guidance.

The current study was a prospective randomized controlled clinical observational study, and treatment-naive patients diagnosed with chronic gastritis accompanying with *H.pylori* infection through gastroscopy and histopathology were selected as the objects of study. Specifically, the bismuth-based quadruple standard eradication regimen was adopted for patient treatment. Patients conforming to the inclusion criteria had signed the informed consent before they were randomly divided into the record group and the control group. In addition, all patients were informed of the dose, time, precautions and potential adverse reactions in details by designated physicians. The control group was given the above education only, while the record group was given a diary card covering the detailed medication method upon the completion of education, which asked the patients to record their time, dose and adverse reactions during medication. Moreover, the patients should return their medication diary cards upon the end of treatment. Besides, both groups were carried out ^{13}C or ^{14}C urea breath test (UBT) 28 days after withdrawal to evaluate the eradication of *H.pylori*.

Results: A total of 120 patients conforming to the inclusion criteria were enrolled in the current study, including 60 in the record group and 60 in the control group. The eradication rates of *H.pylori* in 2 groups were 91.67% (55/60) and 73.33% (44/60), respectively, analyzed using intention-to-treat (ITT), while those were 93.2% (55/59) and 80.0% (44/55), respectively, analyzed using perprotocol population (PP). Difference in eradication rate between record group and control group was statistically significant ($p = 0.008$, $p = 0.037$). Difference in symptom scores between 2 groups before treatment was not statistically significant ($p > 0.05$). Comparing the total response rate between 2 groups after treatment, symptoms in record group after treatment had remarkably improved relative to those in control group ($p = 13.348$, $p < 0.001$).

Conclusion: Distributing the medication diary cards to inform the patients to take medicine as required can improve the medication compliance of patients. Favorable medication compliance can markedly improve the eradication rate of *H.pylori* and evidently improve the clinical symptoms.

Disclosure: Nothing to disclose

P0575 THE EFFECT OF PERIODONTAL THERAPY FOR GASTRIC *HELICOBACTER PYLORI* ERADICATION: A PROSPECTIVE RANDOMIZED CONTROLLED CLINICAL TRIAL IN THAILAND

T Tongtawee[1,2]
[1]*School of Medicine, Surgery, Nakhon Ratchasima, Thailand*
[2]*Suranaree University of Technology, Surgery, Nakhon Ratchasima, Thailand*

Contact E-Mail Address: taweesak.t@sut.ac.th

Introduction: Chronic gastritis associated *H. pylori* infection was found in 50% of the global population and was etiologically relative gastric cancers (63%) or approximately 5.5% of all cancers worldwide, and account for 25% of cancers related with etiology of infection; and is a main public health problem. The recurrence rate is relatively high and still a main public health problem. Oral cavity may be a potential reservoir for gastric infection and transmission.

Aims and Methods: This study aims to evaluate the association between *H. pylori* in the oral cavity and stomach and to investigate the possible way of their treatment in Thailand. Patients were enrolled for 1-week triple therapy (esomeprazole 20 mg bid, clarithromycin 500mg bid, or metronidazole 400mg tid if clarithromycin resistant and amoxicillin 1000 mg bid; group 1, $n = 347$) and triple therapy plus periodontal therapy (group 2, $n = 342$). After completion of therapeutic protocol, stool antigen tests, the rapid urease test and histopathological examination were performed and finally proved by PCR.

Results: A total 689 patients with *H. pylori* associated gastritis patients who underwent EGD at Suranaree University of Technology Hospital. The 16S rRNA and ureA genes were detected in all 689 (100 %) gastric biopsy samples while was detected in oral cavity samples 549 (79.7%) of the 689 patients. The association was observed between oral cavity *H. pylori* and gastric biopsy *H. pylori* ($p = 0.007$).*H. pylori* treatment plus periodontal therapy significantly decreased the recurrence rate of *H. pylori* infection compared with gastric *H. pylori* treatment alone (OR 2.48; 95% CI 1.52 to 5.68; $p = 0.001$) by PP analysis, whereas the eradication rate was not significant differences (OR 0.91; 95% CI 0.87 to 1.13; $p = 0.091$). ITT analysis showed that, the recurrence rate was significantly different between the 2 groups (OR 2.28; 95% CI 1.29 to 4 .75; $p = 0.001$) while the eradication rate was not significant differences (OR 0.96; 95% CI 0.67 to 1.25; $p = 0.083$).

Conclusion: The association between oral cavity *H. pylori* and gastric biopsies *H. pylori* was observed, suggests that oral cavity might be considered as a potential reservoir for gastric *H. pylori* infection and re-infection. Therefore, periodontal therapy should be given to patients. This could be a promising approach for diminishing *H. pylori* infection and reducing the risk of *H. pylori* recurrence in this re-infection associated gastritis.

P0576 EVALUATION OF BACKGROUND FACTORS AFFECTING THE SUCCESS RATE OF FIRST-LINE TRIPLE THERAPY WITH VONOPRAZAN FOR *HELICOBACTER PYLORI* INFECTION

H Tamaki[1], T Noda[1], M Morita[1], A Omura[1], A Kubo[1], C Ogawa[1], T Matsunaka[1], M Shibatoge[1]

Contact E-Mail Address: h-tama@gc4.so-net.ne.jp

Introduction: Recent studies have reported the superior efficacy of vonoprazan (VPZ) compared to that of proton pump inhibitors (PPIs) in first-line triple therapy for *Helicobacter pylori* (HP) infection. However, it is considered that there remains room for improvement because the eradication rate of triple therapy with VPZ in usual post-marketing studies was reported to be lower than that in a phase III study.

Aims and Methods: In the current study, we determined background factors affecting the success rate of first-line triple therapy with PPIs or VPZ to identify those that contribute to the improvement of the eradication rate. The relation between success rate of first-line triple therapy with PPIs (PPI group) or VPZ (VPZ group) and background factors (age, sex, body mass index [BMI], clarithromycin [CAM] resistance of HP determined by a microbial sensitivity test, a history of endoscopic treatment for early gastric cancer, Brinkman index, weekly amount of alcohol intake, daily amount of coffee intake, and estimated glomerular filtration rate [eGFR]) was retrospectively evaluated in 704 patients with HP infection treated between August 2014 and December 2017.

Results: A total of 704 patients (383 men, 321 women; mean age, 62.5 years [range 27–89 years]; PPI group, 369; VPZ group, 335) were enrolled in the study. The first-line eradication rate was significantly higher in the VPZ group than in the PPI group (77.5% vs. 86.6%, $p = 0.002$) and significantly lower in patients infected with CAM-resistant HP than in those infected with CAM-sensitive HP (PPI group, 57% vs. 88.0%, $p < 0.01$; VPZ group, 79.5% vs. 89.8%, $p = 0.02$). A multiple logistic regression analysis showed that the odds ratios (ORs) for CAM-resistant HP infection to CAM-sensitive HP infection for successful eradication in the PPI and VPZ groups were 0.18 (95% CI, 0.10–0.34; $p < 0.001$) and 0.41 (95% CI, 0.19–0.86; $p = 0.019$). In the PPI group, the eradication rate was significantly lower among patients with a high eGFR ($\geq$100 ml/min/1.73 m^2; $n = 52$ [14.1%]) than in the others (59.6% vs. 80.6%, $p < 0.001$) and the OR for patients with a high eGFR compared to that in the others was 0.33 (95% CI, 0.15–0.69; $p = 0.004$), as shown by the multiple logistic regression analysis. In contrast, there was no significant difference in the eradication rate between patients with a high eGFR and the others in the VPZ group. On the other hand, the eradication rate in the VPZ group was significantly lower in the patients whose alcohol intake was more than 140 g/week than in the patients whose alcohol intake was 140 g/week or less (78.5% vs. 88.6%, $p = 0.004$) and the OR for the patients whose alcohol intake was more than 140 g/week compared to that in the others was 0.25 (95% CI, 0.11–0.57; $p = 0.001$), as shown by the multiple logistic regression analysis.

Conclusion: In contrast to the eradication rate of first-line triple therapy with PPIs, the eradication rate of first-line triple therapy with VPZ for HP infection was not affected by a high eGFR (≥100 ml/min/1.73 m^2). Alcohol restriction to or less than 140 g/week can contribute to the improvement in the eradication rate of first-line triple therapy with VPZ.

P0577 THE IMPACT OF *HELICOBACTER PYLORI* ERADICATION ON THE NUTRITIONAL HEALTH IN HEMODIALYSIS PATIENTS

A Majima, Y Sawai, Y Tomita, N Watanabe, K Shigemori, T Morisawa, T Yoh, H Ishikawa, N Akamatsu
Omihachiman Community Medical Center, Omihachiman, Japan

Contact E-Mail Address: a-majima@koto.kpu-m.ac.jp
Introduction: Previous study showed that nutritional condition was a strong predictor of overall mortality in patients with end-stage renal failure on maintenance hemodialysis (HD patients), which indicates that maintaining favorable nutritional condition is vitally important for HD patients in which malnutrition is common. It has been also reported that *Helicobacter pylori* (*H.pylori*) infection negatively affected the absorption of nutrients and the production of hormones related to the appetite and growth, which indicates that *H.pylori* infection has potential to be one of the causes of malnutrition. Therefore, *H.pylori* eradication can be a strategy for improving nutritional condition of HD patients infected with *H.pylori*. However, the relationship between *H.pylori* eradication and the nutritional health in HD patients is still unknown.
Aims and Methods: The aim of this study was to clarify the effect of *H.pylori* eradication on the nutritional health in HD patients. HD patients who were infected with *H.pylori* and achieved successful *H.pylori* eradication at Omihachiman Community Medical Center between January 2012 and December 2017 were investigated retrospectively. All patients included in this study were received triple therapy comprising amoxicillin or metronidazole, clarithromycin and proton pump inhibitor twice daily for 1 week. *H.pylori* negativity after eradication therapy was confirmed by urea breath test in 2 months or later since eradication. Nutritional condition was evaluated using the Geriatric Nutritional Risk Index (GNRI: 14.89 × serum albumin, g/dL + 41.7 × dry weight/ideal body weight). The change of GNRI in 6 months before *H.pylori* eradication (ΔGNRI-pre6: GNRI at eradication - GNRI at 6 months before eradication) was compared with that in 6 months and 12 months after eradication (ΔGNRI-post6: GNRI at 6 months after eradication - GNRI at eradication, ΔGNRI-post12: GNRI at 12 months after eradication - GNRI at eradication).
Results: A total of consecutive 14 patients were analyzed. Subjects comprised 10 men and 4 women with a mean age of 60.1±8.5 years. The mean values of GNRI/serum albumin around *H.pylori* eradication were 94.5±7.5/3.79±0.37 (6 months before eradication), 93.9±7.4/3.74±0.38 (at eradication), 96.7±6.2/3.94±0.37 (6 months after eradication), and 95.6±6.0/3.85±0.28 (12 months after eradication). The mean values of ΔGNRI-pre6/ΔGNRI-post6/ΔGNRI-post12 were −0.64±3.0/2.87±6.0/1.70±5.0, which showed that GNRI tended to increase after successful *H.pylori* eradication (ΔGNRI-pre6 vs ΔGNRI-post6, $p = 0.11$: ΔGNRI-pre6 vs ΔGNRI-post12, $p = 0.24$). The mean values of ΔGNRI-pre6/ΔGNRI-post6/ΔGNRI-post12 in 11 patients whose GNRI at eradication was < 98 (having nutritional risk) were 0.95±2.6/4.74±4.7/3.25±3.6, which showed that GNRI in patients having nutritional risk significantly increased after successful *H.pylori* eradication (ΔGNRI-pre6 vs ΔGNRI-post6, $p = 0.006$: ΔGNRI-pre6 vs ΔGNRI-post12, $p = 0.02$).
Conclusion: The present study showed that eradication therapy of *H.pylori* improved the nutritional health in HD patients, especially having nutritional risk, which may contributes to extend a life prognosis of HD patients.

P0578 COMPARISON OF STANDARD, SEQUENTIAL, AND CONCOMITANT FIRST-LINE ERADICATION THERAPY FOR *HELICOBACTER PYLORI*

E.H Park
The Catholic University of Korea College of Medicine, Seoul, Korea., Division of Gastroenterology, Department of Internal Medicine, Seoul, Korea (Republic of)

Contact E-Mail Address: grape13101@naver.com
Introduction: Approximately 50% of world's population is infected with *Helicobacter pylori*. In developing countries, the prevalence has been reported to be as high as 70%. As *H. pylori* can be a major cause of gastric diseases such as chronic gastritis, gastroduodenal ulcers, mucosa-associated lymphoid tissue (MALT) lymphoma, and gastric cancer, eradication of *H. pylori* infection is important. However, the eradication rates after fist-line standard triple therapy have continuously decreased, mainly because of the widespread development of antibiotic resistance, particularly towards clarithromycin. In fact, many guidelines recommend alternative regimens such as sequential and concomitant therapy.
Aims and Methods: We compared the efficacy, adverse events, and drug compliance of standard triple, sequential, and concomitant therapy for *H. pylori* eradication. This was a prospective study involving 750 patients diagnosed with *H. pylori* infection between January 2014 and July 2016 in Yeouido St. Mary's Hospital. Diagnosis was made by rapid urease test (CLO test) or histological evidence of *H. pylori* via modified Giemsa staining. We compared 3 treatment regimens: the standard triple therapy (250 patients enrolled) consisted of rabeprazole 20 mg, amoxicillin 1 g, and clarithromycin 500 mg twice a day for 7 days; the sequential therapy (250 patients enrolled) consisted of rabeprazole 20 mg, amoxicillin 1 g twice a day for the initial 5 days, followed by rabeprazole 20 mg, clarithromycin 500 mg, and metronidazole 500 mg twice a day for the subsequent 5 days; the concomitant therapy (250 patients enrolled) consisted of rabeprazole 20 mg, amoxicillin 1 g, clarithromycin 500 mg, and metronidazole 500 mg twice a day for 7 days. 6 weeks following completion of therapy, successful *H. pylori* eradication was defined by a negative ^{13}C-urea breath test result. Adverse events and drug compliance were evaluated by physicians via direct questioning. 103 patients did not complete the study because of loss of follow-up or withdrawal of consent.
Results: A total of 647 patients (209, 211, and 227 patients in the standard triple, sequential, and concomitant therapy groups, respectively) were analyzed. The mean age of the patients was 55.7 years. There were 365 male and 282 female patients (male:female ratio = 1.29). The baseline characteristics were not significantly different between the 3 groups. The eradication rate was significantly higher in the concomitant group (89.4%, 203/227) than in the standard group (78.5%, 146/209) and the sequential group (85.3%, 180/211) ($p = 0.006$). Drug compliance and adverse events were not statistically different among the 3 groups.
Conclusion: Concomitant therapy appears to be more effective for *H. pylori* eradication compared to standard triple therapy and sequential therapy. There were no statistically different adverse events among the three groups.
Disclosure: Nothing to disclose

P0579 SUSCEPTIBILITY-BASED TAILORED VS. EMPIRIC AMOXICILLIN MODIFIED BISMUTH QUADRUPLE THERAPY AS *HELICOBACTER PYLORI* THERAPY: A MULTICENTER RANDOMIZED CONTROLLED TRIAL

Introduction: The increase in *Helicobacter pylori* (*H. pylori*) resistance to antibiotics and unsatisfactory efficacies of common empirical eradication regimens suggest that susceptibility-based tailored therapy may be required to achieve high efficacy.[1,2] Previous studies showed that substitution of amoxicillin for tetracycline was highly effective making modified bismuth quadruple therapy an option for first line therapy in China. [3,4]
Aims and Methods: This randomized, open-label, superiority, multi-center trial aimed to compare the eradication rates, safety and adherence of susceptibility-based tailored therapy with empiric bismuth quadruple therapy in treatment-naive patients with *H. pylori* infection. Subjects were randomized in 2 groups by 3:1 ratio: a) tailored therapy, according to antibiotic resistance pattern included esomeprazole 20mg bid, amoxicillin 1g bid, with a third drug (clarithromycin 500mg bid, metronidazole 400mg bid, or levofloxacin 500mg qd) for susceptible strains, or with bismuth 220mg bid plus metronidazole 400mg qid for triple-resistant strains; b) empiric therapy included esomeprazole 20mg bid, bismuth 220mg bid, amoxicillin 1g tid, and metronidazole 400mg tid. All regimens were given for 14 days. Antimicrobial susceptibility was assessed by the agar dilution method. Primary outcomes were *H. pylori* eradication rates. This trial was registered with ClinicalTrials.gov, NCT02935010.
Results: Between February 2017 and March 2018, 491 subjects were screened for eligibility; 382 were randomized in the study. The baseline characteristics were balanced between the 2 groups (Table 1). The intention-to-treat and per-protocol cure rates were 91.6% (262/286, 95% CI 88.4–94.8%) and 97.7% (250/256, 95.8–99.5%) for tailored therapy vs. 85.4% (82/96, 78.4–92.5%) and 97.6% (81/83, 94.3–100%) for empiric therapy. Tailored therapy was not superior to empirical therapy either in ITT analysis (Difference 6.2%, 95% CI −0.3–12.7%, $p = 0.059$) or in PP analysis (Difference 0.1%, −3.1–3.2%, $p = 0.486$). According to antimicrobial susceptibility, tailored therapy eradicated 99.4% (159/160) clarithromycin, 100% (11/11) metronidazole, 100% (27/27) levofloxacin susceptible strains, and 91.4% (53/58) triple-resistant strains respectively. Empiric therapy eradicated 100% (13/13) metronidazole susceptible and 97.1% (68/70) resistant strains. Both tailored therapy and empirical therapy achieved high adherence and low adverse event rates. The eradication rate of subjects with poor adherence was lower than subjects with good adherence, but a significate difference was only observed in empiric therapy (25%, 1/4 vs. 97.6%, 81/83, $p < 0.001$) but not in tailored therapy (85.7%, 12/14 vs. 97.7%, 250/256, $p = 0.058$).
Conclusion: In settings of high and multiple antibiotic resistances of *H. pylori*, susceptibility-based tailored therapy provided excellent results with 14-day PPI triple therapies being optimal choices for susceptible strains. However, empiric

Introduction: Vonoprazan (VPZ) is a novel potassium-competitive acid blocker, which has higher eradication rates comparing with PPI-based therapy. However, in Japan, there are still many patients who failed both first-line therapy using clarithromycin and second-line therapy using metronidazole. Sitafloxacin (STFX) has been shown as a preferable agents in third-line therapy in combination with amoxicillin (AMOX) and PPI. The aim of this study was to investigate the efficacy of triple therapy of VPZ, AMOX and STFX for the third-line therapy.
Aims and Methods: During April 2015 and December 2017, a total of 74 patients who had failed both first-line and second-line therapy were enrolled. If agreed, patients underwent endoscopy to obtain *H. pylori* strains to test the susceptibility to antibiotics if they agreed. VPZ (20 mg bid), AMOX (750 mg bid) and STFX (100 mg bid) were administered for 1 week and the result was tested by ^{13}C-UBT or stool antigen test 6–10 weeks after finishing the treatment.
Results: No major adverse effects were seen and all patients completed the regimen except for 1 patient who did not visit again for the evaluation. Eradication rate of VPZ-AMOX-STFX was 90.5% (67/74; 95% CI, 83.9–97.2%) and 91.8% (67/73; 85.5–98.1%) in ITT and PP analysis, respectively. Antibiotics susceptibility test was available in 29 patients. Eradication was not successful in 3 patients whose strains had MICs of STFX 0.5≤ mg/mL. In contrast, eradication was successful in 26 patients infected with strains which had MICs of STFX < 0.5 mg/mL.
Conclusion: Triple therapy of VPZ, AMOX and STFX would be an effective third-line *H. pylori* eradication therapy in Japan. Low susceptibility to STFX would be a major cause of the treatment failure.
Disclosure: Nothing to disclose

P0581 CHANGE IN HALITOSIS VALUE AFTER *HELICOBACTER PYLORI* ERADICATION: A SINGLE INSTITUTIONAL PROSPECTIVE ANALYSIS

Y Kudo[1], S Kudo[2], H Miyachi[3], K Ichimasa[2], K Suzuki[2], Y Kouyama[2], T Sakurai[2], Y Ogawa[2], T Gotoda[4]

Introduction: Eradication therapy for *Helicobacter pylori* (*H. pylori*) infection is widely performed. Although patients may report that their halitosis has either improved or worsened after eradication therapy, these complaints are subjective. In addition, there are no objectively evaluated reports of changes in halitosis after *H. pylori* eradication.
Aims and Methods: The aim of this study was to investigate changes in halitosis after *H. pylori* eradication. Between February 2015 and March 2016, a total of 5,514 patients visited the Kudo Clinic. Of these, 174 were found to be infected with *H. pylori*. Informed consent for participation in this study was obtained from 71 patients. We assessed halitosis before and 2 months after eradication, and compared the changes. If primary eradication was unsuccessful, secondary therapy was performed. Halitosis values were measured after successful eradication was confirmed with urea breath testing. Halitosis values were evaluated with a Total Gas Detector^{TM} System (Refres HR BAS-108; Adonis Electronics Co., Ltd., Osaka, Japan). The ethics committee of the Kudo Clinic approved this study protocol (Approval number; 2015-01).
Results: Among the 71 patients (18 [25.4%] males and 53 [74.6%] females), 68 completed treatment and had successful eradication. The average age was 64.2 ± 10.5 years old. The Breath Refres Values were 49.4±21.4 before eradication and 52.2±26.4 after successful eradication, and did not decrease significantly (p = 0.55). Within the 27 patients whose Breath Refres Values showed more than 60, those improved significantly form 73.0±10.7 to 61.3±28.2 (p = 0.037).
Conclusion: Among the patients whose Breath Refres Values was high, their halitosis improved after successful eradication. Further examination will be necessary by increasing the number of cases.

Introduction: Amongst the several factors that can affect the efficacy of anti *H. pylori* therapy, resistance to antimicrobials remains the most critical one. Despite this, in only few studies has antimicrobial susceptibility testing performed and there is uncertainty regarding the minimum number of resistant strains that need to be tested in order to get reliable information on the effectiveness of a given eradication regimen in patients harboring those strains.
Aims and Methods: During a 5-year study, we tried to identify a minimum number of patients to study to get a reliable estimate of effectiveness of a given treatment (namely sequential therapy) in patients harboring resistant strains. Consecutive 1682 naïve *H. pylori*-positive patients were studied between 2010 and 2015, and resistances to clarithromycin, metronidazole and levofloxacin assessed by E-test according to the EUCAST guidelines. Sequential therapy was offered and effectiveness evaluated 6 weeks after the end of the treatment. To identify a minimum number of patients to study to get a reliable estimate of effectiveness of sequential therapy in patients harboring resistant strains, a bootstrap analysis was firstly performed. Patients who completed the follow-up were sub-grouped according to the pattern of antimicrobial susceptibility/resistance, considering clarithromycin and metronidazole. For each of these groups, the effect of sampling across the range 10–300 patients was explored based on 500 samples drawn. This allowed the calculation of the variance in eradication estimates to be made for each level of sampling. These parameters were then used to calculate the power of each sample to detect the parent population eradication rate with a margin of error of +/- 1%, assuming a two-sided a-value of 0.05. Afterwards, the estimated minimum sample needed to give consistent results was calculated for theoretical eradication rates ranging from 50% to 95% assuming that the results would follow a standard binomial distribution and choosing a margin of error of +/- 5%, and a value of alpha of 0.05.

Abstract No: P0582: Bootstrap analysis

Characteristics of the Parent Populations

	Cla-S & Metro-S (n = 527)	Cla-S & Metro-R (n = 152)	Cla-R & Metro-S (n = 151)	Cla-R & Metro-R (n = 236)
Eradication rate	97.3% (95% CI: 95.6 to 98.4)	96.1% (95% CI: 91.7 to 98.2)	93.4% (95% CI: 88.2 to 96.4)	83.1% (95% CI: 77.7 to 87.3)
	Sample Size Estimated for each Pattern of susceptibility/resistance evaluated with the bootstrap analysis			
Power	Sample Size (n)			
99%	39	49	71	97
90%	25	30	40	61
80%	19	21	32	43

Results: 45.0% (95% CI: 42.3–47.7) of strains were susceptible to both agents. In the remaining 55% (95% CI: 52.3–57.7), resistance to 1 or 2 agents was present. However, 22.6% (95% CI: 20.5–25.0) of patients were resistant to both antimicrobials. The results of the bootstrap analysis (Table 1) show that the higher the eradication rate in the parent population, the lower the minimum number of strains required to evaluate, at any given power. For therapies whose eradication rates range between 75% and 85%, it could be estimated that a sample size ranging between 98 and 144 patients should be enrolled to get a reliable and consistent estimate of eradication rate.
Conclusion: Our large data set provided evidence showing that a large number of strains needs to be assessed to give reliable estimates of the effectiveness of a given eradication regimen in patients harboring resistant strains.

Introduction: Studies had shown that low antibiotics resistances to amoxicilln, tetracycline even after failed *H. pylori* treatment and high dose metronidazole appeared to be able to overcome antibiotics resistance in Taiwan [(1,2).]
Aims and Methods: We assessed the efficacy of a simple 14-day modified quadruple therapy containing amoxicillin, tetracycline and high dose metronidazole and PPI as an empirical third-line rescue *H. pylori* treatment and the clinical factors influencing the success of eradication.
Methods: This study was conducted by analyzing 70 consecutive prospectively registered patients who failed 2 times *H. pylori* eradication by using the 1st line standard clarithromycin-based triple therapy and 2nd line levofloxacin-based therapy. 7 patients were lost to follow up. All of them received endoscopy for *H. pylori* culture. They were then treated according to the antibiotic susceptibility testing reports (Cultured group, n = 39). Those who failed *H. pylori* culture were prescribed with a simple modified 14-day quadruple therapy containing esomeprazole 40 mg twice daily, amoxicillin 1 g twice daily, tetracycline 500 mg four times daily and metronidazole 500 mg three times daily (empirical group, n = 24).). Follow-up urea breath test was performed 8 weeks later to assess treatment response.
Results: The eradication rates attained by Cultured group and empirical group were 89.7% and 58.3%, respectively in the per protocol analysis (p = 0.004) and 81.4% and 51.8%, respectively, in the intention-to-treat analysis (P = 0.014). Antibiotics resistances after 2 treatment failures were: Clarithromycin (79.5%); Levofloxacin (94.9%); Metronidazole (66.7%); Amoxicillin (2.6%); Tetracycline (0%). Eighty-four percent of patients with Metronidazole resistance were successfully eradicated. Culture-guided therapy was the clinical factors influencing the efficacy of *H. pylori* eradication (OR: 0.16; 95% *confidence interval*: 0.043–0.596, p = 0.006).
Conclusion: Empirical 14-day modified quadruple therapy is not sufficient as an alternative third-line rescue *H. pylori* treatment in spite of the low amoxicillin and tetracycline resistances after 2 treatment failures. Culture guided therapy is still recommended.

Introduction: *Helicobacter pylori* (HP) is the most common pathogen found in humans. Its resistance to clarithromycin is increasing continuously and it is one of the main reasons for eradication failure. The resistance is attributed to 3 point mutations (PM): A2142G, A2142C and A2143G within the peptidyl-transferase encoding region of the 23S rRNA gene. We aimed to analyze the predominance of HP clarithromycin resistance by using our novel high resolution melt (HRM) assay.
Aims and Methods: A total of 151 HP stool samples were collected from naïve patients with general gastric discomfort who also performed $^{13}CO_2$ breath tests (BTs). Stool antigen test (SAT) was also performed on 126 of the 151 stool samples collected HP DNA was extracted from the stool and was analyzed by HRM. The results were compared to the BTs and SATs. The HRM positive results were further analyzed by comparing them to 4 reference plasmids incorporating the three mutations and the WT sequences.
Results: The HRM results presented 106 positive and 45 negative samples. Of the 106 positive samples, 52 had PM - demonstrating a 34% clarithromycin resistance. When compared to the 151 BTs and the 118 SATs, the HRM had a sensitivity of 100% and 99% and specificity of 82% and 78% respectively. Of the 106 positive HRM samples, 54 (51%) had a WT sequence, 10 (9%) had an A2142G PM, 13 (12%) had an A2142C PM, 18 (17%) had an A2143G PM and 11 (10%) were heterozygote (multiple peaks).
Conclusion: Our study is consistent with other reports suggesting an increasing *H. pylori* clarithromycin resistance worldwide, yet further investigation is required in order to determine its prevalence in Israel. Moreover, our HRM assay may be used for screening prior to administration of clarithromycin eradication therapy.

Introduction: Non-steroidal anti-inflammatory drugs (NSAIDs) are some of the most commonly prescribed drugs in the world. However, recently its gastroduodenal complications, especially small intestine injury, has attracted people's attention. The pathogenesis is not yet completely clear, therefore there is no effective treatment measures. RAS is an important regulation system, which plays an important role in maintaining water and electrolyte balance. Ang(1–7) is one of the most important components of the system, which mainly synthesized by ACE2, bypassing the synthesis of Ang II. Studies have shown that Ang(1–7) can reduce the degree of inflammation in colitis and pancreatitis. However, there is few researches on whether Ang(1–7) has a protective effect on NSAIDs induced intestine injury.
Aims and Methods: We aimed to investigate the effect and mechanism of Angiotensin(1–7) on NSAID-induced intestinal injury.
40 Male SD rats weighing 180–200 g were randomly divided into 4 groups. The control group was given 1ml100 $g^{-1}d^{-1}$ saline by gavage; the experimental group was given diclofenac sodium 10 $mgkg^{-1}d^{-1}$ by gavage; the Ang(1–7) intervention group was given diclofenac sodium as the experimental group, meanwhile received Ang(1–7) which was given continued subcutaneously at 24 μg/kg/h from the day before gavage of diclofenac sodium; the Ang(1–7) +MasR antagonist group was treatment as the Ang(1–7) group, meanwhile received MasR antagonist A779 $1mgkg^{-1}d^{-1}$ which was intraperitoneally injected the day and half an hour before gavage of diclofenac sodium. The rats were sacrificed 5 days later. Assessed the injury of the intestine;Mas, AngII, *p*-p38MAPK and NF-κB were measured by western blot; TNF-α were detected by ELISA.
Results: 1. Injury of small intestine: Multiple ulcers were seen in the intestine mucosa of the experimental group, Ang(1–7) can significantly reduced the injury,

while the protect effect was blocked by MasR antagonist ($p < 0.05$). 2. Expression of Mas and AngII in the intestine: Mas in the Ang (1–7) group was significantly higher than that in the experimental group, while the AngII was significantly reduced ($p < 0.05$); the MasR antagonist significantly reduced the expression of MAS, while the AngII was significantly increased ($p < 0.05$). 3. The expression of *p*-p38MAPK, NF-κB and TNF-α in experimental group were much higher than control group, while in the Ang(1–7) group, they were much lower than that in the experimental group, the Ang(1–7) + MasR antagonist group were significantly higher than both the Ang(1–7) group and the experimental group ($p < 0.05$). 4. Pearson correlation analysis: The score of small intestine injury was highly negatively correlated with Mas ($p < 0.05$), and highly positively correlated with AngII, p-p38MAPK, NF-κB, and TNF-α ($p < 0.05$).

Conclusion: Ang(1–7) has a protective effect on NSAID-related small intestinal injury in rats. The protective effect mainly mediated by Mas receptor, then down-regulating the AngII, and inhibiting the activation of p38MAPK, NF-κB and TNF-α.

Introduction: Glepaglutide is a novel, long-acting GLP-2 analog being developed for the treatment of Short Bowel Syndrome. Nonclinical pharmacology studies have shown that glepaglutide is a potent and selective GLP-2 receptor agonist, with activity across species.

Aims and Methods: The objective of these studies was to assess the systemic chronic toxicity and toxicokinetic (TK) profile of glepaglutide in the Wistar rat and the Beagle dog. In addition, pharmacodynamic effects were compared to subchronic exposure in Wistar rats.

In chronic studies, rats were dosed subcutaneously (SC) with vehicle, 1, 3 and 10 mg/kg glepaglutide on a daily basis for 26 weeks. Furthermore, sub-groups of control and high-dose animals were allowed a 6-week recovery period following completion of the dosing period. Dogs were dosed SC with vehicle, 0.25, 1 and 5 mg/kg glepaglutide on a daily basis for 39 weeks. Sub-groups of control and high-dose animals were allowed a 6-week recovery period following completion of the dosing period. Blood samples were taken at regular intervals during the studies for determination of TK profile. In addition to standard toxicology parameters measured during the studies (data not presented), the length and the weight of the small and large intestines were measured at necropsy as indicators of intestinotrophic effects and the intestinal tract was evaluated histologically. In sub-chronic studies, rats were dosed SC with vehicle 1, 4 and 10 mg/kg glepaglutide on a daily basis for 7 days. The length and weight of the small and large intestines were measured at necropsy as indicators of intestinotrophic effects.

Results: At steady state, the TK profiles of glepaglutide within the dosing interval were relatively constant in rats and dogs, and therefore an accurate half-life could not be determined. In chronic studies, glepaglutide induced dose-related significant ($p < 0.01$) increases in length and weight of the small intestines in both rats and dogs (Table 1). Furthermore, the length and weight of the large intestine was also slightly increased in rats. At all dose levels, macroscopic thickening of the duodenum, jejunum and ileum was present. Histologically, glepaglutide produced a dose-related increase in mucosal hyperplasia of the duodenum, jejunum and ileum. Interestingly, at the end of the recovery period significant intestinotrophic effects were still present in the high-dose groups although partial recovery was seen. Sub-chronic treatment in the rat induced significant dose-related increases in small intestinal mass, similar to those observed after chronic dosing.

Species	Rat				Dog			
	Main study animals		Recovery		Main study animals		Recovery	
Dose (mg/kg)	1	3	10	10	0.25	1	5	5
Small intestinal length	21/19	27/34	38/47	39/45	21/19	6/35	46/37	16/19
Small intestinal weight	115/85	155/164	190/238	85/101	71/25	74/91	103/80	78/34

[Table 1: Percentage (%) increase relative to control group (males/females)]

Conclusion: A significant dose-related intestinotrophic effect was seen following 26 and 39 weeks of glepaglutide exposure in rats and dogs, respectively. This response was similar to findings after 7 days of dosing in rats. At all doses, increased length and weight as well as macroscopic thickening and villous hypertrophy were noted in all segments of the small intestine. These findings were still present following a 6-week recovery period, indicating prolonged intestinotrophic effects of glepaglutide.

Introduction: Despite their well-established efficacy, emerging studies are evaluating the effect of Proton Pump Inhibitor (PPI) drugs on gut microbiota composition and on a consequent possible causative role in inducing Small Intestinal Bacterial Overgrowth (SIBO). However, these analyses have so far produced mixing results. Moreover, therapeutical options for SIBO patients are still not well established.

Aims and Methods: The aim of our study was to assess the prevalence of SIBO and CH4 producers consequent to chronic PPI therapy using Lactulose Breath Test (ULBT). Secondary aim was to explore the possible role of Rifaximin in treating PPI-induced SIBO and CH4 producers patients.

125 consecutive GERD patients (>18 years old) constantly treated with PPI (PPI) for at least 6 months were enrolled and underwent ULBT. An age-matched control population (Control) of 100 patients, which had not used PPI in the last 6 months, was also enrolled. 25 Italian General Practitioners and one university hospital participated to the enrollment. Exclusion criteria were: liver and kidney diseases, prior antibiotic treatment in the last month, pregnancy and/or breast-feeding, diabetes, BMI > 29, alcohol abuse disorder, IBS, IBD, neurological/muscle diseases, celiac disease, lactose intolerance, previous gastric/intestinal surgery.

North American Consensus (Rezaie et al, *The American Journal of Gastroenterology* 2017) was used to define SIBO diagnosis and CH4 producers. ULBT samples were centrally read and interpreted. Among PPI, 22 SIBO positive patients and 42 CH4 producers were treated with Rifaximin 1200mg/daily for 14 days and rechecked with ULBT after 1 month. The area under the curve (AUC) before and after treatment was also calculated for both SIBO positive patients and CH4 producers.

Results: In the PPI group, 38/125 (30.4%) had a positive ULBT for SIBO vs. 27/100 (27%) of the Control group ($p < 0.05$). Interestingly, 77/125 (61.6 %) PPI patients were found to be CH4 producers vs. 21/100 (21%) controls ($p < 0.05$). In particular, among SIBO patients in the PPI group, 34 (89.4%) were also CH4 producers vs. 17/27 (63%) controls ($p < 0.05$). After Rifaximin treatment, ULBT resulted negative in 15/22 SIBO patients (68.1%) ($p < 0.05$) and in 23/42 CH4 producers (54.8%) ($p < 0.05$). At the AUC analysis, an overall reduction of 54.2% for H2 in SIBO patients and of 47.7% for CH4 in CH4 producers was assessed after Rifaximin treatment ($p < 0.05$).

Conclusion: Our data showed that chronic use of PPI could be able to increase the prevalence of SIBO and to shift the intestinal microbial composition towards a CH4-producing flora. Rifaximin could represent a useful therapeutical option for PPI-induced SIBO and for modulating CH4-producing flora.

Further studies are underway to determine the exact implications that sustain these findings.

Introduction: The pathogenesis of chronic inflammatory bowel disease (IBD) suggest an inappropriate activation of the intestinal immune system against the intestinal host's flora of genetically predisposed persons. The intestinal microbiota can be involved in different ways in this pathogenesis. Indeed, an excessive proteolytic activity of the intestinal microbiota of IBD subjects was one of the recent and demonstrated hypothesis.

Aims and Methods: A prospective comparative study was enrolled in our medical center from January 2015 to December 2015. Were included to the study all the hospitalized new cases of IBD and a second group of healthy voluntary people. All the subjects (controls and patients) treated with an antibiotic, anti-inflammatory or pro-biotic in the 6 months prior to inclusion were excluded. All patients have benefited of a physical and biological examination and colonoscopy. Stool samples were collected for fecal water extraction. At the first step we measured the global proteolytic activity of fecal water using azocasein or casein as a substrate in both groups. To highlight the nature of the proteases involved, we studied the inhibitory effect of specific serine proteases inhibitors on fecal proteolytic activity. We used PMSF and SBTI as chemical serine protease inhibitors and Serpin ES expressed by a commensal bacterium of the intestinal microbiota. This Serpin was previously purified and optimized in the Ife laboratory, Metagenopolis at INRA Jouy-en-Josas in France using recombinant strain of *E. coli* (plasmid pDEST17). The final step was to search a natural serpin deficit in

IBD group so we studied in both groups the proteolytic activity of the fecal water after using proteases which degraded all the protein except serpins. For the statistical analysis we used Spss software (20.0) (significant difference for $p < 0.05$).
