Markov model consisted of an initial decision regarding treatment with PPI, or any other treatment for FD. Patients who initially received PPI or not could developed GC, but the rate in patients who received PPI is greater (HR between 3 to 10). We considered only patients that PPI had a relief with their symptoms and improved quality of life. The primary outputs of the model included life-years (Lys) and quality- adjusted LYs (QALYs). Patients who developed GC were stratified by prognostic stage group to Markov states in the model. The overall mortality rate was derived from the Kaplan-Meier overall survival (OS) curves. The health states of gastric cancer was assigned a health utility score based on quality-of- life data in the CEA Tufts database. The utility value related to the quality of life regarding the dyspepsia without PPI and the improvement using PPI, was tested with sensitivity analysis over a large range of values (patient preferences). A series of sensitivity analyses were performed to evaluate the robustness of the model and address uncertainty in the estimation of model parameters.
Results: The base case model results showed that the use of PPI compared with placebo, resulted in a gain of 2.09 QALY. Univariable sensitivity analyses demonstrated that the most influential variable was: ''Percentage Increasing of Utility with PPI'' followed by the age of the patients and time horizon. For a greater increasing of improvement with PPI more than 0.8%, the use of PPI is better than placebo strategy. For older patients the benefit of PPI is less than for younger patients.
As the comparison between improvement in quality of life and the burden of GC is not equal in all people, we created a calculator which enable to receive a more personalized and accurate decision in such patients with FD.
Conclusion: We found that it is important to discontinue the usage of PPI when there is no improvement in symptoms. However, when there is even small improvement in the quality of the patient's life it is almost always justified to continue the PPI treatment.

Introduction: Although meta-analysis suggested different effect of body mass index (BMI) on gastric cancer by site, the effect of metabolic components on gastric cancer in general population was rarely reported. We investigated the gender-specific effect of metabolic components and BMI on de novo gastric cancer.
Aims and Methods: This population-based study included subjects who underwent national endoscopic screening and general health examination from March 2011 to December 2011. Data regarding BMI, glucose, high-density lipoprotein (HDL), and age were extracted from the National Health Insurance Service databank and categorized. Adjusted regression analysis was performed to evaluate the risk of de novo gastric cancer using odds ratios (OR) and 95% confidence intervals (CI). Sub-analysis by gender and gastric cancer site was performed.
Results: Gastric cancers were detected in 10,417 subjects in 5.49 million subjects (2.43 million men). In the adjusted analysis, low BMI (<18.5; OR, 1.37; 95% CI, 1.29–1.52), high fasting glucose (≥ 127; OR, 1.28; 95% CI, 1.20–1.36), and low HDL (OR, 1.41; 95% CI, 1.35–1.48) increased gastric cancer. In gender-specific analysis, low BMI increased gastric cancer in men but not in women. High fasting glucose and low HDL had a constant association with gastric cancer in both genders. The effect of most factors on non-cardiac gastric cancer was similar to that on overall gastric cancer. The effect of low HDL (OR, 1.90, 95% CI, 1.34–2.71), high glucose (OR, 1.50; 95% CI, 1.06–2.11), aging, and gender (OR, 3.28; 95% CI, 2.09–5.14) on gastric cancer was more prominent in cardiac cancer than in non-cardiac cancer. Family history, smoking and drinking status was strongly associated with non-cardiac cancer, wherein they had no association with cardiac cancer.
Conclusion: Low BMI, hyperglycaemia, and low HDL independently increased gastric cancer in a large general population. Contributing factors were different by gender and gastric cancer site.

Introduction: Patients with cancer often show signs of malnutrition, which might influence morbidity and mortality while undergoing chemotherapy or surgical treatment. The tolerability of perioperative chemotherapy in patients with gastric cancer is often limited.
Aims and Methods: To evaluate the influence of sarcopenia in patients with locally advanced, not metastasized, gastric or gastro-esophageal junction (GEJ) cancer undergoing curative treatment (perioperative chemotherapy and surgery) on morbidity and mortality in order to identify patients in need for nutritional intervention.
Methods: Retrospective study, conducted in two hospitals (Universitätsklinikum Frankfurt and Krankenhaus Nordwest) as part of the University Cancer Center Frankfurt (UCT). A large proportion of the patients were treated in the FLOT trial (NCT01216644). Patients charts were reviewed for the following items: age, sex, tumor type, histology, TNM stage, treatment, Clavien-Dindo-Score, BMI, survival data. Two consecutive CT scans were retrospectively analyzed to determine the degree of sarcopenia. For this, mean total muscle area (TMA) was measured at L3 and set in relation to body height, resulting in the skeletal muscle index, SMI. SMI = TMA [cm^2]/height [m^2]. Sarcopenia was defined as follows: male patients: BMI <25: SMI <43 cm^2/m^2; BMI ≥ 25: SMI < 53 cm^2/m^2; female patients: SMI <41 cm^2/m^2 (regardless of the BMI). Survival was calculated using the Kaplan-Meier method, multivariate analysis was performed using the Cox regression.
Results: 60 patients (72.3%) were male and 23 (27.7%) female. 45 patients (54.2%) had GEJ type 1–3 and 38 (45.8%) gastric tumors, respectively. Sarcopenic patients were significantly older than non-sarcopenic patients (mean age 65.1 years vs. 59.5 years, $p = 0.041$), terminated the chemotherapy significantly earlier (50% vs. 22.6%, $p = 0.037$) and showed higher Clavien-Dindo scores, indicating more severe perioperative complications (score ≥ 3 43.3 vs. 17.0%, $p = 0.009$). Sarcopenic patients had a significantly shorter survival than non-sarcopenic patients (139.6 [95% CI, 101.3–177.9] vs. 206.7 [95% CI, 179.5–233.8] weeks, $p = 0.004$). Cox regression analysis did not reveal factors influencing survival other than sarcopenia.
Conclusion: Sarcopenia is present in a large proportion of patients with locally advanced gastric or GEJ cancer and is an independent prognostic factor for survival. Besides, it significantly influences tolerability of chemotherapy and surgical complications.

Introduction: HOX genes are highly conserved at the genomic level and have been well-described as important players in regulating numerous processes including differentiation, receptor signaling, motility, apoptosis, angiogenesis, and metastasis.HOXC10 is a member of the HOX gene family and has been found to function as oncogenes in the progression of many cancers, thus it might be useful as a marker for cancer diagnosis or prognosis. We have previously found that HOXC10 is up-regulated in gastric cancer and functions as a candidate tumor promoter, whose high expression indicates poor survival outcome. However, the potential regulatory network of HOXC10 remains less understood.

The WNT signaling pathway is well known for its role in controlling cellular processes such as proliferation, differentiation, and apoptosis. In the nucleus, β-catenin associates with TCF/LEF transcription factors to drive expression of WNT target genes, such as CCND1,CD44, c-MYC and MMP7.
Small, noncoding microRNAs (miRNAs) are important posttranscriptional regulators of gene expression, with each miRNA predicted to regulate hundreds of mRNA target genes. MiR-129 family members were reported to be down-regulated in gastric cancer cells and play important roles in regulating cell proliferation in gastric cancer.
Aims and Methods: The aim of this study is to determine the potential regulatory network of HOXC10 in gastric cancer. As HOXC10 is an important transcription factor, ChIP-seq assay was performed firstly. Bioinformatic analyses, such as Gene Ontology (GO), Kyoto Encyclopedia of Genes and Genomes (KEGG) were used to investigate the molecular mechanism affected by the target genes of HOXC10. Additionally, the potential miRNAs targeting HOXC10 were investigated through miRanda, pita, RNAhybrid and targetSCAN. Reverse transcription polymerase chain reaction (RT-PCR) and western blotting were utilized to measure mRNA and protein expression, respectively.
Results: According to ChIP-seq assay, we found a variety of genes involved in the development of gastric cancer. Through KEGG analyses, these target genes may be involved in many cancer-related signaling pathways. We focused on the Wnt signaling-related genes and found down-regulation of HOXC10 significantly influenced mRNA expression including CCND1, CD44, CCND2, MMP7,CREBBP, especially the downregulation of CCND1. Meanwhile, HOXC10 also modulated the phosphorylation of β-catenin but not its total protein levels, which can also influence the expression of CCND1. Positive correlations were found between CCND1and HOXC10 ($r = 0.13$, $P < 0.01$) based on TCGA database. Besides, combined with miRanda, pita, RNAhybrid and targetSCAN analyses, 130 miRNAs were predicted to target HOXC10. We verified that miR-129-5P can significantly decreased mRNA expression of HOXC10, thereby down-regulating CCND1 expression in two ways.
Conclusion: HOXC10 may be an important direct target of miR-129-5P and play a significant role in gastric cancer by regulating various pathways, particularly the Wnt signaling pathway.CCND1 is found to be a crucial target of HOXC10.

Introduction: Cancer stem cells play a role in tumour recurrence, cell proliferation, invasion, and resistance to therapy. CD44 variant 9 (CD44v9), one of the variant isoforms of CD44, is a specific cell surface marker of cancer stem cells. CD44v9 increases expression of the antioxidant glutathione (GSH) via stabilising xCT, a glutamate-cysteine transporter, which provides resistance against reactive oxygen species (ROS). Trastuzumab, a recombinant monoclonal antibody against HER2, has been shown to selectively exert anti-tumour effects in advanced gastric tumours that overexpress HER2. However, trastuzumab-based therapy is not effective in certain patients. The present study was conducted to investigate how CD44v9 regulates the anti-tumour effects of trastuzumab.
Aims and Methods: NCI-N87, a high HER2-expressing gastric cancer cell line, was used for this study. The pRc/CMV expressing plasmid encoding human CD44v9 and standard CD44 (CD44s) was transfected into NCI-N87 cells (NCI-N87-CD44v9 and NCI-N87-CD44s). Cells were incubated for 48 h with different concentrations of trastuzumab and cell viability was evaluated by the MTS assay. Intracellular GSH levels were measured by a luminescence-based assay. Intracellular ROS was detected using an oxidation-sensitive fluorescent probe (DCFH-DA) while mitochondrial ROS was assessed by staining with MitoSOX followed by confocal microscopy. Protein expression was determined by western blot analysis.
Results: Trastuzumab (10, 50 and 200 μg/ml) caused death of NCI-N87 cells (19.7%, 27.3%, and 37.8% cell death, respectively) and NCI-N87-CD44s cells (16.2%, 20.3%, and 27.8% cell death, respectively). However, efficacy of trastuzumab was attenuated in NCI-N87-CD44v9 cells (13%, 16%, and 17.1% cell death at 10, 50, and 200 μg/ml of trastuzumab, respectively). Trastuzumab increased intracellular ROS levels in NCI-N87 cells and NCI-N87-CD44s, but not in NCI-N87-CD44v9. Trastuzumab also increased mitochondrial ROS responses. The intracellular GSH levels were significantly higher in NCI N87-CD44v9 than in NCI-N87 (2.59-fold; $p < 0.01$) and NCI-N87-CD44s (1.38-fold; $p < 0.01$). The expression of MnSOD, a mitochondrial ROS scavenging enzyme, was significantly higher in NCI N87-CD44v9 than in NCI-N87 (2.78-fold; $p = 0.04$). In addition, *MnSOD* siRNA-treated NCI-N87-CD44v9 reacquired sensitivity to trastuzumab ($p < 0.01$).
Conclusion: CD44v9 positive gastric cancer cells attained trastuzumab resistance via attenuation of ROS accumulation, which was caused by an increase in the antioxidants GSH and MnSOD. Targeting cellular antioxidant enzymes could enhance the efficacy of trastuzumab against CD44v9 positive gastric cancer cells.

Introduction: Gastric carcinogenesis comprises the sequential progression from normal mucosa, atrophic or metaplastic gastritis, dysplasia to adenocarcinoma. MicroRNAs (miRNAs) are non-coding RNAs capable of epigenetic DNA regulation, whose role in gastric carcinogenesis is not fully established.
Aims and Methods: We aimed to characterize plasma and tissue expressions of different miRNAs for different stages of gastric carcinogenesis.
Single-centre cross-sectional study in patients who underwent upper gastrointestinal endoscopy ($n = 42$), who were classified in 3 groups: 14 with normal mucosa (control group); 13 with extensive atrophic/metaplastic gastritis and 15 early gastric neoplasia. In each patient, peripheral blood samples and endoscopic biopsy samples from the antrum, corpus and superficial lesion (if present) were collected. Seven miRNAs (miR-21, miR-146a, miR-181b, miR-370, miR-375 e miR-490) and an endogenous control (RNU-6B) were extracted and quantified in these samples through relative quantification by real time-PCR.
Results: We found a significant decrease in the mucosal expression of miR-146a e miR-370 between the control and metaplasia groups (86% reduction, $p = 0.018$ and 98% reduction, $p = 0.003$, respectively) and between normal gastric mucosa and superficial lesions (71% reduction, $p = 0.02$ and 66% reduction, $p = 0.027$, respectively). MiRNA-181 showed a tissue expression 44 times greater in the superficial lesion group versus control group ($p < 0.001$) and there were no significant differences between controls and gastric metaplasia. In patients with neoplasia, there were no significant differences in miRNA expression between lesion samples and normal antrum and corpus mucosa. We found no statistically significant differences in the plasmatic miRNA expression of the seven miRNAs between the different groups and no association with their tissue expression.
Conclusion: We found significant changes in tissue expression of several miRNAs across the different stages of gastric carcinogenesis, suggesting a tumor suppressor role for miRNAs such as miR-146a and miR-370 and oncogenic potential for miRNA-181 in gastric carcinogenesis pathways. In individuals with early neoplasia, these changes appear to happen diffusely in the gastric mucosa, which may have implications in these patients' surveillance.

Introduction: Data on the association of IL1B gene polymorphism with gastric cancer (GC) risk are quite contradictory. Low serum level of pepsinogen I (PG) and PGI/PGII ratio is detected in atrophic gastritis (AG), including *Helicobacter pylori (H. pylori)* associated and being the main precancerous lesion.
Aims and Methods: We aimed to study the influence of polymorphism -511C/T (rs16944) gene IL1B and low levels of pepsinogens on the GC risk in a prospective case-control study (8 years of prospection).
In the period 2003–2005 within the framework of the international project HAPIEE the population sample of Novosibirsk residents (9360 people aged 45–69 years) was studied and the base of biomaterials was created. Serum and DNA samples were stored at -70^0C. In 2012 this database was compared with the data of the population cancer register. For each GC case in the 1:2 ratio the corresponding age-and sex-control was chosen. As a result, 156 blood serum samples (52-GC; 104-control) were analyzed using a panel of biomarkers (''Gastropanel'', Biohit, Finland) and 167 DNA samples (80-GC; 87-control) were genotyped according to the published method for -511C/T (rs16944) IL1B gene polymorphism. (''Gastropanel'', Biohit, Finland) and 167 DNA samples (80-GC; 87-control) were genotyped according to the published method for -511C/T (rs16944) IL1B gene polymorphism.
Results: In a single-factor analysis, low PGI and PGI/PGII ratio were associated with GC risk: OR 2.9 (95% CI 1.3–6.4, $p = 0.006$) for PGI and OR 3.3 (95% CI 1.5–7.3, $p = 0.002$) for PGI/PGII ratio. In the multivariate regression analysis with the inclusion of quantitative and categorical variables in the model the PGI

level (B = −0.033, p < 0,001, OR = 0.967, 95% CI 0.95–0.98) and PGI PGII ratio (B = −0.548, p = 0.0001, OR = 0.578, 95% CI 0.43–0.77) were significant in the model. Carriers of the T/T genotype of the IL1B had an increased GC risk as compared to carriers of the C/C genotype (B = 2.39; p = 0.047; OR = 10.9; 95% CI 1.03–116.04). In persons with family history of cancers the GC risk was also increased (B = 1.246; p = 0.048; OR = 3.475; 95% CI 1.009–11.97).
Conclusion: The obtained data suggest that the T/T genotype IL1B gene, the low level of PGI and the PGI/PGII ratio are associated with an increased GC risk in Siberian population.

Introduction: Recent molecular analysis by international large-scale collaborative studies of TCGA (The Cancer Genome Atlas) and ICGC (International Cancer Genome Consortium), elucidated the genetic background of gastric cancers into four subgroups e.g., Epstein-Barr Virus (EBV) positive, microsatellite instability (MSI), chromosomal instability (CIN) and genomically stable (GS) gastric cancers. However, the information of genetic analysis of clinically available samples are still limited. In particular, recurrent occurrence of early gastric cancers was often clinically encountered after endoscopic submucosal dissection (ESD), but their molecular events were not elucidated.
Aims and Methods: To explore molecular events in multiple early gastric cancers, tumor tissues from patients who developed synchronous (simultaneous or within one year) and metachronous (one year after initial neoplasm) multiple early gastric cancers were investigated. We performed next generation sequencing on the 83 tumor samples from 31 patients by using "gastric cancer panel" which we created *in house* covering 351,050 base pairs of 58 significantly mutated genes (SMG) (Nature 2014; 513: 202–209). Of these 31 patients, 15 patients had synchronous recurrence, 11 metachronous, and 5 both synchronous and metachronous. Average number of recurrence was 3 (maximum 6 times). In addition, we performed immunohistochemical staining of proteins produced by DNA mismatch repair genes (MLH 1, MSH 2, PMS 2, and MSH 6) and microsatellite instability (MSI) assay.
Results: We found total of 467 somatic mutations of 58 SMGS in 83 samples (cut-off level of allelic fraction-AF above 5%). We also performed immunohistochemical staining of repair genes and microsatellite instability assay. We then classified 83 tumor tissue samples from 31 patients into 4 groups proposed by TCGA and ICGC international collaborative study group. Our analysis revealed that multiple gastric tumors belonged to the three categories. (1) All recurrences in 2 patients are microsatellite instability high (MSI-H only) (2/31, 6%), (2) one tumor is microsatellite stable (MSS)/genetically CIN, but the recurrence is MSI-H (6/31, 19%), (3) all tumors are MSS and genetically CIN (23/31, 75%).
Of particular interest is that in one case with exceptionally frequent recurrence (6 times), microsatellite and immunohistochemical analysis revealed all these 6 tumors showed microsatellite instability high (MSI-H) and the methylation of the promoter region of MLH1.
Conclusion: The multiple gastric tumors belonged to three categories; all microsatellite instability-high (MSI-H) (2/31, 6%), mixture of MSS/CIN and MSI-H (6/31, 19%), all MSS and CIN (23/31, 75%).
It could be concluded as with multiple occurrence, principal genotypes may vary and modality of treatment should be modified according to the molecular types if the tumor advanced.

Introduction: Gastric cancer incidence and mortality in general population were reported to decrease after treatment of *Helicobacter pylori* infection. However, it was reported that overall mortality might be increased after *H. pylori* eradication about 9%. This finding should be studied before *H. pylori* eradication therapy is recommended in general population for gastric cancer prevention.
Aims and Methods: The aim of this study was to investigate whether the overall mortality is increased after the *H. pylori* treatment in patients with hypertension, who might have higher cardiovascular death risk than in general population. We used the database of Korean National Health Insurance Service-National Sample Cohort consisted of 1 million sample population. A total of 198,462 hypertension patients were selected between 2002 and 2010. Of these, 5,541 patients who received *H. pylori* eradication therapy (Hp-treatment group) were matched to 11,082 patients who did not receive *H. pylori* treatments (control group) at a 1:2 ratio by matching of age, sex, Charlson comorbidity index, the year when hypertension treatment started, and observation periods. The primary outcome variable was overall mortality that occurred at 6 months after the *H. pylori* treatment. The secondary outcomes were the specific mortalities due to the cardiovascular diseases, cerebrovascular diseases, and cancer. Cox-proportional hazard model was used to evaluate the mortality risk.
Results: In the matched cohort, the male proportion was 55.2% and proportion of person older than 60 years was 28.6%. In the Hp-treatment group, most of the patients (96.4%, 5,342/5,541 patients) were prescribed proton-pump inhibitor-clarithromycin containing triple therapy. During median follow-up periods of 4.8 years (interquartile range, 2.6–7.3 years), 229 patients (4.1%, 229/5,541) in the Hp-treatment group and 608 patients (5.5%, 608/11,082) in the control group died. Overall mortality was significantly lower in the Hp-treatment group than in the control group (adjusted hazard ratio [aHR] for overall mortality in the Hp-treatment group, 0.70; 95% confidence interval [CI], 0.60–0.81; $P < 0.001$). According to the cause of mortality, Hp-treatment group had significantly lower risk of mortality due to cerebrovascular disease mortality (aHR, 0.46; 95% CI, 0.26–0.82; $P = 0.008$) as compared with the control group. Overall cancer mortality risk was lower in the Hp-treatment group than in the control group with a borderline statistical significance (aHR, 0.75; 95% CI, 0.57–1.00; $P = 0.0502$). However, cardiovascular disease mortality (aHR, 0.96; 95% CI, 0.54–1.71; $P = 0.887$) was not different in both groups.
Conclusion: *H. pylori* treatment seems not be associated with an increase in overall mortality or cardiovascular mortality in patients with hypertension.
Disclosure: Nothing to disclose

P1190 MIGRATORY AND SOCIAL PARAMETERS INFLUENCING RESISTANT HELICOBACTER PYLORI INFECTION IN SOUTHERN CHINA: A MUNICIPALITY-WIDE MULTICENTER PREVALENCE STUDY

T. Lyu[1], **W.-K.W. Seto**[1,2], L. Ni[1], J. Guo[1], P. Mu[1], Y. Li[3], Q. Yang[3], X. Yu[4], H. Sun[4], Z. Lyu[5], J. Wu[5], H. Guo[6], K.S. Cheung[2], W.K. Leung[7]

Introduction: Southern China is witnessing increasing rates of *Helicobacter pylori* (*H.pylori*) eradication failure. Shenzhen, Guangdong province, is one of the rapidly-growing cities in China with a large migrant population. Risk factors for *H.pylori* resistance in relationship to the migratory environment of China have not been well-investigated.
Aims and Methods: Since September 2016, we recruited patients who tested ^{13}C-Urea breath test-positive after first-line *H.pylori* eradication from 5 hospitals located throughout Shenzhen in Southern China. Participants completed a questionnaire profiling potential risk factors of *H.pylori* infection, including geographical origin, educational status, source of drinking water, residential family size, and medication/smoking/alcohol history. All participants underwent an upper gastrointestinal endoscopy with three antral and two corpus biopsies obtained for *H.pylori* culture and antimicrobial susceptibility testing (Zhiyuan Medical Inspection Institute, Hangzhou, China) for 6 antibiotics: amoxicillin, clarithromycin, levofloxacin, metronidazole, tetracycline and furazolidone. Potential risk factors for antibiotic resistance were analyzed.
Results: In this interim analysis, we recruited 746 patients (52.4% male), with a mean age of 43.1 ± 12.5 years. 711 (95.3%) and 473 (63.4%) were born outside Shenzhen and Guangdong province respectively. Among 557 patients (74.7%) with a positive *H.pylori* culture, the antibiotic resistance for amoxicillin, clarithromycin, levofloxacin, metronidazole, tetracycline and furazolidone were 1.3%, 34.1%, 42.4%, 92.5%, 0% and 0% respectively. 313 patients (56.2%) were resistant to multiple antibiotics. Multivariate testing found a geographical origin from non-coastal cities to be independently associated with clarithromycin resistance (p = 0.006, OR 3.322, 95%CI 1.400–7.874), while patients' geographical origin provincial gross domestic product per capita of <20,000 USD showed borderline association (p = 0.070, OR 2.144, 95%CI 0.925–4.973). These two factors had no association with metronidazole or levofloxacin resistance ($p > 0.05$). Other significant factors include increasing age for resistance to clarithromycin (p = 0.007, OR 1.019, 95%CI 1.005–1.033), metronidazole (p = 0.002, OR 1.047, 95%CI 1.017–1.079) and levofloxacin ($p < 0.001$, OR 1.025, 95%CI 1.011–1.039) and prior antibiotic use for resistance to metronidazole (p = 0.024,

OR 2.132, 95%CI 1.106–4.098) Duration of migration to Shenzhen, population density of geographical origin and other social parameters showed no relationship with antibiotic resistance.
Conclusion: High rates of clarithromycin, levofloxacin and metronidazole resistance were noted among Southern Chinese patients with *H.pylori* eradication failure. Migratory and economic patterns may influence local epidemiological *H.pylori* resistance trends especially towards clarithromycin.

Introduction: Recently the prevalence of *Helicobacter pylori* (*H. pylori*) infection has decreased to around 50% in Korea. Atrophic gastritis (AG) and intestinal metaplasia (IM) are the premalignant conditions for gastric cancer of which Korean incidence is the highest in the world.
Aims and Methods: The aim of this study is to investigate the trend of the prevalence and grades of AG and IM according to sex in Korean population. From March 2003 to February 2018, we prospectively enrolled 2002 subjects without significant gastroduodenal disease, which has been checked by esophagogastroduodenoscopy. Biopsies were taken from the lesser and greater curvatures of the antrum and mid-corpus, respectively, and CLOtest was also performed for diagnosis of *H. pylori*. Three periods were divided by 2003 to 2007, 2008 to 2012, and 2013 to 2018. AG and IM were scored histologically by using the Updated Sydney classification. Trend of the prevalence and grades of AG and IM were analyzed according to sex. In addition, multivariate logistic analysis was performed for the AG, IM depending on antrum and corpus.
Results: Total 2002 subjects were categorized by *H. pylori*-negative (n = 1220) and *H. pylori*-positive (n = 782). In each period *H. pylori*-positivity decreased as following: 49.2% (149/303) during the 2003 to 2007, 40.2% (207/515) from 2008 to 2012, and 36.0% (426/1184) from 2013 to 2018 ($P < 0.001$). In the case of male, *H. pylori*-positivity decreased as following: 51.6% (48/93) during the 2003 to 2007, 38.2% (83/217) from 2008 to 2012, and 36.3% (174/480) from 2013 to 2018 ($P = 0.014$). In the case of female, *H. pylori*-positivity decreased as following: 48.1% (101/210) during the 2003 to 2007, 41.6% (124/298) from 2008 to 2012, and 35.8% (252/704) from 2013 to 2018 ($P = 0.001$). By using chi-square test and linear-by-linear association analysis according to period, female prevalence of AG at corpus ($P = 0.001$ and $P < 0.001$) and IM at corpus ($P < 0.001$ and $P < 0.001$) were gradually decreased from 2003 to 2018, different from male (table). In the multivariate logistic analysis, old age [odds ratios (ORs), 4.117; $P = 0.001$ and 8.188; $P < 0.001$ for ages in the 40 ~ 59 and ≥60], Period (OR, 0.628; $P = 0.024$ and 0.471; $P = 0.005$ from 2008 to 2012 and from 2013 to 2018), and *H. pylori* infection (OR, 3.467; $P < 0.001$) were statistically significant in AG at corpus. AG at antrum and IM at corpus had also similar results. In case of IM at antrum old age (OR, 5.154, $P < 0.001$ and 8.899, $P < 0.001$ for ages in the 40 ~ 59 and ≥60) and *H. pylori* infection (OR, 1.491; $P = 0.008$) and smoking status (OR, 1.738; $P = 0.011$) were statistically significant.
Conclusion: Significantly decreased prevalence and grades of AG and IM at corpus only in female in spite of decreased *H. pylori* infection regardless of sex suggests that sex or gender-specific characters such as eating habits including salty or spicy foods are related with the development of AG and IM.

Introduction: *Helicobacter pylori* (Hp) infection is common worldwide, with a global prevalence over 50%, but with substantial geographical variations. Prevalence rates also differ according to ethnicity, socio-economic status, and age, being more prevalent with advancing age. Hp has been defined as a carcinogen class I due to its capacity to induce antrum atrophy that progressively extends to the entire stomach, with subsequent development of gastric metaplasia and eventually adencarcinoma. Patients affected by autoimmune diseases have an higher risk of developing other autoimmune conditions such as autoimmune gastritis (AG); although AG has a different pathogenesis, the relationship between Hp and the development of this condition in patients affected by autoimmune diseases has not been well established yet.
Aims and Methods: The aim of this study was to assess the prevalence of Hp infection in a cohort of patients with at least one of these non-gastric autoimmune diseases: Hashimoto's thyroiditis (HT), celiac disease (CD), rheumatoid arthritis (RA), psoriatic arthritis (PA), Sjögren's syndrome (SS) and vitiligo (VI). Records of patients affected by any of the mentioned autoimmune conditions were evaluated as part of a larger study involving the determination of several biochemical parameters, including dosing of anti-Hp IgG antibodies (Biohit Oyj, Finland). A cut-off value of IgG > 30 EIU was considered positive, indicating Hp infection.

Abstract No: P1191
Table 1: Grades and prevalence for atrophic gastritis and intestinal metaplasia in the antrum and the corpus from 2003 to 2018

		2003–2007	2008–2012	2013–2018	p-value	linear by linear association
Total	AG grade	0.58(0.706)	0.40(0.650)	0.54(0.800)	0.004	0.833

Female	AG grade	0.40(0.710)	0.28(0.608)	0.23(0.590)	0.009	0.003
Corpus	Prevalence (%)	27.7%(53/191)	21.0%(50/238)	15.6%(76/487)	0.001	<0.001
Female	IM grade	0.32(0.685)	0.21(0.543)	0.14(0.458)	<0.001	<0.001
Corpus	Prevalence (%)	21.4%(45/210)	15.8%(47/298)	10.8%(76/704)	<0.001	<0.001

Results: Biochemical evaluation of anti-Hp antibodies was performed in 609 patients with autoimmune diseases (mean age 52.4 ± 14.3); Hp infection was found in 139 (22.8%): 118/527 (22.4%) of TH patients, 3/25 (12.0%) of CD patients, 5/13 (38.5%) of RA patients, 7/21 (33.3%) of PA patients. In patients with two or more coexisting autoimmune diseases, Hp infection was observed in 2/7 subjects with HT and CD, 2/4 patients with HT and PA, 1/3 subjects with HT and RA, and in 1/4 subjects with HT and VI. No cases of Hp infection were found in the 4 patients affected with SS.
Conclusion: The overall prevalence of Hp infection in the population of patients with autoimmune diseases was 22.8%, which is significantly lower than the medium value reported for the Italian general population and is partly due to the lower mean age of patients with autoimmune diseases. This data seems to confirm previous reports of a lower prevalence of Hp infection in patients with autoimmune diseases compared to the general population of the same age.
Disclosure: Nothing to disclose

P1193 NATURAL HISTORY OF GASTRIC ULCER IN A 25 YEARS FOLLOW-UP: ROLE OF HELICOBACTER PYLORI INFECTION AND NONSTEROIDAL ANTI-INFLAMMATORY DRUGS

Contact E-Mail Address: chiaramiraglia33@gmail.com
Introduction: *Helicobacter pylori* (H.p.) remains the main cause of gastric ulcer (GU); however, the role of nonsteroidal anti-inflammatory drugs (NSAIDs) is quickly increasing worldwide.
Aims and Methods: The aim of the present study was to assess the natural history of GU related to H.p. or NSAIDs aetiology, evaluating clinical presentation, recurrence rate and complications occurred during a long-term follow-up.
We conducted a retrospective follow-up study of 256 consecutive patients (M/F = 134/122, mean age 57 yrs, range 20–84 yrs) with endoscopically diagnosed gastric ulcer. After baseline EGD, during a 25 years follow-up clinical assessments every 6 months and at least one EGD with biopsies and H.p. evaluation were performed. Each episode of recurrence of symptoms lasting more than 5 days was investigated by means of EGD. Enrolled subjects were divided into 4 groups according to H.p. infection and intake of NSAIDs.
Results: Overall, 172 patients (67%) with GU had history of H p. infection and 72 pts (28%) were NSAID takers. 115/172 pts H.p.+ did not use NSAIDs. NSAID takers H.p.-negative were only 15 (6%). H p. negative individuals not taking NSAIDs were 67 (26%) and H.p.+ pts with associated NSAIDs use were 57 (22%). At the beginning, the majority (85%) of the pts was symptomatic and presented epigastric pain (30%) and/or heartburn (29%) and/or dyspepsia (28%), whilst 14% presented bleeding as first symptom ($p < 0.0001$). Epigastric pain was the single most important starting symptom in H.p.+ pts in comparison with H.p.- ($p < 0.0001$). There were no significant differences in presenting complaints in NSAIDs+ and NSAIDs- pts. Undergoing EGD, 233 were diagnosed for gastritis, 15 resulted affected by duodenal ulcer, and 3 cases of gastric cancer were discovered. Within 3 years 33% of pts were symptom-free, but in H.p+ NSAIDs+ the persistence of symptoms in comparison with the other groups was prolonged (<0.002). At the end of the follow-up, 90% was asymptomatic and in 207/256 the ulcer disappeared. The recurrence rate was 18% (46/256) and haemorrhagic complications occurred in 5% of pts, more frequent among HP+NSAIDs+ pts (42%).
Conclusion: This study confirms that the natural history of GU depends on the cause and assesses the pathological role of both H.p. and NSAIDs and their frequent (22%) association. There is a synergism between H.p. infection and NSAIDs use for the development of GU bleeding and the persistence of symptoms. A long-term follow-up assessed that GU patients can be symptoms-free.

Introduction: Russia belongs to countries with high prevalence of *Helicobacter pylori* (*H.pylori*) infection ranging from 50% to 92%. Epidemiological studies on *H. pylori* infection among Russian physicians of different regions of country have not been carried out to date.
Aims and Methods: To evaluate the prevalence of *H.pylori* among physicians according to the different regions of Russian Federation by using 13C-urea breath test.
Results: 1154 doctors from 14 different regions of Russian Federation were examined. High prevalence of *H. pylori* (59%) among physicians was found. The lowest prevalence of infection was found in Saratov (38.5%), the highest incidence of infection was recorded in Krasnodar (76.2%). The prevalence of *H. pylori* in the group of doctors under the age of 30 y. o. was 45.2%, in the group of 51–60 y. o. — 65.2%, respectively. 20% of specialists refused to take part in the testing, 50% of doctors noted that they would not take antibiotics if an infection was detected. Treatment for eradication *H. pylori* among 619 of *H. pylori*-positive physicians was received only in 114 (18.9%) doctors and therapy achieved elimination of the infection in 69.2% cases.
Conclusion: The first observation epidemiological study on *H. pylori* infection among Russian physicians showed differences in infection rates in various regions of Russia with an average of 59%. The low awareness of physicians about their own *H.pylori* status and lack of internal conviction in the appropriateness of self-diagnosis and eradication of *H. pylori* was revealed.

Introduction: Gastroesophageal reflux disease (GERD) is largely diffuse in general population. No clear relationship has been established between GERD and the eradication of *H. pylori* (H.p.) infection, although some papers support the onset of esophagitis in patients in whom the infection has been cured.
Aims and Methods: Aim of this study was to investigate the relationship between the cure of H.p. infection and the onset of esophagitis in a long follow-up taking into account the Maximal Acid Output (M.A.O.). A group of 450 patients was recruited (M = 343, F = 107, mean age 42.89 ± 11.8 yrs, range 18–80yrs), all H.p.+ (U.B.T.). All patients underwent to gastric acid aspiration test for measuring B.A.O. in basal conditions and M.A.O. after maximal stimulation with pentagastrin (i.m. 6 μg/kg) in order to determine secretory status and were classified accordingly as: normo-secretory (group A) or hypersecretory (group B).
Patients were treated with standard triple therapy for H.p. eradication and two months later they underwent to esophagogastroduodenoscopy with bioptic sampling to evaluate the presence of lesions, the state of the gastric mucosa and the eradication of H.p. In addition, all of them were subjected to a blood sampling for serum pepsinogen I and G17 determination. We excluded from the study patients tested negative for H.p. infection in U.B.T, patients on antisecretory treatment and patients who denied informed consent.
Results: All patients were divided in two groups according with the secretory status after the results of gastric juice collection:
Group A) Normosecretory status: 135/450 patients (30%) with low or normal acid secretion (M.A.O. 5–25 mEq/h);
Group B) Hypersecretory status: 315/450 patients (70%) with elevate gastric acid secretion (M.A.O. >25 mEq/h).
Eradication rate was elevated, with 320 of 450 (71%) treated patients achieving H.p. eradication. Esophagitis was diagnosed in a total of 157/450 patients (34.9%), and was significantly more frequent in patients in whom eradication was achieved when compared against patients with persistent infection (150/320, 46.9% vs 7/130, 5.4%, respectively, $p = 0.0001$).
In Group A cured patients were 96/135 (71.1% Group A1) versus 39/135 (29.9% Group A2) of patients with persistent infection. In the latter group of subjects, esophagitis was found in 22.2% (30/135) patients, in particular 30 out of 96 (31.2%) in Group A1 developed esophagitis compared to 0% in Group A2. On the other hand, in Group B, cured patients were 224/315 (71.1% Group B1) versus 91/315 (28.9% group B2). In the latter, esophagitis was observed in 127/315 subjects (40.3%) and subdividing them according to the success of eradication therapy, in group B1 53.6% (120/224) of patients developed esophagitis against 7.7% (7/91) in Group B2, $p = 0.0001$.
Comparing patients with hyper (Group B1) and normal (Group A1) acid secretion, in whom H.p. eradication therapy was effective, a statistically significant increase in the occurrence of esophagitis, can be noted in group B1 (120/224 53.6%) against 30/96 31.2% in group A1 $p = 0.0001$.
No statistically significant difference was found in the development of esophagitis in patients with persistent infection when they were divided according to secretory status in group A2, 0/39 (0%) versus Group B2 7/91 (7.7%) $p = 0.077$.
Conclusion: This study shows statistically significance relationship between H.p. eradication and onset of esophagitis particularly in the group of hypersecretory status subjects.
Disclosure: Nothing to disclose

P1196 OPTIMIZATION OF 13C UREA BREATH TEST THRESHOLD LEVELS FOR THE DETECTION OF *HELICOBACTER PYLORI* INFECTION IN A NATIONAL REFERRAL LABORATORY

Contact E-Mail Address: kaiser1974@gmail.com
Introduction: Threshold values for C13-urea breath test (C13-UBT) positivity may be affected by sociodemographic factors, host factors such as C13 excretion kinetics, bacterial factors and laboratory factors including urea dose. Manufacturer-recommended cutoffs for C13-UBT assays may not be applicable in all settings. Optimizing C13-UBT cut-offs may have profound public health ramifications.
Aims and Methods: We aimed to determine the optimal threshold for C13-UBT positivity in our population. Consecutive test samples collected at our central laboratory from patients undergoing a first-time C13-UBT between 1st January 2010 and 31st December 2015 were included. The difference between values at 30 min and at baseline (T30-T0) was expressed as delta over baseline (DOB). Cluster analysis was performed on the C13-UBT test results to determine the optimal cut-off point with minimal interclass variance.
Results: 234,831 patients (87,291 (37.2%) male, age 39.9 ± 19.9) underwent a first-time C13-UBT, including 124,701 (53.1%) negative and 110,130 (46.9%) positive tests, using the manufacturer-recommended cutoff of 3.5 DOB. Cluster analysis determined an optimized cut-off of 2.74 DOB, representing an additional 2180 (0.93%) positive subjects who had been previously categorized as negative according to the manufacturer-specified cutoff of 3.5 DOB. Mean positive and negative DOB values were 19.54 ± 14.95 and 0.66 ± 0.51, respectively. The cut-offs for male and female subjects were 2.23 and 3.05 DOB, respectively. Threshold values for <45 year-olds, 45–60 year-olds and >60 year olds were 2.67, 2.55 and 2.93 DOB, respectively. Of the 2180 (0.93%) patients with DOB 2.73–3.49, 289 (13.3%) performed a subsequent C13-UBT and 140 (48.4%) remained positive when tested at 20.3 ± 14.4 months.
Conclusion: Major referral laboratories should optimize threshold values for C13-UBT positivity for their geographical location. Different cut-off values should be applied for male and female subjects.

P1197 CLARITHROMYCIN RESISTANCE AND FEMALE GENDER AFFECT *HELICOBACTER PYLORI* ERADICATION FAILURE IN CHRONIC GASTRITIS

S.K. Lee, Y.-W. Chang
Kyung Hee University Hospital, Dept. of Inernal Medicine, Gastroenterology, Seoul, Korea (Republic of)

Contact E-Mail Address: ryo7@naver.com
Introduction: *Helicobacter pylori* infection affects 54.4% of population in Korea. The eradication rate of the first-line triple therapy (a proton pump inhibitor, clarithromycin, and amoxicillin) for *H. pylori* infection has gradually decreased in Korea. The eradication failure is influenced by host-related, bacterial, and environmental factors. It has been reported that the clarithromycin (CAM) resistance rate gradually increased from 17.2% to 23.7% between 2003 and 2012 in Korea. Clarithromycin resistance is considered the most important factor of eradication failure and the *CYP2C19* polymorphism is also related to the *H. pylori* eradication.
Aims and Methods: We aimed to evaluate whether clinical parameters, clarithromycin resistance, and *CYP2C19* genotype can affect the eradication failure. A total of 203 patients with *H. pylori*-positive chronic gastritis were consecutively enrolled. All the participants received a diagnosis of *H. pylori* infection by a rapid urease test or detection of *H. pylori* genomic DNA from gastric mucosal tissues. They received clarithromycin-based triple therapy for 7 days. A clarithromycin resistance test was performed by detection of A2142G and A2143G point mutations in *H. pylori* 23S rRNA using a dual-priming oligonucleotide PCR. The *CYP2C19* genotype was examined for polymorphism G681A of exon 5 and G636A of exon 4 by PCR with restriction fragment length polymorphism. The patients were classified into three groups by *CYP2C19* genotype: rapid metabolizers (RM), intermediate metabolizers (IM) and poor metabolizers (PM). Eradication was assessed by a ^{13}C-urea breath test 4 weeks after treatment.
Results: Of 203 patients, 190 completed the study. The eradication rate was 64.0% according to intention-to-treat analysis and 68.4% by per-protocol analysis. *CYP2C19* genotypes were identified as follows: 75 poor metabolizers, 75 intermediate metabolizers, and 40 rapid metabolizers. Nonetheless, this polymorphism was not significantly associated with eradication failure ($p = 0.682$). Clarithromycin resistance was detected in 33/190 patients (17.4%), and their eradication rate was zero. Clarithromycin resistance (odds ratio 19.13, 95% confidence interval 9.35–35.09) and female gender (odds ratio 1.73, 95% confidence interval 1.15–4.25) were significantly associated with eradication failure. The other clinical parameters such as age, cigarette smoking, alcohol intake, the body-mass index, hypertension, and diabetes were not significantly associated with eradication.
Conclusion: Clarithromycin resistance and female gender are factors affecting *H. pylori* eradication failure in patients with chronic gastritis.
Disclosure: Nothing to disclose

Introduction: The rapid identification of antibiotics-resistance of *H. pylori* is important to eradicate *H. pylori* infection. The aim of this study was to examine a newly designed revere blot hybridization assay (REBA) for identification of antibiotics-resistance by using *H. pylori* genomic mutations.
Aims and Methods: REBA for identification of genomic mutations responsible for antibiotic-resistance of H. pylori was developed: clarithromycin resistance (23s rRNA A2143G, A2142G and A2142C), fluoroquinolone resistance (gyrA Codon 87 C261G/A, and Codon 91 A272G and G271A/T), tetracycline resistance (16s rRNA AGA nt, 965–967 TTC). DNA extracted from *H. pylori* strains and other bacterial species. Polymerase chain reaction and REBA was performed.
Results: For diagnostic accuracy, a test using twelve samples of *H. pylori* strains and clones were performed, and findings of PCR-REBA were consistent with those of prepared samples. In cross-reactivity test using 26 other bacterial species, no cross reactivity was observed among bacterial species. For validation of findings of PCR-RBHA, data of direct DNA sequencing of seven samples of *H. pylori* strains were performed. Findings of PCR-REBA were consistent with those of direct DNA sequencing data.
Conclusion: REBA showed a good performance of rapid and accurate identification of antibiotics-resistance of *H. pylori*. It may become an effective diagnostic test for tailored eradication treatment of *H. pylori*.

P1199 EVALUATION OF THE RIDAGENE *HELICOBACTER PYLORI* REAL-TIME PCR ASSAY COMPARED TO CULTURE FOR THE DETECTION OF CLARITHROMYCIN RESISTANCE IN AN IRISH CENTRE

D. Brennan[1], L. Dwyer[2], R. Esmonde[2], Z. Afzal[1], E. Loughman[1], A.R. Douglas[1], C. O'Morain[1], D. McNamara[1], **S. Smith**[1,2]

Introduction: *H. pylori* antimicrobial susceptibility testing is important for determining the prevalence of antibiotic resistance in a given population, in order to recommend the most appropriate treatment regimens. Furthermore, it provides the opportunity to tailor an individual patient's therapy. As traditional culture-based approaches are time-consuming, recently developed molecular methods provide a more rapid alternative for the detection of *H. pylori* and its resistance to antibiotics.
Aims and Methods: Our aim was to evaluate the Ridagene *H. pylori* real-time PCR assay compared to culture-based methods for the detection of clarithromycin resistant *H. pylori* infection.
Following ethical approval and receipt of informed consent, gastric biopsy samples of patients diagnosed with *H. pylori* infection by the rapid urease test (RUT) were processed for culture and clarithromycin susceptibility testing using Etest strips (Biomerieux, France). DNA was isolated from biopsies using the QiaAmp DNA Mini Kit (Qiagen, UK) and analysed for the 3 most common clarithromycin-mediating point mutations (A2146C, A2146G and A2147G) using the Ridagene *H. pylori* real-time PCR assay (R-Biopharm AG, Germany).
Results: In all, samples from 131 RUT- and culture-positive patients (mean age 47.4 ± 14.2 years; 46.6% female) were analysed. The Ridagene assay detected *H. pylori* DNA in 96.9% ($N = 127/131$) of samples. Using biopsies that were both culture- and *H. pylori* DNA-positive, the rate of clarithromycin resistance detected by culture-based methods was significantly higher than that of the Ridagene assay (51.2% ($N = 65/127$) vs 38.6% ($N = 49/127$), respectively; $X^2 = 4.1$; $P = 0.04$). Results were concordant from both methods in 80.3% ($N = 102/127$) of cases. The sensitivity and specificity of the Ridagene assay

compared to culture for the detection of clarithromycin resistance were 67.7% (95% CI: 55.0–78.8%) and 91.9% (95% CI: 82.2–97.3%), respectively. The positive predictive value was 89.8% (95% CI: 78.9–95.4%) and the negative predictive value was 73.1% (95% CI: 65.5–79.5%).
Conclusion: Although the Ridagene assay is rapid and easy to use, the low sensitivity compared to culture for the detection of clarithromycin resistance in our cohort limits its use to cases where culture-based methods are unsuccessful. Further studies are required to characterise the full range of clarithromycin resistance-mediating mutations present in our patients.
Disclosure: Nothing to disclose

P1200 THE USEFULNESS OF LINKED COLOR IMAGING AND THE POTENTIAL OF AUTOMATIC DIAGMOSIS SYSTEM FOR DIAGNOSIS OF *H. PYLORI* INFECTION

N. Yagi[1], T. Yasuda[1], Y. Nakahata[1], T. Kurobe[1], Y. Yasuda[1], T. Omatsu[1], A. Obora[1], T. Kojima[1], T. Hiroyasu[2]

Introduction: Linked Color Imaging (LCI) is a novel image-enhanced endoscopy to enhance the slight difference in mucosal color. The lighting in LCI mode emphasizes hemoglobin related information. Using the latest LASEREO system (VP-7000&LL-7000) and latest endoscopy (EG-L600ZW7, EG-L600WR7) (FUJIFILM Co., Tokyo, Japan), we expected LCI to enhance the diffuse redness in Hp positive patients and support the diagnosis of active Hp infection. However, the endoscopic diagnosis of Hp infection does not have objective indicators; it depends on physician's experience. Therefore, it is necessary to establish universal methods for the endoscopic diagnosis of Hp infection, such as computer-aided diagnosis.
Aims and Methods: The aims of this study are (1) to evaluate the diagnosability of our artificial intelligence (AI) system for Hp infection and (2) to evaluate the usefulness of LCI for diagnosis of Hp infection compared to the conventional endoscopy with white-light image (WLI).
In our new AI system, LCI images were classified into two types based on the slight difference of the red color, high hue images (red-purple) and low hue images (red-orange). Then, the presence or absence of Hp infection was learned by machine learning for each type of LCI image. The trained classifiers gave us the diagnosis of Hp infection automatically. We retrospectively analyzed 133 patients with Hp positive (55 patients) or negative (78 patients) those were examined with WLI and LCI at Asahi University Hospital from December 2016 to January 2018. The presence of Hp infection was determined by more than two different examinations: histologic examination, serum antibody test, stool antigen test, ^{13}C-urea breath test. The absence of Hp infection was determined by the ^{13}C -urea breath test at least 2months after Hp eradication therapy. For this study, we used 3 endoscopic images per patient, which were taken from lesser curvature or greater curvature of middle to lower of gastric body. Three LCI images were read into AI system, and randomly arranged 3 LCI and 3 WLI images were made a judgment of Hp-positive/negative by 3 endoscopists, A: an expert involved in the development of LCI, B: a gastroenterology specialist, C: a senior resident.
Results: The levels of accuracy/sensitivity/specificity of diagnosis of Hp infection by AI system with LCI were 82.0%/74.5%/85.9%, respectively. On the other hand, those of diagnosis by A with WLI and LCI were 78.9%/74.5%/82.1%, and 88.0%/85.5%/89.7%, respectively. Those of diagnosis by B with WLI and LCI were 75.9%/58.2%/88.5%, and 87.2%/78.2%/93.6%, respectively and diagnosis by C with WLI and LCI were 74.4%/69.1%/78.2%, and 85.7%/85.5%/85.9%, respectively.
The accuracy and sensitivity of diagnosis with LCI was significantly higher than those of WLI by all three endoscopists ($p = 0.018$–0.048). There was no significant difference between diagnosis of physicians and AI system. The kappa value of variability among 3 physicians for LCI (kappa value: between A&B = 0.86, A&C = 0.71, B&C = 0.72) was higher than that for WLI (kappa value: between A&B = 0.58, A&C = 0.57, B&C = 0.65). There were 7 cases (5%) that were wrongly diagnosed by both 3 physicians and AI system.
Conclusion: LCI had significantly higher accuracy and sensitivity of diagnosis of Hp infection compared to conventional WLI. We recommend LCI mode for screening of Hp infection in routine endoscopy as costless and convenience.
The AI system could diagnose the Hp infection with great accuracy. Learning more images, our new proposed AI system will be able to support an inexperienced physician.
Disclosure: Nothing to disclose

P1201 SPANISH PRIMARY CARE SURVEY ON THE MANAGEMENT OF *H. PYLORI* INFECTION: PERCEPTIONS, ACCESS TO INFORMATION AND CONTINUOUS MEDICAL EDUCATION

A.G. McNicholl[1,2], J. Amador[3], M. Ricote Belinchon[4], P.J. Cañones-Garzón[5], E. Gene[6], X. Calvet Calvo[7], J.P. Gisbert[8,9]

Introduction: The preferences and decisions of Primary Care physicians in the management of *H. pylori*, or their access to different health technologies (i.e. diagnostic methods), courses and information have not generally been taken in consideration, even though Primary Care physicians currently manage this infection in most of the cases.
Aims and Methods: To evaluate the perceptions, access to continuous medical education and information of Spanish Primary Care physicians. A multidisciplinary committee formed by *H. pylori* experts from the Spanish Association of Gastroenterology (AEG) and the three societies of Primary Care in Spain (SEMFyC, SEMERGEN and SEMG) designed an online survey registering 140 variables regarding demographics, type of practice, continuous education received, preferences on management and access to health technology. Survey was submitted via e-mail to the members of the three societies. Responses were anonymously codified. Truncated responses were included up to last question answered. Responses were weighted by province, gender, age and type of practice. Categorical variables were represented as percentage and 95% confidence interval (CI), numerical variables as mean and standard deviation (for normal distribution) or median and inter-quartile range (IQR) (if not normal). Survey was performed using the AEG-REDCap platform.
Results: A total of 1,581 responses were received between December 2017 and March 2018. After removing blank and duplicate responses 1,425 were valid for analysis (representing 5% of all Primary Care doctors in Spain). Of them, 66% (95%CI = 64–68%) were women and the average age was 48 years (SD = 11). 59% were from urban context, 20% from semi-urban and 21% from rural. 93% provided public practice. No respondent bias was identified in the known variables. 48% of physicians had read at least one Maastricht consensus, and 21% had read Maastricht V. 87% of doctors had read at least one national or international guideline or consensus on *H. pylori* or dyspepsia. 34% had attended a continuous education course related to *H. pylori*, the majority of them in the last four years (median 2, IQR = 1–4 years). Course access was region dependent, ranging from 18% in Andalucia to 65% in Madrid. Only 16% of doctors responded they knew local *H. pylori* prevalence, 63% did not know and 21% knew that there was no data or it was outdated. Local prevalence reported by those who "knew" was higher than the prevalence expected by those who "did not know" (43% vs. 32%). Information on resistance to clarithromycin rates showed similar patterns: only 13% reported knowing them, and 21% reported there was no data or outdated, and expected resistance was lower (16%) than reported (23%).
Conclusion: Although Spanish Primary Care physicians seem relatively updated through literature, continuous medical education updates are region dependent and should be extended nationally. Lack of knowledge on, and underestimation of, prevalence and resistance rates are due both to lack of educational updates as well as lack of scientific studies in the literature.

Contact E-Mail Address: giulia.fiorini@fastwebnet.it
Introduction: Stool antigen has become a widely acceptable method for detection of *H. pylori*. This non-invasive method provides an alternative to the more invasive techniques of biopsy. Gastric disease attributed to *Helicobacter pylori* includes chronic gastritis and peptic ulcer disease. The recent Maastricht V[1] Consensus Report indicates that serology tests performance may be variable due to geographic location and recommends the use of the stool antigen tests as an aid in the detection of *Helicobacter pylori* disease in the primary care setting.
The purpose of this study was to evaluate the sensitivity and specificity of a novel, rapid immunoassay compared to the gold standard method of detection. Curian HpSA Fluorometric (RUO), is an innovative, rapid, qualitative, immunoassay that utilizes fluorescent technology for the detection of *Helicobacter pylori* antigens in human stool specimens. The test uses monoclonal anti-*Helicobacter pylori* antibodies for both capture and detection. For clear interpretation, the Curian Analyzer (reader) is used to report results.

Aims and Methods: The Curian HpSA Fluorometric (RUO) assay was compared using 95 prospective positive stools and 53 retrospective negative stools characterized by UBT, Histology and Culture (Gold Standard). Samples were acclimated to room temperature and tested according to the Curian HpSA (RUO) Package Insert.
Results: The Curian HpSA Fluorometric assay (RUO) demonstrated Sensitivity of 94.73% and Specificity of 98.11% compared to the gold standard for diagnosis of *Helicobacter pylori* infection. Overall correlation was 95.95%.
Conclusion: The Curian HpSA Fluorometric (RUO) assay performance demonstrated comparable sensitivity and specificity compared to the gold standard for detection of *H. pylori*. The 20 minute, rapid, qualitative assay provides the end user with accurate interpretation of results without subjective review. Curian HpSA Fluorometric is a 20 minute rapid test for the accurate, non-invasive detection of *Helicobacter pylori* in human stool specimens.
Disclosure: Nothing to disclose

P1203 EFFICACY OF VONOPRAZAN-BASED THERAPY COMPARED TO PROTON PUMP INHIBITOR (PPI) IN *H.PYLORI* ERADICATION THERAPY

T. Machida, Y. Fukami, R. Ishii, H. Hara, T. Mochida, Y. Yonemoto, Y. Sugiyama, A. Watanabe, M. Kaneshiro, H. Ikemiyagi, K. Yoshino, S. Sakita
Yokohama City Minato Red Cross Hosipital, Gastroenterology, Yokohama, Japan

Contact E-Mail Address: tomoyo.machida@gmail.com
Introduction: PPI-based therapy is one of the most popular *H.pylori* eradication therapies in the world. However, first-line eradication rate is decreasing in Japan, because *H.pylori* acquired resistance to antibiotics. It is known that most antibiotics are not effective under strong acid secretion. So in order to improve the eradication rate, gastric acid secretion must be reduced more rapidly and strongly.
Vonoprazan is newly developed potassium competitive acid blocker (P-CAB) and more effective in reducing gastric acid secretion than PPI.
Aims and Methods: The aim of this study is to clarify the efficacy of Vonoprazan-based eradication therapy and compare to PPI-based therapy.
The subjects were 1215 patients who were diagnosed as *H.pylori* infection in our institution from June 2014 to December 2017 using blood antibody positive. These patients were grouped into three; Vonoprazan group (VPZ) and Rabeprazole group (RPZ) and Lansoprazole group (LPZ). We evaluated retrospectively first-line and second-line eradication rate and statistical analysis.
Each first-line regimen of VPZ was 7days, Vonoprazan 20mg bid + AMPC750mg bid + CAM and second-line regimen was 7days, Vonoprazan 20mg bid + AMPC750mg bid + MNZ250mg bid.
Each first-line regimen of RPZ was 7days, Rabeprazole 10mg bid + AMPC750mg bid + CAM. Second-line regimen of RPZ was 7days, Rabeprazole 10mg bid + AMPC750mg bid + MNZ250mg bid.
Each first-line regimen of LPZ was 7days, Lansoprazole 30mg bid + AMPC750mg bid + CAM, second-line regimen of LPZ was 7days, Lansoprazole 30mg bid + AMPC750mg bid + MNZ250mg bid.
Results: The number of first-line regimen of VPZ patients was 350, and eradication was achieved in 321 patients (91.7%). RPZ patients was 309, and eradication was achieved in 229 patients (74.1%), and LPZ patients was 378, and eradication was achieved in 301 patients (79.6%) respectively. Eradication rate of VPZ is higher than RPZ and LPZ ($P < 0.0001$ and < 0.0001 respectively).
The statistically number of second-line regimen of VPZ patients was 40, and eradication was achieved in 34 patients (85.0%).
RPZ patients was 65, and eradication was achieved in 60 patients (92.3%), and LPZ patients was 70, and eradication was achieved in 61 patients (87.1%) respectively. There were no significant difference in second-line regimen.
Adverse events such as rash, diarrhea, 6.9% in VPZ, 16.2% in RPZ, 6.3% in LPZ.
Conclusion: Vonoprazan-based regimen was superior to conventional PPI (Rabeprazole and Lansoprazole) in eradication rate of *H.pylori*. In addition, it was a safe regimen on the issue of adverse events.
Disclosure: Nothing to disclose

P1204 EFFICACIES OF DIFFERENT PROTON PUMP INHIBITOR-BASED 14-DAY BISMUTH-CONTAINING QUADRUPLE REGIMENS FOR THE INITIAL ERADICATION OF *HELICOBACTER PYLORI* IN THE SOUTHEAST COASTAL REGION OF CHINA: AN OPEN-LABEL, RANDOMIZED CLINICAL TRIAL

L. Chen[1,2], J. He[1,2], L. Wang[1,2], A. Li[1,2], S. Chen[1,2]
[1]*Sir Run Run Shaw Hospital, School of Medicine, Zhejiang University, Gastroenterology, Hangzhou, China*
[2]*Institute of Gastroenterology, Zhejiang University, Hangzhou, China*

Contact E-Mail Address: clyemma@163.com
Introduction: *Helicobacter pylori (H. pylori)* is reported to be associated with a range of gastrointestinal diseases, such as gastritis, peptic ulcer, gastric cancer, and mucosa-associated lymphoid tissue lymphoma. Although the prevalence of *H. pylori* infection has decreased on a global scale, it remains a serious concern in China with a prevalence of 66% among rural populations and 47% among urban populations. The Kyoto global consensus report on *H. pylori* gastritis has defined it as an infectious disease and suggested that all populations infected with *H. pylori* should receive eradication treatment. Therefore, the selection of a cost-effective regimen for the initial eradication of *H. pylori* is urgently needed in China for the consideration of regional prevalence and cost-benefit ratio.
Standard triple regimens have failed to reach 80% efficacy and 14-day bismuth-containing (BQ) regimen is the most commonly used regimen in China currently according to a real-world Asia-Pacific *H. pylori* survey. Resistance rates towards amoxicillin and furazolidone in the southeast coastal region of China were 0.1% and 0.1%. Furthermore, as a component of BQ regimens, proton pump inhibitor (PPI) plays an important role in the eradication of *H. pylori.*
Aims and Methods: We aimed to evaluate the efficacy and safety of different PPI-based 14-day BQ regimens for the initial eradication of *H. pylori* and to provide credible evidence to justify the clinical use of PPIs. In total, 175 eligible patients were enrolled and randomly assigned to 14-day BQ regimens consisting of colloidal bismuth pectin (0.4g), amoxicillin (1000mg), furazolidone (100mg) and a PPI, all twice a day. The PPIs used in the five regimens were Group A (SOMAC, pantoprazole sodium enteric-coated capsules, 40mg), Group B (Pantoloc, pantoprazole enteric-coated tablets, 40mg), Group C (Takepron, lansoprazole enteric-coated capsules, 30mg), Group D (Nexium, esomeprazole magnesium enteric-coated tablets, 20mg), and Group E (Pariet, rabeprazole sodium enteric-coated tablets, 10mg). *H. pylori* status was reassessed by ^{13}C urea breath test on day 56 and negative status indicated the success of eradication treatment. Gastrointestinal symptoms and stool type in patients were assessed on day 0 and day 56 using a simplified Gastrointestinal Symptom Rating Scale (GSRS) and Bristol Stool Scale (BSS). Parenteral adverse effects and compliance were recorded simultaneously. Patients who took less than 80% of the total dose were poorly compliant.
Results: The total eradication rate of 14-day BQ regimens was 86.9% (152/175) and 95.6% (152/159) by intention-to-treat (ITT) and per-protocol (PP) analysis, respectively. The efficacies of groups A, B, C, D, and E by ITT analysis were 91.4% (32/35), 85.7% (30/35), 88.6% (31/35), 85.7% (30/35), and 82.9% (29/35), respectively ($p > 0.05$). In the PP analysis, the efficacies were 97.0% (32/33), 93.8% (30/32), 93.9% (31/33), 100% (30/30), and 93.5% (29/31), respectively ($p > 0.05$). The total GSRS score decreased significantly from day 0 to day 56(5.48 ± 0.321 vs. 2.76 ± 0.238, $p < 0.01$), and 12 of 15 gastrointestinal symptoms were observed to have prominent remission ($p < 0.05$). The stool type was improved distinctly after eradication treatment ($p < 0.01$). The rate of total parenteral adverse effects was 15.7% (25/159) and the total rate of poor compliance was 5.0% (8/159).
Conclusion: 14-day BQ regimens consisting of amoxicillin and furazolidone are effective and safe for the initial eradication of *H. pylori*. Efficacies of different PPI-based 14-day BQ regimens showed no significant difference.
Disclosure: Nothing to disclose

P1205 APPARENT INTRACELLULAR *HELICOBACTER PYLORI* DETECTION BY IMMUNOHISTOCHEMISTRY AS INDEPENDENT RISK FACTOR FOR FAILURE OF FIRST-LINE ERADICATION THERAPY

Introduction: *Helicobacter (H.) pylori* is considered as an extracellularly living bacterium; however, the microorganism can also be found in canaliculi of parietal cells resembling intracellular occurrence by immunohistochemistry, or even in the cytoplasm of surface epithelial cells, parietal cells and chief cells. Using immunohistochemical staining we have been able to observe that the detection of apparent intracellular *H. pylori* (aiHp) has been associated with reduced eradication rates after antimicrobial therapy.
Aims and Methods: Considering antimicrobial resistance, we aimed to investigate the impact of aiHp detection on the success rate of the first-line eradication therapy.
Paraffin-embedded gastric corpus biopsies of 52 *H. pylori*-infected patients, in which the pathogen was found by immunohistochemistry, not only extracellularly but also apparently intracellularly, and of matched controls with solely extracellular *H. pylori* (eHp) occurrence were analysed. All patients were naïve to treatment and have received antimicrobial therapy consisting of amoxicillin, clarithromycin and PPI. Further inclusion criteria were the occurrence of a second corpus biopsy obtained between two and four months after the first endoscopy and a positive PCR result of the first biopsy. The PCR was targeting a *H. pylori*-specific sequence of the 23S rRNA gene, which includes the region of potential point mutations associated with resistance to clarithromycin.
Results: The overall eradication rate was 78.8% by eHp versus 46.2% by eHp/aiHp cases; in clarithromycin susceptible cases the respective values were 89.5% and 57.1%. Logistic regression analysis revealed that both resistance to clarithromycin and apparent intracellular detection are highly significant ($p \leq 0.001$) and independent predictors of eradication failure with an odds-ratio (95% CI) of 5.2 (2.1–12.7) and 4.3 (1.8–10.3), respectively. Out of 13 aiHp cases that failed eradication with a clarithromycin sensitive strain in the first biopsy, 12 (92.3%) developed a resistance associated mutation.
Conclusion: Occurrence of aiHp was clearly shown to be an independent risk factor for failure of the first-line eradication therapy. Our data suggest the importance of immunohistochemical staining for *H. pylori* in corpus biopsies; aiHp should be taken into consideration with regard to therapy options.

Introduction: The specific impact of antibacterial resistance on *Helicobacter pylori* eradication treatments is a fundamental factor in designing management strategies.

Aims and Methods: Our aim was to evaluate the effect of *H. pylori* resistance in different first-line treatments by European Gastroenterologists in their routine clinical practice. A Local Coordinator was selected from each country with more than 10 *H. pylori* references in PubMed. Each Coordinator selected a representative group of recruiting investigators from his/her country. An e-CRF was created on AEG-REDCap to systematically register all adult patients infected with *H. pylori*. Variables included: *H. pylori* diagnostic test used, use of culture and susceptibility testing, or molecular tests for the evaluation of antibiotic resistance.

Results: Resistance data was available in 677 treatment-naïve patients. Although culture and antibiotic susceptibility testing were not systematically performed and more data is needed to draw definite conclusions of the effect of resistance to some antibiotic combinations, the data from the present study show that resistance affected nearly all prescribed combinations (data shown in table). The negative impact of resistance was more marked in triple therapies, in which clarithromycin resistance halved (89 vs. 44%) the efficacy of triple therapy with clarithromycin and amoxicillin.

Conclusion: Triple therapies are greatly affected by single resistance to their constituent antibiotics. Non-bismuth quadruple therapies appear to be unaffected by single resistance but may be affected by dual clarithromycin-metronidazole resistance.

	No resistance		Clarithromycin		Metronidazole		Dual (C + M)	
	N	%E	N	%E	N	%E	N	%E
PPI+C+A	345	88.7%	23	43.5%	137	83.2%	7	57.1%
PPI+C+A+M	34	94.1%	11	90.9%	11	81.8%	5	80.0%
PPI+C+M	20	80.0%		NA		NA		NA
PPI+C+A+T seq	218	88.5%	29	86.2%	218	84.9%	123	84.6%

Introduction: Single-capsule bismuth quadruple therapy (scBQT) plus a proton pump inhibitor (PPI) has been proposed as first alternative and rescue therapy for the eradication of *Helicobacter pylori*.

Aims and Methods: To perform a meta-analysis evaluating the efficacy and safety of scBQT as any line of treatment. Studies were selected up to January 2018. Efficacy was estimated using the generic inverse variance method, and safety through the incidence rate of adverse events (AEs).

Results: In total, 20 studies (2,685 patients) were included in the analysis. Intention-to-treat (ITT) efficacy was 92% (95%CI = 89–95%, 14 studies, $I^2 = 87\%$) in first-line, 91% (95%CI = 87–95%, 9 studies, $I^2 = 75\%$) in second-line and 80% (95%CI = 77–8%, 5 studies, $I^2 = 0\%$) in third-line. There were no significant differences per type or dosage of PPIs across treatment lines. In clarithromycin and metronidazole resistant infection, the ITT efficacy in first-line was 92% (95%CI = 88–97%, 3 studies, $I^2 = 0\%$) and 93% (95%CI = 89–97%, 4 studies, $I^2 = 0\%$) respectively. In patients previously treated with clarithromycin, ITT efficacy was 93% (95%CI = 89–98%, 6 studies, $I^2 = 63\%$). The incidence of AEs was 46% (95%CI = 36–56%, 16 studies, $I^2 = 90\%$), and mostly mild.

Conclusion: Treatment with Single-Capsule Bismuth Quadruple Therapy for 10 days represents a highly effective option (≥ 90%) in first and second-line, regardless of the type and dose of PPI, even in patients with clarithromycin or metronidazole resistant strains or in those who were previously treated with clarithromycin.

Introduction: Bismuth quadruple therapy with a PPI, bismuth salts, tetracycline and metronidazole has resurfaced in Europe thanks to a new single-capsule formulation.

Aims and Methods: Our aim was to evaluate the efficacy and safety of the single-capsule bismuth quadruple therapy in the European Registry on *Helicobacter pylori* management. International multicenter prospective non-interventional registry starting in 2013 aimed to evaluate the decisions and outcomes of *H. pylori* management by European gastroenterologists. National coordinators were selected from each country to identify a representative group of recruiters. All infected adult patients were systematically registered at an e-CRF by AEG-REDCap. Variables included: Patients' demographics, previous eradication attempts, prescribed treatment, adverse events, and outcomes. Intention-to-treat and per-protocol analyses were performed. Data monitoring was performed to ensure the quality of the data.

Results: So far, 21,302 patients from 27 European countries have been evaluated. Of these, 1,258 have been treated with single capsule bismuth quadruple therapy, of which 1,231 have finished follow-up. Of them, 1,148 have been prescribed following the technical sheet (10 days, 3 capsules q.i.d.) Average age was 52 years, 66% were women, and 18% had peptic ulcer. Results are shown in the Table. The majority of cases (60%) were naïve to *H. pylori* treatment. PPI type or dose did not influence eradication rate. 33% of cases suffered from adverse events (severe in 3%, and only 1% withdrew treatment due to adverse events). Only two serious adverse events were reported: hospitalization due to diarrhea and an allergic reaction treated with anti-histamine drugs, both solved without complications.

	ITT			PP			Compliance
	Hp-	N	%	Hp-	N	%	%
First-line (naïve)	610	666	92	602	633	95	96
Second-line	243	273	89	240	260	92	96
Third-line	124	151	82	120	142	85	95

ITT: intention-to-treat; PP: per-protocol.
[Table 1]

Conclusion: Treatment with single capsule bismuth quadruple therapy achieves *H. pylori* eradication in approximately 90% of patients by intention-to-treat in clinical practice, both in first- and second-line, with a favorable safety profile.

Disclosure: Dr. Gisbert has served as a speaker, a consultant and advisory member for or has received research funding from Almirall, Nycomed, AstraZeneca, Casen Recordati, Mayoly and Allergan. Dr. McNicholl has received retribution from Allergan and MSD for formative actions and is an advisor of Mayoly.

P1209 OUTCOMES OF FURAZOLIDONE-BASED QUADRUPLE THERAPY FOR *HELICOBACTER PYLORI* INFECTION AND PREDICTORS OF FAILED ERADICATION

Y. Zhang[1], W. Hu[1], W. Zheng[1], Q. Du[2], J. Kim[3], J.Y. Kao[4], **L. Chen**[1], N. Dai[1], J. Si[1]

Introduction: With the increasing antibiotic resistance to *Helicobacter pylori* (*H. pylori*) worldwide, traditional triple therapies have become increasingly ineffective, with some studies reporting eradication rates as low as 50%. High antibiotic-resistant rate is one of the most important reasons. Selecting optimal therapies for antibiotic-resistant *H. pylori* infection has become an important global public health task. Compared to high rates of resistance observed with clarithromycin, metronidazole, and levofloxacin, *H. pylori* to furazolidone remains low in China. Although a number of studies with limited sample size demonstrate high efficacy of furazolidone, amoxicillin-based quadruple therapy (FABQT) for treatment of *H. pylori*, data on the impact of adverse events are not well described. Predictors of failed *H. pylori* eradication other than the choice of regimen or poor medication adherence are largely unknown. Therefore, we performed a retrospective study of patients who received FABQT for treatment of *H. pylori* at our center.

Aims and Methods: The aim of the study is to evaluate the outcome of furazolidone-based quadruple therapy for treatment of *H. pylori* and identify predictors of failed eradication. Patients with *H. pylori* infection treated with furazolidone, amoxicillin, bismuth, and proton pump inhibitor therapy (from January 2015 to December 2015 in Sir Run Run Shaw Hospital,Hangzhou, China) and received ^{13}C-urea breath test >4 weeks after treatment were evaluated. *H. pylori* eradication rate, treatment-related adverse events, and predictors of failed eradication, including age, gender, education levels, prior treatment history, smoking and alcohol status during treatment, PPI types, bismuth dose, treatment duration, diagnosis according to endoscopy and medication adherence were evaluated. Intention-to-treat (ITT) and per-protocol (PP) analyses were used to assess the H. pylori eradication rates. Categorical variables were compared using the χ^2 test or Fisher's exact student *t*-test. Univariate and multivariate analysis were performed to identify predictors of failed *H. pylori* eradication.

Results: Of the 992 patients treated and retested for *H. pylori*, the overall eradication rates were 95% (95%CI 94–96%) by intention-to-treat (ITT) and 95% (95%CI 94–97%) by per protocol (PP) analyses. *H. pylori* eradication rates as primary therapy were 95% (95%CI 94–97%) and 96% (95%CI 94–97%), while as rescue therapy were 91% (95%CI 87–96%) and 91% (95%CI 86–96%) per ITT and PP analyses, respectively. Among the 859 patients who completed the study protocol, 144 (17%) reported treatment-related adverse events including 24 (3%) leading to premature discontinuation of therapy. In the multivariate analysis, poor medication adherence (AOR = 6.7, 95%CI 2.8–15.8), >2 previous *H. pylori* treatments (AOR = 7.4, 95%CI 2.2–24.9), alcohol consumption during therapy (AOR = 4.4, 95%CI 1.5–12.3), and possibly smoking during therapy (AOR = 1.9, 95%CI 0.9–4.3) were associated with failed *H. pylori* eradication. Age, gender, education level, PPI type, bismuth dose, therapy duration, and the indication for treatment were not associated with failed *H. pylori* eradication.

Conclusion: Furazolidone-amoxicillin quadruple therapy in high clarithromycin-resistant area for *H. pylori* demonstrated high eradication rates as primary and rescue therapy with a favorable safety profile. Patient education targeting complete abstinence from alcohol and improved medication adherence may further optimize *H. pylori* eradication.

Contact E-Mail Address: bouchabou.bochra@gmail.com
Introduction: The objective of this study is to compare, in Tunisia, a region with 15% mean local resistance to clarithromycin, the efficacy rates of the concomitant versus the sequential *H. pylori* eradication therapy.
Aims and Methods: Our prospective randomized study included 152 patients with newly diagnosed H. pylori infection, randomized to receive a 10-day concomitant or 10-day sequential therapy. Treatment outcome was assessed by histopathological examination at least 6 weeks after therapy. Only patients per protocol (PP) ($n = 106$) were analyzed for eradication rates. Secondary end points included patient compliance and safety.
Results: The concomitant therapy group achieved statistically significant higher eradication rates when compared with the sequential treatment group in the PP analysis (49.1% versus 32.7%, $p = 0.001$), after adjusting for age, gender and the presence or not of ulcer and/or non-ulcer dyspepsia. Both groups displayed medium compliance rates (71.4%, 95% CI 97%-100% with sequential vs. 75.4%, 95% CI 98%-100% with concomitant). Regarding treatment safety, major adverse events that led to the discontinuation of both regimens were few, with no statistical difference between the two groups (36.8% for the concomitant therapy group and 30.6% for the sequential therapy group). However, diarrhea, dizziness, headache and anorexia were related with concomitant therapy with statistical significance ($p = 0.03$, 0.002, 0.000, 0.002, respectively).
Conclusion: Concomitant therapy led to statistically significant higher eradication rates over sequential therapy with moderate efficacy. Both therapies showed moderate compliance and an acceptable safety profile. The 10-day quadruple concomitant scheme should be the adopted for first-line *H. pylori* eradication in Tunisia.

Introduction: *Helicobacter pylori* (*H. pylori*) infection is highly prevalent in Portugal and its eradication is formally recommended in multiple circumstances. However, the indiscriminate use of antimicrobials has led to a drastic rise in antibiotic resistance, with failure of traditional eradication schemes. Bismuth was not available in this South-European country, but a single-capsule bismuth-based quadruple treatment became recently available. This study aims to determine whether this quadruple regimen is useful as a second-line or salvage therapy.
Aims and Methods: This was a multicentric, retrospective study, with most patients included in a prospective database but without any direct intervention of the investigation team before or during treatment. All consecutive patients that were treated with bismuth-based quadruple therapy as second-line or salvage treatment between July-2017 and February-2018 were enrolled. Their medical records were reviewed and clinical and laboratorial parameters, as well as data on treatment efficacy and adverse events were retrieved. Patients were also contacted by telephone after treatment in order to confirm compliance (considered as adequate when at least 90% of prescribed medication was taken), adverse events and global satisfaction with this specific therapy.
Results: A total of 73 subjects were included (female – 74%; mean age – 56 ± 13.6 years). Patients had previously completed a mean of 2 eradication schemes (1 to 5): triple clarithromycin-based – 45.2%; sequential – 28.8%; concomitant – 17.8%; fluoroquinolone-based – 16.4%; rifabutine-based – 2.7%. The proton pump inhibitor of choice was esomeprazole (32.9%), followed by omeprazole (31.5%). Compliance was achieved in 87.7% and the overall eradication rate was 87.7% (95% confidence interval: 78.9–93.9). Treatment-related adverse effects were experienced by 22 patients (30.1%), being mild in 8, moderate in 6 and severe in 8. The main drawbacks of the treatment in the patient's perspective were its' high price (26%) and the adverse effects (17.8%). Failure to eradicate *H. pylori* was correlated with the following: previous rifabutine-base scheme (28.6% vs. 0%) and higher number of previous treatment regimens (2.6 ± 1.2 vs. 1.7 ± 0.7).
Conclusion: In this South-European country a single-capsule bismuth-based quadruple therapy is an excellent alternative in patients who have failed previous eradication schemes, with acceptable compliance and side effects.

P1212 HIGH-DOSE CLARITHROMYCIN WITH P-CAB PLUS AMOXICILLIN TRIPLE THERAPY REGIMEN IS MOST RECOMMENDED ON 1ST *H.PYLORI* ERADICATION REGIMEN; A MULTICENTER CENTER PROSPECTIVE CASE STUDY

T. Yamasaki[1], M. Chibai[2], Y. Arai[1], E. Nishio[1], M. Aizawa[1], Y. Nakamura[3], M. Saruta[1]

Introduction: It has been believed that drug resistance is the most important cause of eradication failure on Amoxicillin (AMX) and Clarithromycin (CLR) based *H.pylori* (Hp) eradication therapy for a long time. Unfortunately, we have been permitted to prescribe only AMX and CLR as antibiotics of 1st eradication in Japan. So far, several proton pomp inhibitors (PPIs) have been used in Hp eradication therapy, most of reports said that the success rate of eradication about 70% regardless of CLR dose (400 or 800 mg/day) in Japan. Recently the ratio of CLR resistance in Japan comes up to over 30 %, we need to overcome CLR resistance on Hp eradication. On the other hand, recently it is considered that the stability of continuous gastric acid suppression is more important factor rather than CLR resistance. At the point of gastric acid suppression, we have been used so strong acid suppressive drug P-CAB (Potassium-Competitive Acid Blocker) rather than conventional PPIs. Since Feb. 2015, we have used P-CAB instead of previous PPIs in AMX and CLR based Hp eradication therapy to improve success rate of eradication.
Aims and Methods: The aim of this study is to elucidate the importance of CLR dose on success rate of P-CAB Vonoprazan (VPZ)-based triple therapy regimens. This study is a multicenter center (8 hospitals), prospective case study from Jan. 2012 to Jan. 2018. A total of 3,471 patients (Hp positive) were enrolled. Mean age of the patients was 52.1 years old. Fisher's exact test was used in all statistical analyses. Regimen of VAC (400 or 800) was VPZ (40 mg/day) b.i.d., AMX (1,500 mg/day) b.i.d. plus CLR (400 or 800 mg/day) b.i.d. for 7 days. The judgement of success or failure on the eradication therapy had been done with urea breath test on 3 months after eradication therapy to avoid false negative results. We compared which is better CLR 400 or 800 mg/day on P-CAB based triple therapy regimens of Hp eradication and checked their adverse events.
Results: The average success rate of VAC regimens was 91.0 % (3,032/3,332 = 91.0%, PPS). Success rate of VAC 800 showed significantly high (1,301/1,331 = 97.7%, PPS) rather than VAC 400 (1,762/2,001 = 88.1%, PPS) ($p < 0.001$). It was noteworthy that the average success rate of VAC 800 regimens (238/251 = 94.8 %) were significantly high rather than the average success rate of VAC 400 regimens (207/249 = 83.1%) ($p < 0.001$) on CLM resistance group. These results suggest that using high dose CLR with VPZ (P-CAB) plus AMX regimen is better on Hp eradication triple therapy regimen to overcome CLR resistance. Although its mechanism is unclear, the rapid and potent gastric acid-inhibitory effect of VPZ would provide a good environment for effective antibacterial action. VPZ has been available for Hp eradication since 2015, and the efficacy of first-line eradication therapy in Japan has dramatically improved.
Conclusion: High-dose CLR with P-CAB plus AMX triple therapy regimen is much better on Hp eradication therapy even if CLR resistance. We have been able to expect significantly high success rate (more than 97 %) as Hp 1st eradication therapy. This regimen is most recommended on 1st eradication regimen.

Introduction: The Helicobacter Eradication Aspirin Trial (HEAT) is a multicentre, double blind, randomised controlled trial investigating whether *Helicobacter pylori* eradication reduces the incidence of hospitalisation for peptic ulcer bleeding (1). Participants are subjects aged over 60, taking low dose aspirin for at least four months at the time of recruitment; all participants were recruited from primary care. *H. pylori* positive participants were randomised to receive one week active trial treatment (lansoprazole 30mg, clarithromycin 500mg and metronidazole 400mg twice daily) or placebo. Recruitment to the trial started in 2012 and completed in 2017; follow-up is endpoint driven and is ongoing.

Aims and Methods: Participants are followed up using a bespoke web-based trial management system that communicates directly with HEAT Toolkit software downloaded at participating GP practices, which issues MIQUEST (2) queries searching follow-up criteria. The primary endpoint of the study is the rate of hospitalisation due to definite or probable peptic ulcer bleeding. The study will end when 87 adjudicated events have occurred. Events are tracked by accumulating information from MIQUEST searches of GP databases via the HEAT toolkit, patient contact, review of national secondary care admission and mortality data.

Results: HEAT is being conducted in practices across the whole of the UK with 188,428 invitation letters sent from 1,208 GP practices. A total of 37,247 positive responses were received, representing a 20% response rate. Of those, 30,025 patients were consented to the study of whom 5,356 *H. pylori* positive patients were randomised. The percent of *H. pylori* positive patients varied from 13% to 39% throughout the country. Multiple deprivation scores applied to the data indicated an increase in response with less deprivation, but a decrease in the number of randomised patients.

The mean age at randomisation for all participants was 73.6 ± 7.0 (SD) years, and 73.8% of participants are male. Only 7.2% of participants are smokers although 52.9% are ex-smokers. A total of 15% of the randomised patients have withdrawn from the trial, and 100 patients have died so far.

Conclusion: The trial methodology has shown that recruitment of large numbers of patients from primary care is attainable, with the assistance of the NIHR Clinical Research Network, and could be applied to other outcomes studies at relatively low cost.

Last year, there were almost 17,000 hospital admissions for gastric ulcers (3) and more than 1,850 recorded deaths for gastric and duodenal ulcers (4). If successful, the study will help to reduce NHS costs and improve health outcomes by reducing hospital admissions, increasing patient safety and preventing premature deaths.

Disclosure: Nothing to disclose

P1214 IMBALANCE OF TREG/TH17 IN RAT NSAID-INDUCED INTESTINAL INJURY

M. Wang, L. Lian, Z. Chen, B. Lv, **L.-N. Meng**
The First Affiliated Hospital of Zhejiang Chinese Medical University, Gastroenterology, Hangzhou, China

Contact E-Mail Address: mln6713@163.com

Introduction: Non-steroidal anti-inflammatory drugs (NSAIDs) are some of the most commonly prescribed drugs in the world. However, recently its gastroduodenal complications, especially intestine injury has attracted people's attention. The pathogenesis is not yet completely clear, therefore there is no effective treatment measures. Treg/Th17 have been described as two distinct subsets from Th1 and Th2 cells and have the opposite effects on autoimmunity. Treg/Th17 balance controls inflammation and may be important in the pathogenesis of inflammatory bowel disease and other autoimmune diseases. However,there are few studies on the imbalance of Treg/Th17 in NSAIDs induced intestinal injury.

Aims and Methods: We aimed to explore whether there's an imbalance of Treg/Th17 in NSAIDs induced intestinal injury.

20 Male SD rats weighing 180–200g were randomly divided into 2 groups. The control group was given 1ml100 $g^{-1}d^{-1}$ saline by gavage; the experimental group was given of diclofenac sodium 10 $mgkg^{-1}d^{-1}$ by gavage, the rats were sacrificed 5 days later. Assessed the gross and pathological injury of the intestine, the Th17 and Treg were detected by flow cytometry; Foxp3, RORγt were detected by RT-qPCR and IL-6, TGF-β, IL-17A, IL-10 were detected by ELISA.

Results: 1. The injury of small intestine:Multiple ulcers were seen in the small intestine mucosa of the experimental group, the mucosal were evidently congestion and edema. H&E staining revealed that the villous were edema and necrosis,massive inflammatory cells were observedin the lamina propria. 2. The proportion of Th17 and Treg cells in the mesenteric lymph node: The percentage of IL-17^+T cells and $CD25^+Foxp3^+$ cells in gated $CD4^+$ T cells both significantly increased in the experimental groups ($P<0.05$). However the ratio of $CD25^+Foxp3^+$Treg/IL-17^+T cells decreased significantly in the experimental group ($P<0.05$). 3. The specific transcription factor RORγt of Th17 and Foxp3 of Treg. The expression of RORγt-mRNA significantly increased ($P<0.01$), and the Foxp3-mRNA expression level also increased,although it was not statistically significant ($P>0.05$), while the ratio of Foxp3/RORγt decreased ($P>0.05$). 4. The IL-6 and IL-17A levels in the experimental group increased significantly ($P<0.05$), while the IL-10 expression was significantly decreased ($P<0.05$), although the TGF-β1 expression was decreased, it was not statistically significant ($P>0.05$). 5. Pearson correlation analysis: The injury scores has a significant negative correlation with Treg/Th17, Foxp3/RORγt, IL-10, TGF-β1 ($P < 0.05$), and has a significant positive correlation with IL-6, IL-17A ($P < 0.05$).

Conclusion: There is an imbalance of Treg/Th17 in NSAID induced intestine injury, immune imbalance may be involved in the pathogenesis of NSAID induced intestinal injury.

Introduction: Terminal ileitis (TIS) is defined as inflammation of the terminal ileum (TI) signified by ulcers, erosions, oedematous/erythematous mucosa. It can be idiopathic or secondary to crohn's disease (CD), infections and medications. The aim of this study was to assess the outcome of patients with idiopathic terminal ileitis (ITI).

Aims and Methods: Patients with TIS and no history of CD (ITI group) were compared to patients with terminal ileum Crohn's disease (TICD). Patients with a recent history of gastroenteritis, NSAIDs and angiotensin receptor blockers use were excluded.

Results: 23 patients with ITI (mean age 39 years; 57% females) were compared to 27 patients with TICD (mean age 39 years; 59% females).

Reasons for small bowel capsule endoscopy (SBCE) in the ITI group included: abdominal pain (52%), bloating, nausea, vomiting (48%), diarrhoea (39%), persistent iron deficiency anaemia (22%), weight loss (4%), rectal bleeding (4%), low b12 and calcium (4%). All patients in the CD group had a SBCE to assess disease activity.

In patients with ITI, 17% had evidence of minor findings on colonoscopy including erosions/aphthous ulcers with histology showing non-specific inflammation in 2 patients (n = 4 50%).

In tandem, all patients with ITI (5) who underwent small bowel (SB) MRI had a normal investigation compared to the TICD group in whom MRI SB was abnormal in 75%.

Similarly the mean faecal calprotectin (FC) (160 vs 99 ug/g $p = 0.791$) and CRP (13 vs 7 mg/L; $p = 0.209$) were higher in the TICD group compared to the ITI group, although these did not reach statistical significance.

The mean number of ulcers on (SBCE) in TI were significantly less in the ITI group (3) than in those with TICD (5) ($p = 0.005$). There was luminal narrowing in 2 patients (7%; $p = 0.493$) and mucosal oedema in 10 patients with TICD (37%; $p = 0.001$) with CD. Whereas patients with ITI had more aphthous/small ulcers, patients with TICD had more circumferential, deep, large, linear ulcers ($p = 0.018$).

Follow-up data with an average of 9 month was available for 78% (18) of the ITI group. 80% of those who underwent a repeat SBCE showed an improvement in the findings which corresponded to an improvement in CRP (3 previously 7mg/L; $p = 0.523$). At follow-up 39% improved clinically without treatment whilst 33% were treated as IBS. One patient who was treated with budesonide, improved.

Conclusion: Patients with ITI demonstrated a lower CRP, FC, and a normal MRI. SBCE findings for the ITI group were milder compared to TICD group and they were more likely to improve over time without treatment. Milder findings on SBCE can further reassure physicians to treat patients with a small number of ulcers in TI conservatively.

Introduction: *Helicobacter pylori* (*H. pylori*) infection is a primary cause of gastric ulcer, duodenal ulcer, and gastric cancer. Capsule endoscopic studies for healthy volunteers revealed that 5–10% of healthy volunteers had small intestinal mucosal breaks. Many infectious disease and immunological disease are known to cause small intestinal mucosal injury. However, the etiology of small intestinal mucosal breaks in healthy volunteers, who have suffered from no such diseases and/or medicated no drugs, is unclear. In the studies of healthy volunteers, the several subjects brought into the act as healthy volunteers having an infection of *H. pylori*. Because *H. pylori* infection is seen as not having small intestinal influence, subjects infected with *H. pylori* are included in the studies. *H. pylori* infection is main cause of duodenal ulcer. In fact, it is undeniable that *H. pylori* infection has an impact on small intestinal mucosa. The aim of the study was to investigate whether there is an association between *H. pylori* infection and small intestinal mucosal injury.

Aims and Methods: This study was a retrospective study at the Nippon Medical School Hospital from January 2008 through March 2016. Patients aged 20–85 years were selected from a general pool of subjects who underwent capsule endoscopy for current or past obscure gastrointestinal bleeding. The background included age, gender, history, treatment with NSAIDs and/or acid suppressant (PPI, or histamine H2-receptor antagonist), final diagnosis, and *H. pylori* infection were investigated. Patients infected with *H. pylori* had a positive result by at least one diagnostic method: the serum antibody of *H. pylori*, ^{13}C-Urea breath test, or *H. pylori* antigenic agent of the stool within before and after 30 days capsule endoscopy examination. Patients diagnosed with inflammatory disease, malignant tumor, etc. were excluded. All subjects' video images were re-evaluated by two skilled reviewers to count small intestinal mucosal breaks. Eligible analyzable patient variables were compared between patients infected *H. pylori* and uninfected patients.

Results: Ninety-two patients (30 infected *H. pylori*/62 uninfected) were eligible for the study. By multivariate analysis of variables regarding the number of small intestinal mucosal breaks, patients treated with NSAIDs had more small-intestinal mucosal breaks than patients untreated NSAIDs (38%:8/21 vs. 18% 13.71P = 0.009), and the possible association was detected between patients infected *H. pylori* and uninfected patients 67%:14/21 vs. 37%:26/71; (P = 0.056). In comparing between patients infected *H. pylori* and uninfected patients, the rate of patients with small intestinal mucosal breaks was greater in patients infected *H. pylori* (7%:14/30 vs. 11%:7/62; P = 0.001). After excluding the patients treated with NSAIDs, the number of small intestinal mucosal breaks was also statistically greater in patients infected *H. pylori* than in uninfected patients (1.16 ± 1.51 vs. 0.38 ± 0.62; P = 0.001).

Conclusion: There is high possibility that *H. pylori* infection induces small intestinal mucosal injury.

Introduction: Functional dyspepsia (FD) and the irritable bowel syndrome (IBS) are functional gastrointestinal disorders (FGIDs), for which there are no explicit pathological changes identified on routine endoscopy. There is evidence in the literature of a dysregulated gastrointestinal immune response potentially driving the onset and continuation of symptoms such as early satiety, bloating, abdominal pain and nausea in FD and IBS, however the mechanisms by which this occurs has not been fully characterised.

Aims and Methods: We systematically reviewed the FD and IBS literature in order to collate the evidence for immune activation in common FGIDs. Our review focused on answering the research question: 'Do IBS and FD have clinically definable immune profiles?' We aspired to elucidate the cell types and associated molecules that may be implicated in the subtle inflammatory phenotype observed in these conditions. A search of seven literature databases was conducted using the following keywords and phrases: 'immun*', 'functional gastrointestinal disorder', FGID, 'functional dyspepsia', 'non-ulcer dyspepsia', 'idiopathic dyspepsia', 'irritable bowel syndrome', and IBS. References were then screened for suitability based on defined inclusion and exclusion criteria. Data presented relating to immune effectors such as cytokines and cellular populations were collated for analysis.

Results: The 51 papers determined to meet stringent selection criteria for this review provided evidence of specific alterations in the systemic and local immune systems in both FD and IBS. In addition to duodenal eosinophilia (FD) and increased colonic mast cells (IBS), variations in circulating IL-6 and IL-10 cytokine activity, along with increases in circulating $\alpha4^+\beta7^+$ gut-homing T cell number appear to be linked to the pathophysiology of both FD and IBS. There seems to be no change in the proportion of either circulating or local $CD3^+$ lymphocyte numbers in either condition. Patients with FD have higher peripheral proportions of both activated ($CD45RO^+$) and naïve ($CD45RA^+$) T lymphocytes, however there is debate in the literature regarding the proportions of small intestinal mast cells in this condition suggesting disease heterogeneity. There was evidence for a peripheral B cell activation in IBS patients, with studies reporting increased expression of activation markers ($CD80^+$, $CD86^+$) and higher IgG expression, suggestive of antigen presentation and reaction. Further to this, increased numbers of activated T lymphocytes ($CD45RO^+$) were reported in the colon of IBS patients.

Conclusion: Evidence from the literature suggests that underlying immune activity in FD and IBS is likely related to subtle alterations in the activation status of the cellular populations at both the systemic and local level, rather than an influx of newly recruited cells. Heterogeneity among subgroups of patients with either FD or IBS complicate studies in the field. It is evident that well-characterised patient cohorts including sufficient participant numbers will be required to elucidate the interplay of immune mechanisms that drive the development of FGIDs.

Contact E-Mail Address: clymma@zju.edu.cn

Introduction: SIBO is common among patients with IBS, and symptoms of IBS are relieved after treatment of SIBO with antibiotics. The reported prevalence of small intestinal bacterial overgrowth (SIBO) among individuals with irritable bowel syndrome (IBS) is highly variable,ranging 4% to 84%, which may be related to the testing methods performed to diagnose SIBO.

Aims and Methods: The primary aim of the study was to evaluate overall and test-specific pooled prevalence of SIBO among individuals with IBS. The secondary aims were to determine the pooled odds ratio (OR) of SIBO among individuals with IBS compared to controls, and also to examine predictors associated with SIBO among patients with IBS. PubMed, Cochrane Library, and EMBASE through July 2017 were searched to identify studies evaluating the prevalence of SIBO in IBS. The pooled prevalence of SIBO among individuals with IBS and the pooled odds ratio (OR) of SIBO among those with IBS compared to healthy controls was calculated. Predictors of SIBO among IBS patients were also evaluated.

Results: Fifty studies (8,398 IBS, 1,432 controls) met the inclusion criteria. Overall pooled prevalence of SIBO in IBS was 38% (95%CI 32–44%) and was higher among individuals with IBS (OR = 4.7, 95%CI 3.1–7.2) compared to controls. The pooled prevalence of SIBO in IBS was higher in studies diagnosed by breath tests (40%, 95%CI 33–46%) compared to cultures (19%, 95%CI 8–30%). Furthermore the prevalence of SIBO was higher in studies diagnosed by LBT (47%, 95%CI 39–56%) compared to GBT (31%, 95%CI 24–38%). Among those with IBS, female gender (OR = 1.5, 95%CI 1.0–2.1), older age (standard mean difference = 3.1 years, 95%CI 0.9–5.4), and IBS-diarrhea (OR = 1.7, 95%CI 1.3–2.3) compared to other IBS subtypes increased the odds of SIBO; proton pump inhibitor (PPI) use (OR = 1.1, 95%CI 0.7–1.7) was not associated with SIBO.

Conclusion: More than one-third of IBS patients tested positive for SIBO, and the odds of SIBO in IBS were increased nearly five-fold. The prevalence of SIBO varied according to the diagnostic modality performed. Female gender, older age, and IBS-diarrhea, but not PPI use, were associated with SIBO among individuals with IBS.

Disclosure: Nothing to disclose

Contact E-Mail Address: giuseppelos@alice.it

Introduction: Small intestinal bacterial overgrowth (SIBO) is a syndrome characterized by increased colonization of the small bowel by colonic bacteria. Despite jejunal culture remains the diagnostic mainstay, in clinical practice the diagnosis is achieved by glucose breath test (GBT) or lactulose breath test (LBT). Therefore we performed a meta-analysis aimed to estimate pooled sensitivity and specificity of breath tests for SIBO diagnosis.
Aims and Methods: We searched in main databases (PubMed, Scopus, ScienceDirect, EMBASE) articles using the following keywords: (Small intestinal OR bacterial overgrowth) AND (breath test OR diagnosis OR lactulose OR glucose). Only studies in which breath tests were compared to culture of jejunal aspirate were selected. Data were entered the MetaDisc 1.4 software to calculate pooled sensitivity, specificity, positive and negative likelihood ratio (LR) and summary of area under the curve (SROC), as well as their 95% confidence intervals (CI).
Results: Twelve studies, enrolling 630 patients overall were selected. GBT showed a pooled sensitivity of 58.3% (95% CI 51.4–64.9%), a specificity of 83.5% (95% CI 79.1–87.2%), a positive LR of 2.7 (95% CI 1.6–4.7), a negative LR of 0.5 (95% CI 0.4–0.8) and a SROC of 0.76.
LBT had a sensitivity of 42.0% (95% CI 31.6–53.0%), a specificity of 70.6% (95% CI 61.9–78.4%), a positive LR of 1.3 (95% CI 0.7–2.2), a negative LR of 0.8 (95% CI 0.6–1.1) and a SROC of 0.56.
Conclusion: Breath tests do not show excellent performances in comparison to the gold standard. However, keeping into account that SIBO is a benign disease that in most cases requires a simple antibiotic therapy, they can be considered as a surrogate test to replace the invasive one. In this context, GBT has a better sensitivity and specificity than LBT and, therefore, should be preferred.
Disclosure: Nothing to disclose

P1220 THE CHANGING AND CHALLENGING FACE OF PROTON PUMP INHIBITORS -RELATED SMALL INTESTINAL BACTERIAL OVERGROWTH

Introduction: In the last decade the relationship between proton pump inhibitors (PPI) and small intestinal bacterial overgrowth (SIBO) has covered an extensive, controversial interest in the literature, with meta-analysis confirming this association (1,2).
Aims and Methods: To update, in our experience, this phenomenon from a temporal point of view, comparing two periods: 2005–2010 *vs* 2012–2017. This dichotomy was chosen based on an increased interest on this issue in the literature from 2010 on.
Methods: From November 2012 to November 2017, 970 consecutive out-patients entered the study. 458 were eligible for Glucose Hydrogen Breath test for SIBO diagnosis (GHBT) (388 on PPI; 70 pts off PPI for at least 5 years: 50 IBS, 20 Control). This cohort of patients (group A) was compared to that of 450 out-patients studied in 2010, for the prevalence of SIBO (group B) (3) and to that of 1056 out-patients studied in 2011 for the epidemiology of the use of PPI in the period 2005–2010 (group C) (4). GHBT was assessed by Breath Tracker digital microlyzer. Symptoms frequency and intensity (abdominal pain, bloating, diarrhea) were recorded by means of a visual analogue scale. Exclusion criteria: neoplasia, malabsorption diseases, metabolic/hormonal disturbances, use of antibiotics, laxatives, neurological treatment. Long-term continuous PPI therapy (LTc) was defined >9 months/yr for at least 2 yrs. Medium-term T (MT): 6–8 months/yr for at least 2 yrs. Short-term T (ST):1–5 months/yr for at least 2 yrs. Statistical analysis were carried out by SPSS software.
Results: Mean age and gender distribution in the group A, B and C were comparable (46 ± 18 SD, 39 ± 20, 45 ± 21 yrs; M: 55%, 57%, 59%). The use patterns of PPI in the 2 period were:
*LTc MT *ST
2005–10 79% Not evaluated 21%
2012–17 25% 35% 40%. * $P < 0.001$
SIBO in group A e B was as follows:
LTc MT ST IBS C
Group A 50% 19% 17% 18% 5%
Group B 68% 22% 14% 20% 5%
Conclusion: 1) LTc treatment has decreased significantly from 79% to 25%, leaving room to a MT (35%) and ST (40%) patterns of therapy.
2) Although the frequency of SIBO in LTc in group A remains high (50%), it involves only 25% of pts on PPI, practically "saving" those on MT and on ST modalities.
3) Informed medical culture, increased awareness of potential side-effects and financial restraints from Health Institutions may be the reasons for such changes.

P1221 SERUM REGENERATING ISLET-DERIVED 3-ALPHA PREDICTS THE EVOLUTION OF POTENTIAL COELIAC DISEASE INTO OVERT COELIAC DISEASE

P. Giuffrida[1], F. Biagi[1], A. Schiepatti[1], I. Marafini[2], F. Laudisi[2], N. Aronico[1], G. Monteleone[2], G.R. Corazza[1], A. Di Sabatino[1]

Introduction: Potential coeliac disease (PCD) is a form of coeliac disease (CD) characterized by positive coeliac antibodies, but normal duodenal mucosa. Currently, there are not noninvasive biomarkers able to predict the onset of villous atrophy in PCD patients. Serum regenerating islet-derived 3-alpha (Reg3alpha) is a biomarker of mucosal damage in enteropathies, including CD.
Aims and Methods: The aim of this study was to determine whether serum Reg3alpha predicts the development of villous atrophy in PCD patients. We included 12 PCD patients who maintained gluten-containing diet and yearly underwent upper endoscopy with duodenal biopsies. Sera were taken from all these patients at the same time of upper endoscopy over their follow-up. Serum Reg3alpha was detected using a commercial ELISA kit.
Results: Along the follow-up, four out of the 12 PCD patients developed an overt CD so that they started gluten-free diet (GFD). In all these four PCD patients serum levels of Reg3alpha increased at or immediately prior to overt CD diagnosis (median 32.30 ng/ml, range 13.62–42.59 ng/ml) in comparison to baseline concentrations (median 18.33 ng/ml, range 10.83–25.25 ng/ml). In addition, serum levels of Reg3alpha were down-regulated by at least 12 months of GFD (median 11.14 ng/ml, range 4.73–26.12 ng/ml) at similar concentration to baseline in these four patients. Low levels of serum Reg3alpha (median 15.00 ng/ml, range 0.77–25.59 ng/ml) were found in the remaining eight PCD patients.
Conclusion: In a relatively small sample of PCD patients, when considering that PCD is quite rare, we demonstrated that serum Reg3alpha predicts the evolution of PCD into overt CD. These findings suggests that Reg3alpha can identify PCD patients who should undergo upper endoscopy to confirm overt CD, thus reducing time- and cost-consuming procedures.

Introduction: Coeliac disease (CD) is a lifelong autoimmune disease affecting about 1% of the population, although many are undiagnosed. Coeliac disease is caused by an abnormal immune response, in genetically susceptible individuals, against gluten proteins from wheat, rye and barley. We screened for coeliac disease in a previous cross-sectional population-based study (1). In the current study we screened for coeliac disease antibodies in seven additional population-based studies from our biobank.
Aims and Methods: The aim was to determine coeliac disease prevalence, as reflected by coeliac disease antibody positivity, in the eight Danish studies from the biobank at Center for Clinical Research and Disease Prevention and evaluate a possible change over time. The studies are listed in the table below. In total, we screened serum samples from 16.779 participants collected between 1976 and 2012 for tissue transglutaminase (TTG) IgA/IgG and deamidated gliadin peptide (DGP) IgG.
Results: The results of the screening are listed in the table below, both for the coeliac disease antibody positivity (IgA/IgG-TTG≥7 U/ml and/or IgG-DGP≥10 U/ml) and the additional cut-off of only TTG≥10 U/ml.
Conclusion: The coeliac disease antibody positivity was around 1 % in all the 8 studies. We found no marked changes of the prevalence over time.
Disclosure: Conflict of interest: The study was supported by the Tryg Foundation (7-11-0213), Dansk Cøliaki Forening (the Danish Celiac Disease Patient Organization), The Novo Nordisk foundation (NNF160C0022464), Independent Research Fund Denmark and Thermo Fisher Scientific, Allerød, Denmark. Thermo Fisher Scientific, performed the coeliac disease screening.

P1223 SERONEGATIVE COELIAC DISEASE: CLINICAL FEATURES AND PREVALENCE AMONG COELIAC PATIENTS

Introduction: Seronegative coeliac disease (SCD) is characterized by villous atrophy (VA) responding to a gluten-free diet (GFD) but without both/either IgA/IgG endomysial (EMA) and IgA/IgG tissue-transglutaminase (tTG) antibodies [1]. The quality of data on the epidemiology of SCD is limited due to the rarity of the condition and the confusion pertaining to the nomenclature. Prevalence of SCD among coeliac patients was historically reported to be as high as 10–20% [1–5]. However, more recently it has been shown to be around 2% of all coeliac patients [6,7]. In SCD age at diagnosis has been reported to be higher than in seropositive CD, classical presentation more common, while results for sex are discordant [3, 6–8]. We think we should distinguish true SCD in which reasons for seronegativity include early disease, late disease (with possible refractory CD), dermatitis herpetiformis and first degree familiarity for CD. Masked SCD is a second group of patients which display seronegativity at diagnosis because immunosuppressants or a GFD had already been started prior to antibody testing. Finally, a third group is that of patients with total IgA deficiency (serum IgA $\leq$ 2 standard deviations below normal age-adjusted means) in whom the finding of positive IgG EMA/tTG should support the diagnosis of conventional seropositive CD and not that of SCD [1].
Aims and Methods: To define prevalence and clinical features of patients affected by true SCD, masked SCD and CD+IgA deficiency among all the coeliac patients directly diagnosed in two referral centers for CD (Sheffield, UK and Pavia, Italy) from 01/2010 to 12/2017. IgA positive EMA/tTG and a VA while on a gluten-containing diet allowed the diagnosis of conventional seropositive CD. For IgA deficient patients class IgG antibodies were tested. HLA DQ2/DQ8 positive patients with IgA and IgG negative EMA/tTG and a certain degree of VA responsive to a GFD met the criteria for true SCD. VA and negative IgA/IgG EMA/tTG due to concomitant GFD or immunosuppressants allowed diagnosis of masked SCD.
Results: 692 coeliac patients (229M, mean age at diagnosis 42 ± 17 years, 154 classical) were directly diagnosed in 7 years. 24 patients (4M, 47 ± 17 years, 17 classical) had negative IgA and/or IgG EMA/tTG at diagnosis (prevalence 3.47%). In this group true SCD was diagnosed in 17 of them (prev 17/692 = 2.45%, 2M, 50 ± 17 years, 12 classical). 5 had masked SCD (prev 5/692 = 0.72%, 1M, 40 ± 19 years, 3 classical, 4 on a GFD and 1 on steroids and azathioprine at time of diagnosis) and showed positive serology after discontinuation of immunosuppressors or during gluten challenge. Finally, 2 patients had positive IgG EMA/tTG in the context of total IgA deficiency (prev 2/692 = 0.29%, 1M, mean age 35 ± 12 years, all classical). Classical presentation and female sex were statistically more common ($p < 0.001$) in the 24 seronegative patients and in true SCD than in conventional seropositive coeliacs (668, 225 M, 42 ± 17 years, 137 classical). Age at diagnosis was higher in true SCD than in the group of seropositive CD ($p = 0.50$) and masked SCD ($p = 0.70$), but not statistically significant.
Conclusion: We proposed a redefinition of the diagnostic categories of SCD. Our partial data show that true SCD is rare among coeliac patients, being this result in accordance with the high sensitivity of EMA/tTG. SCD is characterized by peculiar clinical features allowing the distinction from seropositive CD. With the recruitment of a larger sample size we think we will be able to see if prevalence of this condition has changed over the years.

Introduction: The diagnosis of Coeliac disease (CD) requires the presence of villous atrophy on duodenal biopsy. The duodenal bulb (D1) has been shown to be a sensitive site for detecting villous atrophy (VA) in newly diagnosed CD. However there is a scarcity of data from those with established CD.
Aims and Methods: In patients with established CD, we aim to determine whether D1 biopsies improved the identification of VA compared to biopsies from the second part of the duodenum (D2) alone. 251 patients with established CD were prospectively recruited from the endoscopy department at the Royal Hallamshire Hospital between 2013 and 2017. All patients were undergoing repeat gastroscopy to assess dietary adherence, with one biopsy taken from D1 and four from D2. Biopsies were classified according to Marsh criteria. We assessed concordance of histology between the D1 and D2 sites, and 95% confidence intervals were calculated for all results using a binominal distribution.
Results: 251 patients were recruited (70.5% female, age range 17–81 years, median age 53 years) having been on a gluten-free diet for a median duration of 6 years. Concordant results: 35.1% (n = 88, 95% CI = 29.16–40.96) had normal duodenal biopsies in both D1 and D2; 32.3% (n = 81, 95% CI = 26.49–38.05) had VA in D1 and D2; 18.3% (n = 46, 95% CI = 13.54–23.11) had raised intra-epithelial lymphocytes (IELs) only in both D1 and D2. Disconcordant results: 4.4% (n = 11, 95% CI = 1.85–6.91) had VA in D1 but not D2; 2.4% (n = 6, 95% CI = 0.50–4.28) had raised IELs in D1 but normal histology in D2. 2.8% (n = 7, 95% CI = 0.75–4.83) had VA in D2 but normal histology in D1; 4.8% (n = 12, 95% CI = 2.14–7.42) had IELs in D2 but normal histology in D1.
Conclusion: VA was confined to the duodenal bulb in 4.4% of patients with established CD. Thus a D1 biopsy in addition to distal duodenal biopsies increases the likelihood of detecting VA, although the significance of isolated VA in the bulb in patients on a gluten-free diet is yet to be determined.

P1225 EFFECTS OF BLINDED ACUTE AND SUB-ACUTE GLUTEN CHALLENGE ON EXTRA-INTESTINAL AND GASTROINTESTINAL SYMPTOMS IN NON-COELIAC GLUTEN SENSITIVITY VERSUS HEALTHY CONTROLS

J. Iven[1], A. Geeraerts[1], T. Vanuytsel[1], J. Tack[1], L. Van Oudenhove[1], J. Biesiekierski[1,2]

Introduction: Non-coeliac gluten sensitivity (NCGS) is characterised by gastrointestinal (GI; e.g. bloating) and extra-intestinal (e.g. fatigue) symptoms that subjectively disappear after dietary exclusion of gluten, in the absence of coeliac disease. Previous research has shown that a 3-day exposure to gluten increases depression scores in self-reported NCGS patients, however acute effects of gluten were not investigated (Peters et al., 2014).
Aims and Methods: We aimed to investigate the effect of single-blind acute and sub-acute administration of 16g gluten on psychological and GI symptoms in healthy volunteers (HV) and NCGS patients.
Sixteen grams of gluten or whey protein (placebo) were mixed in 250mL of low fat, unsweetened yoghurt, which was consumed as an acute challenge. GI symptoms (bloating, cramps) were assessed using visual analogue scales (VAS;

100mm) every 15' until 180' after administration. At the same time points, extra-intestinal symptoms (fatigue, tension, depression) were assessed using VAS derived from the Profile of Mood States Questionnaire. Participants then consumed two gluten-free or gluten containing (8g) muffins at different time points per day for the following 5 days, as a sub-acute challenge. GI symptoms (ordinal values; zero until 7) and extra-intestinal symptoms (VAS) were scored at the end of each day. After a washout period of 2 weeks, participants crossed over to the alternative dietary arm. Responses over time (compared to pre-administration for the acute challenge and compared to the mean of the 2 days before the intervention period for the sub-acute challenge) were analysed using (generalized) linear mixed models.

Results: Twenty HV (3 men, 29.7 ± 2.6 years) and 10 NCGS patients (4 men, 32.9 ± 3.1 years) completed the study. After acute administration of gluten compared to placebo, fatigue scores increased in NCGS patients ($p = 0.015$), but not in HV ($p = 0.74$). Similarly, NCGS patients had higher tension scores after gluten compared to placebo ($p = 0.043$), contrary to HV ($p = 0.31$). Acute challenge of gluten did not alter depression scores compared to placebo ($p = 0.41$). After 5 days of sub-acute administration, no significant differences in fatigue scores were observed between healthy controls and NCGS patients ($p = 0.70$) nor between conditions ($p = 0.48$), but tension and depression scores were higher in both groups after gluten compared to placebo ($p = 0.053$ and 0.076, respectively).
Immediately following the acute challenge, NCGS patients showed more bloating ($p < 0.0001$) and pain ($p = 0.019$) compared to HV, regardless of whether gluten or placebo was ingested. This continued during the sub-acute challenge where GI symptoms increased in the NCGS patients compared to healthy controls (abdominal pain: $p = 0.038$, bloating: $p = 0.015$), regardless of gluten versus placebo intake.

Conclusion: These findings provide new insights into NCGS, which might be characterised by acute gluten-induced increases in extra-intestinal symptoms such as fatigue, rather than GI symptoms. During a sub-acute challenge, using the same dose spread over two different time points per day for five consecutive days, GI symptoms were elevated in the patient group regardless of gluten versus placebo intake. Further, there was a tendency towards higher levels of tension and depression after gluten intake regardless of patient versus control status. Further research on the mechanisms underlying these effects as well as other (dietary) factors involved in symptom generation in NCGS is warranted.

Introduction: Monitoring of mucosal remission is essential in Coeliac Disease (CD) to assess adherence in patients with persisting symptoms and to prevent complications. However, duodenal biopsies are invasive, expensive and poorly tolerated by many patients. Recent work has suggested that an IgA-tissue transglutaminase (tTG) < 1.2 U/mL may predict mucosal healing in those with established CD, reducing the need for gastroscopies and biopsies in some patients.

Aims and Methods: This study examines whether the combination of serological markers may be used as a surrogate marker for the detection of villous atrophy (VA) in known CD patients. We undertook a prospective analysis of known CD patients diagnosed in a university hospital. All patients underwent a gastroscopy, with four biopsies taken from the second part of the duodenum, and one from the duodenal bulb. Serological markers were assessed at the time of endoscopy. tTG, IgA-endomysial antibodies (EMA), IgA-antigliadin antibody (IgA AGA) and IgG-anti-gliadin antibody (IgG AGA), and their performances in isolation and in combination were compared to histological outcomes.

Results: 107 patients (67.3% female, median age 53 years (20–81 years)) that were on a gluten-free diet for a median duration of 6 years were included. The performance of the different serological markers to detect VA, both in isolation and in combination are shown in Table 1. The performance of tTG using the previously used cut-off of < 1.2u/ml produced a sensitivity of 38.5%, a specificity of 73.8%, a positive predictive value of 64.9% and a negative predictive value of 43.7% to detect VA.

	Sensitivity	Specificity	Positive Predictive Value	Negative Predictive Value
tTG	39.0% (CI 29–48%)	97.0% (CI 89–99%)	88.9% (CI 64–98%)	70.8% (CI 61–81%)
EMA	40.5% (CI 26–57%)	96.9% (CI 88–99%)	89.5% (CI 65–98%)	71.6% (CI 61–80%)
IgA AGA	47.5% (CI 32–64%)	95.5% (CI 87–99%)	86.4% (CI 64–96%)	75.3% (CI 65–84%)
IgG AGA	37.5% (CI 23–54%)	90.0% (CI 80–96%)	68.2% (CI 45–85%)	71.6% (CI 61–80%)
EMA + tTG	33.3% (CI 20–50%)	98.5% (CI 91–100%)	93.3% (CI 66–100%)	30.4% (CI 21–41%)
IgA + IgG AGA	28.6% (CI 16–45%)	100% (CI 93–100%)	100% (CI 70–100%)	68.4% (CI 58–77%)
IgA or IgG AGA + EMA	28.6% (CI 16–45%)	100% (CI 93–100%)	100% (CI 70–100%)	68.4% (CI 58–77%)
IgA or IgG AGA + tTG	31.0% (CI 18–47%)	100% (CI 93–100%)	100% (CI (72–100%)	69.1% (CI 59–78%)

[Ability of serological markers to detect villous atrophy]

Conclusion: This study is the first to evaluate the combination of serological markers to detect VA in patients with established CD. Our findings oppose recent work that serology may be used as a surrogate marker of mucosal healing in known CD.

Introduction: Currently, the diagnosis of adult Coeliac disease (CD) requires the presence of villous atrophy (VA) on duodenal biopsy. However, biopsies are expensive, invasive and poorly tolerated by many patients. Paediatric ESPGHAN guidelines support a diagnosis of CD when immunoglobulin-A anti-tissue transglutaminase (IgA tTG) antibody titres are greater than 10 times the upper limit of normal (ULN) and combined with supportive criteria. This study examines whether serological testing alone could be sufficient for diagnosis in adult patients, thus avoiding the need for gastroscopy and duodenal biopsies.

Aims and Methods: The aim of this study was to assess whether an IgA tTG value of greater than 10 times the ULN could produce a 100% positive predictive value (PPV) for the detection of VA. We performed a prospective analysis of CD patients diagnosed in a university hospital. Symptoms of CD, VA on biopsy, IgA-endomysial (IgA-EMA) antibodies, tTG and Human Leukocyte Antigen (HLA) genotype were used for analysis. We then compared the tTG antibody level against small bowel histology.

Results: 443 CD patients (66.8% female, median age 41 years, range 15–84 years) were diagnosed between 2008 and 2016. 56.9% ($n = 252$, 95% CI = 52.12–61.53) had a tTG value of greater than 10 times the ULN, and 100% of these patients had VA on biopsy. 292 fulfilled ESPGHAN guidelines for features of malabsorption (diarrhoea = 157, weight loss = 45 and anaemia = 190). Of these symptomatic patients, 70.4% ($n = 179$, 95% CI = 64.86–76.08) had a tTG value $10 \times$ ULN. The proportion reaching the $10 \times$ tTG threshold was 55.4% ($n = 87$, 95% CI = 47.64–63.19) for diarrhoea, 60.0% ($n = 27$, 95% CI = 45.69–74.31) for weight loss, and 74.2% ($n = 141$, 95% CI = 67.99–80.43) for anaemia. Of the 151 patients who did not experience malabsorptive features, 49.0% met the $10 \times$ ULN tTG level ($n = 74$, 95%CI = 41.03–56.98). The sensitivity of tTG antibodies and EMA antibodies for predicting VA was 93.2% (95% CI = 90.89–95.57) and 90.7% respectively (95% CI = 88.05–93.44). Combined tTG and EMA was 98.6% (95% CI = 97.67–99.72). All patients had compatible HLA typing, thereby failing to add any further diagnostic value.

Conclusion: An IgA tTG level of greater than 10 times the ULN had a PPV of 100% for detecting VA. Using this threshold, 56.9% of patients would have been correctly diagnosed with CD and avoided duodenal biopsy. Symptoms and HLA typing did not add any supportive information. This study provides evidence that a biopsy avoidance strategy may be implemented into adult gastroenterological practice.

Contact E-Mail Address: maxim_roxxana@yahoo.com
Introduction: Celiac disease (CD) is an autoimmune enteropathy caused by gluten ingestion in genetically susceptible individuals. Genetic susceptibility to CD has been associated with human leukocyte antigen (HLA)-DQ2 heterodimer, encoded by the DQA1*05 and DQB1*02 genes. Our aim was to investigate whether the DQB1*02 allele could influence anti-tissue transglutaminase (tTG) titres in adult patients with CD.
Aims and Methods: A total of 75 patients with established CD, tested for tTG antibodies at diagnosis, were typed for HLA- DQA1, and -DQB1 genes, and divided according to the number of DQB1*02 alleles: group 1, homozygous; group 2, heterozygous; group 3, no gene.
Results: We report that the mean of tTG antibody indexes was not significantly higher in group 1 patients than in group 2 (118.90 ± 93.98 *versus* 142.45 ± 100.24, $P = 0.529$), or group 3 patients (90.74 ± 91.87 *versus* 142.45 ± 100.24, $P = 0.221$). Nevertheless, patients in group 1 showed more severe histological lesions (Marsh3a-c) compared to those in the other groups. When assessing disease phenotype, the carriage of 2 copies was associated with the presence of anaemia, abdominal pain, weight loss, and chronic diarrhoea.
Conclusion: The study demonstrates that tTG titers are not significantly influenced by the number of HLA-DQB1*02 copies. Moreover, individuals with at least 1 HLA-DQB1*02 allele tend to have a higher degree of histological damage and different clinical features compared to those carrying other alleles.

Introduction: Tissue transglutaminase (tTG) antibodies are hallmarks of CD diagnosis. The aim of our study was to assess whether serum IgA- tTG tests are useful to detect villous atrophy in patients with CD treated with gluten free diet (GFD).
Aims and Methods: We performed a prospective study using the information entered into a structured database including adult patients diagnosed with CD hospitalized at the Institute of Gastroenterology and Hepatology, adherent to GFD for at least 12 months after diagnosis. Data from adult patients with CD (diagnosed between January 10, 2010 through December 10, 2015) with biopsy, and serological tests (IgA/IgG-tTG antibodies) were retrieved from a computerized database. Results of non-invasive tests were compared with the persistence of villous atrophy on follow-up biopsy.
Results: The study group included 81 adult patients with a female: male ratio of 3:1, mean age 40.02 ± 12.14 years. When assessing the serological parameters, IgA-tTG levels (61.45 ± 76.458 u/mL *vs* 162.02 ± 106.179 u/mL, $P = 0.001$) correlated with intestinal villous atrophy (Marsh 1–2 *vs* Marsh 3a-c) in CD patients, with a sensitivity of 82.56% and a specificity of 91.78% for mucosal atrophy upon diagnosis (AUC = 0.909; IC95%: 0.86–0.95). Follow-up biopsy and serology testing were available for 47(74.6%) treated patients. Twenty one patients had variable degrees of villous atrophy, and IgA-tTG assay was 51% sensitive and 67.3% specific in identifying Marsh 3 lesions among patients allegedly adherent to a GFD with normal IgA-tTG levels.
Conclusion: Increased IgA-tTG levels in the treated population may reflect quantity and frequency of gluten exposure. The diagnostic accuracy of IgA-tTG antibodies for detecting persistent villous atrophy on a GFD is limited, showing relatively high specificity, but low sensitivity. Consequently, the majority of patients with villous atrophy on a GFD had normal levels of IgA- tTG.
Disclosure: Nothing to disclose

P1230 HLA TYPING AND CELIAC DISEASE IN ROMANIANS

Contact E-Mail Address: maxim_roxxana@yahoo.com
Introduction: Celiac disease (CD) is considered to have a high heritability involving HLA genes, which provide the genetic risk to develop the disease. The aim of the study was to investigate whether the genetic profile influences age of onset and diagnosis in CD.
Aims and Methods: High- resolution class 2 HLA genotyping was performed in a sample (n = 75) of North-Eastern Romanian residents residents with CD to determine the contribution of DQA1 and DQB1 on the age of diagnosis. The complete inpatient and outpatient medical record of each candidate were carefully reviewed. Age of onset was the age at which the patient first complained of symptoms subsequently explained by CD. Age at diagnosis was established as the date of interpretation of the initial intestinal biopsy or positive serology. Depending on the heterodimers inherited, 3 study groups were identified and compared: high risk (DQ2.5/DQ2.5, DQ2.5/DQ2.2, DQ2.5/DQ8, DQ8/DQ8), moderate risk (DQ2.5/X, DQ2.2/X, DQ8/X, DQ2.2/DQ2.2), and low risk (DQ7/X, DQ7/DQ7, DQX/DQX).
Results: A total of 32 (42.6%) patients had high-risk heterodimers. The age at diagnosis and the age of onset of patient symptoms attributable to CD were associated with the number of copies of DQB1*02. Mean age at diagnosis was significantly higher among patients in the low-risk group compared to those in the high-risk group (46.83 ± 7.93 *versus* 37.72 ± 12.39, $P = 0.004$). Disease severity (at least 10-pound weight loss and diarrhea) was found to be associated with high risk haplotypes, and the number of copies of DQB1*02.
Conclusion: Both HLA- DQA1*05 and DQB1*02 alleles are associated with earlier disease onset, diagnosis and disease severity.
Disclosure: Nothing to disclose

P1231 USEFULNESS OF DOUBLE-BALLOON ENTEROSCOPY FOR DIAGNOSIS OF MECKEL'S DIVERTICULUM

O. Yuki[1]
[1]*Kobe city medical center general hospital, Gastroenterology, Kobe, Japan*

Contact E-Mail Address: ookuboyuuki01@gmail.com
Introduction: Meckel's diverticulum (MD) is a congenital malformation of the gastrointestinal tract. The number of reports of MD observed by balloon assisted enteroscopy is increasing since the development of the double-balloon enteroscopy (DBE) and single-balloon enteroscopy. The present case series describes 14 patients with MD in whom DBE was useful for diagnosis.
Aims and Methods: Thirteen retrograde and one anterograde DBE were performed for fourteen patients (11 men, 3 women) with MD at Kobe City Medical Center General Hospital from May 2004 through Octorber 2017.
Results: DBE diagnosed MD in thirteen out of fourteen patients (92.3%), but one of them (inverted MD) was misdiagnosed as a lipoma. MD was identified using iodinated contrast medium through the scope during anterograde DBE in one patient. Abdominal computed tomography was performed in all fourteen patients and revealed abnormalities in eight (61.5%), but MD was suspected in only two cases (14.5%). Technetium-99 m pertechnetate scintigraphy and capsule endoscopy were carried out in six and four patients, revealing MD in one and two patients (16.7%, 50%) respectively. Surgery was performed in thirteen patients, and endoscopic resection was carried out in one patient (inverted MD) by DBE. Ulcer formation was found in or near MD in eight patients.
Conclusion: Compared with other modalities such as CT scan, Technetium-99 m pertechnetate scintigraphy and capsule endoscope, DBE is excellent for the diagnosis of MD because direct observation of both MD and ulceration is possible. This study shows that DBE is highly useful in the diagnosis of MD either alone or in combination with other methods. In addition, endoscopic resection using DBE could be one method of treatment of inverted MD.

Introduction: Morbid obesity is an increasing common chronic health problem in the world including in China. Currently, Laparoscopic Sleeve Gastrectomy (LSG) is the most favored surgical bariatric procedure for the treatment of morbid obesity**.** The LSG procedure requires removal of the greater curvature of the stomach along with its blood vessels and nerves.
Inspired by the complication esophageal stenosis after large area Endoscopic Submucosal Dissection (ESD) for the treatment of early esophageal cancer, we hypothesized that ablation of a sufficiently large area of the gastric mucosa might result in permanent contracture and a reduction in gastric volume. We therefore performed Endoscopic Gastric Mucosal Ablation (EGMA) using pigs as an animal model to confirm our hypothesis (manuscript in preparation). EGMA resulted in shrinkage of the pig stomach producing a reduction in gastric volume. Based on the success with animal experiments, we performed EGMA on an obese patient.
Aims and Methods: The patient was a 38-yr-old obese woman (BMI 37.2 kg/m^2) with type 2 diabetics (blood glucose level 15–20 mmol/L) who required 25 units of Insulin and 850 mg of metformin both twice a day. Her total gastric volume was 787.70 mL measured by CT scan before the procedure. EGMA procedure was performed under general anesthesia with endotracheal intubation. A cap-based single-channel endoscope (GIF-Q260J; Olympus, Tokyo, Japan) was used for the procedure. Endoscopic Submucosal Dissection (ESD) and Endoscopic Mucosal Resection (EMR) procedures were performed to resect the mucosal layer of the fundus and body of the stomach. The goal was to resect 80% of the circumference of the anterior, posterior, greater curvature mucosal layer of the stomach (Figure 1a). Small portions of mucosa (mucosal islands) were left to promote wound healing and regeneration of the gastric mucosa after the procedure

(Figure 1b). Coagulation forceps were used to coagulate any bleeding or potential bleeding sites in the submucosal and muscular layer and to prevent recurrent bleeding (Soft coagulation 50W, ICC 200; ERBE Erbotom, Germany).
The patient then remained fasting for 3 days followed by a liquid diet for days 4 through 7. A proton-pump inhibitor (40 mg esomeprazole sodium injection) was given intravenously for 7 days. A semi-liquid was given for day 7 to 15 after which a normal diet was resumed.
Results: The post-procedure period was not associated with bleeding, severe abdominal pain, nausea or vomiting. After the procedure her blood glucose level decreased to normal without anti-diabetic drugs. One week after the procedure, gastroscopy showed a large area of ulceration on the greater curvature of the stomach covered by yellow plaque. One month after the procedure, the area of the ulcer was noticeably smaller, the mucosal islands were wider, and the plaque was white and clean. The BMI had decreased to 31.8 kg/m^2. There were no major adverse events and complications during the procedure or during the 18 months follow-up.
Conclusion: EGMA appears to be an effective, safe, and less invasive restrictive-type bariatric procedure with low technical complexity and complications.
Disclosure: All authors were involved in this work, agreed to submit it for UEG Week 2018, and assumed responsibility for the accuracy and completeness of the data. The authors declare that there are no conflict of interest.

P1233 ALT REDUCTION IN GERIATRIC PATIENTS WHO HAVE UNDERGONE BARIATRIC SURGERY

Introduction: Nonalcoholic fatty liver disease (NAFLD) is one of the most common causes of chronic liver disease. Treatment recommendations include weight reduction, with a number of studies showing that bariatric surgery to lose weight leads to an improvement in NAFLD in obese patients. Alanine aminotransferase (ALT) has been used as a marker to monitor NAFLD, and reductions in ALT have been demonstrated with weight loss. To date, there have been no studies looking at reduction in ALT in geriatric patients who have undergone bariatric surgery.
Aims and Methods: The aim of this study was to see if geriatric patients who have undergone bariatric surgery show the same improvement in ALT as seen in younger, bariatric patients. This is a retrospective study of 90 morbidly obese, adult patients, divided into two arms based on age. Patients were labeled as geriatric if they were 65 years of age or greater at the time of surgery and non-geriatric if they were 64 years of age or below at the time of surgery. There were 45 patients in each arm, and patients were BMI and sex matched and followed for one year. All patients either underwent laparoscopic roux-en-y gastric bypass (RYGB) or laparoscopic sleeve gastrectomy. Gender, age, pre-surgical body mass index (BMI), percent weight loss and pre and post-surgical ALT levels were recorded.
Results: Among the two different arms, 33% of patients were male and 66% were female. The average age in the non-geriatric group was 40.4, and the average age in the geriatric group was 67.9. The pre-surgical BMI was 40.8 and 40.7 in the non-geriatric and geriatric groups, respectively. In the non-geriatric group, 49% of patients underwent a RYGB and 51% underwent a sleeve gastrectomy. In the geriatric group, 40% of patients underwent a RYGB and 60% underwent a sleeve gastrectomy. There was no significant difference in frequency of sleeve gastrectomy vs RYGB between these two groups ($p = 0.40$). Percent weight loss in the non-geriatric group was 29% and 24% in the geriatric group ($p < 0.001$). The non-geriatric patients had an average pre-surgical ALT of 47.4 and average post-surgical ALT of 31. The geriatric patients had an average pre-surgical ALT of 49 and had an average post-surgical ALT of 28.8. Percent decrease in ALT levels was 25.3% in the non-geriatric group and 33.5% in the geriatric group, respectively ($p = 0.222$). The non-geriatric group had 9 out of 45 patients with elevated pre-surgical ALT, and the geriatric group had 14 out of 45 patients with elevated pre-surgical ALT ($p = 0.23$). In both the non-geriatric and geriatric groups, all patients who had a pre-surgical ALT above the upper limit of normal had normalization of ALT after bariatric surgery.
Conclusion: Our study shows that geriatric, morbidly obese patients have a reduction in ALT after bariatric surgery, similar to what is seen in younger, morbidly obese patients who have undergone bariatric surgery. As ALT can be used as a marker to monitor NAFLD, this suggests that geriatric patients likely have a reduction in NALFD after bariatric surgery.
Disclosure: Nothing to disclose

P1234 ORAL AND EXTRA-ORAL BITTER TASTE RECEPTOR EXPRESSION IN A MODEL OF ANTIBIOTIC-INDUCED DYSBIOSIS

M. Veysey[1,2], G. Burns[3], M. Lucock[4], S. Keely[3], E. Beckett[2]

Contact E-Mail Address: martin.veysey@hyms.ac.uk
Introduction: Antibiotic treatment is associated with weight gain and risk for obesity. The mechanisms driving this association are not clear. However, dysbiosis has been identified as a potential causative factor for weight gain. Procedures that impact diet, weight, and the gastrointestinal microbiota, such as gastric banding surgery, have been linked to modified expression of taste receptors on the tongue. Taste receptors are expressed throughout the gastrointestinal tract, and so may be involved in detecting dietary compounds, appetite control and gut motility.
Aims and Methods: We, therefore, aimed to assess how antibiotic-induced dysbiosis influenced expression of *tas2r114, tas2r116 and tas2r138,* three broadly tuned bitter taste receptors, on the tongue and in the colon in a mouse model**.** Mice (8/group) received amoxicillin and clavulanate (five day course), or control treatment. Three days post-treatment colon and tongue tissues were collected, RNA was isolated (TRIZOL) and expression of *tas2r114, tas2r116 and tas2r138* assessed by qPCR.
Results: Expression of each receptor assayed was increased in the colon following antibiotic treatment (*tas2r114* 1.0 ± 0.18 vs 3.39 ± 0.44 relative expression units (REU), $p = 0.001$; *tas2r116* 1.0 ± 0.2 vs 6.57 ± 1.41 REU, $p = 0.0001$; *tas2r138* 1.0 ± 0.20 vs 2.1 ± 0.40 REU, $p = 0.05$). However, expression of *tas2r116* and *tas2r138* expression was reduced on the tongue following antibiotic treatment (*tas2r116* 1.0 ± 0.36 vs 0.09 ± 0.02. REU, $p = 0.03$; *tas2r138* 1.0 ± 0.19 vs 0.4 ± 0.08 REU, $p = 0.04$). Expression of *tas2r144* was not significantly different between the two groups.
Conclusion: The change in expression of taste receptors found may lead to reduced sensation of bitter dietary compounds on the tongue, and increased enteroendocrine signalling in the colon. Further studies are required, to assess the duration of effects, how altered mRNA expression translates into changed protein expression levels, and the consequences for the host.

Introduction: Probiotic strains *Lactobacillus* and *Bifidobacteria* demonstrated efficacy to reduce weight of animals and cholesterol level, changed liver morphology and modulated gut microbiota on obesity mice model in our recent study [1]. New updated prebiotic concept supposes perspectives to search for new substances. Our recent studies have shown starin-specific properties of *Lactobacillus* and *Bifidobacteria* probiotic actitvity [2] and suggested nanoceria to be used as potential prebiotics to enhance their probiotic properties (unpublished data).
Aims and Methods: The aim of this study was to evaluate the possibility of combined use of nanoceria and *Lactobacillus* and *Bifidobacteria* strains in monoculture and compositions to reduce cholesterol level on obesity model in mice. Previously studied probiotic strains *Lactobacillus acidophilus* IMV B-7279, *L. casei* IMV B-7280, *L. delbrueckii* subsp. *bulgaricus* IMV B-7281, *Bifidobacterium animalis* VKL, *B. animalis* VKB and cerium dioxide nanoparticles (size 3–7 nm) were used in the study. We used female mice of two lines and age groups: 6–8 weeks (18–24 g) BALB/c line mice, and 11–12 months (20–26 g) CBA line mice. Animals were divided into fifteen groups to test probiotic strains and nanoceria. All groups except the control received a special fat-enriched diet during three weeks before the experiment. Animals orally received probiotic strains and nanoceria in various compositions. One group of intact animals was used as a control. Cholesterol level and weight of mice were studied during 30 days.
Results: We revealed that all studied probiotic bacteria and composition of *B. animalis* VKL/*B. animalis* VKB/*L. casei* IMV B-7280 decreased the weight of obese BALB/c mice and concentration of different cholesterol types; adding nanoceria to the probiotic strains of *L. casei* IMV B-7280, *B. animalis* VKB and *B. animalis* VKL in monoculture and composition more effectively reduced levels of free, bound and ester cholesterol in serum. The rate and intensity of this process depends on the age of animals, as well as the type and concentration of the drug. The combination of 0.01 M nanoceria and probiotic strain *L. casei* IMV B-7280 oral administration resulted in the fastest decrease in cholesterol levels to the indicators of control groups of mice both in young and adult animals. The level of total cholesterol in the blood serum after tretement with *L. casei IMV B-7280* orally decrease to 7.37 ± 0.25 mmol/L, after treatment with 0.01 M CeO_2 + *L. casei IMV B-7280* orally 3.50 ± 0.47 mmol/L vs 7.83 ± 0.11 mmol/L in intact animals.
Conclusion: Combined use of nanoceria as prebiotic substance and probiotic strains *L. casei* IMV B-7280, *B. animalis* VKB and *B. animalis* VKL in monoculture and combination reduce weight and the level of free, bound and ester cholesterol in serum of young and adult obese mice. This can provide novel insights for using of probiotics compositions and nanomaterials considered as safe and effective prebiotic substances.
Disclosure: Nothing to disclose

Introduction: After undergoing RYGB, remission of type 2 diabetes (T2D) occurs in >60% of patients. The mechanism behind this remission is not completely understood. Beta cell activity (BCA) and beta cell mass (BCM) could possible play a role. While RYGB is beneficial for the health and quality of life of most patients, a rare complication is hyperinsulinemic hypoglycaemia. Also here the mechanism is still unclear, but a role for BCA and BCM is hypothesized.
Measuring BCA and BCM could provide useful information on the role of beta cells in patient responses to RYGB and possibly offer predictive value. Exendin-4, a stable analogue of glucagon-like peptide-1, specifically accumulates in the beta cells. ^{68}Ga-exendin-4 PET/CT can be used to quantify BCM *in vivo* and could help to study the role of BCM in changes of glycemic control after RYGB.
Aims and Methods: BCA and BCM were compared between patients with different responses after RYGB. Patients with complete remission of T2D (responders) and without complete remission of T2D (non-responders) after RYGB were included as well as patients with hypoglycaemia after RYGB.
BCA was measured by an arginine stimulation test and either an oral glucose tolerance test (in responders and non-responders) or a standard meal tolerance test (in the hypoglycaemia patients). BCM was measured in all patients as pancreatic uptake of ^{68}Ga-exendin-4 by quantitative analysis of PET/CT scans.
Results: In total, 12 responders and 12 non-responders will be included. So far, four responders and four non-responders were included. Preoperative patient characteristics and postoperative weight loss were comparable between the groups. The BCM was 37% lower in the non-responders (131 ± 78 kBq) compared to the responders (206 ± 90 kBq), although not statistically significant ($p = 0.25$). BCA was significantly lower in the non-responders compared to the responders, with an arginine stimulated acute C-peptide response of 0.4 ± 0.2 and 0.9 ± 0.3 nmol/l, respectively ($p = 0.02$).
In total, 8 hypoglycaemia patients and 8 matched controls will be included. At this moment, three hypoglycaemia patients have completed the study and in these patients the mean BCM was 226 ± 69 kBq.
Conclusion: These preliminary data show that measuring BCM in vivo is possible using ^{68}Ga-exendin-4 PET/CT. The data suggest that BCM is lower in patients with incomplete remission of T2D compared to those with complete remission. Furthermore, BCM in patients with hypoglycaemia seems to be even lower than in patients with remission of T2D after RYGB. These data may suggest a role for BCM in patient response to RYGB.
Disclosure: Nothing to disclose

P1237 LIRAGLUTIDE TREATMENT IN OBESE DIABETIC PATIENTS MODULATES GAS PRODUCTION DURING LACTULOSE BREATH TEST: A NEW POTENTIAL TREATMENT TO MODULATE GUT MICROBIOTA

Introduction: Colonic bacteria fermentation produces hydrogen (H2) and methane (CH4), which can be easily measured using breath test method. Breath tests (BT) represent a valid and non-invasive diagnostic tool in many gastroenterological disorders. C13 Octanoic Acid breath test, is used to analyze gastric emptying, often altered in various gastrointestinal disorders.
To date the link between diabetes and intestinal microbiota is well known.
Liraglutide is a human GLP-1 analogue approved for type 2 diabetes, to reduce glycosylated hemoglobin (HbA1c) and achieve better effects on glucose control. Delayed gastric emptying has been previously associated with Liraglutide treatment.
So far it has never been analyzed colonic gas production, with lactulose breath test, before and after Liraglutide treatment.
Aims and Methods: Ten obese diabetic patients (age 63.8 ± 12.6; HbA1C 8.1 ± 1.4 %; weight: 105.4 ± 19.1 kg), candidates to receive GLP1-analogs therapy, where included in the study. All subjects underwent, before (B) and after 6 weeks of treatment (PT) with liraglutide 1.2 mg, metabolic evaluation including glucose, HbA1c, glucose self-monitoring, Lactulose Breath test (LBT) and Octanoic Acid breath test in our Gastroenterology Unit.
Methane and Hydrogen production, by the area under the time-concentration curve calculation (AUC), and the peak value were calculated, during LBT. Gastric emptying was assessed by C13 Octanoic Acid BT.
Results: All subjects experienced a significant weight loss (6% of the basal body weight; BMI B: 37 ± 5.1 kg/m^2, BMI PT: 27.4 ± 1.5 kg/m^2 p: 0.05), as well as a significant reduction of fasting plasma glucose (B FPG pre: 149.4 ± 15 mg/dl, FPG PT: 98.2 ± 23 mg/dl p: 0.09) and a Hb1Ac (HbA1C B: 8.1 ± 1.4 %, HbA1C PT: 5.5 ± 1% p: 0.01). Methane and Hydrogen production (AUC) and peak value were significantly reduced by Liraglutide in the post-treatment group; moreover, the LBT revealed that Liraglutide is able to significantly slow down the Oro-cecal transit time (OTT). Also Gastric emptyng was significantly reduced after Liraglutide treatment.
Conclusion: These results confirm the effect of Liraglutide on delayed gastic emptying and suggest that the glucose lowering effect of this molecule, may be potentially mediated by modulation of intestinal gas production, and OTT. These new findings could represent a new potential effect of Liraglutide treatment on the modulation of Gut Microbiota, underlying new potential mechanisms of microbiota-mediated metabolic effects.

Introduction: Nonalcoholic fatty liver disease (NAFLD) is the main cause of liver diseases worldwide that poses heavy health-related metabolic problems associated with the increasing trends of obesity and diabetes. NAFLD is affected with lifestyle practices including nutrition and sedentary life. Therefore, the common treatment is weight loss through dietary restrictions and practicing exercise. However, there is no consensus regarding the best diet to treat NAFLD, not merely focusing on weight loss but to improve the metabolic health of patients.
Aims and Methods: The aim is to study the role of dietary intervention program including dietary and exercise plan in the clinical improvement of NAFLD.
110 patients were recruited from the hepatology outpatient clinic in the Main Alexandria University Hospital and diagnosed as NAFLD based on Ultrasound examination and exclusion of other causes of acute and chronic liver disease like post viral, alcoholic, autoimmune and metabolic liver diseases. Also, patients who have diabetes mellitus, cirrhosis, or receiving hormonal treatment were excluded. Assessment of dietary intake, dietary habits, lifestyle practices, body composition measurements, laboratory investigations, clinical examination and evaluation of liver fat with ultrasound based hepatorenal index calculations was done. For 12 weeks, each patient received individualized dietary plan based on Mediterranean diet restricted in carbohydrates (40–45%), moderate in fat (35–40%) and protein (15–20%). Physical exercise including aerobic training and abdominal exercises 5 times/week and resistant training 1–2 times/weeks.
Results: The dietary intake of carbohydrate and energy were decreased, while the percent of fat intake were increased. This was associated with reduction of liver fat among 70% of patients as assessed by reduction in HRI scores, improvement of serum transaminases as well as components of metabolic syndrome and gastrointestinal tract symptoms. Moderate reduction in body weight 5–6% with more loss of body fat (12%) and good preservation of muscle mass were observed.
Conclusion: Proper nutrition counseling based on Mediterranean diet restricted in total calories and carbohydrates, has significant impact on improving the metabolic health of NAFLD patients.

Introduction: Obesity represents a paramount clinical problem for short and long-term cardiovascular and metabolic complications, with consistent increasing incidence in many countries. Gastric balloon is a relevant non-surgical option for such patients, but the positioning and the removal requires endoscopic procedure

and sedation. ELIPSE balloon is a novel device that do not require endoscopy and/or sedation, since it is swallowed by the patients and spontaneously excreted after a progressive deflatation. We conducted a prospective pilot study at S. Giovanni Hospital in Rome, Italy, to evaluate safety and efficacy of ELIPSE balloon in obese adult patients.
Aims and Methods: Eleven consecutive patients (8 females), with mean age 40 ± 5 and BMI 40 ± 4, were included in the study. ELIPSE balloon was swallowed with water, filled with 560 mL of fluid. Patients were followed up by a nutritionist during the study. Body weight were recorded before ingestion and after excretion of the balloon, and potential adverse events were monitored at ingestion time and during follow up till the excretion of the balloon.
Results: All the patients successfully swallowed the device, and no major adverse event was recorded during the study. Minor and transient symptoms reported were: dyspepsia, vomiting, and diarrhea. All the patients spontaneously excreted the balloon after 16 ± 2 weeks. At the end of the study, all the patients had a significant weight loss (mean: 14 ± 5 Kg).
Conclusion: In a single-center pilot study, ELIPSE balloon has demonstrated safety and efficacy in adult obese patients. This device do not require endoscopy and sedation and may represent a feasible and effective option even in primary setting. Data confirming efficacy and safety of ELIPSE are increasing, and further studies will better clarify the positioning of this promising device for the treatment of obesity.

Introduction: An association between obesity and elevated levels of thyroid stimulating hormone (TSH) has been reported. One of the suggested mechanisms is the influence of adipokines, namely adiponectin. Bariatric surgery is a currently recognized technique for the treatment of obesity, with a favorable effect on weight loss; however, the impact of the postoperative period on thyroid function has not been clarified.
Aims and Methods: The aim of this study was to evaluate the changes in TSH and free thyroxine (fT4) in the obese population submitted to bariatric surgery.
Prospective analysis of patients undergoing undergoing Roux-en-Y gastric bypass (RYGB) by obesity. Clinical and laboratory data were analyzed before and 1 year after surgery. Patients with a known history of thyroid disease were excluded. Statistical analysis performed in SPSS V24.
Results: 38 patients were included; mean age was 43 ± 11.2 years, 80% were women and mean Body Mass Index (BMI) before surgery was 41.7 ± 5.4 kg/m2. After surgery, patients lost an average of 33.4% of their total body weight and 87.8% of BMI in excess. There was a significant reduction in weight (111 vs 73.7 kg) and BMI (41.7 vs 27.7 kg/m2) before and after surgery (p-0.00). There was also a reduction in FT4 and TSH levels before and after surgery (FT4 0.92 vs 0.87 mg/dL, p-0.02 and TSH 1.13 vs 1.04 μUI/mL, p-0, 14). There was a significant correlation between TSH levels and BMI before surgery (r = 0.37, p-0.021). After surgery, there was only a correlation in the female subgroup (r = 0.36, p-0.048). There was a significant reduction in TSH levels with increased levels of adiponectin (r = −0.39; p -0.04), but only in the subgroup of women.
Conclusion: There seems to be a reduction in thyroid hormone levels due to weight loss after bariatric surgery. Changes in adipokine production, such as adiponectin, in adipose tissue may explain some of the variation in TSH.
Disclosure: Nothing to disclose

P1241 DIAGNOSIS OF LACTOSE MALABSORPTION BY THIRD GENERATION HYDROGEN BREATH TEST: TIME IMPLEMENTATION AND SAMPLES DATA REVIEW

Introduction: Hydrogen breath test using various substrates like glucose, lactulose, lactose and fructose are being used more and more to diagnose malabsorption and small intestinal bacterial overgrowth (SIBO). While glucose and lactulose hydrogen breath tests are more acceptable the diagnosis of SIBO, lactulose and fructose hydrogen breath tests are useful to diagnose various types of sugar malabsorption and lactose intolerance.
Technique and interpretation of different hydrogen breath tests are outlined in this review.
Aims and Methods: The third generation of hydrogen breath test monitors has reached a level of precision which makes such continuous air flow device (Gastrolyzer Bedfont, Scientific Ltd Harrietsham) or Heliprobe (Kilion, Mayoli Spindler) a helpful assist for diagnosis of gastrointestinal disorders.
Gases as H2, CH4 or CO2 are detected in a semi-conductor flow cell an displayed as ppm (part per million). The original sluggish development has now made room for a useful screening test in the cases where lactose intolerance is suspected.
Genetic test of lactose intolerance may help to differentiate patients with primary hypolactasia from those with lactose intolerance caused by secondary hypolactasia. Also it is useful for differing lactose intolerance from irritable bowel syndrome (IBS) which has very similar symptoms. So for the differentiation of adult-type hypolactasia from secondary causes of lactose intolerance, hydrogen breath testing (H2BT) might not need further genetic approach.
The third generation of H2BT is to prove and establish whether a simplified two or three sample test may reduce time, costs and staff resources without reducing the sensitivity of the procedure.
Data from 32 patients (20 males, 12 females) with a positive 4 h, nine samples H2BT were fully tested. Patients were stratified according to the degree of lactose malabsorption, the occurrence and type of symptoms. Sensitivity in the H2BT was tested taking into account two samples tests (0 and 120 min or 0 and 210 min) or three-sample tests (0 min,120 min and 180 min or 0 min 120 min and 210 min).
Results: Using a two sample test (0 min and 120 min or 0 min and 210 min) the false- negative rate was 35.6% and 27.8% respectively. With a three-sample test (0 min 120 min and 180 min or 0 min 120 min and 210 min) lactose malabsorption was diagnose in 94.6% (30 of 32) patients and in 97.1% (31 of 32) patients respectively. Of 20 patients with abdominal symptoms 5 (26.6%) and 2 (12.2%) would have false-negative results with 0 min and 120 min or 0 min and 210 min two-sample tests respectively. The three-sample tests, 0 min, 120 min and 180 min or 0 min, 120 min and 210 min, would have a false-negative rate of 5.9% and 2.1% respectively.
Conclusion: H2BT is an inexpensive, useful, simple and safe diagnostic test in the evaluation of lactose malabsorption. Standardization of the indications, performance and interpretation of the test still needs to be improved in clinical practice and research.
The third generation quantitative detection of rare gases with the breath expiration with three-sample H2BT is time and cost sparing without significant loss of sensitivity for the diagnosis both of lactose malabsorption and lactose intolerance
Disclosure: Nothing to disclose

Introduction: Abnormalities in duodenal mucosa, nutrient absorption and enteroendocrine cell population are thought to play a pathophysiological role in the development of insulin resistance in patients with type 2 diabetes (T2D). Duodenal exclusion via bariatric surgery confers an insulin sensitizing metabolic benefit that is, in part, weight-independent. Duodenal Mucosal Resurfacing (DMR) is an endoscopic procedure that entails catheter based circumferential mucosal lifting followed by hydrothermal ablation (targeted circumferential treatment area of 9–10 centimetres in length) and may confer similar metabolic benefits using a less invasive procedure. DMR has been shown to improve glycaemic control at 6 months in T2D patients in a single centre first-in-human study. Here we report the 12 month safety and efficacy data of all patients included in the first multicentre study involving DMR.

Aims and Methods: We conducted a single-arm, open-label, prospective, multicentre study in which T2D patients (HbA1c 7.5–10.0%; age 25–75y; BMI 24–40kg/m^2; using oral glucose lowering medication) received a single DMR procedure. Adverse events and impact on glycaemic control (HbA1c and fasting plasma glucose [FPG]), insulin resistance (HOMA-IR), and liver enzymes (AST and ALT) was determined at baseline and 1, 3, 6, 9, 12 months post DMR. Glucose lowering medication was kept stable for ≥ 6 months post DMR but could be adjusted according to care guidelines thereafter. We used ANOVA for repeated measurements with Bonferroni correction for the analysis of the multiple measurements after DMR. Values are mean ± SD.
Results: Baseline characteristics (n = 46) are 63% male, mean age of 55 years [range 31–69], mean T2D duration of 6 years [range 0.1–12]), and mean BMI 31.6 ± 4.3 kg/m^2. Additional baseline values are shown in Table 1. DMR was well tolerated in all 46 patients. Eight serious adverse events (SAEs) were reported, of which one was considered procedure-related and non were considered device-related. The single procedure-related SAE was mildly elevated body temperature (38°C) with an increase in C-reactive protein that started one day post-DMR and involved one extra day of hospitalization for observation. The 6 and 12 month post DMR follow-up values of HbA1c, FPG, HOMA-IR, weight, ALT and AST with significance levels (as compared to baseline) are shown in Table 1. Change at 12 months are: Δ HbA1c -1.0 ± 0.2% (p ≤ 0.001), Δ FPG -41 ± 8 mg/dL (p ≤ 0.001), Δ HOMA-IR -3.6 ± 0.9 (p = 0.005), Δ weight -2.7 ± 0.6kg (p = 0.003), Δ ALT -10 ± 2 (p = 0.005), and Δ AST -6 ± 2 (p = 0.002).

Measurement	Baseline	6 months	P-value*	12 months	P-value*
HbA1c [%]	8.6 ± 0.8	7.5 ± 0.8	≤0.001	7.5 ± 0.9	≤0.001
FPG [mg/dL]	196 ± 48	160 ± 40	≤0.001	156 ± 39	≤0.001
HOMA-IR	7.7 ± 5.6	5.0 ± 3.5	0.027	4.8 ± 3.0	0.005
Weight [kg]	91 ± 13	89 ± 12	≤0.001	90 ± 12	0.003
ALT [IU/L]	38 ± 22	29 ± 12	0.014	29 ± 16	0.005
AST [IU/L]	26 ± 10	21 ± 6	0.042	21 ± 6	0.002

*[Table 1. Baseline and 6 and 12 months values in complete population (n=46). *Following ANOVA repeated measurements Bonferroni correction.]*
Conclusion: The endoscopic DMR procedure was found to be safe and effective in 46 patients with suboptimally controlled T2D using oral glucose lowering medication. DMR elicited a substantial improvement in parameters of glycaemia as well as a decrease in liver transaminase levels up to 12 months post-procedure, suggesting considerable potential of DMR for the treatment of T2D.
Disclosure: This study was sponsored by Fractyl Laboratories Inc.

Introduction: Structural alterations of the intestinal microbiota and its metabolic capacities are associated with various disease states in humans. There is hope that remodeling of a dysbiotic microbiome towards a normal shape could improve health. Prebiotics are one possibility to beneficially modulate a dysbiotic microbiome. Despite increasing knowledge, mechanistic insight linking dietary fiber with health benefits, beyond the well-known role of short chain fatty acids (SCFA), is still scarce.
Aims and Methods: This study aimed to decipher novel mechanistic links between a dietary fiber intervention with partially hydrolyzed guar gum (PHGG) and structural and metabolic alterations of the human microbiome. We performed a clinical trial including 19 healthy volunteers (8m, 11f). Stool, serum and urine samples were collected weekly for 9 weeks allowing every study participant to serve as his/her own control. The study included three periods, namely a 3 week lead-in, a 3 week intervention, and a 3 week wash-out phase. During the 3 week intervention phase participants received daily dosing of 5g PHGG for 3 days followed by 10g PHGG for four days in the first week, proceeding with two weeks of 15g PHGG per day. A minute medical and nutritional history was taken for every participant at baseline, questions regarding abdominal symptoms were collected weekly and stool habits using the Bristol Stool Chart (BSC) were recorded on a daily basis. Alterations in the structural composition of the microbiome were assessed by 16S metagenomics using both V1-V3 and V3-V4 chemistry. Furthermore, stool metabolomics was studied by magnetic resonance spectroscopy. Data from metagenomics and metabolomics were linked using sparse regression matrices employing the 'Sparcc' software module.
Results: As expected, PHGG administration increased stool frequency and reduced stool consistency. Notably, this effect was more pronounced in males than females and persisted during the wash-out period. 16S sequencing revealed an increase in alpha-diversity during and also persisting after the intervention. Beta-diversity with respect to treatment periods was not different due to large inter-individual variability. NMR spectroscopy of the stool metabolome identified >30.000 signals, principal component analysis again revealed significant gender-specific differences and we identified >150 significantly changed metabolites before, during and after intervention. Interestingly, the concentration of SCFA showed an early peak that was not persistent, in contrast to numerous other metabolites.
Conclusion: In the PAGODA study, we show that a dietary intervention with PHGG induces beneficial and durable alterations of gut microbial structures along with changes in microbiota-derived metabolites. With more than 150 significantly regulated compounds we propose that microbe-host communication due to dietary fibers induced metabolites goes far beyond SCFA.
Disclosure: The study was supported by an unrestricted grant form Nestle Health Sciences to ARM. Otherwise there are no potential conflicts of interest regarding this study.

P1244 MICRONUTRIENT STATUS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

Introduction: Micronutrient (MN) status in patients with inflammatory bowel disease (IBD) is important in evaluation of malnutrition. Malnutrition and weight loss are the most common causes of altered status of MN due to reduced food intake, enteric loss of nutrients and malabsorption. A wide range of vitamin and mineral deficiencies has been noticed in IBD patients, with varying degrees of clinical importance.
Aims and Methods: Aim of our study was investigate levels of micronutrients in patients with IBD, as well as assessment of possible correlation of micronutrients levels and disease activity.
A case-control study was preformed among 30 newly diagnosed IBD patients and the same number age, sex-matched healthy controls. All patients underwent a total colonoscopy with ileoscopy. Complete blood count was obtained in addition to inflammatory markers (CRP, erythrocyte sedimentation rate-ESR). Serum levels of selenium, zinc, copper and magnesium were measured spectrophotometrically, while serum iron was assesed with an electrochemiluminesence immunoassay. Mayo score and CDAI respectively were calculated for each patient.
Results: Serum levels of iron, zinc, magnesium and selenium were significantly lower ($P < 0.05$) in IBD patients than controls. There was no statistically significant difference in levels of copper between the two groups ($P > 0.05$). In patients group mean levels of iron (7.1 ± 8.2 μmol/L), zinc (23.6 ± 5.3 μmol/L), magnesium (0.6 ± 0.2 mmol/l) were reduced below the reference values, while the levels of copper (28.2 ± 24.1 μmol/L) were elevated. Serum values of iron and zinc levels negatively correlated with CDAI and Mayo score ($P < 0.05$), while the levels of copper and magnesium did not show significant correlation with CDAI and Mayo score ($P > 0.05$).
Conclusion: Our results suggest that deficiency of MN can be a result of the inflammatory process, so regular MN monitoring is essential, considering that zinc and iron deficiency could be potential indicators of disease activity.

P1245 INFLUENCE OF INTRAGASTRIC AND INTRADUODENAL BITTER TASTANT ADMINISTRATION ON HUNGER RATINGS AND GUT PEPTIDE RELEASE IN HEALTHY CONTROLS

W. Verbeure[1], B. Pussig[1], J. Tóth[1], A. Pauwels[1], L. Timmermans[2], L. Van Oudenhove[1], I. Depoortere[1], J. Tack[3], E. Deloose[1]

[2]*UZ Leuven, Leuven, Belgium*
[3]*University of Leuven, University Hospital Gasthuisberg, Gastroenterology, Leuven, Belgium*

Contact E-Mail Address: wout.verbeure@kuleuven.be
Introduction: Intragastric (IG) administration of the bitter tastants denatonium benzoate (DB) or quinine hydrochloride (QHCl) decreases orexigenic gut peptide levels, and reduces hunger sensations. *In vitro* studies on human gastric tissue showed that DB stimulated somatostatin (SST) release.
Aims and Methods: We hypothesized that 1) the reduction in hunger ratings and orexigenic hormone levels is stronger after IG administration in comparison to ID administration, and 2) these differences are mediated by the inhibiting effect of released SST.

11 healthy female volunteers (age: 22 ± 0.7y; BMI: 21.7 ± 1.2kg/m^2) participated in a randomized, placebo-controlled crossover study. After an overnight fast, DB (1µmol/kg), QHCl (10µmol/kg) or placebo were given IG or ID via a feeding tube. A baseline blood sample was taken 10 min prior to administration. Following bloods samples were collected every 10 min after administration for a period of 2 hours. Hunger was rated at the same points on a visual analogue scale (VAS). *Ad libitum* milkshake intake was assessed at the end of the experiment and taste was scored on a VAS. Percentage change of SST and hunger were calculated from baseline. AUC of positive and negative peaks was calculated for both percentage change of hunger and SST. Net increment was calculated by subtracting the negative from the positive area. Data were analyzed using mixed models with planned contrast analysis. Comparisons of interest were QHCl vs placebo and DB vs placebo for both IG and ID administration together with the comparison between IG and ID for these differences. Observed p-values were corrected for multiple testing with stepdown Bonferroni.

Results: The net increment of hunger was significantly different after IG administration between QHCl and placebo (p = 0.03). There was no significant difference between the other comparisons. The net increment of SST, milkshake intake or taste showed no significant differences for the comparisons of interest.

Conclusion: Administration of QHCl has the potential to reduce hunger sensations in healthy female volunteers, but without significant effect on the amount of consumed milkshake and on taste scores. The effect was however, site specific as it was only seen after IG administration. SST release did not differ between the different treatments, suggesting that SST is not the inhibiting factor of orexigenic hormone secretion after IG bitter administration.

Introduction: Excessive loss of water and sodium leading to dehydration is a frequent complication in patients with an ileostomy or those with a (near) short bowel syndrome (1). To maintain electrolyte and fluid balances in these patients, measurement of sodium concentration in a single portion of urine is a simple and helpful tool. In general a sodium of over >20 mmol/L rules out significant dehydration and/or sodium depletion (when not using diuretics and in the absence of significant renal disease). A direct measurement of sodium concentration in urine by means of POCT might enable patients to monitor their sodium status at home and as such might reduce complications like dehydration-related complaints such as general malaise, cramps and (eventually) problems such as kidney function loss provided that low urine sodium concentrations can be reliably measured. In this pilot study, the performance characteristics of the a home POCT tool, the Medimate Minilab, were validated.

Aims and Methods: The Medimate Minilab (Medimate BV) is a self test to measure sodium concentration in urine by means of POCT. The technology is based on microchip capillary electrophoresis combined with conductivity detection, consisting of disposable lab chips, the Medimate Lab Chip and a measurement device, the Medimate Multireader ®) (2). For validation, 50 ml of urine of xx subjects was collected and mixed with 5 ml of lithium containing buffer freshly collected urine was used to determine the limit of quantification (LOQ), imprecision and agreement with the academic laboratory reference, i.e. the Cobas 8000 ISE Roche system.

Results: Imprecision of urine samples was low: a maximum CV of 6.1% was determined in repeated measurements during five days. The smallest concentration of sodium that can be reliably measured with an acceptable imprecision was 17 mmol/L, i.e. well below the threshold of 20 mmol/l. The agreement with Sodium on the Cobas 8000 ISE system showed an overall positive bias of 23% with substantial deviation in individual points. The device was easy to handle, and found to be suitable for patients in a home setting. It is of essential importance that instructions are adequately followed, such as filling the cup to a certain volume (55 ml) of urine, to avoid falsely low results.

Conclusion: Our results suggest that home measurement of sodium concentration in urine of patients with intestinal failure to establish their hydration status seems feasible, given the high reporducability and threshold of measurements in the lower sodium concentration range observed with the current technology.

Introduction: Hospital malnutrition is underestimated among physicians, even in gastroenterological settings.

Aims and Methods: To evaluate prevalence and impact of malnutrition in an Internal Medicine and Gastroenterology Department of an Italian large hospital (Fondazione Policlinico Gemelli, Rome). Patients were evaluated within 72 hours from admission according to Nutritional Risk Screening-2002 (NRS-2002) and European Society for Clinical Nutrition and Metabolism (ESPEN) criteria. Bioelectrical Impedance Analysis (BIA) derived Phase Angle (PhA) was used as a prognostic marker of length of stay and hospital mortality.

Results: In 10 months, 300 patients were enrolled. Male patients were 172 (57.3%), females were 128 (42.7%); mean age was 63.7 years (±17.6). The most frequent admission diagnoses were cancer (112 patients, 37.4%), followed by cirrhosis (43, 14.3%) and biliary diseases (31, 10.3%). 157 patients (52.5%) were at risk of malnutrition according to NRS-2002; 116 (38.7%) were malnourished according to ESPEN Criteria. Patients with a PhA <4.8° had a longer length of stay (10.9 ± 7.5 vs 8.9 ± 5.7: p = 0.018). PhA <4.8° significantly affected length of stay even when adjusted for other variables such as age, cancer, handgrip strength test and Nutritional Risk Screening-2002 < 3 (HR = 1.476; 95% CI: 1.102–1.976; p = 0.009). A Phase Angle <4.8° was independently associated with hospital mortality ($p < 0.005$).

Conclusion: Over half (52.5%) of gastroenterological patients were at risk of malnutrition and over a third (38.7%) are malnourished at admission. PhA may be used as a prognostic nutritional tool to identify patients at risk of worsening outcomes (length of stay and hospital mortality), who deserve to receive a specific nutritional support.

Introduction: Percutaneous Endoscopic Gastrostomy (PEG) is widely accepted as an efficient mean to provide long term nutritional support. A soft inner bumper allows an easy external removal. Meanwhile, it similarly contributes to the growth of accidental dislodgment as a frequent complication of the procedure. The dislodgment rate is high and can lead to major harm and severe morbidity. We seek to acknowledge risk factors that commonly contribute to PEGs' accidental removal, thus allowing for a better selection of patients' individual vigilance care requirements.

Aims and Methods: We aimed to identify predictive factors for PEG's accidental dislodgment

Retrospective, unicenter study, including patients that underwent PEG procedure, from January 2014, to March 2017. Every patient had a 12 months minimum follow-up.

Statistical variables were chosen according to clinical experience and previous evidence in the literature. Univariate analysis allowed us to select variables with marginal association (p < 0.15) with the outcome variable, PEG dislodgment, which were then included in a logistic regression multivariate model. Finally the discriminative power was assessed using area under curve (AUC) of the receiver operating curve (ROC).

Results: We included 164 patients, 67.7% (111) were female and the mean age was 81 years. We report 59 (36%) PEG dislodgment and 13 (7.9%) early dislodgments. The variables with marginal association towards PEG dislodgment were hypoalbuminemia (p = 0.095); living at home (p = 0.049); living in a nursing home (p = 0.074); Cerebrovascular disease (CVD) (p = 0.028); weight fluctuation (p = 0.001); psychomotor agitation (p < 0.001); distance skin-bumper (p = 0.034) and irregular appointment follow up (p = 0.149).

We applied a logistic multivariate regression that specified the variables that remained statistically significant after model adjustment (CVD OR 4.8 [CI 95% 2.0–11.8]; weight variation OR 4.7 [CI 95%1.6–13.9] and psychomotor agitation OR 18.5 [CI 95% 5.2–65.6]).

Finally we report an excellent discriminative power (AUC ROC 0.797 [CI95% 0.719–0.875])

Conclusion: PEG is a common procedure and accidental dislodgment is a frequent complication. CVD, psychomotor agitation and weight fluctuation, by increasing this complication, are factors that would let us prudently select patients' individual vigilance care requirements.

Introduction: Introduction: In 2004 the National Confidential Enquiry into Patient Outcome and Death (NCEPOD) report highlighted the high 30-day mortality related to Percutaneous Endoscopic Gastrostomy (PEG) insertion and the need for careful patient selection. Subsequent studies have demonstrated a higher mortality in certain patient groups, for example severe dementia. In 2010 the British Society of Gastroenterology (BSG) published guidelines recommending a nutrition support team (NST) to identify appropriate cases for PEG insertion.
A NST was set up in a district general hospital providing a review process for PEG referrals. Prior to this, patients were referred to neighbouring trusts for PEGs or to the radiology team for a per-oral inserted gastrostomy (PIG). A new standard operating procedure and dedicated electronic request form was created. A nutrition nurse was appointed to perform the initial vetting. Complex cases are discussed in a weekly nutrition multidisciplinary team (MDT) and subsequent ward round. Despite recommendations and evidence regarding PEG insertion, for many patients it remains a difficult clinical and ethical decision. Increasing bed pressures with an ageing population have complicated matters further. We have noted increasing demands for PEG to facilitate discharge to care homes.
Aims and Methods: Our aim was to assess whether the implementation of the NST led to improved patient selection and reduced 30-day all-cause mortality.
We conducted a retrospective analysis of all electronic PEG referrals and referral review notes held by the nutrition nurse between 1st December 2015 and 1st April 2017.
Results: We identified 136 referrals in total. Before the review process could be completed by the NST 8 patients died; 7 patients declined to have a PEG and 13 had already recovered their swallow and therefore these patients were excluded. 108 referrals were reviewed in full by the NST. Of the 108 referrals 81 were deemed suitable for gastrostomy insertion and 27 were not thought appropriate. 73/81 had PEGs placed. The remaining 8 were not placed due to suspicious findings during the procedure which required further investigation (1); agitation during endoscopy (1); recovered swallow prior to procedure (1); oesophageal stricture (1); and pharyngeal pouch (1); patient required referral on for radiologically inserted gastrostomy (RIG) (4). The 27 patients identified as inappropriate referrals were for the following reasons; not medically fit for procedure due to ongoing sepsis, other co-morbidities or low BMI (11); patient having end of life care (11); patient wishes to feed orally at risk (5). Of the total of those who did not proceed to PEG insertion, 22 patients died within 30 days (81.5%). In the group that did proceed to PEG 7 patients died within 30 days (9.6%): to our knowledge no deaths were related to PEG insertion.
Conclusion: Having a dedicated NST who review PEG referrals results in a significant reduction in mortality, inappropriate procedures and respects patient autonomy. It is important to maintain the NST and not let decisions surrounding gastrostomy be eroded by increasing pressures on the health care service.

Introduction: Short bowel syndrome (SBS) is present when the length of the remnant small intestine after surgical resection is <200 cm. The decreased absorpting area and shortened transit-time increase the absorption of nutrients, electrolytes and water and lead to a permanent need for parenteral nutrition in many cases. The surgical shortening of the bowel causes a qualitative-quantitative change of the human microbiome. These alterations influence greatly the quality of life of the SBS-patients through the immun-, and nutritional status.
Aims and Methods: To investigate the composition of the microbiome of patients with SBS.
Patients >18 years old with SBS were included. After informed consent anthropometric parameters (weight, height, BMI, body composition- Inbody) were registered. To identify the microbiome-composing bacteria, stool samples were collected and the 16S rRNS (member of the subunit of procaryotic ribosome 30S) genetical sequencing was made. Beside evaluating the composition we calculated the Microbiome Diversity Index (MDI) comparing the diversity of the microbiome of patients with SBS to the data derived from the normal population.
Results: 5 female patients with SBS are under care at our clinic (mean age: 49 ± 13 év, mean bowel lenght: 81 ± 65cm, BMI:17.8 ± 2.1 kg/m^2), 3 of 5 patients are on parenteral nutrition permanently. The diversity is extremly reduced compared to the normal population (MDI: 5.5 ± 1.9, 0–30 between percentiles). The main phylum is Firmicutes, and Proteobacterium and Actinobacterium phyla are present, but the ratio of Bacterioides phyla is extremly low. Among Firmicutes the lactate-producing and -consuming bacteria (Lactobacillus, Bifidobacterium, Veillonella) form the majority of the microbiome.
Conclusion: The composition of microbiome of SBS patients differs largely from the normal population; the diversity is extremely reduced. Being able to enrich the diversity of bacteria in patients with SBS has probably therapeutical consequences.

P1251 RAPID DIAGNOSIS OF BLOODSTREAM INFECTIONS IN PATIENTS ON HOME PARENTERAL NUTRITION

Y. Wouters, D. Dalloyaux, H. Roelofs, R. te Morsche, G.J.A. Wanten
Radboudumc, Gastroenterology and Hepatology, Nijmegen, Netherlands

Contact E-Mail Address: yannick.wouters@radboudumc.nl
Introduction: Home parenteral nutrition (HPN) patients have an increased risk of catheter-related bloodstream infections. Early identification of causative microorganism (s) is critical to optimize patient care and antimicrobial use. The droplet digital polymerase chain reaction (ddPCR) is a novel culture-independent molecular technique to rapidly identify pathogens in whole blood.
Aims and Methods: The aim of this study was to measure the diagnostic accuracy of the ddPCR in the HPN-setting in comparison with the current gold standard blood cultures. We analyzed a set of historically collected frozen blood samples from adult HPN patients with a suspected bloodstream infection, and compared these with blood cultures drawn on the same day. In a relative short procedure (± 4 hours), whole blood samples with possible DNA from microorganisms were isolated and analyzed with ddPCR. The analyses were independently performed by two research analysts, without knowledge of the blood culture results. Study outcomes included sensitivity, specificity, the positive- and negative predictive value, and the positive- and negative likelihood ratio of the ddPCR.
Results: In total, 40 blood samples were analyzed (Table 1). The sensitivity was 80% (95%CI 44–97) and the specificity 83% (95%CI 65–94). The positive- and negative predictive value were 62% (95%CI 40–79) and 93% (95%CI 78–98), respectively. The positive- and negative likelihood ratio were 4.8 (95%CI 2.0–11.3) and 0.24 (95%CI 0.07–0.84), respectively.

		Bloodculture		
		Positive	Negative	Total
ddPCR	Positive	8	5	13
	Negative	2	25	27
	Total	10	30	40

[Table 1]
Conclusion: ddPCR has an acceptable sensitivity and specificity for identifying pathogens from whole blood. At this moment, ddPCR seems to work especially well in predicting true negative results. A larger prospective study will be conducted to confirm these results.

Introduction: Non-alcoholic steatohepatitis is a serious and progressive disease, with no definitive treatment for it. Statins, as cholesterol-lowering drugs, are one of the treatments proposed for this disease.
Aims and Methods: The aim of the present study is to determine the effect of rosovatatin on steatosis and fibrosis in patients with non-alcoholic steatohepatitis. In this double-blind clinical trial, 44 patients with non-alcoholic steatohepatitis without metabolic syndrome, non-diabetic and BMI less than 30 were randomly divided into intervention (6 months daily 10 mg of rosuvastatin with nutrition and lifestyle education) and control (Placebo with the same protocol) groups. The condition of liver fibrosis and steatosis were evaluated by transient elastography (FibroScan) at the beginning and the end of the study.
Results: After 6 months, the percentage of steatosis in both groups was lower than the beginning of the study, which was significant in the intervention group ($P = 0.014$). At the beginning of the study, the liver fibrosis index in the control group was significantly lower than intervention group ($P = 0.01$) and at the end of the study, this difference was maintained between the two groups ($P = 0.002$). In the intervention group, the index of fibrosis decreased, although this difference was not significant ($P = 0.22$).
Conclusion: The use of rosuvastatin can affect the reduction of steatosis and may prevent the progression of liver fibrosis.
Disclosure: Nothing to disclose

P1253 MICRORNA-199A-3P PROMOTES THE ACTIVATION OF HEPATIC STELLATE CELLS AND LIVER FIBROSIS BY SUPPRESSING CAVEOLIN-2

Introduction: There is limited therapy for liver cirrhosis although it constitutes a large proportion in the world. The activation of hepatic stellate cells (HSCs) is known as the key contributors to liver fibrosis/cirrhosis. MicroRNAs have been widely reported to regulate various diseases including liver fibrosis, and are promised to be novel therapeutic targets.
Aims and Methods: The aim of the study is to investigate the role of miR-199a-3p and its target caveolin-2(CAV2) in liver fibrosis and the underlying mechanisms. Rat HSCs was isolated by in situ perfusion with pronase and collagenase B, followed by Nycodenz density gradient centrifugation. We perform microRNA microarray to detect microRNA expression profile in quiescent and activated rat HSCs. We validated the microarray data by qPCR in rat HSCs, and further examine the expression in rat and human liver fibrotic tissues. Based on these results, the increased miR-199a-3p in both activated HSCs and liver fibrotic tissues was selected for further analysis. The human HSCs line, LX_2 and rat HSCs were transfected with miR-199a-3p mimics and antagomir, followed by qPCR and western blot to examine the expression of fibrotic markers. Moreover, MTT assay and colony formation experiment were used to detect the proliferation of HSCs. The targets of miR-199a-3p were predicted by Targetscan and miRanda. The effect of miR-199a-3p in vivo was assessed in mice liver fibrosis model induced by CCL_4.
Results: miR-199a-3p was dramatically up-regulated during HSCs activation and liver fibrotic tissues from both rat and human. Forced expression of miR-199a-3p in LX_2 and rat HSCs significantly increased fibrotic markers expression. Additionally, inhibition of miR-199a-3p reduced fibrotic markers expression. MiR-199a-3p suppressed CAV2 protein expression without mRNA repression. Further study reveled that CAV2 obviously inhibited fibrotic markers expression and the proliferation of HSCs. We then found the protein expression of TGFβRI, a key receptor in TGF-β signaling pathway, was reduced by CAV2. Interestingly, Twist1 could bind with the promoter sequences of human miR-199a-3p to drive miR-199a-3p expression in HSCs, then promoting liver fibrosis. More importantly, we provided evidence that antagomiR-199a-3p injection relieved mice liver fibrosis induced by CCL_4.
Conclusion: Our data indicate that miR-199a-3p mediates the regulation of liver fibrosis by suppressing CAV2 expression, and promoting TGF-β signaling pathway probably through increasing TGFβRI expression. Thus miR-199a-3p may represent potential targets for novel therapeutic strategies against hepatic fibrogenesis and also might evolve as biomarkers in the diagnosis of liver fibrosis.

Introduction: Non-alcoholic fatty liver disease (NAFLD) is the most common chronic liver condition in the Western world and is considered a hepatic manifestation of the metabolic syndrome. It is associated with an increased risk of type 2 diabetes and cardiovascular diseases, and is characterized by an accumulation of lipids in the liver, which can lead to liver fibrosis and/or inflammation, eventually progressing to hepatocellular carcinoma. Although liver biopsy is still the gold standard for diagnosis and staging of patients with suspected NAFLD, it has many drawbacks, such as sampling errors, costs, and risks of complications. Furthermore, it is impractical for regular screening of patients because of the large number of individuals who have NAFLD. Therefore, tools for non-invasive assessment of disease severity are urgently needed.
Aims and Methods: The aim of this study was to identify novel non-invasive markers that are associated with key histology lesions of progressive NAFLD. Therefore, patients with biopsy-proven NAFLD (n = 74) and healthy controls (n = 62) were recruited; among the NAFLD patients, 13 had advanced fibrosis (≥F2) and 61 had no or mild fibrosis (F0-F1). EDTA plasma samples were obtained from blood by centrifugation and analyzed using gas chromatography-mass spectrometry and liquid chromatography-tandem mass spectrometry-based metabolomics. Statistical analysis was performed by multivariate (random forest, elastic net, and linear discriminant analysis) as well as univariate (analysis of variance) algorithms, and peak signals were compared to key histology lesions of NAFLD, i.e. fibrosis, activity, and steatosis.
Results: We identified a metabolite panel that successfully distinguishes between patients with fibrosis stage F≥2 and those with fibrosis stage F < 2. Our biomarker, consisting of an androgen, a bile acid and an eicosanoid, showed an area under the curve (AUC) value of 0.95 (sensitivity of 0.92, specificity of 0.90), outperforming current non-invasive diagnostic tests, including the measurement of caspase-cleaved keratin 18 levels (AUC = 0.68), the fibrosis-4 index (AUC = 0.80), and the enhanced liver fibrosis score (AUC = 0.82).
Conclusion: Our results proved that metabolomics is a powerful technology platform for studying complex disease mechanisms. By using whole metabolite profiling, we could identify a biomarker that is strongly associated with the stage of liver fibrosis in NAFLD patients. Since it provides an excellent performance in the detection of fibrosis in plasma samples from NAFLD patients, it can serve as a new non-invasive screening tool for NAFLD patients.

Contact E-Mail Address: d.w.kurniawan@utwente.nl
Introduction: Non-alcoholic fatty liver disease (NAFLD) affecting about 25% of population, is becoming the leading and growing cause of mortality worldwide. The prevalence of NAFLD is growing rapidly due to western life style, and increasing incidences of diabetes and obesity. 30% of affected people develop liver Inflammation or non-alcoholic steatohepatitis (NASH) which further progresses to advanced fibrosis or cirrhosis to hepatocellular carcinoma. Currently, there is an unmet need for the effective and safe therapies for the treatment of this disease. Inflammatory macrophages play a crucial role in the pathogenesis of NASH and NAFLD. Therefore, molecular therapies inhibiting macrophage activation would be highly promising therapy for the treatment of NASH.
Aims and Methods: Transcriptome analyses in NASH patients and inflammatory macrophages revealed Src kinase, a tyrosine-protein kinase, as a prospective therapeutic target in inflammatory M1 macrophages. In this study, we investigated the implication of Src signaling pathway inhibition in inflammatory macrophages and NASH. We further developed a PLGA nanoparticles delivery system to deliver Src kinase inhibitor, for improved pharmacokinetic profile and therapeutic efficacy, to inhibit M1 macrophages thereby ameliorating liver inflammation and NASH.
To accomplish the goals of this project, we used KX2-391, a small-molecule Src kinase inhibitor. We tested the therapeutic efficacy and toxicity of KX2-391 in the differentiated inflammatory RAW macrophages and bone marrow derived macrophages. Thereafter, we synthesized PLGA nanoparticles to deliver Src kinase inhibitor (KX2-391) to increase the drug pharmacokinetics for the efficient treatment of liver inflammation. We investigated the efficacy of KX2-391-PLGA nanoparticles in differentiated RAW macrophages, bone marrow derived macrophages and murine precision cut liver slices (PCLS). Finally, we evaluated the therapeutic effects of KX2-391 and KX2-391-PLGA nanoparticles *in vivo* in Methionine Choline deficient (MCD)-diet NASH model.
Results: Analysis of livers from NASH patients showed a highly significant induction of Src kinase expression that correlated with the increasing NAS score as compared to normal livers as determined from transcriptome analysis (GEO accession number: GSE48452). Expression of Src kinase and M1-specific genes (iNOS, IL-1β, CCL2, Fcγ$R1) was found to be significantly upregulated in inflammatory macrophages. Src kinase pathway activation (Src phosphorylation) was confirmed in inflammatory macrophages. KX2-391 dose-dependently inhibited the phosphorylation of Src and pSTAT1 signaling pathway. Furthermore, KX2-391 significantly attenuated M1-induced Nitric oxide (NO) release (an indicator of M1 activation) and expression of M1 markers in RAW macrophages, BMDMs and murine precision cut liver slices (PCLS). PLGA loaded KX2-391 (KX2-391-PLGA) showed favorable size, stability, and drug entrapment efficiency. KX2-391-PLGA inhibited NO release and M1-specific markers expression in RAW macrophages and BMDMs. KX2-391 and KX2-391-PLGA showed significant inhibition of M1 macrophage markers in PCLS without inducing toxicity. Recently, we have performed an *in vivo* study on MCD diet-induced murine model of NASH and preliminary results suggests inhibition in liver inflammation as assessed by quantitative PCR. Further analyses are currently ongoing.

Conclusion: Inhibition of Src signaling pathway in inflammatory macrophages suggests a potential therapeutic approach to treat non-alcoholic steatohepatitis.

Introduction: Non-alcoholic steatohepatitis (NASH) is the leading cause of cirrhosis worldwide and is the most rapidly growing indication for liver transplantation. Macrophages are an important cellular component in the inflammatory milieu in NASH. The inflammatory and pro-fibrotic mediators produced by macrophages causes significant tissue injury leading to initiation and progression of many inflammatory diseases especially NASH. These inflammatory (classically-activated or M1) macrophages also recruit scar-forming fibrogenic myofibroblasts and inflammatory cells further driving liver injury to fibrosis, cirrhosis, and hepatocellular carcinoma. Therefore, inhibition of the inflammatory macrophages would be a promising approach to attenuate liver inflammation.
Aims and Methods: Bukong et al. have recently demonstrated the immunomodulatory role of spleen tyrosine kinase (SYK) pathway in alcoholic liver disease [1]. In this study, (i) we aim to study the implication of SYK signaling pathway in NASH and inflammatory macrophages; (ii) we investigated PLGA nanoparticles based delivery of SYK signaling pathway inhibitor as an highly effective and promising therapeutic approach for the treatment of NASH.
Methods: To accomplish the goals of this study, we used R406, a small-molecule Syk kinase inhibitor that blocks Fc receptor signaling pathway and reduces immune complex-mediated inflammation [2]. We tested the therapeutic efficacy of R406 in the differentiated inflammatory RAW macrophages. Thereafter, we synthesized PLGA nanoparticles to deliver SYK kinase inhibitor (R406) to increase the drug pharmacokinetics for the efficient treatment of liver inflammation in NASH. We investigated the efficacy of R406-PLGA nanoparticles in differentiated RAW macrophages and bone marrow-derived macrophages. Furthermore, we evaluated the therapeutic effects of R406 and R406-PLGA nanoparticles *in vivo* in Methionine Choline deficient (MCD)-diet NASH model.
Results: Analysis of livers from NASH patients showed a highly significant induction of SYK expression that correlated with the increasing NAS score as compared to normal livers as determined from transcriptome data analysis (GEO accession number: GSE48452). We observed significant upregulation of SYK expression and activation of SYK signaling pathway (SYK phosphorylation) in inflammatory macrophages. R406 dose-dependently inhibited LPS- and IFNγ-induced activation of SYK signaling pathway consequently resulting in inhibition of M1-induced nitric oxide (NO) release (M1 activation) and M1-specific markers (IL-1β, FcγR1, CCL2, iNOS, and IL-6) in RAW macrophages and bone marrow derived macrophages (BMDMs). R406 loaded PLGA nanoparticles (R406-PLGA) were successfully synthesized and were characterized for the size, charge, stability, and the drug entrapment efficiency. R406-PLGA inhibited NO release and M1-specific markers (IL-1β, FcγR1, CCL2, iNOS, and IL-6) in RAW macrophages and BMDMs. Finally, we performed an *in vivo* study on a typical murine model of NASH-associated liver inflammation and liver injury i.e. diet-induced (methionine-and-choline-deficient, MCD) model and further analyses are currently ongoing.
Conclusion: Inhibition of SYK signaling pathway using small molecule inhibitor and delivery of SYK inhibitor using PLGA nanoparticles can be a highly effective and potential therapeutic approach for the treatment of Non-alcoholic steatohepatitis.

Introduction: In 2015, a new gene called as mitochondrial open reading frame of the 12S rRNA-c (MOTS-c) was found in 12S rRNA region of mtDNA. MOTS-c encodes a 16-amino-acid peptide. It has been reported that this new peptide reduces insulin resistance and obesity in experimental animal models. Insulin resistance and obesity are important components of non-alcoholic steatohepatitis. Therefore, variations in the MOTS-c gene may be responsible for insulin resistance in nonalcoholic steatohepatitis (NASH).
Aims and Methods: We aimed to find potential association between MOTS-c nucleic acid variations and NASH. DNA was isolated from the peripheral blood of 100 NASH patients and age and sex-matched 100 healthy controls. Primers were designed by using the Primer3 program for amplification of the MOTS-c gene (GenBank: KP715230.1). Whole MOTS-c gene was sequenced by using ABI 3500 Genetic Analyzer.
Results: We only detected one mutation in the NASH group. This mutation converts stop codon of MOTS-c gene to glycine amino acid. However, there was no variation found in the control group.
Conclusion: To the best of our knowledge, this is first human study is related to MOTS-c genetic variations in the NASH. We found that the MOTS-c gene is quite conserved, although mtDNA is highly variant. There was not found to be an association between NASH and MOTS-c genetic variations but this preliminary finding should be investigated in the different ethnic and geographical populations. This mutation may result a non-functional peptide formation longer than MOTS-c. In this case, our hypothesis is that, nonfunctional peptide can not activate AMPK pathway and so blood glucose levels may increase and insulin resistance may develop in skeletal muscles. However the effect of this mutation on MOTS-c peptide should be tested in the in-vitro study.
Disclosure: This study was supported by grants from Marmara University, Scientific Research Research Projects Committee (Project No:SAG-C-YLP-070617-0342).

P1258 THE RELATIONSHIP BETWEEN SMALL INTESTINAL BACTERIAL OVERGROWTH AND ENDOTOXEMIA LEVELS AND TLR2,TLR4 EXPRESSION IN PATIENTS WITH CIRRHOSIS

Y.J. Ma, X. Gao, D. Zhou, G. Chen
Zhengzhou People's Hospital, Zhengzhou, China

Contact E-Mail Address: mayingjie19@sina.com
Introduction: In cirrhotic patients, portal hypertension, hypohepatia, intestinal mucosal hyperemia and edema, dyskinesia, dysfunction of bile salt transporters and other factors could influence the species, colonization and metabolism of bacteria, leading to disbiosis of gut microbiota. While due to direct toxicity of endotoxin and inflammatory mediated-damage, intestinal dysbacteriosis could further aggravate liver damage. It has been found that TLR2,TLR4 and CD14 is the main endotoxin receptor. This study were to evaluate the effect of SIBO by lactulose hydrogen breath test, measure the plasma concentrations of endotoxin, and TLR2,TLR4 expression to determine the relationship among SIBO, endotoxemia and TLR2,TLR4 expression. Small intestinal bacterial overgrowth (SIBO) gets great attention because of its clinical significance in systemic and local complications in patients with liver cirrhosis, but there are still many controversies about the mechanisms.
Aims and Methods: We aimed to determine the frequency of SIBO in cirrhotics and correlate with endotoxemia, TLR2,TLR4 expression.
Between July 2015 and December 2016, there were 58 cirrhotic patients enrolled in our department. Based on the Child-Pugh classification, there were 18 cases of Child-Pugh grade A, 17 cases of grade B and 23 cases of grade C.36 males and 22 females, aged between32 and 75 years, with a mean age of 45.62 ± 12.50 years. The study involved 26 cases of healthy controls (16 men and 10 women; range, 23–78 year; mean age, 42.25 ± 14.18 year). Patients were included in the study if they had not been using any antibiotics, lactulose, antacids, or other drugs affecting gastrointestinal motility in the past 4 weeks. The serum endotox were tested by TAL chromogenic substrate Assay. The expression of TLR2,TLR4 on the surface of PBMC were tested by flow cytometry. Small-intestinal bacterial overgrowth was determined by LHBT. A rise of ^{3} 20p.p.m from basaline or a rise of ^{3}20 p.p.m from basaline in hydrogen by 90 min should be considered SIBO positive test. Hydrogen breath gross were also measured in all subjects who exhaled gas within 90 minutes (LHBT set-value). The LHBT set -value is expressed by the sum of the seven measured values in 90 minutes or before the second peak. In addition,it can be used as an indicator to indirectly reflect the growth of bacteria in the small intestine.
Results: Of the 58 cirrhotics, 25 (43.10%) had SIBO positive, compared to two (7.69%) control ($x^2 = 10.32$, $P = 0.001$). The LHBT intestinal set value,serum endotox level and the expression TLR2,TLR4 on the surface of PBMC in cirrhosis were obviously higher than the control group ($t = 11.573$, $P < 0.05$; $t = 9.958$, $P < 0.05$; $t = 12.380$, $P < 0.05$; $t = 10.319$, $P < 0.05$); It was shown by Pearson correlation analysis that LHBT intestinal set value was positive correlated with endotox level and the expression TLR2,TLR4 among cirrhotic patients and live cirrhosis with SIBO-negative.
Conclusion: Small-intestinal bacterial overgrowth was prevalent in patients with liver cirrhosis, and was related to the severity and complications of the liver disease. LHBT set-value as an indicator of bacterial contamination in the small intestine, it was significantly higher in liver cirrhosis than that in normal people, and it was positively correlated with the severity of symptoms. SIBO is associated with endotoxemia, and through TLR2,TLR4 signaling pathways lead to inflammatory damage, thereby involving in the developing cirrhosis. The early diagnosis and treatment of SIBO in liver cirrhosis will be possible to reduce complications, hold-up or delay the disease procession.

Introduction: It has been indicated that gut microbiota plays critical roles in non-alcoholic fatty liver disease (NAFLD). Our previous study has demonstrated that the abundance of *Escherichia* is significantly increased in fecal and mucosal microbiota in non-alcoholic steatohepatitis (NASH) patients. Our aim is to investigate the role of clinically isolated mucosal-adherent *Escherichia coli* (*E.coli*) strains in the development of NAFLD in high-fat diet (HFD) mice.
Aims and Methods: Colonic mucosa from one biopsy-proven NASH patient was obtained and cultured in Luria-Bertani (LB) medium, followed by planking on *E.coli* Chromogenic Medium. One hundred monoclone isolates were obtained and identified as *E.coli* through full-length 16s ribosomal RNA sequence and *E.coli*-specific gene uidA. Phylogenetic tree (maximum likelihood method) showed 3 clusters, which contained 73, 23, and 4 isolates respectively. They were named NF73-1 to NF73-73, NF23-1 to NF23-23, and NF4-1 to NF4-4. C57BL/6J mice were fed with HFD for 12 weeks. At 10th week, mice were treated daily with an oral administration of NF73-1, NF23-1, NF4-1 or LB for 2 weeks. In vitro, intestinal epithelial cells HT-29 were seeded on 12-well plates and treated with NF73-1, NF23-1, NF4-1 or LB.
Results: Compared with LB medium, NF73-1, NF23-1 and NF4-1 all increased NAFLD activity score (NAS). NF73-1 group showed the worst liver pathology and the highest NAS. In addition, Sirius-Red staining revealed that merely NF73-1 initiated hepatic fibrosis. Furthermore, bacterial load in liver was increased in NF73-1 and NF4-1 group, with NF73-1 higher. Consistently, highest mRNA levels of IL-6 and iNOS were observed in NF73-1 group, followed by NF4-1 and NF23-1 groups. The proportion of $CD11c^{+}MHCII^{+}$ $F4/80^{-}$ dendritic cells (DCs) in liver exhibited no significance among all groups. However, NF73-1, NF23-1 and NF4-1 all increased $IL\text{-}1\beta^{+}$DCs, and NF73-1 elevated $IL\text{-}6^{+}$ DCs in liver compared with other three groups, indicating enhanced hepatic immune responses of NF73-1 group. The mRNA and protein levels of MUC-2, Occludin and ZO-1 in colonic mucosa were markedly downregulated in NF73-1 treated mice compared with NF23-1 and NF4-1 groups. Similar with in vivo study, the mRNA levels of Occludin and ZO-1 in HT-29 cells were lowest in NF73-1 group.
Conclusion: Mucosal-adherent *Escherichia coli NF73-1* induces more serious liver injury than other isolates NF23-1 and NF4-1, indicating that NF73-1 might be a critical strain in NAFLD. Our research shed some light on diagnosis and treatment of NAFLD targeting specific bacterial strain.

Introduction: Metabolic syndrome is one of the most important health issues worldwide. Its liver phenotype is called nonalcoholic fatty liver disease (NAFLD). We have previously demonstrated that high fat diet (HFD)-induced liver damage is reverted by coffee consumption thought a reduction of fat deposition in the liver and an amelioration of antioxidant and anti-inflammatory status.
Aims and Methods: We hypothesize that the first target organ of coffee is the gut, supporting the protective effect on the liver by modulating the gut permeability and contributing to the concept of relevant role of gut-liver axis. Twenty-four C57BL/6 mice were divided into 3 groups of 8 mouse each: one group received standard diet (SD: 3.3 Kcal/g, 5% from fat), one group received HFD (5.6 Kcal/g, 58% from fat), and a third group received HFD plus decaffeinated coffee solution (HFD+Coffee) for 12 weeks. Coffee daily dosage corresponded to 6 cups of espresso coffee or 2 cups of filtered coffee for a 70 kg person. At the end of treatment, hepatic histology was examined by H&E staining. Alanine-aminotrasferase (ALT), total cholesterol levels were measured in serum samples. Gene expression of PPAR-α and LXR-α was assessed in the liver. The expression of molecular mediators of fatty acids ABCA1, ABCG1, FFAR-1 and of gut permeability Zonulin and Claudin were evaluated in duodenum and colon by RT-PCR. Cecum fecal samples were collected for triglycerides and fatty acids analysis.
Results: Mouse body weight was significantly lower in HFD+Coffee group *vs* HFD ($p < 0.003$). Coffee treatment also reduced cholesterol and ALT serum levels ($p < 0.001$ and $p < 0.05$, respectively), and ameliorated liver macrovesicular steatosis ($p < 0.001$) and ballooning degeneration ($p < 0.05$). Coffee supplementation increased the expression of PPAR-α and LXR-α in the liver and upregulated the expression of ABCA1, ABCG1, FFAR-1, Zonulin, and Claudin in the duodenum and colon. The fecal cecum content of HFD+Coffee group showed higher levels of total triglycerides and fatty acids *vs* HFD group.
Conclusion: Coffee modulates the intestinal permeability and molecular expression of fatty acids mediators increasing fat oxidation and ameliorating fatty acids efflux. Coffee *via* of gut-liver axis exerts a beneficial effect on the liver reducing hepatic steatosis.

Introduction: Progression from non-alcoholic fatty liver disease (NAFLD) to steatohepatitis is associated with severity of steatosis. Accurate assessment of hepatic steatosis in liver biopsy specimens is thus important. Steatosis is graded using the semi-quantitative Brunt score (grade 0 = 0–5%; grade 1 = 5–33%; grade 2 = 33–66%; grade 3 >66% of fatty droplets in a variable numbers of high-power fields). This score is subject to inter- and intra-observer variability, which may affect reproducibility and accuracy of results. Digital automated quantification of the whole liver tissue slide, in contrast to random area selection, has the potential to overcome this.
Aims and Methods: We aim to develop and validate a steatosis quantification algorithm for automated digital analysis of whole slide images. For the training and validation cohort, hematoxylin-eosin stained liver tissue slides from patients with or without NAFLD are included and digitally scanned at 20x magnification. Steatotic areas are manually annotated in representative biopsies from each steatosis grade. Next, thresholds for size and roundness parameters are identified by logistic regression to discriminate steatosis from surrounding liver tissue. The resulting algorithm produces a steatosis proportionate area (SPA; ratio of steatotic area to total tissue area described as percentage) which will be correlated to the steatosis grade. The software is implemented as a Java plugin in FIJI, in which digital whole slide images can be processed automatically with use of the Pathomation extension.
Results: Liver tissue specimens of 61 NAFLD patients and 18 controls were included. The area under the curve of correctly classified steatosis by the algorithm was 0.970 (95% CI 0.968–0.973), $p < .001$. Accuracy of the algorithm was 91.9%, with a classification error of 8.1%.
The median SPA per steatosis grade was: grade 0 1.41% (IQR 1.03–1.80%); grade 1 4.99% (IQR 2.97–9.31%); grade 2 13.65% (IQR 10.90–16.10%), and grade 3 16.34% (IQR 14.48–20.54%). SPA correlated significantly with steatosis grade (Rs = .845, CI:.749-.902, $p < .001$). In post-hoc analyses, SPA increased significantly with each individual steatosis grade, except between grade 2 and 3. Median fat droplet size increased with steatosis grade (grade 0 108 um^2 (IQR 94–124); grade 1 170 um^2 (IQR 158–233); grade 2 249 um^2 (218–309); grade 3 226 um^2 (207–321), $p < .001$). Number of fat droplets (median 169.8 (IQR 136.1–304.2)) did not increase with steatosis grade.
Conclusion: We have developed a novel digital analysis algorithm that accurately quantifies steatosis in whole liver slides. SPA percentages were in all cases lower than the percentage range resembled by the steatosis grade. This underlines the variability, typically associated with visual examination. Automated analyses of whole slide images benefits from objective and labor-free analysis. This algorithm can be incorporated when quantification of steatosis is warranted, such as in clinical trials studying efficacy of new therapeutic interventions in NAFLD.

P1262 FATTY LIVER PROMOTES GAMMA-GLUTAMYL TRANSPEPTIDASE ACTIVITY-INDUCED ARTERIAL PLAQUE FORMATION

K. Kinoshita, N. Toshikuni, M. Tsuchishima, M. Tsutsumi
Kanazawa Medical University, Hepatology, Ishikawa, Japan

Contact E-Mail Address: kaorin@kanazawa-med.ac.jp
Introduction: Recent studies have provided evidence for a pivotal role of gamma-glutamyl transpeptidase (GGT) activity in arterial plaque formation. Furthermore, many studies have suggested a positive association of fatty liver disease with carotid atherosclerosis, a well-known risk factor for cardiovascular disease (CVD). In a previous cross-sectional study, we reported a strong relationship between the combination of fatty liver and an elevated serum GGT level and the presence of carotid plaque (*J Atheroscler Thromb*. 2015; 22(10): 1051–60). The aim of the current longitudinal study was to determine whether this combination can indeed cause carotid plaque formation.
Aims and Methods: This study included subjects who had no evidence of carotid plaque at baseline and received an annual health checkup more than 7 years. Exclusion criteria were as follows: a history of CVD; hepatitis B or C virus infection; heavy drinking (more than 60 g per day of alcohol); medications capable of influencing the course of atherosclerosis in the past and during the follow-up period, including antihypertensive agents, antidyslipidemic agents,

antidiabetic agents, and antiplatelet/anticoagulant agents. We performed ultrasound examinations for assessing fatty liver and carotid plaque. Carotid plaque was defined as an intima-media thickness greater than 1.5 mm in any portion of the carotid arteries. We calculated cumulative incidence rates of carotid plaque formation by the Kaplan-Meier method and investigated predictors for carotid plaque formation using the Cox proportional hazards model.
Results: A total of 599 subjects had received a health checkup more than 7 years until the end of 2016. After excluding subjects according to the above criteria, we enrolled 107 subjects (median age, 49 years; 76 male and 31 female). At baseline, fatty liver and serum GGT levels ≥ 50 U/L (the median value as the cut-off) were observed in 15 and 38 subjects, respectively. During a median follow-up period of 13.3 years (range, 7.2 to 15.5 years), carotid plaques emerged in 34 subjects (24 male and 10 female); the cumulative incidence rates were 10%, 23%, and 40% at 5, 10, and 15 years, respectively. There was no significant difference in the incidence rates of carotid plaque emergence between subjects with and without fatty liver, while the rates were significantly higher in subjects with a serum GGT level ≥ 50 U/L than in those with GGT levels < 50 U/L (p = 0.02). Surprisingly, when combining fatty liver and serum GGT levels, subjects with both fatty liver and a serum GGT level ≥ 50 U/L had the highest incidence rates (62.5% at 10 years; n = 8), followed by those only with a serum GGT level ≥ 50 U/L (34.3% at 10 years; n = 30), those without the conditions (14.5% at 10 years; n = 64), and those only with fatty liver (0% at 10 years; n = 5) (p = 0.017). Univariate analysis revealed that variables with p < 0.1 were smoking, HDL cholesterol, triglyceride, and the combination of fatty liver and a serum GGT level ≥ 50 U/L. In multivariate analysis, this combination was the only significant predictor for carotid plaque formation (age- and sex-adjusted hazard ratio 4.4; 95% confidence interval 1.5–13.0; p = 0.007)
Conclusion: Our results suggest that the presence of fatty liver may promote GGT activity-induced arterial plaque formation. Checking the combination of fatty liver and an elevated serum GGT level can help identify subjects who are at high risk of future CVD.
Disclosure: Nothing to disclose

P1263 THE ASSOCIATION BETWEEN NONALCOHOLIC FATTY LIVER DISEASE AND MILD COGNITIVE IMPAIRMENT IN THE ELDERLY

D. Lihua, L. Jiaojiao, W. Yanan, C. Lingxia, L. Jie, J. Wang
Peking University People's Hospital, Geriatrics, Beijing, China

Contact E-Mail Address: 18813185381@126.com
Introduction: Up to now, more and more researchers have found that metabolic syndrome (MS) and its elements are closely related to cognitive impairment. Since nonalcoholic fatty liver disease (NAFLD) was regarded as an element of MS in liver and they share a lot of similarities in pathogenesis, it is fair to hypothesize that NAFLD is also related to cognitive impairment. However, the correlation between NAFLD and cognitive impairment in the elderly and the underlying mechanisms had not been revealed. Considering the elderly is the major population affected by cognitive impairment, and we lack effective treatment for serious cognitive impairment as dementia, MCI may be a good period to prevent serious cognitive impairment.
Aims and Methods: We aimed to investigate the association between NAFLD and MCI and the possible underlying mechanisms in the elderly.
A total of 392 elderly objects (60 years), with and without NAFLD were enrolled in this study and were subdivided into NAFLD group (n = 191) and non-NAFLD group (n = 201). Their clinical data including medical history, medications, blood pressure, body mass index (BMI), liver function, kidney parameters, glucose metabolism parameters, serum lipid profile, NAFLD fibrosis score and carotid plaques were collected, and logistic regression analysis was used to investigate the association between NAFLD and MCI.
Results: Detection rate of MCI in NAFLD group is significantly higher than that in non-NAFLD group (19.9% vs 10.4%, 2 = 6.837, P = 0.009); and NAFLD is an independent risk factor (OR = 2.625, 95% confidence interval (CI) 1.250–5.512, P = 0.011) for MCI after adjusting confounding variables such as age, gender, education, cardiovascular disease and its risk factors. In addition, female (OR = 2.775, 95%CI 1.363–5.651, P = 0.005), unstable plaques of carotid (OR = 2.736, 95%CI 1.131–6.620, P = 0.026), history of stroke (OR = 4.122, 95%CI 1.374–12.363, P = 0.011), serum albumin (OR = 0.908, 95%CI 0.840–0.982, P = 0.015), fast serum glucose (OR = 1.268, 95%CI 1.076–1.493, P = 0.004), serum AST/ALT ratio (OR = 2.984, 95%CI 1.370–6.500, P = 0.006) were also independently associated with MCI in the elderly. Among them, female, unstable plaques of carotid, a history of stroke, higher levels of fasting serum glucose and AST/ALT ratio were independent risk factors for MCI in the elderly.
Conclusion: NAFLD is independently associated with MCI in the elderly.

Contact E-Mail Address: alinamircea.popescu@gmail.com
Introduction: Several noninvasive fibrosis assessment tests were developed in order to replace liver biopsy.
Aims and Methods: Our goal was to assess the correlation between APRI, FIB 4 Index and BARD score with transient elastography (TE) in diabetic patients with fatty liver disease.
We conducted a prospective study from October 2016- December 2017 which included 413 diabetic patients out of which 353 had liver steatosis (mean age 61 ± 8.5 years, 55.8% females, 44.2% males) evaluated both by serum markers (TGO, TGP, platelets) as well as by TE (Fibroscan, Echosense,Paris, France, with incorporated CAP function). Based on specific formulas we calculated APRI, FIB 4 index and BARD score. We excluded all patients without liver steatosis at ultrasound. Liver stiffness measurement was considered reliable only if 10 valid values were obtained, with an IQR < 30% and a success rate > 60%. For differentiation between different stages of liver fibrosis, the following cut-off values were used (1): F2-F3: 7–10.2kPa, F4≥10.3 kPa. We considered mild steatosis if CAP = 230–275dB/m, moderate steatosis-CAP = 275–300 dB/m and severe steatosis-CAP > 300 dB/m (recommended by the manufacturer).
Results: Severe steatosis according to CAP measurements prevailed: 68.7% of patients, whereas the distribution between mild and moderate steatosis was similar 17% vs 14.1% (p > 0.05). The patients' distribution regarding the different stages of fibrosis was the following: F0-F1–202 patients (57.2%), F2-F3 -78 patients (22.2%), F4-73 patients (20.6%).
Out of the 353 patients, 27.1% of them were overweight (BMI 25–29.9 kg/m2), whereas 64% patients were obese (BMI≥30 kg/m2).
We found a weak, but significant correlation between liver stiffness assessed by TE and liver stiffness predicted by APRI (Pearson r = 0.24, p = 0.001). Considering an APRI score < 2 to rule out liver cirrhosis, 349 patients had APRI < 2, among which 259 patients (74.2%) had also LSM < 10.3 kPa.
Regarding FIB 4 score, we found out that 95.3% of patients had FIB4 < 2.6 thus ruling out advanced liver fibrosis (as compared to 79.3% patients (280) with LSM < 10.3kPa). The correlation between them was very weak, but statistically significant (r = 0.15, p = 0.005).
16.4% (58) of patients had a BARD score < 2, having a strong negative predictive value for advanced hepatic fibrosis. Among them, only 1.7% had LSM≥10.3 kPa.
Conclusion: An APRI score < 2, FIB 4 score < 2.6 and BARD score < 2 can rule out advanced fibrosis quite accurately. These simple scores can be used as first line tests to rule out patients without advanced fibrosis in diabetic patients with fatty liver disease.

Introduction: The Enhanced Liver Fibrosis (ELF) test is a noninvasive fibrosis panel composed of hyaluronic acid (HA), procollagen-3 N-terminal peptide (P3NP), and tissue inhibitor of metalloproteinase-1 (TIMP1). Nonalcoholic steatohepatitis (NASH) with advanced fibrosis (F3) or cirrhosis (F4) shows increased liver-related mortality. Noninvasive tests are needed to identify patients with these advanced stages of NASH who require lifestyle intervention and/or are eligible for enrolment in clinical trials.
Aims and Methods: Aim of the present study was to determine the diagnostic accuracy of ELF score for prediction of NASH with advanced fibrosis/cirrhosis. We enrolled consecutive patients with NAFLD admitted to two Austrian outpatient liver clinics who underwent liver biopsy. Histological NASH was defined as presence of steatosis > 5%, hepatocellular ballooning and lobular inflammation. Fibrosis was staged according to the clinical research network (CRN) score. Serum samples obtained at the time of liver biopsy were used to perform ELF test (Siemens Health Care, Vienna, Austria). The predictive value of ELF score for diagnosis of fibrosis stage was assessed by receiver operating characteristic (ROC) analysis and compared to that of NAFLD fibrosis score (NFS) and FIB-4, two simple fibrosis tests based on routine clinical and laboratory parameters.
Results: Our study cohort contained 188 patients with NAFLD. On liver histology, NASH was present in 111 patients (59%), advanced fibrosis stage (F3-4) in 49 patients (26%), and both features in 38 patients (20%). ELF score was significantly higher in patients with NASH plus fibrosis stage F3-4 compared to the rest of the cohort (11.0 ± 1.8 vs. 8.8 ± 1.3, p < 0.001). ROC analysis revealed superior diagnostic accuracy of ELF score (AUROC 0.87 [CI 0.79–0.95]) vs. FIB-4 (AUROC 0.81 [CI 0.71–0.92]) or NFS (AUROC 0.77 [CI 0.67–0.88]) for prediction of NASH with fibrosis stage F3-4. An ELF score of ≥9.5 was identified by Youden index as the best cut-off for diagnosis of NASH with fibrosis stage F3-4 (sensitivity 86%, specificity 80%, PPV 51%, NPV 96%).
Conclusion: Based on our findings, ELF score shows high accuracy for noninvasive diagnosis of NASH with advanced fibrosis among patients with NAFLD. An ELF score < 9.5 was found to reliably rule out NASH with fibrosis stage

F3-4 and thus may be very useful in assessing eligibility of NAFLD patients for clinical trials with drugs in development for treatment of NASH.

Introduction: Patients who have undergone liver transplantation often develop metabolic syndrome (MetS) and de-novo non-alcoholic fatty liver disease (NAFLD).
Aims and Methods: Our aim was to evaluate the cardiovascular risk in these patients using CXCL10, a serum biomarker whose expression levels have been associated with inflammatory diseases. CXCL10 was chosen considering that early changes of immune biomolecules in peripheral blood, reflecting immune status, could be candidate biomarkers able to diagnose or predict cardiovascular complications.
60 liver transplant recipients were assessed for clinical and biological features, performing abdominal ultrasound and transient elastography (TE) with controlled attenuation parameter (CAP), calculated non-invasive scoring systems for advanced fibrosis and NAFLD (APRI, FIB-4, NAFLD score). The cardiovascular risk was assessed using the Framingham risk score and the presence of metabolic syndrome.
Results: The main indication for liver transplantation was HCV (69% of patients) and the mean age 56 years. The paired t-test showed a significant association of CXCL-10 with the presence of the metabolic syndrome ($p < 0.001$) and also with the non-invasive scores for advanced fibrosis and NAFLD. The metabolic syndrome was present in 51% of patients. 23% of patients had a Framingham risk score higher than 12 (10% mortality in 10 years) and 13% a score higher than 17 (30% mortality in 10 years). The multivariate analysis indicated as independent prediction factors for higher values of the Framingham score the serum levels of ferritin ($p = 0.03$) and urea ($p = 0.02$). The Spearman rank correlation test showed a significant association between the serum levels of CXCL10 and ferritin ($p = 0.04$), urea ($p = 0.003$), but also with uric acid ($p = 0.04$), an already established risk factor for cardiovascular mortality.
Conclusion: Serum levels of CXCL10 could have an important role in assessing the cardiovascular risk in liver transplant recipients, especially when features of the metabolic syndrome are present. Our study is ongoing, aiming to establish the role of biomarkers, including CXCL10 in cardiovascular related mortality in these patients.
Disclosure: Nothing to disclose

P1267 UDCA IMPROVED INSULIN SENSITIVITY AND METABOLIC PARAMETERS IN NASH PATIENTS

S. Vyalov[1]
[1]*Peoples Friendship University of Russia, Gastroenterology, Moscow, Russian Federation*

Contact E-Mail Address: doctor@vyalov.com
Introduction: Nonalcoholic steatohepatitis (NASH) is a prevalent liver disease associated with increased morbidity and mortality. Ursodeoxycholic acid (UDCA) may have antioxidant, anti-inflammatory, and antifibrotic properties and may reduce liver injury in NASH.
In the pathogenesis of fatty liver disease are the main hypercholesterolemia and impaired glucose tolerance. Studies in recent years have suggested an improvement in cholesterol on UDCA therapy, which could potentially be due to a direct effect on cholesterol or an improvement in the course of the disease. UDCA is a potent modulator of GLP1, which are all important regulators of lipidand glucose metabolism.
To date, no studies have assessed the efficacy of UDCA in treatment of insulin resistance in patients with NASH.
Aims and Methods: We conducted a 6-month randomized controlled multicenter trial to evaluate the efficacy of UDCA (10–15 mg/kg per day) in 228 patients with NASH and insulin resistance. The comparison group of 76 patients used only low-fat hypoglycemic diet (LFHD). The primary study end point was reduction in glucose and insulin levels from baseline in patients treated with UDCA. Secondary study end points were the proportion of patients with HOMA-IR normalization, relative reduction in the scores of serum markers of fibrosis and hepatic inflammation, and safety and tolerability.
Results: UDCA significantly reduced mean ALT levels at 58.4% from baseline after 3 months compared with 12.6% with diet ($p < 0.001$). At the end of the trial, ALT levels normalized in 84.5% of patients treated with UDCA. The median GGT reduction was 62.1% vs 9.6%. UDCA significantly reduced the FibroTest serum fibrosis marker ($p < 0.001$) compared with diet. Patients treated with UDCA experienced significant reductions in serum glucose, glycosylated hemoglobin, and serum insulin levels. Serum glucose improved in 16.3% vs 4.5%, glycosylated hemoglobin improved in 8.4% vs 3.8%, and serum insulin level improved in 18.5% vs 6.2%. UDCA also significantly improved markers of glycemic control and reduce insulin resistance in 21%. There were no safety issues in this population. Treatment with UDCA was safe, improved cholesterol and glucose levels, atherogenicity index, HOMA-IR and selected metabolic parameters.
Conclusion: This study demonstrates that UDCA, 10–15 mg/kg per day, is safe and well-tolerated in patients with NASH. Treatment with UDCA resulted in a strong and sustained reduction of ALT levels, suggesting that the numerous hepatoprotective actions of this molecule.
UDCA treatment resulted in an improvement of hypercholesterolemia and insulin resistance in patients with NASH. UDCA resulted in beneficial effects on glycemic control and insulin sensitivity.

Introduction: Due to the increasing prevalence of NAFLD and the difficulties to select patients who need closer surveillance for fatty liver, various serum surogate markers were proposed. The evaluation of steatosis severity is important for the correlation with metabolic features and for the impact on followup and prognosis. We used the metabolomic approach for determining new diagnostic markers through specific high performance liquid chromatography coupled with mass spectrometry (HPLC-MS) and principal component analysis (PCA). As reference, we used the morphological analysis, which was estimated using SteatoTest (R) (Biopredictive, Paris, France) for the steatosis grading and NASHTest (R) (Biopredictive) for the confirmation and exclusion of steatohepatitis.
Aims and Methods: We aimed to determine new metabolomic markers the diagnosis and assessment of steatosis severity and to find new diagnostic markers for NASH. We used the metabolomic approach for determining new diagnostic markers through specific high performance liquid chromatography coupled with mass spectrometry (HPLC-MS) and principal component analysis (PCA). As reference, we used the morphological analysis, which was estimated using SteatoTest (R) (Biopredictive, Paris, France) for the steatosis grading and NASHTest (R) (Biopredictive) for the confirmation and exclusion of steatohepatitis.
Results: We included in the study 30 patients with NAFLD and 10 controls. Seven patients (23.3%) had NASH as confirmed by NASHTest. A significant association was found between vitamin D (25(OH)D3) levels and steatosis grades evaluated through SteatoTest ($p = 0.013$). Vitamin D was also useful for the exclusion of steatosis in three patients that were firstly enrolled in the NAFDL group based on ultrasound ($p < 0.001$). Other markers were also found to be associated with steatosis: androstenon ($p = 0.002$), phenyl lactic acid ($p = 0.001$) and hexacedenoic choline ($p = 0.03$). Of these markers, androstenon and hexadecenoic choline were significantly associated with the presence of NASH ($p = 0.013$ and 0.042 respectively). The asscociation of phenyl lactic acid with NASH did not reach the statistic significance ($p = 0.07$).
Conclusion: In conclusion, our pilot data suggest that new metabolomics markers can be used for the diagnosis of steatosis and for the rapid assessment of steatosis severity and steatohepatitis in NAFLD.

Introduction: Metabolic syndrome (MS) is a set of metabolic and cardiovascular risk factors that have the capacity to predict a better cardiovascular and type 2 diabetes mellitus (T2DM) risk development than its individual components. Non-alcoholic fatty liver disease (NAFLD) is considered to be the hepatic manifestation of metabolic syndrome (MS). A definition that includes NAFLD among the mandatory criteria for defining MS is still missing. In patients with NAFLD, cardiovascular disease is the primary cause of death. Classical cardiovascular risk scores underestimates the cardiovascular risk in patients with MS.
Aims and Methods: Our aim was to identify objective criteria in order to include NAFLD as a mandatory criteria for the definition of MS. We included 4 groups of patients: NAFLD with MS patients, NAFLD without MS patients, MS patients and controls. MS was diagnosed with the presence of any three out of the five criteria (abdominal obesity, hypertriglyceridemia, hipo-HDL-cholesterolemia, hypertension, impaired fasting glucose or T2DM). NAFLD diagnosis was established based on clinical examination and ultrasonography. Diagnosis of non-alcoholic steatohepatitis (NASH) was based on Fibromax determination. For the cardiovascular risk (CVR) assesment, ultrasound measurement of carotidian intimate-media thickness (CIMT-in cm, normal value = 0.07cm) was used. Anthropometric parameters and usual paraclinical parameters were recorded.
Results: The CIMT values were higher than normal, except the control group (NAFLD + MS 0.134 +/−0.099, MS 0.149 +/−0.086, NAFLD 0.076 +/−0.051, controls 0.061 +/−0.023), with statistical difference between NAFLD + SM vs NAFLD patients ($p = 0.002$), but no statistical difference between NAFLD+SM vs SM patients ($p = 0.21$).
In patients with NAFLD, the presence of NASH implied higher values of CIMT, statistically significant (0.09 vs 0.06, $p = 0.025$).
Of the histological changes of NAFLD, there was a correlation between the presence of fibrosis and the CIMT values ($\rho = 0.595$, $p = 0.004$).
The presence of T2DM nor impaired fasting glucose did not correlate statistically significantly with higher CIMT values in all the four groups of patients included in the study ($p = 0.159$, $p = 0.345$, $p = 0.450$, $p = 0.261$).
Of the classical metabolic risk factors, in patients with NAFLD, with and without MS, there was a statistically significatnt correlation between CIMT values and abdominal circumference ($\rho = 0.284$, $p = 0.005$), body mass index ($\rho = 0.227$, $p = 0.027$), hypertension ($\rho = 0.446$, $p < 0.001$), and between the presence of hypertension and CIMT values in patients with NAFLD and MS ($\rho = 0.497$, $p < 0.001$).
Conclusion: The patients with NAFLD are a particular set of patients regarding cardiovascular risk. Taking into account the particularities of the patients with metabolic risk factors for cardiovascular diseases development, we propose a new definition for MS. The current MS ordinances to be marked with 1 point (including impaired fasting glucose), except for the presence of T2DM, which is to be marked with 2 points, NAFLD – 1 point, and NASH – 2 points. The diagnosis of MS is set when there are at least 4 points (10 possible). Of course, it is mandatory for this new model to be validated in further studies.

Introduction: Non- Alcoholic fatty liver disease (NAFLD) is a common disease associated to several clinical conditions. Prevalence of comorbidities associated to NAFLD has not been deeply evaluated in epidemiological studies so far.
The aim of this study is to assess the prevalence of common chronic diseases in a cohort of consecutive NAFLD subjects referred to a tertiary center. Moreover, assuming their possible impact on liver disease, the association between comorbidities and liver fibrosis (non-invasively assessed) has been evaluated.
Aims and Methods: From January 2016 to January 2017 we prospectively recruited subjects with clinical suspicious of NAFLD/NASH because hypertransaminasemia or ultrasound evidence of steatosis referred to the Outpatient Liver Unit of Fondazione Policlinico Gemelli in Rome. Patients with chronic liver disease related to viruses (HBV, HCV), alcohol or autoimmune disease were excluded. Medical comorbidities, anthropometric measurements, and laboratory tests were obtained during assessment. The Charlson Comorbidity Index (CCI) was used for the stratification of patients based on comorbidity.[1] Multimorbidity was defined as CCI≥2. Fibrosis-4 score (FIB-4) was used for non-invasive evaluation of fibrosis. Significative fibrosis was considered as FIB-4 > 3.25 (or >2.0 in patient >65 years old).[2]
Results: We enrolled 398 consecutive patients (males 55.7%, age 56.9 ± 13.8 y). 207 patients (52%) fit the diagnostic criteria for Metabolic syndrome, 115 (28.9%) have type 2 diabetes mellitus and 207 (52%) have arterial hypertension. In our cohort of NAFLD patients the most common comorbidities included in CCI is diabetes mellitus followed by non-metastatic tumors (7.5%). The most common coexistent chronic conditions, excluding those included in CCI, were gastroesophageal reflux (14.5%), hypothyroidism (10.8%), cholelithiasis (6%) and sigmoidal diverticulosis (5.8%).
Multimorbidity (CCI≥2) was present in 252 patients (63.3%). In Multimorbid patients was present a higher prevalence of metabolic syndrome (68.3% vs 28.6%) and diabetes (43.6 % vs 3.4%) and a higher severity of fibrosis (FIB-4 2.0 ± 3.8 vs 0.9 ± 0.4) when compared with patients without Multimorbidity.
Conclusion: Our study highlights the great prevalence of comorbidities in NAFLD patients, especially in those affected by metabolic syndrome or diabetes. Thus, a multidisciplinary clinical assessment of NAFLD patient, especially in those with significant fibrosis, is advisable.
Disclosure: Nothing to disclose

Introduction: Non-alcoholic fatty liver disease (NAFLD) represents the most common chronic liver disease in western countries with a global prevalence of 25% in adults. It encompasses a wide spectrum of liver damage ranging from benign simple steatosis, to non-alcoholic alcoholic steatohepatitis (NASH), liver fibrosis and cirrhosis. The detailed pathogenic mechanisms involved in the development of NAFLD remain unclear. There is no established pharmacological treatment of NAFLD. Weight reduction and lifestyle modification with increased physical activity stay the only effective therapeutic measures, but they are difficult to achieve and sustain. It has been reported that n-3 polyunsaturated fatty acids (PUFA) are able to ameliorate hepatic steatosis and insulin resistance, whereas a diet deficient in PUFA with a high n-6/n-3 ratio could induce fatty liver. Up to date published papers using PUFA have yielded contradictory results.
Aims and Methods: The aim of the study was to assess the effects of administration of PUFA in development of NAFLD in patients during one year follow-up. We have examined 60 patients with metabolic syndrome and NAFLD in different stage of disease (simple steatosis/NASH (n = 55)/liver cirrhosis (n = 5)). Patients were randomized into two groups: 30 used PUFA in daily dose 1.8 g of eicosapentaenoic acid and 1.36 g of docosahexaenoic acid in four divided doses; 30 patients used placebo in the same scheme. During one year follow-up were patients periodically examined – anthropometry (weight, waist circumference, BMI), biochemistry (liver enzymes, glucose metabolism etc.), blood count, abdominal ultrasound, liver stiffness measurement using ARFI®, nuclear magnetic resonance spectroscopy (MRS; at the start and end of follow-up). After one year follow-up results were evaluated and statistically processed.
Results: Of the 60 patients enrolled in the study were 45 men and 15 women, the mean age was 51.9 ± 12.2 years, the weight was 97.1 ± 15.2 kg and the mean BMI was 31.25 ± 4.25. There was no significant difference in any of these parameters among the monitored groups (PUFA versus placebo) at the beginning of the study. Similarly, between both groups there was no significant difference in other key parameters – ALT, GGT, or the percentage of fat in the liver tissue determined by MRS. After one year follow-up, no changes in anthropometric data (weight, waist circumference, or BMI) were observed in the patients enrolled in the study. On the other hand, there was a significant decrease in GGT activity in the PUFA group (2.27 ± 2.71 vs. 1.43 ± 1.55 ukat/L, $P = 0.0397$), without any change in the placebo group (2.31 ± 3.37 vs. 2.03 ± 2.8 ukat/L, $P = 0.064$). Other observed biochemical parameters (ALT, AST, ALP, and bilirubin) remained unchanged in both groups. During the follow-up liver elastography did not change in either group, as well as percentage of fat in hepatic tissue measured by MRS in both groups (PUFA 13.44 ± 7.7%, placebo 13.24 ± 9.1%).
Conclusion: We observed significant decrease in GGT serum activity after 12 months of PUFA administration, the total amount of liver fat remained unchanged. We conclude that PUFA could represent a potential agent in preventing the development of NAFLD in patients with metabolic syndrome.

Introduction: Fatty liver is classified as alcoholic and nonalcoholic according to the amount of alcohol consumed. In some cases, however, both drinking and overnutrition are involved in the development of fatty liver. Furthermore, epidemiological studies have demonstrated that light to moderate alcohol consumption appears to protect against fatty liver. The relation between alcohol and fatty liver possibly varies in each patient, depending on several cofactors. To make recommendation to modify patients' lifestyle, it may be not appropriate to distinguish alcoholic fatty liver and nonalcoholic fatty liver by a simple quantitative threshold of alcohol intake.

Aims and Methods: To answer whether they should drink or stop drinking, we aimed to distinguish alcohol-induced fatty liver and nutrition-induced fatty liver among drinkers. We obtained clinical and laboratory data from 8.879 Japanese subjects who underwent ultrasonography as a part of systematic health checkups at Junpukai Health Maintenance Center between 2006 and 2010, excluding individuals with the concurrent liver disease, any missing components of data, or missing follow-up study. The amount of alcohol consumed was stratified into following 5 groups: <70 g/week, 70–140 g/week, 140–280 g/week, 280–420 g/week, and >420 g/week. We hypothesized that abstinence or cutting down on alcohol intake would be required for remission of the alcohol-induced fatty liver and that remission of fatty liver without cutting down on alcohol consumption would indicate nutrition-induced fatty liver. Among patients who had remission of fatty liver, we compared those with cutting down on alcohol consumption (group A) and those without (group N) to elucidate the difference between them.

Results: In 8879 examinees, 31% had fatty liver and 60% reported habitual drinking at baseline. The prevalence of fatty liver in drinkers was significantly lower than that in non-drinkers (40% vs. 49%, $P < 0.001$ in men; 11% vs. 15%, $P < 0.001$ in women). During the observation period, the remission of fatty liver was observed in 345 out of 1.756 drinkers with fatty liver at baseline (20%). While the median amount of alcohol consumed had decreased from 154 g/week to 132 g/week in group A ($n = 80$), it increased from 132 g/week to 154 g/week in group N ($n = 265$). In comparison between group A and group N, significant differences were found in high-density lipoprotein levels (60 mg/dl vs. 55 mg/dl as median, $P = 0.025$) and in uric acid levels (6.4 mg/dl vs. 6.2 mg/dl, $P = 0.025$). When cases were stratified by the amount of alcohol consumed at baseline, the difference in HDL levels remained significant in cases with alcohol intake of >420 g/week (81 mg/dl vs. 56 mg/dl, $P = 0.029$). Among those without medication for dyslipidemia or hyperuricemia ($n = 316$), receiver operating characteristic analysis indicated that each optimal cut point for high-density lipoprotein level and uric acid level to distinguish group A and group N is 63 mg/dl ($AUC = 0.570$) and 7.0 mg/dl ($AUC = 0.587$), respectively. In cases with high-density lipoprotein levels >63 mg/dl and uric acid levels >7.0 mg/dl, group A accounted for 80%.

Conclusion: High-density lipoprotein levels and uric acid levels are possibly useful to judge whether the fatty liver was induced by alcohol consumption or by overnutrition. Abstinence or cutting down on alcohol intake may resolve fatty liver in patients with high-density lipoprotein levels >63 mg/dl and uric acid levels >7.0 mg/dl.

Introduction: Exposure to excessive alcohol consumption, its breakdown metabolites and gut-derived endotoxins dysregulates immune signaling. As a result the non-resolving inflammatory response and damage within the gastrointestinal tract and other organs may occur. The programed cell death 1 (PD-1) receptor and its ligand PD-L1 play a critical role in inhibition of self-reactive and inflammatory effector cells and the protection against immune-mediated tissue damage.

Aims and Methods: Evaluation of the PD-1/PDL-1 expression on peripheral T and B lymphocytes, its correlation with markers of inflammation and the severity of liver dysfunction in the course of alcoholic liver disease (ALD).

Fifty six inpatients with ALD (38 males, 18 females, aged 49.23 ± 10.66) were prospectively enrolled and assigned to subgroups based on their: 1/ gender, 2/ severity of liver dysfunction (Child-Pugh, MELD scores, mDF), 3/ presence of ALD complications, and followed for 30 days. Twenty five age- and gender-matched healthy volunteers, who consumed no more than 10 g alcohol per day, served as the control group. Flow cytometric analysis of the PD-1/PD-L1 expression on peripheral lymphocyte subsets were performed.

Results: The general expression of PD-1 and PDL-1 on T and B cells did not differ between the ALD and control group. Although, when the groups were analyzed based on their gender, significantly higher expression of PD1 and PD-L1 on CD19+ B cells in ALD females comparing to controls was observed. ALD females with severe alcoholic hepatitis (AH) and $mDF > 32$ or $MELD > 20$ showed significantly higher expression of PD-1 on CD19+ B cells and PD-L1 on all studied T and B subsets. The same pattern of the PD-1/PD-L1 expression was found when ALD females were compared with ALD males including the subgroups with $mDF > 32$ and $MELD > 20$. No correlations of PD-1+/PD-L1+ expression with mDF, CTP and MELD scores, nor with complications of ALD were observed, but significant correlations of CD19+ PD-L1+ frequencies with all conventional markers of inflammation (i.e. white blood cell and neutrophil counts, C-reactive protein and neutrophil-to-lymphocyte ratio) were found.

Conclusion: Gender-related differences in the PD-1/PD-L1expression on peripheral T and B cells may account for the different susceptibility to ethanol-related liver damage in males and females. Upregulation of PD-1/PD-L1 expression paralleled the severity of AH and liver dysfunction in females with ALD.

Introduction: Excessive inflammatory response in the course of alcoholic liver disease /ALD/ may induce a massive loss of hepatocytes leading to irreversible liver damage and progressive fibrosis. Chemokines are immune messengers implicated in pro-inflammatory signaling by recruiting selected subsets of leukocytes to the site of inflammation.

Aims and Methods: We aimed to explore the systemic blood expression of selected CCL and CXCL chemokines in patients with ethanol-related liver dysfunction and their accuracy in the noninvasive assessment of ALD liver failure and outcome.

Sixty-three inpatients with ALD /45 males, 18 females, aged 48.63 ± 11.38/ were prospectively recruited and followed for 30 days. Twenty five age-, sex- and ethnicity-matched healthy volunteers served as the control group. Selected CCL (CCL2/MCP1; CCL17/TARC; CCL20/MIP-3a) and CXCL (CXCL9/MIG, CXCL10/IP-10, CXCL16) chemokine concentrations were quantified in blood samples using immunoenzymatic ELISAs. Correlation coefficients between plasma chemokine levels and (i) indicators of systemic inflammation (neutrophil-to-lymphocyte ratio, C-reactive protein, white blood cell and neutrophile counts, modified Glasgow Prognostic Score (mGPS), (ii) liver dysfunction severity scores (Child-Turcotte-Pugh, MELD scores, mDF) and (iii) complications of liver disease were calculated. The receiver operating curves (ROC) for studied chemokines were constructed and their areas under the curve (AUCs) were checked in order to assess their accuracy in predicting the degree of liver failure and the development of ALD complications. Multivariable logistic regression was applied in order to select independent predictors of advanced liver dysfunction.

Results: Significant systemic upregulation of both CCL and CXCL chemokines was observed in patients with ALD. Only CCL17 (TARC) concentrations were markedly decreased indicating that Th2-type immune reactions are attenuated in ALD. This was in line with increased CCL2 and CXCL10, which polarize towards Th1 response. None of studied chemokines correlated with aminotransferase activity, but CCL20, CXCL9, CXCL10, CXCL16 showed positive correlations with the alkaline phosphatase level. CCL20 and CXCL16 correlated with standard indicators of inflammation. Patients with advanced liver dysfunction (MELD > 20, mDF > 32, Child B and C class) presented with significantly higher CCL20 and the six non-survivors with significantly higher CXCL10 concentrations.
Conclusion: Our findings emphasize the importance of both major chemokine subfamilies in the pathogenesis of ALD, therefore they represent a promising area of the potential therapeutic intervention. The high blood CCL20 concentration seems to be the disease severity indicator, while CXCL10 the predictor of the poor prognosis in ALD.

P1275 CALCULATION OF LILLE MODEL BETWEEN DAY 3 AND 4 CAN ACCURATELY PREDICT CORTICOSTEROID RESPONSE: A SINGLE-CENTER RETROSPECTIVE STUDY

J. Carvão, V. Magno Pereira, A. Oliveira, C. Sousa Andrade, L. Jasmins
Hospital Central do Funchal, Gastroenterology, Funchal, Portugal

Contact E-Mail Address: joanacarvao@hotmail.com

Introduction: Patients with severe alcoholic hepatitis (SAH) should be treated with corticosteroids (CT). Response do CT is assessed at 1 week using the Lille Model score (LM). Adverse effects of CT specially the risk of infection raise concerns amongst practitioners. A recent study demonstrated that LM calculated at day 4 is as accurate as LM calculated at day 7.[1] This finding needs further validation.
Aims and Methods: To access the accuracy of the LM calculated between day 3 and 4 in predicting CT response compared with the standard day 7.
Single-center retrospective study that included all patients admitted between January 2012 and December 2017 with a diagnosis of SAH defined by clinical and laboratory evidence and a Maddrey Discriminant Function (DF) $\geq$ 32. Response to CT treatment was determined by calculation of the LM score between day 3 and 4 and then at day 7 according to the cutoff >0.45. Statistical analysis was performed with SPSS v.24 Agreement between LM3-4 and LM7 was assessed by the Cohen's kappa (κ). Receiver operating characteristics (ROC) curves were used to compare accuracy between LM3-4 and LM7 in predicting 30-day mortality.
Results: 49 patients with SAH were included in the study. 81.6% were male and the mean age was 51.16 ($\pm$8.73) years. Median DF was 71.7 (40–195.2). 30 patients were treated with corticosteroids (CT). 16 patients had their LM score calculated at day 3, 12 at day 4 and 26 at day 7. Median LM3-4 and LM7 for patients who received CT was 0.45 (0.10–0.97) and 0.37 (0.10–0.98) respectively ($\rho = 0.067$). A substantial agreement was found between the two scores in predicting CT response ($\kappa = 0.92$, $\rho < 0.0005$). 30-day mortality was 40.8% (n = 20). There were no significant differences between LM3-4 and LM7 in predicting 30-day mortality (AUC 0.750 vs. 0.735 $\rho = 0.615$, respectively).
Conclusion: Until the development of newer and safer alternatives for SAH limiting corticosteroid therapy may benefit patients. Further prospective studies are needed to validate these findings.

Introduction: Neutrophils are the first-line effectors of human innate immune system. Inflammatory dysregulation and neutrophil infiltration are hallmarks of alcoholic liver disease (ALD). Given their destructive potential, extracellularly released neutrophil enzymes should be carefully controlled to avoid damage to host tissues.
Aims and Methods: Assessment of the systemic profile of neutrophil-derived mediators i.e. neutrophil elastase (NE), myeloperoxidase (MPO), as well as alpha1-antitrypsin (A1AT)- a potent inhibitor of neutrophil proteases, with emphasis on their potential relevance in the course of ALD.
Sixty-two patients with ALD /47 males, 15 females, aged 49.2 $\pm$ 9.9/ were prospectively recruited and assigned to subgroups based on their 1/ gender, 2/ severity of liver dysfunction (Child-Pugh, MELD scores, mDF) 3/ presence of ALD complications, and followed for 30 days. Twenty four age-, sex- and ethnicity-matched healthy volunteers served as the control group. Selected plasma markers of neutrophil activation were quantified using immunoenzymatic ELISAs. Correlation coefficients between their blood concentrations and (i) indicators of systemic inflammation (the neutrophil-to-lymphocyte ratio, C-reactive protein, white blood cell and neutrophil counts), (ii) liver dysfunction severity scores (Child-Pugh, MELD, mDF), and (iii) ALD complications were calculated. The receiver operating curves (ROC) for studied molecules were constructed and their areas under the curve (AUCs) checked in order to assess their accuracy in predicting the degree of liver failure and the developmant of ALD complications.
Results: Concentrations of MPO and NE were significantly increased in the blood of patients with ALD in comparison with controls, but the A1AT level was not different. ALD females presented with higher MPO levels in comparison with ALD males. There were no gender-related differences in NE levels in ALD group. NE, but not MPO, correlated with MELD and mDF scores. MPO, but not NE, correlated with standard markers of inflammation. ALD subgroups with mDF > 32, Child class C and hepatic encephalopathy presented with significantly higher NE, but not MPO levels.
Conclusion: Our results support the value of MPO and NE in the ALD assessment. MPO seems to be an inflammatory marker, while NE the disease severity indicator. The higher systemic NE/A1AT ratio in the course of ALD may facilitate the expansion of the inflammatory cascade. Gender-related differences in neutrophils' activation in ALD may impact the different susceptibility to toxic liver injury in males and females.

P1277 EVALUATION OF CYTOSTATIC-INDUCED LIVER INJURY RISK IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

I. Skrypnyk[1], G. Maslova[2]
[1]*Ukrainian Medical Stomatological Academy Internal Medicine, Internal Medicine #1, Poltava, Ukraine*
[2]*Ukrainian Medical Stomatological Academy, Internal Medicine #1, Poltava, Ukraine*

Contact E-Mail Address: scrin69@yandex.ru

Introduction: Chemotherapy (CHT) for acute myeloid leukemia (AML) is accompanied by the risk of hepatotoxic reactions, severity of which influences patients' further management and leads to the need of drugs dose reduction. The main

negative prognostic factor, which does not depend on tumor morphology and patient's state, is an absence of adherence to the dosage and administration regimens of cytostatic agents. Timely performed diagnostics of hepatotoxic reactions, induced by cytostatic agents, and their prophylaxis play the main role.
Aims and Methods: – to study the frequency and character of hepatotoxic reactions in patients with AML depending on morphologic variant according to the FAB classification and prescribed CHT scheme.
A total of 63 patients with firstly diagnosed AML and normal liver function tests were examined, 29 (46%) of them were females and 34 (54%) – males. ECOG performance status was I-II, Karnofsky index was 60–80%. Patients were divided into groups: I (n = 27) – patients with AML M_0, M_1, M_2 according to FAB-criteria; II (n = 36) – patients with AML M_4, M_5 according to FAB-criteria. Patients were receiving the 1-st remission induction course. Activity of serum alanine and asparagine aminotransferases, alkaline phosphatase, concentration of total bilirubin were assessed before the CHT course, on 7-th, 14-th, and 28-th days of treatment.
Results: Conduction of the 1-st remission induction course in AML patients with M_0-M_2 variants was accompanied by the I grade hepatotoxicity on the 7-th and 14-th days in 2 (7.4%) patients, and in AML patients with M_4-M_5 variants – in 11 (30.5%) patients, in 8 (22.2%) out of them the grade I of severity was detected, in 3 (83%) – grade II. Hepatotoxic reactions in 2 (7.4%) patients with AML M_0, M_1 and M_2 variants of the group I were characterized as cytolytic. Among the patients of the group II with AML M_4 and M_5 variants the next types of hepatotoxic reactions were registered: in 2 (5.5%) – cytolytic, in 4 (11.1%) – cholestatic, and in 5 (13.9%) – mixed.
Hepatic function state was restored until 28-th day in all groups of comparison, where liver tests disturbances were observed on the 7-th and 14-th days.
Conclusion: M_4-M_5 variants of AML are associated with an increased risk of hepatotoxic reactions onset, that is determined by hemoblastosis morphology and higher toxicity of CHT regimens with etoposide inclusion.

P1278 SAFETY ASSESSMENT IN THE HERBAL FIELD: COMMON PITFALLS

O. Kelber[1], C. Fink[2], K. Nieber[3], K. Kraft[4]
[1]*Steigerwald Arzneimittelwerk GmbH, Innovation & Development, Darmstadt, Germany*
[2]*Steigerwald Arzneimittelwerk GmbH, Innovation and Development, Medical and Clinical Affairs Phytomedicines, Darmstadt, Germany*
[3]*Universität Leipzig, Pharmaceutical Institute, Leipzig, Germany*
[4]*University Medicine Rostock, Chair of Complementary Medicine, Center of Internal Medicine, Rostock, Germany*

Contact E-Mail Address: olaf@kelber.org
Introduction: While safety of herbal products is recently gaining increased attention (1), safety assessments in this field often suffer from methodological weaknesses, as limitations of available data are often not sufficiently taken into account in the assessment. This applies both to data on quality, as to non-clinical as well as clinical and post marketing surveillance data.
Aims and Methods: To address this issue, a systematic data base search for reviews in this field, combined with hand searching in text books, was conducted. Sources of bias were classified according to data types involved.
Results: Depending from the data involved, different sources of bias were identified:
1. Data on quality: Often the great differences of the composition of herbal products prepared from the same plant, but from e.g. different plant parts or by different manufacturing processes are neglected, so leading to flaws by the transfer of data from products with a less favourable safety profile to safe products and vice versa, as e.g. in Kava and St. John's wort (2, 3).
2. Nonclinical data: Common pitfalls are the transfer of data from in vitro studies to the clinical setting, without taking into account the influence of ADME. Often also effects from sublethal high-dose settings are used without sufficiently taking into account dose dependency or, e.g. in carcinogenicity studies on ginkgo, methodological ambiguities (4).
3. Data from clinical studies and post marketing surveillance: While the lack of differentiation between negative studies and failed studies leads to wrong conclusions on inefficacy (5), the evaluation of safety using NIS data and spontaneous reports from pharmacovigilance data bases is often seriously flawed by neglecting background incidences of concomitant diagnoses as e.g. in case of hepatotoxicity (6), by protopathic bias, and by the clinical and academic settings influencing the awareness and views of authors of case reports (7).
Conclusion: A higher awareness of common pitfalls in the assessment of safety data on herbal products is needed, especially in case of hepatotoxic risks, if we want to avoid that methodological artefacts and misperceptions of the generalizability of data continue to influence our view of the safety of herbal products and their regulatory environment, both by neglecting risks, as, more abundant, by exaggerating non-existing risks.

Introduction: Cirrhotic cardiomyopathy (CCM) is a relatively new concept that currently appears as a particular clinical entity, characterized by impaired contractile response to stress, diastolic dysfunction and electrophysiological abnormalities in the absence of a known cardiac disease. Data on the epidemiology and natural history of CCM is still lacking.
Aims and Methods: We aimed to determine the prevalence of CCM and investigate its predictive factors in patients with liver cirrhosis.
This cross-sectional study was conducted on all cirrhotic patients (N = 109) who were admitted in our department from September 2016 to May 2017. Patients with structural or ischemic heart disease, hypertension, chronic alcoholism, severe anemia (Hemoglobin < 7 g/dl) or recent bleeding (< 1 month) were excluded (N = 33). Resting ECG was done in all patients. QTc interval of > 0.44 sec was considered as prolonged. A detailed two-dimensional echocardiography was also performed in all patients. CCM was considered present when diastolic and/or systolic dysfunction was diagnosed at rest, together with supporting criteria such as electrophysiological abnormalities, based on the criteria of the Montreal 2005 consensus. A stepwise Cox regression model was fitted to determine factors associated with the diagnosis of CCM. All statistical analysis were performed using the SPSS 21.0 version.
Results: A total of 76 patients were included in this study, out of which 45 (59%) were males and 31 (41%) were female. The mean age was 54 years (±11.8). The most common etiology was hepatitis B (38.2%). Median Child Pugh and MELD scores were 7 [5–12] and 11 [7–33], respectively. Twenty-five patients (32.9%) had ascites. Diastolic dysfunction was noted in 39 patients (51.3%) while 4 patients (5.3) showed evidence of systolic dysfunction. A prolonged QT interval was found in 33 patients (43.5%). CCM was then diagnosed in 43 patients (53.9%). In multivariate analysis, 3 independent predictive factors were identified: age > 50 years (OR 1.05; CI 95% :1.003–1.103; $p < 0.039$), female gender (OR 3.006; CI 95%: 1.029–8.778; $p = 0.044$) and Child Pugh score ≥9 (OR 4.363; CI 95%: 1.328–14.331; $p = 0.015$).
Conclusion: Cirrhotic cardiomyopathy is a frequent complication of cirrhosis. Given its association with the severity of liver disease, we recommend cardiac assessment in all Child Pugh B and C cirrhotic patients.

Contact E-Mail Address: wafadh115@gmail.com
Introduction: Cardiac dysfunction in cirrhosis, labeled "Cirrhotic cardiomyopathy" (CCM) includes a variety of structural myocardial changes, systolic and diastolic dysfunction and electrophysiological changes. Its diagnosis is based mostly on conventional echocardiography which is frequently unable to detect abnormalities at rest and identifies only the late stages of cardiac dysfunction.
Aims and Methods: We aimed to evaluate cardiac function in cirrhotic patients using newer methods: Tissue Doppler imaging (TDI) and Speckle Tracking Echocardiography (STE) and to compare it with previously proposed definition criteria of CCM.
We prospectively evaluated consecutive patients with a diagnosis of cirrhosis based on clinical, laboratory, ultrasonographic, endoscopic and/or histologic criteria. Patients with a history of any cardiovascular disease, chronic alcoholism, severe anemia (Hemoglobin < 7 g/dl), recent bleeding (< 1 month) and those who were technically unsuitable for STE and TDI analysis were excluded. A single experienced operator performed the echocardiograms. Left ventricle ejection fraction (LVEF) and LV diastolic function were assessed as recently recommended by the American and European societies of echocardiography. STE allowed the measurement of global longitudinal strain (GLS); systolic dysfunction was defined as a GLS value < -18%.
Results: Out of 109 cirrhotic patients, 76 were eligible for the study (median age 54 ± 11.8 years, males 59%). The most frequent underlying disease was Hepatitis B infection (38.2%) followed by cryptogenic cirrhosis (22.3%). Regarding the Child Pugh score, 45% of the cirrhotic patients were stratified in the Child score

B, and 43% were categorized in the Child score A. On conventional echocardiography, systolic dysfunction (LVEF < 55%) was found in 4 patients (5.3%). On STE, an altered GLS was found in 10 patients (13.1%). Based on mitral-flow pattern, diastolic dysfunction was present in 39 patients (51.3%). Using a TDI based definition, the prevalence of diastolic dysfunction was 32.9%. The agreement between the two definitions of diastolic dysfunction was moderate (kappa = 0.448, P = 0.001).
Conclusion: Patients with cirrhosis have both systolic and diastolic cardiac dysfunction at rest. Newer echocardiographic techniques may identify patients with functional impairment more accurately than conventional methods.

Introduction: Our group had started a randomised controlled trial in April 2012 to study the effect of argon plasma coagulation (APC) after esophageal varices eradication using endoscopic variceal ligation (EVL) on recurrence of esophageal varices after previous bleeding episode. Recurrence of esophageal varices during 2.5 years was 21% in the APC group against 68% in the EVL only group. (P = 0.003). No one in the APC group needed rebanding while 63.2% of the EVL only group underwent rebanding (P < 0.001). These results were published.(1)
Aims and Methods: To continue the follow up of both groups to determine the ability of Argon plasma coagulation to maintain its efficacy in prevention of esophageal varices recurrence over a longer period (5.5 years). Endoscopic follow up intervals in the APC group were increased to be every 12 months, while in the EVL only group they became every 6 months if there were no recurrent varices and every 3 months if there were small recurrent varices without risk signs.
Results: In the APC group 35.3% of cases experienced recurrence of esophageal varices during the 5.5-year follow up against 93.8% of cases in the EVL only group (P < 0.001). Still no one from the APC group needed rebanding as all recurrent varices were small and without risk signs.
Conclusion: APC after esophageal varices eradication using EVL can decrease the risk of esophageal varices recurrence and the need for rebanding over long period with the possibility of decrease in endoscopic follow up intervals. This also can decrease the burden on endoscopic units especially in countries where liver diseases are endemic.

Introduction: Renal dysfunction is a marker of poor prognosis in liver cirrhosis. Serum creatinine tends to overestimate the true value of the glomerular filtration rate (GFR) in these patients.
The equations commonly used to calculate GFR are the MDRD-4, MDRD-6, and CKD-EPI equations. These equations are commonly used in clinical practice due to their easy access. However, these equations are not validated in patients with cirrhosis. Recently, a new equation was developed and validated specifically for cirrhosis: "Royal Free Hospital Glomerular Filtration Rate" (RFH).
Aims and Methods: We propose to evaluate the relationship between GFR based on commonly used equations in clinical practice and the equation already validated in decompensated cirrhosis.
A retrospective analysis of the GRF values based on different formulas was performed in cases of decompensated liver cirrhosis admitted to a tertiary center during a 7-year period. Renal dysfunction was considered clinically significant for GFR lower than 30 mL/min/m^2, being that this GFR values generally imply modification of therapeutic strategies in clinical practice.
Results: A total of 418 cases were evaluated [78.7% men (n = 329), mean age 66.25 ± 11.79 years]. The median serum creatinine was 0.91 mg/dL (IQR 0.7–1.36 mg/dL). Death occurred within the first 100 days after admission in 20.1% of the patients.
At admission, the GFR was less than 30 mL/min/m^2 in 15.3% (MDRD-4), 19.6% (MDRD-6), 16% (CKD-EPI) and 21.5% (RFH) of the cases.
The GFR measured by the RFH formula showed a strong correlation with the GFR measured by the other equations (MDRD-4: r = 0.97, p < 0.001; MDRD-6: r = 0.98, p < 0.001; pCKD-EPI r = 0.95, p < 0.001).
Active infection and ascites were associated with the lowest mean value of GFR measured in all formulas (Active disease, MDRD-4 p = 0.008; MDRD-6 p = 0.003; CKD-EPI p < 0.001; RFH p = 0.007; Ascites: MDRD-4 p = 0.001; MDRD-6 p = 0.001; CKD-EPI p = 0.001; RFH p = 0.001).
The data concerning early mortality (<100 days) showed that average survival was significantly lower for GFR <30mL/min/m^2 calculated by RFH (GFR > 30, mean 47.2 ± 28.2 mL/min/m^2; GFR < 30, mean 32.8 ± 28.4, mL/min/m^2, p = 0.040), but not when the GRF was estimated by CKD-EPI (GFR > 30, mean 46.01 ± 29.04 mL/min/m^2; GFR < 30, mean 30.53 ± 24.91, mL/min/m^2; p = 0.06), MDRD-4 (GFR > 30, mean 45.59 ± 29.05 mL/min/m^2; GFR < 30, mean 31.57 ± 25.51 mL/min/m^2; p = 0.097) and MDRD-6 (GFR > 30, mean 46.73 ± 28.42 mL/min/m^2; GFR < 30, mean 32.10 ± 27.95 mL/min/m^2; p = 0.05) equations.
Conclusion: In this study, the new RFH formula had a strong correlation with the other creatinine-based estimated glomerular filtration rate equations. This supports that the most common formulas can still be used in the clinical management of patients with cirrhosis.
However, a GFR under the value of 30mL/min/m^2 estimated by the RFH formula (but not with other formulas) was related with a lower survival at 100 days.

[2]*Habib Thameur Hospital, Tunis, Tunisia*

Contact E-Mail Address: raniazgolli@gmail.com
Introduction: The non-selective Beta-Blockers (BBs) are widely used in the prevention of variceal hemorrhage (VH). Their benefit has been demonstrated. However, are they safe in advanced cirrhosis? The aim of this study was to study the complications observed in patients under BBs in advanced cirrhosis.
Aims and Methods: We conducted a retrospective study that collects all Child-Pugh C cirrhotic patients followed in the Gastroenterology Department of Habib Thameur Hospital over a period of 45 months. These patients were divided into 2 groups according to whether they received BBs (Group 1; G1) or did not (group 2;G2). Complications of cirrhosis were then compared in both groups.
Results: Ninety patients were included. The mean age at diagnosis was 56. The sex ratio (M/F) was 0.6. Most of cirrhosis were due to viral hepatitis C (30%) followed by viral hepatitis B (23%). The most frequent circumstance of discovery of cirrhosis was an oedemato-ascitic decompensation (79%). Endoscopic signs of portal hypertension were observed in 95% of patients. First group included 68 patients (75.6%): 37 patients were under BBs in primary prevention of VH while 31 patients received the treatment in secondary prevention. In the 2nd group (24.4%), BBs were not indicated in 15 patients; 4 patients had a contraindication such as asthma (N = 1), atrio-ventricular block (N = 2) and severe heart failure (N = 2). Three patients stopped BBs for poor tolerance.
At least one complication was observed in all the patients of G2 (100%) against 94% of patients of G2. The spontaneous bacterial peritonitis was noted in 25% of the patients under BBs against 13% of the patients without BBs (p = 0.49). Hepatic encephalopathy occured in 36.7% of patients of G1 against 54.4% of patients of G2 (p = 0.21). Hepatorenal syndrome was observed in 26.5% of patients under BBs against 22.7% of patients of G2 (p = 0.48). It was type 2 in all cases. BBs did not reduce the occurrence of hepatocellular carcinoma (G1 = 26.6%, G2 = 13.6; p = 0.53).
However, BBs significantly decreased the occurrence of decompensation by ascites (95% in G2 Vs 75% in G1, p = 0.019). In addition, they significantly improved the median survival time (72 months in G1 Vs 18.8 months in G2, p < 0.0001).
Conclusion: According to our results, BBs do not generate more complications and are even protective since they significantly reduced the frequency of decompensation by ascites and improved survival. They should be pursued in the advanced stages of cirrhosis.

Introduction: Prognostic value of acute-on-chronic liver failure (ACLF) definiton of the North American Consortium for the Study of End-Stage Liver Disease (NACSELD) in predicting 30-day survival was confirmed in a large recent study.
Aims and Methods: The aim of this work was to analyze the NACSELD-ACLF score performance to predict intrahospital mortality in patients with decompensated cirrhosis.
We retrospectively enrolled patients with decompensated cirrhosis (April to December 2017). Organ failure assessment were performed upon admission.

NACSELD-ACLF were analyzed in terms of prediction of 30-day using either a Chi-square test or Fisher's Exact test. Backwards elimination multi-variable logistic regression analyzing 30-day mortality was performed on all patients.
Results: Eighty-two patients were included with a sex-ratio at 0.9 and a mean age of 60 ± 9 years (23–74). The main comorbidities were diabetes mellitus (25%) and hypertension (20%). Hepatitis C was the most common etiology of cirrhosis (42%). Child-Pugh score was mainly C (63%) and 13 ± 3. Main MELD score was 10 ± 6. Bacterial infection was the main cause of decompensating (27%). 30-day mortality was 16%. In comparison with the surviving group, deceased patients had similar demographic characteristics. NACSELD-ACLF was ≥ 2 in 15% of patients. Patients who met criteria for NACSELD-ACLF had an overall 20% 30-day survival vs 85% in patients without NACSELD-ACLF ($p < 0.001$). RR was 22 (95% IC :5.47–91.15).
Conclusion: NACSELD-ACLF might predict 30-day mortality in cirrhotics in decompensation with a good sensitivity and specificity. However, it concerns only 15% of patients admitted for acute decompensation of cirrhosis which makes it a very restrictive score.
Disclosure: Nothing to disclose

P1285 THE NEW RECOMMENDED CRITERIA FOR SEPSIS ARE INAPPROPRIATE FOR PATIENTS WITH DECOMPENSATED CIRRHOSIS

Introduction: The new criteria of sepsis published in 2016, based on the SOFA (*Sequential Organ Failure Assessment*) score is very difficult to apply in patients with advanced cirrhosis. On the other hand the modified SOFA score for decompensated cirrhosis *(Chronic Liver Failure – Sequential Organ Failure Assessment* - CLIF-SOFA), do not have a specific focus on infection and sepsis. Early diagnosis of sepsis is crucial in patients with decompensated cirrhosis. Recent studies have shown a good performance of presepsin and resistin as early diagnostic tools for sepsis but their performances in patients with cirrhosis is not known.
Aims and Methods: The aims of the study were: 1.) to identify the most accurate definition for sepsis in cirrhosis using the 28-day mortality as endpoint; 2.) to compare the diagnostic performances of procalcitonin, presepsin and resistin as early sepsis markers in patients with decompensated cirrhosis.
114 consecutive patients with decompensated cirrhosis were enrolled. Complete infectious workup and determination of procalcitonin, presepsin and resistin levels was done at admission. SOFA, CLIF-SOFA, CLIF-OF (*Chronic Liver Failure – Organ Failure)* scores and ACLF (*Acute on Chronic Liver Failure*) grade were calculated. In infected patients, for sepsis diagnosis we used the following definitions: the presence of SIRS (*Systemic Inflammatory Response Syndrome*), a SOFA score ≥2, CLIF-SOFA≥ 8 with an ACLF grade ≥1 and a CLIF-OF subscore of 3 points. Data regarding 28-day mortality were registered, and the accuracy for sepsis definition was calculated using 28-day mortality as endpoint. Statistical analysis was performed using SPSS software.
Results: The most accurate definition for sepsis diagnosis was a CLIF-SOFA score≥8 with an ACLF grade≥1 (accuracy 74%), while a SOFA score ≥2 in the presence of infection had significant lower accuracy, only 64% ($p < 0.0001$). The classic definition using the presence of SIRS and the CLIF-OF subscore = 3 in infected patients, had both a 72% accuracy for the diagnosis of sepsis, without statistically significant difference compared with the first definition ($p = 0.7$). The AUROC for sepsis diagnosis (defined as CLIF-SOFA≥8 with ACLF≥1) was 0.82 for presepsin (95% CI: 0.74–0.90, $p < 0.0001$, accuracy of 80%, cutoff 1444.5 pg/ml), 0.72 for PCT (95% CI: 0.60–0.83, $p < 0.0001$, accuracy of 77%, cutoff 0.99 ng/ml), 0.70 for resistin (95% CI: 0.56–0.83, $p = 0.006$, accuracy of 70%, cutoff 20.3 ng/ml).
Conclusion: The present definition for sepsis (SOFA score ≥2 in context of infection) is not appropriate for decompensated cirrhosis. The most accurate definition for sepsis diagnosis in these patients is a CLIF-SOFA score ≥8 points with an ACLF grade of at least 1. Presepsin is the most accurate tool for early diagnosis of sepsis in patients with decompensated cirrhosis.

Introduction: Transient elastography (TE) assesses liver stiffness as a measure of liver fibrosis but is influenced by hepatic perfusion pressure. TE-based controlled attenuation parameter (CAP) is a non-invasive marker for hepatic steatosis. However, the diagnostic performance of CAP has yet to be investigated in patients with advanced chronic liver disease (ACLD)/portal hypertension (PH; hepatic venous pressure gradient (HVPG) ≥6 mmHg).
Aims and Methods: Eighty-eight patients with liver stiffness values ≥10 kPa and/or HVPG ≥6 mmHg undergoing simultaneous liver biopsy, CAP and HVPG measurement were included in this retrospective analysis. Steatosis (S) was histologically graded according to the Brunt classification.
Results: Sixty-four (72.7%) Child-Pugh A, 16 (18.2%) Child-Pugh B and 8 (9.1%) Child-Pugh C patients with a mean MELD Score of 11 (SD ± 4) points were included. The underlying causes of liver disease were viral hepatitis in 22 (25.0%), non-alcoholic fatty liver disease in 12 (13.6%) and alcoholic liver disease in 11 (12.5%) patients. Twenty-two (25.0%) patients had other etiologies, while the cause was cryptogenic in 21 (23.9%). Median HVPG was 16 (IQR:10–19) mmHg, median liver stiffness was 27.4 (IQR:16.2–48.9) kPa and mean CAP value was 221 (SD ± 75) dB/m.
According to histology, 47 (53.4%) patients had no steatosis (S0), 28 (31.8%) had S1, 11 (12.5%) had S2, and 2 (2.3%) had S3. CAP was significantly different between patients with any hepatic steatosis (S1/2/3; 252(SD ± 70) dB/m) and without (S0; 202(SD ± 72) dB/m; $p = 0.002$). The AUROC of CAP for diagnosing any hepatic steatosis (S1/S2/S3 vs. S0) was 0.692 (95% confidence interval (95%CI): 0.582–0.802) in the overall cohort, 0.667 (95%CI: 0.552–0.783) in patients with PH, 0.629 (95%CI: 0.497–0.761) in the subgroup with clinically significant portal hypertension (CSPH, HVPG≥10mmHg; n = 69). Among patients with cirrhosis diagnosed by histology (n = 56), the AUROC was 0.607 (95%CI: 0.459–0.756). Applying the previously defined cut-off of 248 dB/m, sensitivity and specificity of CAP for diagnosing any steatosis (S1/S2/S3 vs. S0) were 48.8% and 76.6% with a positive predictive value (PPV) and a negative predictive value (NPV) of 64.5% and 63.2% in the overall cohort.
CAP correlated with the percentage of steatotic hepatocytes (Spearman's $\rho = 0.402$, $p = < 0.001$) and liver stiffness ($\rho = 0.225$; $p = 0.035$). HVPG neither correlated with percentage of steatotic hepatocytes ($\rho = 0.055$; $p = 0.654$), histological steatosis grade ($\rho = 0.026$; $p = 0.829$), nor with CAP values ($\rho = 0.054$; $p = 0.653$).
Conclusion: The diagnostic performance of CAP for assessing hepatic steatosis seems to be limited in patients with ACLD/PH, especially in patients with CSPH or cirrhosis based on histology.

Introduction: Ultrasound-based elastographic methods are non-invasive techniques for the evaluation of liver stiffness that might have also a place in the assessment of portal hypertension.
Aims and Methods: The aim of this study was to evaluate the value of 5 ultrasound-based elastographic methods for rule out the presence of esophageal varices in patients known with liver cirrhosis.
The study included 69 consecutive subjects diagnosed with liver cirrhosis (patients known with history of chronic liver disease with clinical, biological, ultrasound, endoscopical or histological signs of liver cirrhosis), in whom liver stiffness (LS) was evaluated in the same session by means of 5 elastographic methods: Transient Elastography (TE)-FibroScan, EchoSens; Point shear wave elastography techniques: Virtual Touch Tissue Quantification (VTQ)-Acuson S2000, Siemens and ElastPQ technique-Affinity, Philips; 2D Shear Waves Elastography-Aixplorer, Supersonic Imagine (2D SWE.SSI) and the LogiqE9, General Electric (2D-SWE.GE). Reliable LS measurements were defined as follows: for TE, ElastPQ, VTQ and 2D-SWE.GE- the median value of 10 measurements and for 2D-SWE.SSI the mean value of 3 measurements acquired in a homogenous area.
Results: In 50 patients out of 69, all 5 elastographic methods had valid measurements and were included in the final analysis. 19/50 patients from the study group had varices, while 31/50 did not have varices.

The best cut-off values for "rule out" esophageal varices for the 5 different techniques are presented in the following table:

Method	Cut-off	Se	Sp	PPV	NPV	LR-	LR+	AUROC
TE (1)	≤21.5 kPa	85.7%	73.9%	66.7%	89.5%	0.45	1.2	0.67
VTQ (2)	≤1.88 m/s	90%	23.3%	43.9%	77.8%	0.48	1.1	0.57
ElastPQ (3)	≤10.4 kPa	95%	13.3%	42.2%	80%	0.38	1.1	0.66
2D-SWE.SSI (4)	≤13.2 kPa	95%	23.3%	45.2%	87.5%	0.24	1.24	0.58
2D-SWE.GE (5)	≤12.2 kPa	95%	53.3%	51.7%	76.2%	0.48	1.61	0.68
NPV $p > 0.05$ for 1 vs. 2 vs. 3 vs. 4 vs.5								

[The best cut-off values for "rule out" esophageal varices for the 5 different elastography techniques]

Conclusion: Ultrasound based elastographic methods seem to have the same performance for rule out the presence of esophageal varices in patients with liver cirrhosis.

Introduction: Liver biopsy provides important diagnostic and prognostic information in patients with (unknown) liver disease. Transjugular liver biopsy (TJLBX) represents an alternative to percutaneous liver biopsy, especially in patients with impaired coagulation. Here we describe our experience with TJLBX performed by hepatologists being experienced in HVPG measurements.

Aims and Methods: 445 TJLBX (16G Menghini aspiration needle) of 399 adult patients at the Vienna Hepatic Hemodynamic Laboratory (01/2004–12/2016) were retrospectively included. Safety and diagnostic value of TJLBX were assessed.

Results: Mean age was 51 (SD ± 13) years, 273 (61.3%) were male, 156/399 (39.1%) had decompensated cirrhosis, and 36/399 (9.0%) patients had undergone liver transplantation. A mean number of 6.2 portal tracts (SD ± 4.8; median: 5 [IQR: 2–9]) was obtained, median sample length was 6mm (IQR: 5–10mm).

Among patients with an unknown cause of acute liver failure (n = 11; 2.5%) or unknown etiology of liver disease (n = 151; 33.9%), a diagnosis could be established in eleven (100%) and 126 (83.4%) individuals, respectively.

Complications occurred in 28 patients (6.3%) including 22 (4.9%) with minor complications (subclinical capsule perforation [n = 12], puncture site bleeding [n = 4], benign tachyarrhythmia [n = 2], hypotension [n = 2], abdominal pain [n = 2]). Major complications occurred in six patients (1.3%) including renal biopsy (n = 2), pneumothorax (n = 2), ventricular fibrillation (n = 1) and mediastinal hematoma (n = 1). No deaths due to TJLBX were observed.

Neither the presence of ascites (n = 151, 39%) nor of coagulopathy (platelets < 50G/L and/or prothrombin time index < 50%; n = 82, 18.4%) was associated with a higher risk of complications: 6.6% complications (1.3% major complications) in ascites, 4.8% complications (0% major complications) in patients with coagulopathy.

Conclusion: TJLBX performed by hepatologists experienced in HVPG measurements is safe – even in patients with ascites or coagulopathy. TJLBX has sufficient diagnostic value for histological evaluation of liver disease.

Introduction: The Baveno VI criteria based on platelet count $>150x10^9$cells/L and liver stiffness measurement (LSM) <20kPa, have been proposed for identification of compensated advanced chronic liver disease (cACLD) patients who could safely avoid screening endoscopy. However, evidence are inconsistent. We performed a systematic review and meta-analysis to assess the diagnostic accuracy of Baveno VI criteria for diagnosis of any size varices and varices needing treatment in patients with cACLD.

Aims and Methods: We systematically searched MEDLINE, EMBASE, Cochrane Library and grey literature sources through April 2018. We included diagnostic studies that assessed the accuracy of Baveno VI criteria for any varices or high risk varices (HRVs), as defined by the authors, in patients with cACLD. We evaluated studies that utilized upper endoscopy as reference standard. We evaluated study quality by using the Quality Assessment of Diagnostic Accuracy Studies (QUADAS)-2 tool.

Results: We included 27 studies with 5091 participants. Fourteen studies (2916 patients) provided data for varices of any size and 17 studies (3742 patients) evaluated the criteria for HRVs. All studies were cross-sectional with sample size ranging from 32 to 774 patients. Time interval between liver stiffness measurement and endoscopy was usually 6 to 12 months. The median prevalence of varices of any size was 0.38 (range 0.15–0.72) and the median prevalence of HRVs was 0.10 (ranged from 0.04 to 0.20). Most of the studies were retrospective and deemed at unclear risk of bias. Pooled sensitivity of Baveno VI criteria for diagnosis of any varices was 88% (95% CI 82 to 92), specificity 43% (95% CI 32 to 55), positive likelihood ratio (LR+) 1.5 (95% CI 1.3 to 1.8), negative likelihood ratio (LR-) 0.27(95% CI 0.22 to 0.34). Pooled sensitivity for HRVs was 98% (95% CI 93 to 99), specificity 27% (95% CI 22 to 33), positive likelihood ratio (LR+) 1.3 (95% CI 1.2 to 1.4), negative likelihood ratio (LR-) 0.09(95% CI 0.03 to 0.27).

Conclusion: The Baveno VI recommendations can adequately rule out the presence of clinically significant varices in cACLD patients. They could be used as a triage test since they can identify low risk patients who could safely avoid screening endoscopy.

Introduction: Portal hypertension is a major pathophysiological alteration in liver cirrhosis. Upper gastrointestinal (GI) endoscopy is generally required in these patients since their management is defined by the presence and type of esophageal varices. Since Baveno VI, the use of fibroscan and platelets count is recommended to avoid endoscopy in some low-risk patients. Recently, new evidence about the usefulness of MELD score and platelets count to avoid endoscopy mainly in patients with HCV-related cirrhosis has been published.

Aims and Methods: We aimed at assessing the accuracy of MELD and platelets count to rule out high-risk varices in a population of mainly alcohol-related cirrhosis.

A retrospective analysis of patients with compensated cirrhosis of any etiology under follow-up at our Liver Unit was performed. Patients with Child-Pugh score 5 or 6 (A), upper endoscopy indicated for evaluation of portal hypertension over the last 5 years, and blood analysis done ≤3 months before or after endoscopy, were included. Patients with previous variceal bleeding, history of endoscopic variceal ligation, splenectomy, liver transplantation or esophageal or gastric surgery were excluded. High-risk varices were defined as large varices or varices with red spots. Results are shown as mean and percentages and analyzed by chi-square test and Student-t test. Accuracy of MELD and platelet count for predicting high-risk varices was calculated.

Results: 115 patients were included (80.3% male), with a median age of 57 years (range 17–81). The main aetiology was alcohol (72.1%), followed by virus (12.1%) and steatohepatitis (6.8%). Upper GI endoscopy excluded the presence of varices in 60% of patients. 32 patients (27.8%) had small varices without red spots (low-risk), whereas high-risk varices were detected in 14 patients (12.1%). Patients with low-risk and high-risk varices were similar in terms of gender, age, aetiology and MELD score (7.57 vs 8.71; $p = 0.063$). Platelet count was significantly lower in patients with high-risk varices (86.071 vs 134.039/μL; $p < 0.01$). High-risk varices were never present in patients with a MELD score of 6 and a platelet count ≥100.000/μL (n = 36). Only one out of 62 patients (1.61%) with MELD ≤8 and platelets ≥100.000/μL had high-risk varices. A negative predictive value of 90.4% for high-risk varices was obtained in patients with MELD ≤8 and platelets >150.000/μL

Conclusion: A MELD≤8 together with a platelet count ≥150.000/μL allows avoiding upper GI endoscopy for esophageal varices screening in patients with liver cirrhosis.

P1291 NON-ALCOHOLIC FATTY LIVER DISEASE AFTER LIVER TRANSPLANTATION IN PATIENTS WITH NON-ALCOHOLIC STEATOHEPATITIS AND CRYPTOGENIC CIRRHOSIS: THE IMPACT OF PRE-TRANSPLANT GRAFT STEATOSIS

A. Eshraghian, S. Nikeghbalain, S.A. Malek-Hosseini
Transplant Research Center, Shiraz University of Medical Sciences, Shiraz, Iran (Islamic Republic of)

Contact E-Mail Address: eshraghiana@yahoo.com

Introduction: Non- alcoholic fatty liver disease (NAFLD) is a growing disease worldwide and is an increasing cause of liver transplantation when progresses to non-alcoholic steatohepatitis (NASH) and cirrhosis. NAFLD may also complicates liver transplant recipients especially in patients who have undergone liver transplantation for NASH and cryptogenic cirrhosis.

Aims and Methods: This study aimed to investigate prevalence and risk factors of fatty liver disease after liver transplantation in patients with NASH and cryptogenic cirrhosis. In a cross-sectional study liver transplant data of all patients who had undergone liver transplantation between 2013 and 2017 at Shiraz Organ Transplant Center, Shiraz, Iran were reviewed. Fatty liver was diagnosed by ultrasound. Data regarding post-transplant diabetes mellitus (DM), hyperlipidemia, height, weight, body mass index (BMI), laboratory data and allograft steatosis were recorded. Patients were treated with tacrolimus based immunosuppressive regimen. Obesity was defined as BMI$>$ 30 kg/m2. To investigate the impact of macrovesicular steatosis of graft on development of fatty liver after liver transplantation, recipients were grouped as those with $\leq$ 15% graft steatosis and those with $>$15% graft steatosis. Data were analyzed using the Student's t-test, and Chi-square test. Logistic regression analysis was used to calculate the influence of independent variables on development of fatty liver.

Results: 267 patients were included in the study (72 patients with NASH and 195 with cryptogenic cirrhosis). In a mean follow up of 14.7 months, 56.9% of NASH patients and 26.9% of cryptogenic patients developed fatty liver after liver transplantation (OR = 3.59; 95% CI: 1.94- 6.62, P $<$ 0.001). There was no statistically significant difference in development of fatty liver between patients with $>$15% pre-transplant graft steatosis and patients with $\leq$ 15% pre-transplant graft steatosis (OR = 1.07; 95% CI: 0.49–1.73, P = 0.817). In univariate analysis, post-transplant DM, hyperlipidemia, obesity, age, serum fasting blood sugar, triglyceride and cholesterol were associated with NAFLD after liver transplantation (P $<$ 0.05). In regression analysis, post-transplant DM was an independent predictor of development of NAFLD after liver transplantation (OR = 2.29; 95% CI: 1.01–5.18, P = 0.045). Post-transplant DM (OR = 5.58; 95% CI: 3.03- 10.29, P $<$ 0.001), hyperlipidemia (OR = 4.17; 95% CI: 2.23- 7.80, P $<$ 0.001) and obesity (OR = 4.65; 95% CI: 2.17- 9.94, P $<$ 0.001) were more prevalent in patients with NASH compared to patients with cryptogenic liver cirrhosis.

Conclusion: NAFLD and components of metabolic syndrome are prevalent after liver transplantation in patients with NASH and cryptogenic cirrhosis. Post-transplant DM is an independent predictor of hepatic steatosis after liver transplantation. These patients should be followed for metabolic complications after liver transplantation.

	OR (Odds ratio)	95% CI (confidence interval)	P- value
Post-transplant DM	2.29	1-01-5.18	0.045
Hyperlipidemia	2.06	0.92–4-61	0.077
Obesity	2.52	0.73–8.75	0.144
Age	1.01	0.95–1.03	0.644
BMI	1.02	0.90–1.15	0.686

Introduction: There is an unmet need for non-invasive markers to facilitate individualized surveillance strategies after hepatitis C virus (HCV) eradication.

Aims and Methods: We evaluated changes in relative liver enhancement (RLE; indicating hepatic fibrosis and inflammation) obtained by gadoxetic acid enhanced MRI (GA-MRI) in the hepatobiliary phase, as well as the changes in splenic volume (SV; indicating portal hypertension) as indicators of liver function in patients before and after SVR to IFN-free therapy. In addition, we assessed their predictive value for (further) hepatic decompensation during follow-up (FU).

We enrolled 31 consecutive HCV patients with advanced chronic liver disease who underwent GA-MRI before and after successful IFN-free treatment and were followed for the development of (further) hepatic decompensation. (Further) hepatic decompensation was defined by variceal (re-) bleeding, incident ascites/worsening of ascites (requirement of paracentesis), incident hepatic encephalopathy (HE)/worsening of HE (admission for grade 3/4 HE).

Fourteen untreated chronic HCV patients with paired GA-MRI served as a control group.

Results: RLE increased significantly by 66%(95%CI:20%-94%; $P < 0.001$) from pre- to post-treatment. SV decreased by -16%(95CI:-28%–8%; $P < 0.001$). However, SV increased in 5 out of 31 patients (16%), the identical patients who showed a decrease in RLE ('GA-MRI non-response'). There was an inverse correlation of moderate strength between the changes in RLE and SV ($\rho = -0.608$; $P < 0.001$).

In contrast, in the untreated control group, we observed a decrease in RLE by -11%(95%CI:-25%–3%; $P = 0.019$) and an increase in SV by 23%(95%CI:7%-43%; $P = 0.004$) (both $P < 0.001$ vs. treated patients).

During a median post-treatment FU of 25.2(IQR:16.9) months, 6 patients developed (further) hepatic decompensation, with variceal bleeding (n = 1), ascites (n = 2), or HE (n = 3) being the first events. Two patients underwent liver transplantation and one patient died after developing further hepatic decompensation. Interestingly, GA-MRI non-response was associated with a substantially increased risk of (further) hepatic decompensation at 2 years (80%vs.8%; $P < 0.001$).

Conclusion: This is the first study demonstrating that GA-MRI might be able to distinguish between individuals with improving liver function (i.e. regression of liver fibrosis and portal hypertension) and those with persistent liver damage despite HCV eradication. Thus, it might have important prognostic implications. If confirmed by larger studies, GA-MRI might facilitate individualized post-SVR surveillance.

Disclosure: M.M. has served as a speaker and/or consultant for AbbVie, Bristol-Myers Squibb, Gilead, Janssen, and W. L. Gore & Associates.

P1293 THE CLINICAL DIFFERENCES BETWEEN CRYPTOGENIC CIRRHOSIS WITH CIRRHOSIS SECONDARY TO NON-ALCOHOLIC STEATOHEPATITIS AND AUTOIMMUNE HEPATITIS

A. Eshraghian[1], S. Nikeghbalian[1], S.A. Taghavi[2], S.A. Malek-Hosseini[1]

Introduction: It has been suggested that majority of patients with diagnosis of cryptogenic cirrhosis (CC) have been evolved from non-alcoholic steatoheptitis (NASH) and autoimmune hepatitis (AIH) and some experts use CC and NASH cirrhosis synonymously. However, it seems that demographic, risk factors and disease course are different in cryptogenic cirrhosis compared to patients with NASH and AIH related cirrhosis.

Aims and Methods: This study aimed to investigate differences in clinical characteristics between patients with CC and patients with cirrhosis due to NASH and AIH based on the hypothesis that patients currently diagnosed as CC may not be evolved from NASH or AIH and have really an unidentified liver disease. Pre- transplant data of patients with liver cirrhosis referred to Shiraz Liver Transplant Center, Shiraz, Iran between January 2000 and December 2017 were reviewed. Demographic data and clinical characteristics of patients including body mass index (BMI), history of diabetes mellitus (DM), hypertension (HTN), hyperlipidemia, hepatocellular carcinoma (HCC), portal vein thrombosis (PVT), and were recorded. CC was defined as cirrhosis when causes of chronic liver diseases were thoroughly searched and excluded. NASH cirrhosis was diagnosed if patient had liver biopsy compatible with NASH and AIH was diagnosed based on serological and/or biopsy findings of patients before liver transplantation. Data were analyzed using student t- test or chi- square test using SPSS software.

Results: 1044 patients were included in the study (72 patients with NASH, 526 with CC and 446 patients with cirrhosis due to AIH. 37 patients (51.4%) with NASH and 115 patients with CC (21.9%) had DM before liver transplantation (OR = 3.77; 95% CI: 2.27–6.28, P $<$ 0.001). 34 patients with NASH (47.3%) and 61 patients with CC (11.6%) were obese (BMI$>$30 kg/m2) (OR = 6.24; 95% CI: 3.62–10.75, P $<$ 0.001). DM was diagnosed in 47 cirrhosis patients with AIH (10.5%) compared to the 115 patients with CC (21.9%) (OR = 2.37; 95% CI: 1.64–3.42, P $<$ 0.001). Obesity was detected in 61 patients with CC (11.6%) and 30 patients (7.2%) with cirrhosis due to AIH (OR = 1.99; 95% CI: 1.26–3.16, P = 0.004). 304 patients (68.2%) with AIH were female compared to 176 patients (33.5%) with CC (OR = 4.25; 95% CI: 3.25–5.57, P $<$ 0.001). 57 patients (79.2%) with NASH cirrhosis were male compared to 350 patients (66.5%) with CC (P = 0.031). Patients with NASH cirrhosis were older and had higher mean BMI when compared to the patients with AIH and CC (P $<$ 0.001) (Table). There was also significant difference in trend of incidence of NASH, AIH and

CC. NASH was significantly increasing as a cause of liver cirrhosis requiring liver transplantation while trend of CC and AIH is stable ($P < 0.05$).
Conclusion: Clinical characteristics of patients with cryptogenic cirrhosis are totally different from NASH cirrhosis and patients with cirrhosis due to AIH. Therefore, cryptogenic cirrhosis may not be simply consider equal to cirrhosis secondary to NASH or AIH. Further studies are needed to discover true nature of cryptogenic cirrhosis.

	Cryptogenic cirrhosis	NASH	P-Value	AIH	P-Value
Age (years)	43.06 ± 13.45	54 ± 7.8	<0.001	33.86 ± 11.52	<0.001
BMI	25.80 ± 6.9	31.73 ± 10.5	<0.001	23.80 ± 4.10	0.020

Introduction: Eradication of HCV infection with direct acting antiviral (DAA) therapy in patients with compensated advanced chronic liver disease (cACLD) is an important step further in the management of these patients, but brings new questions regarding the reliability and the accuracy of noninvasive tests in the post-HCV settings. Recent data reported that liver stiffness (LSM) rapidly decreases especially during first 4 weeks of DAA, with no notable changes at EOT or SVR12 (1). Data from the Peg-IFN era showed that baseline HVPG (hepatic-vein portal gradient), irrespective of achieving SVR, is the sole predictor of long-term decompensation and mortality (2).
Aims and Methods: Knowing that LSM is a very good predictor of clinically significant portal hypertension (CSPH) (3.4), we aimed to investigate whether obtaining SVR diminishes the accuracy of LSM to estimate CSPH, and, as a consequence, if LSM could still be used to diagnose CSPH and to predict long-term outcome in cACLD patients that achieved HCV eradication.
Consecutive HCV cirrhotic patients evaluated for DAA therapy were included. Baseline LSM and HVPG measurement were performed in the same day. LSM was further assessed at EOT and when estimating SVR12, while HVPG was reassessed only at SVR12. Descriptive, correlation and accuracy statistic tests were performed using SPSS.21software.
Results: Of the 69 HCV+ cACLD patients (mean age 59.2(±8.2) years; 63.8% females) treated with DAA, 55 already finalized the therapy and achieved SVR. LSM decreased from 23.15(6.4–62.7) kPa at baseline to 18.7(7.3–47.2) kPa at EOT ($p = 0.015$) and remained unchanged at SVR12 [19.8(5.9–55.1) kPa; $p = 0.37$]. HVPG dropped from 12.5(3–27) mmHg at baseline to 9(3–27) mmHg at SVR12, $p = 0.013$. The proportion of patients with CSPH decreased from 74.2% at baseline to 46.7% at SVR12 (chi-square = 13.48; $p < 0.001$). Interestingly, the correlation between LSM and HVPG increased at SVR12 ($r = 0.839$; $p < 0.001$) as compared to baseline ($r = 0.698$; $p < 0.001$). Furthermore, the performance of LSM to detect CSPH was better after obtaining viral clearance [AUROC of 0.88(95%CI: 0.82–1.00) vs. 0.82(95%CI: 0.70–0.94) and diagnostic accuracy of 80% vs 57.6%] and the best cut-off values (calculated using the Youden index) were different: 12 kPa at SVR12 vs, 20.5 kPa at baseline. The baseline LSM cut-off value (20.5 kPa) has a 91% PPV, it could be used to rule-in CSPH. while the SVR12 cut-off (12 kPa) has a 100% NPV, being more suitable to rule-out CSPH, especially in the absence of HCV infection.
Conclusion: In conclusion, the HCV clearance due to DAA therapy induces a reduction in LSM and HVPG, mainly because of eliminating the inflammatory component of hepatic resistance. As a consequence, in the absence of HCV infection, LSM and HVPG are better correlated and LSM is a better noninvasive tool to rule-out CSPH.

Introduction: The new direct antiviral agents (DAAs) provide a safe and efficacious treatment for liver transplant recipients with recurrent HCV infection.
Aims and Methods: The aim of this study is to evaluate the impact of HCV eradication on the metabolic factors in liver transplant recipients.
Retrospective single-centre study on HCV-related liver transplant recipients treated with IFN-free DAAs including both treatment naive and treatment-experienced patients. DAA impacts on the metabolic profile assessed at baseline and SVR >24 weeks.
Results: In total, 91 liver transplant recipients with recurrent HCV infection received IFN-free DAA treatment, 62 patients had IFN-based treatment failure and 29 were treatment-naïve, of whom 87(96%) achieved SVR. Eradication of recurrent HCV infection was associated with reduction in the treatment of diabetes and hypertension by 38% and 22% from the baseline respectively.
HbA1c levels declined from mean 35.5 ± 4.3mmol/mol to 33.3 ± 3.6 mmol/mol beyond 24 weeks post-treatment. [p 0.03]. Total cholesterol levels increased from 3.8 ± 0.9 mmol/L to 4.9 ± 0.9 mmol/L beyond 24 weeks post-treatment. [$p < 0.0001$] reflecting a significant increase in serum LDL levels [2.0 ± 0.8 to 2.9 ± 0.8; $p = < 0.0001$]. Estimated eGFR (ml/min) levels increased from 64.9 ± 20 ml/min to 69.6 ± 20 ml/min beyond 24 weeks post-treatment. [$p = 0.0004$]. Glucose, lipid profile and eGFR changes were independent of weight changes and immunosuppression dosage and trough levels.
Conclusion: Eradication of recurrent HCV infection by DAA therapy has beneficial impact on glucose metabolism and renal profile and reverses the hypolipidemic effect of HCV in liver transplant recipients. These extrahepatic effects of DAA therapy need to be validated by larger prospective studies.

Introduction: In July, 2015, sofosbuvir (SOF) (an NS5B inhibitor) and ledipasvir (LDV) (an NS5A inhibitor) combination therapy were authorized for the treatment of chronic hepatitis or compensated cirrhosis in patients with HCV genotype 1 in Japan. An open-label phase 3 clinical trial in Japan showed that an SVR was achieved by 100% of patients. However, in the real world, some patients experience virologic failure.
Aims and Methods: We aimed to reveal the factors associated with virologic failure in patients treated with SOF/LDV, and to identify the baseline NS5A and NS5B resistance-associated substitutions (RASs). Four hundred ninety-three patients with Hepatitis C Virus (HCV) genotype 1b infection were treated with SOF/LDV; 31 had a history of interferon (IFN)-free treatment with daclatasvir and asunaprevir. The effect of baseline RASs on the response to SOF/LDV therapy was analyzed. We investigated the viral genome sequence by direct sequencing.
Results: The age of the patients ranged from 26 to 90 years (mean, 68 years). There were 295 female patients (60%) and 105 (21%) patients with cirrhosis. Sixty-three patients (13%) had previously been treated for hepatocellular carcinoma (HCC). Overall, a sustained virologic response at 12 weeks (SVR12) was achieved in 476 patients (96.6%). The SVR12 rates in the patients with IFN-free treatment-naïve and retreatment were 97.6% and 80.6%, respectively. HCV eradication was not achieved in 17 patients, 11 (including 5 with IFN-free retreatment) of whom had virologic failure. Eight patients had coexisting NS5A RASs of Q24, L28 and/or R30, L31, or Y93 and one patient had coexisting NS5A RASs of P32L and A92K. Interestingly, 10 and 8 patients had NS5B A218S and C316N RAS respectively. No patients had NS5B L159, S282, L320 or V321 RASs at the baseline. In particular, the patients who had NS5B C316

RAS also had coexisting A218 RAS. In addition, no patients acquired these RASs. According to a multivariate analysis, coexisting NS5A RASs, NS5A P32 RAS, NS5B A218 and/or C316 RASs, and γ-glutamyltranspeptidase were associated with virologic failure. In the naïve patients, all patients without NS5B A218 and/or C316 RAS achieved an SVR12. Notably, the SVR12 rates of patients with coexisting NS5A and NS5B RASs were significantly lower (83.3%).
Conclusion: Although SOF/LDV therapy resulted in a high SVR12 rate, coexisting NS5A and NS5B RASs were associated with virologic failure. These results might indicate that the coexisting baseline RASs influence the therapeutic effects of SOF/LDV.

Introduction: Hepatitis C virus (HCV) is the main leading cause of liver disease in Egypt. A new era of HCV treatment has been started with the evolution of direct acting antiviral agents which are expected to change epidemiology of the disease. Sofosbuvir (SOF)-based therapy was introduced by the Egyptian ministry of health through a national HCV treatment program in 2014 in an attempt to decrease disease burden.
Aims and Methods: To evaluate efficacy and safety of Sofosbuvir-based regimens in HCV Egyptian patients with compensated liver disease. In the period between February 2015 and December 2016, 758 chronic HCV patients with compensated liver disease were randomized into 4 groups according to treatment regimen applied for each group; group 1 received SOF, PEG-IFN plus ribavirin (RBV) for 12 weeks, group 2 received SOF plus RBV for 24 weeks, group 3 received SOF and Simeprevir (SIM) with or without RBV for 12–24 weeks according to the state of fibrosis and treatment status, group 4 SOF and Daclatasvir with or without RBV for 12–24 weeks according to the state of fibrosis and treatment status. Patients with Child-Pugh score more than 8, impaired kidney functions or hepatocellular carcinoma (HCC) whether active or recently treated with less than 4 weeks elapsed after successful treatment have been ruled out. SVR12 was the end point used to assess treatment efficacy. All adverse events have been reported in each group.
Results: Seven hundred out of 758 patients fulfilled the inclusion criteria; group 1 included 159 patients, group 2 included 138 patients, group 3 included 201 patients and group 4 included 202 patients. The mean age was 49.4 ± 9.2, 54.6 ± 9.3, 49.5 ± 11.4 and 50.3 ± 10.8 years in the 4 groups respectively. The overall SVR was 90.9% in group 1, 81.5% in group 2, 95% in group 3 and 98% in group 4. SVR in patients with liver cirrhosis was 90.56, 79.16, 95 and 96% in the 4 groups respectively. In treatment experienced patients, SVR was 86.8% in group 1, 78.3% in group 2, 100% in group 3 and 86.7% in group 4. The overall SVR and SVR among patients with liver cirrhosis was significantly higher in group 4 ($p < 0.001$) while SVR in treatment experienced patients was significantly higher in group 3 ($p < 0.001$). The rate of adverse events was 55.97, 59.42, 40.79 and 9.4% in the 4 groups respectively with significantly lower rate in group 4 ($p < 0.001$). The most reported adverse events were flu-like illness (15.1%) and anemia (12.6%) in group 1, anemia (18.8%) and hyperbilirubinemia (18.1%) in group 2, hyperbilirubinemia (11.9%) and fatigue (6.5%) in group 3, hyperbilirubinemia (5.9%) and anemia (3.5%) in group 4.
Conclusion: Sofosbuvir plus daclatasvir with or without ribavirin is the safest and most effective SOF-based regimen in treatment of HCV Egyptian patients with compensated liver disease.
Disclosure: Nothing to disclose

Introduction: The improvement of liver fibrosis assessed using transient elastography (TE) by FibroScan® is leading to new insights in the concepts of fibrosis regression.
The possibility of using new direct antiviral agents (DAA) in cirrhotic patients, previous excluded from PegInterferon treatment for risk of hepatic failure, has permitted to verify the hypothesis of fibrosis regression in these patients. TE should be interpreted taking into account the inflammatory profile associated with hepatitis.
Aims and Methods: To establish the stiffness variations in a court of HCV patients before and after antiviral treatment to assess the correct follow up in patients with high stiffness value.
We enrolled 246 consecutive patients treated with DAA for chronic hepatitis C. TE and blood tests were performed before therapy and during follow-up.
Results: Each patient underwent TE before therapy; 60 of them performed TE at 24th week after end of treatment (EOT) and also at 24th month after EOT. Before therapy, 91 of 246 patients (37%) had stiffness >12 kPa (suggestive of advanced fibrosis stage); all 91 had a Child-Pugh score A5 but only 49 (56%) had APRI score suggestive of cirrhosis. Regardless of DAA-schedule, all 246 patients reached SVR. At follow-up only 3 patients presented stiffness >12 kPa (5%) and they were the same patients who maintained APRI score >1. Respect to the basal stiffness, after therapy all patients showed a significant decrease at 24th week after EOT (mean 14.9 kPa vs 9.5 kPa, $P = 0.0009$). This decay was unchanged at 24th month after EOT (mean 9.5 kPa vs 8 kPa, P = NS).
Conclusion: The sudden improvement of liver stiffness assessed by TE within the 24th week after EOT could be related to the "switch-off" of necro-inflammatory activity achieved by antiviral therapy. Follow-up should be established regarding APRI score and TE performed at 24th week after EOT instead of the pretreatment values.

Introduction: Hepatitis C virus (HCV) infection is a public health problem on a global scale. In Portugal, it is estimated that the prevalence of seropositivity is between 1–1.5%, and there are no studies regarding this reality in Madeira archipelago. The World Health Organization has proposed an ambitious goal of eradicating the disease 2030.
Aims and Methods: Identification of the areas with the highest prevalence and the caracterization of HCV infection in Madeira archipelago. Retrospective study was made based on the population with HCV seropositivity from 2012 to 2017. Data from the patients were analyzed together with the 2011 Census, for the study of the distribution of 11 municipalities and 54 civil parishes. The data were analyzed using Excell software and SPSS.
Results: We evaluated 3741 tests involving 1759 patients. 88% male (n = 1548), with a mean age of 36 ± 10.86 years. The prevalence in the archipelago and in the island of Madeira was 0.61%, in the island of Porto Santo was 0.5%. The prevalence in varying between 0.12 and 1.05%, and there was a more marked asymmetry at the level of parishes (0–2.03%) When adjusted for the masculine gender, 17 parishes, belonging to 5 municipalities, present more than 1% (0–3.7%). Drug-addicted patients were the largest at-risk group with 48% (n = 844) of the total and inmates with 13% (n = 234). 41% (n = 727) of the patients had loss of follow-up.
Conclusion: The patients identified in this study with HCV-HCV seropositivity allowed to estimate a prevalence of 0.61% in Madeira archipelago.
Our data showed some geographical heterogeneity, which reinforces the importance of a "targeted" population strategy to eradicate infection in the most prevalent areas, as envisaged in the "micro elimination or eradication" strategy.

Introduction: The severity of liver disease should be assessed prior to therapy. Identifying patients with cirrhosis is of particular importance, not only for treatment, but also for prognosis. Noninvasive evaluation of liver fibrosis can be

performed using biological tests, such as the FibroMax, or by using ultrasound based elastographic methods, such as Transient Elastography (TE).
Aims and Methods: The aim of the present study was to evaluate the accuracy of these tests (FibroMax and Transient Elastography) for predicting HCV liver cirrhosis (LC), in viremic naive or treatment-experienced patients, with compensated liver disease.
The study prospectively included 460 consecutive patients previously diagnosed with compensated HCV LC based on clinical, biologic, ultrasonographic, endoscopic (esophageal varices), liver biopsy or/and laparoscopic criteria, who were considered for interferon-free treatment (Viekirax/Exviera). Liver fibrosis was assessed during a two weeks period by means of TE (using M or XL probe) and by FibroMax. For TE, reliable measurements were defined as median value of 10 liver stiffness measurements, with a SR≥60% and an IQR < 30%. For diagnosing cirrhosis by means of TE we used a cut-off value 12 kPa (1) and for FibroMax a value of 0.75.
Results: Out of the 460 patients, reliable measurements by TE were obtained in 453 (98.4%). According to the FibroMax cut-off, 77% (349/460) patients were correctly classified, while according to TE cut-off – 94.2% (427/453) patients ($p < 0.0001$). Out of the 453 cirrhotics, 1.5% were misclassified by TE as having significant fibrosis (F2) and 4.3% with severe fibrosis (F3). When we evaluated the performance of FibroMax, 8.1% of the 460 patients with LC were misclassified as having F1, 2.2% as having F2.10.8% as having F3 and 1.9% as having F3/F4.
Conclusion: The accuracy of FibroMax for predicting HCV liver cirrhosis in viremic naive or treatment-experienced patients, with compensated liver disease was significantly lower than of TE (77% vs. 94.2%; $p < 0.0001$).
Disclosure: Nothing to disclose

Introduction: Patients with HCV-associated cirrhosis and hepatocellular carcinoma (HCC) maintain a high rate of HCC recurrence even after subsequent DAA therapy resulting in sustained viral response. Further research is needed in order to establish the impact of DAA therapy on the recurrence rates and survival in these patients.
Aims and Methods: From a national prospective cohort enrolling 5861 Romanian patients with virus C compensated liver cirrhosis who received reimbursed DAA with Paritaprevir/ Ombitasvir /r, Dasabuvir and Ribavirin (OBV/PTV/r + DSV + RBV) for 12 weeks during december 2015- august 2016, we analyzed 22 patients with a history of treated HCC. Most of them were treated by resection (8/22), followed by radiofrequency ablation (RFA) 6/22 and transarterial chemoembolisation (TACE) 8/22. DAA treatment was administered on the condition that the absence of tumor relapse was confirmed 6 months after the last session of therapy. A control group was defined including an equal number of HCC patients treated by surgery/RFA/TACE with matching age, gender and Barcelona Clinic Liver Cancer (BCLC) staging. All the patients were screened for tumor recurrence every 3–4 months with dynamic CT scan and/or MRI. They were divided in 4 groups: DAA- resection+ RFA (patients with HCC treated through resection or RFA who received DAA therapy), Control- resection+ RFA, DAA- TACE (patients with HCC treated through TACE who received DAA therapy), Control- TACE. Data were obtained from the Romanian National health Agency. Ordinal and scale variables with non-normal distribution were summarized as mean (±standard deviation), and compared by t-student test, while categorical variables were summarized as number (%) and compared by Fisher exact test.
Results: Results are depicted in table 1

Parameter	DAA-RESECTION +RFA (14)	CONTROL-RESECTION +RFA (14)	p-value
Sex M	7/14 (50%)	6/14 (42.3%)	0.7
Mean age (±SD) *	62.8 ± 7	64.4 ± 8.2	0.59
Follow-up (mean ± SD) **	46.7 +/− 20.1	33.7+/− 27	0.16
SVR 12 (per protocol)	12/14 (85.7%)	NA	NA
Recurrence rate	3/14 (21.4%)	12/14 (85.7%)	0.001
Survival without recurrence	45.1+/− 12.5	18.1 +/−16.2	0.005
Parameter	DAA-TACE (8)	CONTROL-TACE (8)	p-value

(continued)

Continued

Parameter	DAA-RESECTION +RFA (14)	CONTROL-RESECTION +RFA (14)	p-value
Sex M	2/8 (25%)	2/8 (25%)	1
Mean age (±SD) *	67.9 +/− 7.2	64.9 +/− 8.3	0.453
Follow-up (mean ± SD) **	40.4+/−12.9	16.5+/− 9.2	0.001
SVR 12 (per protocol)	7/8 (87.5%)	NA	NA
Recurrence rate	3/8 (37.5%)	8/8 (100%)	0.007
Survival without recurrence **	37.3 +/− 7.3	14.3 +/− 8.1	0.003

[Table1. Main characteristics, SVR 12, recurrence rate and survival without recurrence of the 4 groups, SVR 12 where applicable]
Two female patients died of acute liver insufficiency (9.5%) one after completing 12 weeks of treatment, and the other in week 7 of DAA therapy (in the DAA-resection+ RFA group). One male patient from the DAA-TACE group had a viral relapse 12 weeks after EOT.
Conclusion: SVR rate per protocol analysis in patients with treated HCC and compensated liver cirrhosis that received DAA with OBV/PTV/r + DSV + RBV was 86.4% Although a recruitment bias may be involved, recurrence rate in patients with HCC treated by resection and RFA that received DAA therapy was 21% compared with 86% in the control group. In those with HCC treated by TACE on DAA therapy the recurrence rate was 37.5% vs 100% in the control group. This favorable impact of DAA therapy on the recurrence rate of HCC was reflected into an improved survival without recurrence in both groups.

Introduction: Cirrhosis development is an important stage in the natural history of chronic hepatitis C(CHC), because it heralds significant morbidity and mortality and higher health care costs related to complications of end-stage liver disease. Treatment response has been proven to be the determinant factor for the development of cirrhosis. It has also been shown that disease progression can be predicted by AST/ALT, Fibrosis-4 (FIB-4) and AST/Platelet ratio index (APRI) scores (1.2,3). In the present study, we aimed to evaluate the impact of sustained virological response (SVR) and some other predictive factors on development of cirrhosis secondary to chronic hepatitis C.
Aims and Methods: 100 patients with CHC, who were followed at least for 1 year between 2000–2015 in Uludag University, School of Medicine Hospital were reviewed and cirrhosis development was investigated. AST/ALT ratio, APRI (AST (IU/L)/Platelet) and FIB-4 ((Age (year) × AST(IU/L))/(Platelet × (sqr (ALT) (IU/L)) scores were calculated. SVR was defined as aviremia 24 weeks after completion of therapy. Annual rates and the cumulative incidences of cirrhosis for 3-5-10 years were estimated.
Results: The median follow-up period was 5.9 (1–14.4) years. The 10 year cumulative incidence of cirrhosis was significantly lower in the treated group compared to untreated group (19.5% and 44.4%, $p = 0.025$). In the treated group; cirrhosis wasn't observed in the cases with SVR ($p < 0.001$). Univariate analysis revealed that female gender ($p = 0.041$), age ≤ 40 ($p = 0.05$), platelet count >150,000 ($p < 0.001$), low AST/ALT score ($p = 0.003$), low Fib-4 score ($p < 0.001$), low APRI score ($p < 0.001$), SVR ($p < 0.001$) resulted in statistically significant less cirrhosis. In cox regression analysis; SVR was found to be the only independent factor affecting development of cirrhosis (Hazard ratio, HR = 0.279; $p = 0.04$).
Conclusion: Although there are useful parameters in predicting the development of cirrhosis in CHC patients, SVR is the only independent factor to prevent cirrhosis. Elimination of cirrhosis with higher SVR rates with currently used new direct-acting antiviral agents will be probably shown in the future long-term studies.

Introduction: Hepatitis C is an infectious disease of viral origin with primarily blood transmission. It is a real public health problem. Screening for hepatitis C is very interesting for preventing the spread of the infection, improving access to care and reducing the risk of chronic liver complications. The rapid diagnostic tests (RDTs) represent an interesting alternative to enzyme immunoassay.
Aims and Methods: The aim of this study is to prospectively evaluate the diagnostic performance of CE-marked RDTs (Toyo® tests) which detects the anti-hepatitis C virus (HCV) antibodies in capillary whole blood and to study their sensitivity and specificity as well as their predictive values.
This is a prospective comparative study done in the Hepato-Gastroenterology service of Oujda's Mohammed VI university hospital, over a period from March 2017 to July 2017 and collected all the patients hospitalized during this period. We analyzed 150 blood samples tested for HCV by RDTs.
Results: One hundred and fifty patients were included. The average age of our patients was 47.74 years old with extremes: 17 years-98 years. There are 79 men and 71 women with a sex ratio H/F: 1.11. The risk factors for contamination by hepatotropic viruses were found in 71.33% (Non-medical care: 82.24%, tattooing: 32.71%, transfusion: 28.03%, cupping therapy: 18.70%, unprotected sex: 4.67%). The viral serology of hepatitis C (anti-HCV antibodies) was positive in 13 cases, or 8.66%. RDTs were positive in 10 cases (6.66%), as well as polymerase chain reaction (PCR). The sensitivity of the RDTs to viral serology was 76.92%, while its specificity was 100%. The positive predictive value was 100% and the negative predictive value was 97.8%. The same results were found by calculating the specificity, sensitivity and predictive values of PCR in relation to viral serology.
Conclusion: Based on this work, we found that the positivity of RDTs allows the establishment of the hepatitis C diagnosis for 100 per cent. However, the use of a serological assay remains necessary when the test is negative. While our study involved a small number of patients, it is a rough sketch for a work with a larger sample to thoroughly assess the efficiency of HCV RDTs and to estimate the real impact of their use in reducing the diagnosis of the infection at an advanced stage and facilitate access to rapid therapeutic management.

P1304 PREDICTIVE FACTORS OF RESPONSE TO URSODESOXYCHOLIC ACID IN PRIMARY BILIARY CHOLANGITIS

O. Gharbi, H. Kchir, D. Issaoui, H. Chaabouni, N. Maamouri
La Rabta Hospital, Tunis, Tunisia

Contact E-Mail Address: gharbi.ons@gmail.com
Introduction: Primary biliary cholangitis (PBC) is an autoimmune chronic cholestatic disease. Its treatment is based on ursodesoxycholic acid (UDCA) which purpose is to normalize liver tests and delay progression to cirrhosis.
Aims and Methods: The aim of this study was to determine the factors influencing the response to UDCA in PBC.
We investigated all the PBC patients admitted in our department in the period between January 1996 and December 2014. Only patients with treated with UDCA and followed for at least one year. The definition of response to UDCA was based on Paris II criteria[1].
Results: Thirty patients were included in our study among 75 having a PBC. Their mean age was 51.3 years [31–73] and the sex ratio was 0.07 (2M/28F). Discovery of the disease was fortuitous in 26% of patients. The mean levels of aspartate aminotransferase, alanine aminotransferase, gamma glutamyl transferase, alkaline phosphatase, total bilirubin, albumin and IgM were respectively 1.97 ULN [1–6 ULN], 2.85 ULN [1–15 ULN], 7.4 ULN [1–30 ULN], 3.09 ULN [1–8 ULN], 2.22 ULN [1–14 ULN], 36 g/l [25.2–46.8g/l] and 2.44 g/l [1.06–11.4 g/l]. serological tests showed positive antimitochondrial antibodies (AMA) in 83% of cases, their mean level was 1/2737, in addition, antinuclear antibodies (ANA) were positive in 70% of cases and smooth muscle antibodies in 6 patients only. A second autoimmune disease was associated to PBC in 63% of cases (N = 19). Three patients had cirrhosis at diagnosis, the rest had a liver biopsy (N = 27), showing a PBC scheuer's stage $\geq$ 2 in 60% of cases with a fibrosis score $\geq$ 2 in 37%.
All patients were treated by UDCA at the dose of 14 mg/kg/day. Response to UDCA therapy at one year of follow-up was adequate in 63% of cases. we compared the groups of patients with and without response to UDCA, no differences were found according to age, sex, absence of symptoms, pretherapeutic levels of serum transaminase activity, ALP and GGT, levels of AMA and ANA, positivity of AML, histological liver steatosis, Bile duct loss and ductular reaction, stage according to scheuer's classification, fibrosis, coexistence of other autoimmune diseases, and delay in starting UDCA therapy. However, biochemical response was inversely correlated o pretherapeutic level of total bilirubin ($p = 0.023$).
Conclusion: According to our study, an elevated pretherapeutic of total bilirubin (superior to 2 ULN) is a predictive factor to the absence of a biochemical response to UDCA therapy in PBC.
Disclosure: Nothing to disclose

Contact E-Mail Address: martapatita21@gmail.com
Introduction: Most patients with Primary Biliary Cholangitis (PBC) respond to ursodeoxycholic acid (UDCA) therapy. For those who do not respond to UDCA, therapeutic alternatives are scarce. Fibrates have been suggested as second-line agents in patients who do not achieve adequate biochemical response to UDCA monotherapy. The objective of this study is to evaluate the role of fibrates as second-line therapy in PBC.
Aims and Methods: PBC was diagnosed according to accepted criteria and staged according to the Ludwig classification. The absence of response to UDCA therapy was assessed using the GLOBE score. Liver function tests, renal function and the UK-PBC score were assessed at 6 and 12 months after fibrate onset and at the date of the last follow-up visit. Patients receiving fibrate were compared with a control group of patients not responding to UDCA who did not receive fibrates.
Results: Thirty-nine patients were included (fibrates group n = 13; control group n = 26). Patients in both groups did not differ in terms of age, gender or follow-up time. Side effects were observed in two patients (arthralgias and myalgias), leading to the suspension of the fibrate in one patient. There was a significant decrease in alkaline phosphatase levels at 6 and 12 months and at the end of the follow-up in the group that received fibrates compared to the control group ($p < 0.05$). Transaminase and IgM levels also decreased significantly, while bilirubin and albumin levels remained unchanged in the group receiving fibrates. A higher proportion of patients in the fibrate group achieved POISE response criteria compared to the control group at all time points studied ($p < 0.05$).
Conclusion: Combination therapy of fibrate and UDCA is safe and induces significant biochemical and prognostic scores improvement in patients with PBC and incomplete response to UDCA.

P1306 PREDICTIVE FACTORS OF URSODESOXYCHOLIC ACID IN PRIMARY BILIARY CHOLANGITIS

A. Ben Slama, M. Ksiaa, S. Hamdi, H. Jaziri, N. Elleuch, A. Hammami, A. Jmaa
CHU Sahloul Faculty of Medecine, Gastroenterology, Sousse, Tunisia

Contact E-Mail Address: aida.benslama@yahoo.fr
Introduction: Primary biliary cholangitis (PBC) is a cholestatic chronic liver disease characterized by a progressive destruction of small intrahepatic bile ducts. Ursodesoxycholic acid (UDCA) have benefit in slowing down the liver disease progression. However, some (30 -40%) patients experience treatment failure.
The aim of our study was to evaluate the prognostic factors of UDCA failure in patients with PBC.
Aims and Methods: We retrospectively collected the medical files of patients with PBC who received UDCA from January 2005 to December 2016. Non-reponse to treatment was evaluated with Paris criteria.
Results: Seventy- one patients were included in our study. There were 66 females (93%) and 5 (7%) males. Ages ranged from 23 to 81 years (median 55.23). All patients were treated with UDCA (13–15 mg/Kg/ day) associated with corticosteroids and azathioprine in overlap syndromes (28.1%). The average of follow-up time was 64 months (range 3–64 months).
Complete response was observed in 34 (48%) patients. Partial response or non-response were seen in 34 (52%) patients.
Predictive factors of treatment failure were: high serum bilirubin level $>$50 µmole/L ($p = 0.039$), advanced cirrhosis ($p = 0.026$), overlap syndrome ($p = 0.046$) and interface hepatitis ($p = 0.006$). Gender, age and association with other autoimmune diseases were not identified as prognostic factors. The evolution into an advanced cirrhosis was significantly observed in patients who failed UDCA ($p = 0.038$). Interestingly, 2 cases of hepatocellular carcinoma were diagnosed in patients with UDCA failure.
Conclusion: UDCA has a crucial role in PBC treatment. It may slow down the progression into advanced liver disease. However, high serum bilirubin level,

advanced cirrhosis, overlap syndrome and interface hepatitis predicted poor outcome.

Introduction: Primary sclerosing cholangitis (PSC) is a chronic, usually progressive, stricturing disease of the biliary tree that may eventually lead to cirrhosis and cholangiocarcinoma (CCA). The etiopathogenesis is heterogeneous, involving both genetic and environmental factors. Early diagnosis and better tools for monitoring disease progression and detection of biliary dysplasia poses a major medical challenge. Novel serum biomarkers enabling a more precise diagnostic and prognostic of both PSC and biliary dysplasia are urgently needed.
Aims and Methods: This study aimed identifying a set of serum lipids that would serve as biomarkers for detection and prognosis of PSC and biliary dysplasia. After informed consent, serum samples (n = 185) were drawn from participants (n = 175) distributed across four experimental groups representing different disease stages: non-advanced PSC (n = 67), advanced PSC (n = 73), biliary dysplasia (n = 34), and healthy controls (n = 11). These samples were subsequently analyzed using a novel lipid-screening platform (Lipidyzer^{TM}, Sciex) to determine the concentration of 1134 lipids species across 13 lipid classes.
Results: Model-based analyses (Generalized Estimating Equations) pinpointed a set of triglycerides as significantly altered in PSC patients respect to healthy controls, after correction for type-I error: TAG48:5-FA18:3 (triglycerides with 48 carbons and 5 double bonds, including alpha-linolenic acidin its composition; p-value: 5.2710^{-7}), TAG50:5-FA18:1 (triglycerides with 50 carbons and 5 double bonds, including oleic acid in its composition, p-value: 3.5110^{-5}), and TAG54:3-FA20:1 (triglycerides with 50 carbons and 5 double bonds, including 11Z-eicosenoic acidin its composition, p-value: 1.7010^{-6}). In addition to the above mentioned, one more lipid was pinpointed when comparing all affected patients (PSC and dysplasia) to healthy controls: TAG56:2-FA20:0 (triglycerides with 50 carbons and 5 double bonds, including arachidic acid in its composition, p-value: 7.2610^{-5}). Finally, a set of triglycerides were detected when comparing patients with biliary dysplasia respect to those with PSC: TAG54:5-FA22:4 (triglycerides with 54 carbons and 5 double bonds, including arachidonic acid in its composition; p-value: 8.4510^{-5}), TAG54:6-FA22:5 (triglycerides with 54 carbons and 6 double bonds, including 7,10,13,16,19-docosapentaenoic acid in its composition; p-value: 1.3610^{-4}), TAG54:7-FA16:1 (triglycerides with 54 carbons and 7 double bonds, including cis-9-palmitoleic acid in its composition; p-value: 5.9110^{-5}), and TAG56:4-FA22:4 (triglycerides with 56 carbons and 4 double bonds, including adrenic acid in its composition; p-value: 1.6010^{-5}).
Conclusion: From the extensive lipid panel initially screened, this study was capable of detecting a set of 4 triglycerides as candidate serum biomarkers that allowed differentiating between persons affected with PSC or biliary dysplasia from the healthy controls. Importantly, 4 additional triglycerides allowed discriminating between PSC and biliary dysplasia patients.

Introduction: Pruritus of the skin is a clinical symptom characteristic of primary biliary cholangitis (PBC), but the frequency and severity has not been studied enough in detail. The purpose of this study is to document the actual state of pruritus in PBC patients.
Aims and Methods: The subjects were 49 patients who were diagnosed with PBC at our department. By means of a questionnaire, we evaluated the patients regarding pruritus, and classified them into 5 stages (0: none, 1: slight, 2: mild, 3: moderate, 4: intense), using Shiratori's criteria on the severity of pruritus, and compared them by age, duration from diagnosis, values of total bilirubin (mg/dl), albumin (g/ml), prothrombin time (%), platelet count, values of type 4 collagen 7S (ng/ml), and hyaluronic acid (ng/ml).
Results: The patients were 3 men and 46 women, with an average age of 67.8. Pruritus evaluated in 5 stages (0/1/2/3/4) were present during the day in (12/13/17/6/1) patients, and during the night in (14/12/18/3/2) patients. The rate of patients feeling pruritus during the day was 75.5%, and during the night, 71.4%, accounting for a high percentage. There was no relation between pruritus and age or duration from diagnosis with PBC, for both day time and night time. There was no correlation between pruritus and the value of total bilirubin(daytime: 0.6/0.5/0.7/0.5/0.8, night time: 0.6/0.6/0.5/1.4/0.5), the value of albumin(-day time: 4.2/4.1/3.9/4.0/4.1, night time: 4.2/4.0/4.0/3.4/4.1), the prothrombin time(daytime: 99/99/96/100/100, night time: 99/98/99/82/100), platelet count(day time: 20.4/17.3/20.2/18.2/15.2, night time: 21.4/17.1/19.2/17.5/17.7), type 4 collagen 7S(day time: 4.2/4.0/4.0/3.8/3.5, night time: 4.0/4.2/4.0/4.2/3.5), or hyaluronic acid(day time: 109.3/100.9/88.1/62.0/31.3, night time: 98.3/107.5/80.1/106.4/49).
Conclusion: The liver lesions of the patients in this study were mostly not advanced, but the rate of those feeling pruritus was high. There was no significant correlation between pruritus and age, duration of disease, or indicators of liver reserve. It has become clear that in PBC, pruritus manifests in the early stage.
Among PBC patients there are many who have pruritus regardless of the degree of advancement, but at the present point, there is no other way to confirm it than by history taking. Identification of a useful biomarker for confirming pruritus will be needed.

Introduction: Early hepatocellular carcinoma (HCC) is often absent of pathognomonic symptoms, and thus many patients have untreatable disease when first diagnosed. Single-nucleotide-polymorphisms (SNPs) on the *UDP glucuronosyltransferase gamily 2 member B28 (UGT2B28)* gene have been proved associated with hepatitis B virus e-antigen clearance in response to peginterferon therapy, prostate cancer progression and colorectal cancer risk. The gene product, UGT2B28, is an enzyme associated with sex hormone metabolism, an important factor in HCC progression, whereas its clinical role in HCC has never been studied. Here, we aimed to investigate this issue and to explore the possible application of our findings in diagnosis of HCC.
Aims and Methods: A cohort of 382 patients with HCC having received curative resection was retrospectively recruited. We evaluated the correlation between *UGT2B28*-rs2132039 genotypes and clinicopathological factors.
Results: Among these patients, 52.6% patients had rs2132039-CT genotype, and the others had rs2132039-TT genotype. Intriguingly, none had rs2132039-CC genotype. Univariate analysis revealed that "CT" genotype was associated with age (OR, 1.021; 95% CI, 1.006–1.036; P = 0.005), ascites (OR, 3.223; 95% CI, 1.264–8.215; P = 0.014) and hepatitis C (OR, 1.839; 95% CI, 1.148–2.945; P = 0.011). Multivariate analysis showed that these three factors were independent of each other. Subgroup analysis discovered that "CT" genotype was most significantly associated with age in alcoholism-related HCC patients (OR, 1.079; 95% CI, 1.035–1.125; P < 0.001). The average ages at diagnosis (onset ages) of alcoholism-related HCC were 59.3 ± 10.7 and 49.6 ± 12.2 years (a 10-year difference) for "CT" and "TT" genotypes, respectively.
Conclusion: Alcoholic patients with *UGT2B28*-rs2132039-TT genotype had a 10-year earlier onset of HCC, compared to the "CT" genotype. Intensive ultrasound surveillance for HCC should start before 50 years of age in alcoholic patients with "TT" genotype.

Introduction: Recognition of circulating DNA can be useful for the diagnosis of many cancers, including the hepatocellular carcinoma (HCC). The pathogenesis of HCC involving different genetic and epigenetic alterations. HCV viral proteins may participate in epigenetic regulation of hepatic cancer and induce HCC-specific epigenetic changes. HCV infection was related to aberrant methylation on multiple genes. Runt-related transcription factor 3 (RUNX3), Ras association domain family1 isoform A(RASSF1A) and E-Cadherin genes are tumor suppressor genes which could be inactivated by hypermethylation in many tumors including HCC, causing a decrease of gene expression.

Aims and Methods: In this study, the methylation of RUNX3, RASSF1A, and E-Cadherin genes were studied in the serum of patients with HCV related liver cirrhosis and patients with HCC as diagnostic biomarkers for HCC. DNA was extracted from the peripheral blood of 53 healthy volunteers, 207 HCV related liver cirrhosis (LC) patients and 193 HCC patients. Routine laboratory investigations, assessment of serum AFP and detection of circulating hypermethylated RASSF1A, RUNX3 and E-Cadherin genes by methylation-specific PCR were done for all participants.
Results: A significant hypermethylated RASSF1A gene was found in HCC group when compared to both LC and healthy groups (OR = 9.9675), (OR = 5.6802) respectively. As regard gene RUNX3 a significant hypermethylation was found in HCC group when compared to both LC and healthy groups (OR = 3.2380), (OR = 6.5732) respectively. As regard E- Cadherin gene a significant hypermethylation was found in HCC group when compared to both LC and healthy groups (OR = 6.4459), (OR = 4.7850) respectively with p-value <0.0005. whereas there was no significant hypermethylation was found between LC and healthy group as regard the 3 tumour suppressor genes ($P > 0.05$). No significant association was found between methylation of the 3 genes with neither the size nor the staging of HCC ($P > 0.05$). Furthermore no Association was found between the methylation and Child Turcotte Pugh scoring system ($P > 0.05$). A significant association was found only between AFP value (>200 nl) and hyper methylated E-Cadherin in HCC group ($p = 0.036$) while no significant association was found as regard RASSF1A and RUNX 3 genes in HCC group ($p = 0.902$, $p = 0.496$) respectively. When ROC curve was applied to assess the diagnostic performance of hyper methylated RASSF1A, E-Cadherin and RUNX 3 genes in discrimination between HCC and LC it was found that at cut of levels of >0.389, >0.14 and >0.23 respectively the sensitivity was 46.36%,83.96% and 76.19% respectively and specificity was 86.7%,59.46% and 58.6% respectively.
Conclusion: The presence of hypermethylated RASSF1A, RUNX3, and e Cadherin in serum may be useful biomarkers for HCC early prediction in patients of LC with HCV.

Introduction: Hepatocellular carcinoma (HCC) is the most prevalent primary liver tumour and the third most common cause of cancer-related death. Even though a number of interventional treatment methods are currently in use, this tumour remains highly chemo-resistant and shows a poor prognosis. HCC slowly unfolds on a background of chronic liver injury, where inflammation and liver regeneration processes are involved. Toll-like receptor (TLR) derived signalling in non-parenchymal liver cells accelerates carcinogenesis by modulating inflammatory responses. Therefore, regulation of pro-inflammatory signals arises as a promising therapeutic strategy for HCC. The triggering receptor expressed on myeloid cells 2 (TREM2) acts as an anti-inflammatory receptor, as it inhibits TLR-derived signalling in various tissues, yet its role in HCC is still unknown.
Aims and Methods: This study aims to unravel the role of TREM2 in HCC development and progression. For that, TREM2 mRNA expression was analysed in liver tissue samples from patients with HCC compared to control individuals and in murine models of HCC and liver regeneration. To study the role of TREM2 in HCC development and progression, *wild type* (WT) and *Trem2*$^{-/-}$ mice were treated with the hepatocarcinogen diethylnitrosamine (DEN) and analysed at different time-points during disease development. The early molecular mechanisms triggered in response to DEN were analysed in WT and *Trem2*$^{-/-}$ mice in acute phases (6, 24, 72h). To evaluate the role of TREM2 in liver regeneration a ~70% partial hepatectomy (PHx) model was performed in WT and *Trem2*$^{-/-}$ mice, and animals were sacrificed at 1, 6, 36, 72 hours and 5 days post-surgery.
Results: *TREM2* mRNA expression is significantly upregulated in human HCC samples compared to control livers and correlates with markers of inflammation. Similarly, *Trem2* mRNA expression is also elevated in murine HCC and in a liver regeneration model compared to control livers. *Trem2*$^{-/-}$ mice show augmented tumour number and bigger tumours after DEN. This was accompanied by an increase in the expression of liver damage and hepatocyte proliferation markers. *Trem2*$^{-/-}$ mice exhibited exacerbated liver damage and ROS in acute phases in response to DEN. Regarding liver regeneration following PHx, PCNA expression and BrDU incorporation indicated an increased hepatocyte proliferation in the *Trem2*$^{-/-}$ mice. The expression of pro-inflammatory genes was also elevated in these mice. Interestingly, the results observed in the HCC model could be rescued with an anti-inflammatory diet (BHA).
Conclusion: TREM2 is upregulated in human and murine HCC and in murine liver regeneration. This anti-inflammatory receptor inhibits proliferation and HCC tumour generation in mice through the inhibition of liver inflammation and ROS. TREM2 arises as a novel therapeutic strategy for HCC.

P1313 MUSASHI 2 CONTRIBUTES TO THE MAINTENANCE OF STEMNESS OF CD44V6+ LIVER CANCER STEM CELLS VIA NOTCH SIGNALING PATHWAY

B. Cheng, **X. Wang**, R. Wang
Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Dept. of Gastroenterology and Hepatology, Wuhan, China

Contact E-Mail Address: wangxijutj@163.com

Introduction: Liver cancer stem cells (LCSC) drive hepatocellular carcinoma (HCC) recurrence and metastasis. Notch signaling pathway play crucial roles in the maintenance of stemness characteristics. Musashi 2 (Msi2), a member of conserved gene family of RNA binding protein, was highly expressed in HCC tissues correlating with poor prognosis of HCC patients. We hypothesize that Msi2 contributes to the maintenance of stemness of CD44V6+ liver cancer stem cells through activation of Notch signaling pathway via LFNG gene.
Aims and Methods: CD44v6+/− cells were isolated from human hepatoma cell lines (SNU398 and MHCC-97H) using microbeads sorting. Stem-like properties, such as self-renew and metastasis ability were analyzed in vitro and in vivo (xenograft tumor model in mice). In order to investigate the role of Msi2 gene in CD44v6+ LCSCs, we downregulated Msi2 with lentiviral particles (Lenti-ShRNA Msi2) in CD44v6+ cells, upregulated Msi2 with Lenti Msi2 in CD44v6- cells, and analyzed stem-like characteristic. Furthermore, we detected the mRNA and protein levels of Notch signaling pathway in the system above. The roles of Notch signaling pathway in the CD44v6+ LCSCs was verified by inhibiting with lentivirus or γ-secretase inhibitor (RO4929097). To explore the mechanism of Msi2 gene and Notch signaling pathway, RT^2 Profiler PCR Array was carried out after Msi2 gene was downregulated in CD44v6+ liver cancer cells, and CO-IP was used to verify the direct binding of Msi2 and LFNG gene in Notch pathway.
Results: In our study, CD44V6 could be one of the surface makers of liver cancer stem cells. CD44V6+ cells expressed more Msi2, compared with CD44V6- cells. We demonstrated that downregulating Msi2 in CD44V6+ CSCs could decrease the ability of self-renewal, invasion and migration, proliferation, tumorigenicity and the expression of stemness-associated genes. Meanwhile, upregulating Msi2 in CD44V6- cells increased the ability of self-renewal, invasion and migration, chemotherapy resistant and tumorgenicity. In CD44v6+ cells, the key molecules of Notch signaling pathway down-regulated after Msi2 gene was down-regulated, while in the CD44v6- cells the key molecules up-regulated after increasing Msi2 gene. Furthermore, the self-renewal ability and tumorigenicity of CD44v6+ cells was obviously decreased after inhibiting notch signaling pathway. Last but not the least, according to the result of RT^2 Profiler PCR Array, Msi2 contributes to the maintenance of stemness of CD44V6+ liver cancer stem cells via activation of Notch signaling pathway by binding to LFNG.
Conclusion: Msi2 play an important role in the maintenance of stemness of CD44V6+ liver CSCs. Msi2 contributes to the maintenance of stemness of CD44V6+ liver cancer stem cells through activation of Notch signaling pathway via binding directly to LFNG. Our study provided a new insight to the recurrence and metastasis of HCC and potential molecular targets for targeted therapy for liver cancer.

Introduction: MicroRNA-195 (miR-195) plays an important role in many types of tumors. However, the roles of WEE1 in cancer and miRNAs that directly regulate WEE1 have not been elucidated. The purpose of this experiment is to assess

the effects of miR-195 on inhibiting WEE1 and to clarify the regulating mechanism of miR-195 in pancreatic cancer.
Aims and Methods: Real-time fluorescence quantitative PCR was used to detect the expression of miR-195 in HCC tissues and adjacent normal tissues from 36 cases. We also detected the expression level of miR-195 in eight human hepatoma cell lines including HepG2, Huh7, PLC/PRF/5, SMMC-7721, SK-HEP-1, MHCC97-H, MHCC97-L and Hep3B, as well as in human normal liver cell lines L02 and Chang liver. The effect of miR-195 and siWEE1 on cell viability was evaluated using cck-8 assays, apoptosis levels were determined using FACS analysis of Annexin V/PI stained cells, and target protein expression was determined using western blot. To investigate the potential anti-tumor activity of miR-195 in vivo,we constructed Tumorigenesis assay in nude mice.
Results: We found that miR-195 was downregulated in HCC cell lines and tissues. We also found that over-expression of miR-195 could suppress the proliferation and increase the apoptosis of HCC cell line. Knockdown of WEE1 by RNAi in HCC cells, similar to miR-195 overexpression, decreased liver cancer cell growth and induced apoptosis. In a mouse model, therapeutic administration of miR-195 mimics could significantly suppress the growth of hepatoma xenografts in nude mice.
Conclusion: MicroRNA-195 increases apoptosis in hepatocellular carcinoma by targeting the key cell cycle regulator WEE1. This finding suggests a potential novel strategy for therapeutic interventions of this disease.

Introduction: The development and progression of hepatocellular carcinoma (HCC) is a multistage process involving the deregulation of genes that are crucial to cellular processes. Multiple risk factors are correlated with HCC. MicroRNA is differentially expressed in development of different types of malignancies, including hepatic malignancy. Single nucleotide polymorphisms (SNPs) are the most common sequence variation in human genome. SNPs in miRNAs may affect transcription, processing or target recognition and result in malignant diseases.
Aims and Methods: We aimed to determine the association between micro-RNA gene polymorphisms and development of HCC in Egyptian Patients.
This study included 200 individual who were matched in age and sex. Tumor staging was done using BCLC staging system. Quantification and genotyping of Micro-RNA were performed.
Results: Among the 200 patients, 2 groups were described: group I included 90 HCC patients with a male majority (72.2%) and 110 controls in group II. Diabetes and hypertension were detected as risk factors. Three microRNA SNPs were assayed. There was a significant association between rs10061133 miR-499b and the risk of HCC. The genotypes GG or G allele were associated significantly to an increased risk of HCC (GG: OR (95% CI) = 2.91 (1.23–4.22), p = 0.013; G allele: OR (95% CI) = 1.79 (1.12- 2.15), p = 0.026) compared with the genotype of AA or AG or A allele.
Conclusion: There is an association between the mi-RNA SNPs and the susceptibility to HCC, aiming to explore some roles and mechanisms of SNPs within miRNAs in the occurrence and development of HCC.

Introduction: Hepatocellular carcinoma (HCC) mostly arises from underlying chronic inflammatory liver disease. Periostin is one of the matricellular proteins and the association of periostin with inflammation or tumor invasiveness and prognosis has been reported. We investigated a role and mechanism of periostin in the development of liver cancer.
Aims and Methods: Hep3B cells, a human hepatocellular carcinoma cell line, were used. Cell growth was assessed using the MTS assay and epithelial-mesenchymal transition signaling was explored by immunoblot analysis. Male wild type or periostin -/- mice (C57BL/6, 8 weeks old) were injected with diethylnitrosamine (DEN, 100mg/kg at week 8) and tetrachloride (CCl4, 1mg/kg biweekly from week 10~50) intraperitoneally to induce liver inflammation, fibrosis and tumor. Anti-tumor effects were evaluated by number of tumors and histopathological examination.
Results: Cell proliferation did not show significant change in Hep 3B cells treated with recombinant periostin or periostin siRNA. Recombinant periostin (50nM) promoted cell migration and invasion in Hep3B cells. E-cadherin expression was decreased while N-cadherin expression was increased in recombinant periostin-treated Hep3B cells. Recombinant periostin also induced JNK expression and inhibition of JNK signaling restored N-caderin expression. Compared to wild type mice, the number of hepatic tumors was significantly lower in periostin -/- mice.
Conclusion: Periostin may play a role in the tumorigenesis through epithelial-mesenchymal transition and is suggested as a potential target for the treatment of liver cancer.

Introduction: Transcription factors of the p53 family (p53, p63, p73) respond to cellular stress signals by inducing a defined set of target genes. In tumors such as hepatocellular carcinoma (HCC) they exert tumorsuppressive functions. p63 is known as a tumor suppressor with an important role in the development of epithelia and in epithelial mesenchymal transition, a process that results in metastasis of primary cancer. However, the role of p63 in the development of HCC is yet unknown. microRNAs (miRNAs, miR) are small non coding RNA molecules that control gene expression by binding to target mRNAs and inhibit their translation. Expression profiles of miRNAs can be regulated by p53-family members. In previous studies we identified a set of p53-regulated miRNAs in HCC (miR34a, miR149, miR192 and miR194). It is known that miRNA 34a can be induced by p53 and – in turn – exerts its tumorsuppressive functions by stabilizing the robustness of p53 responses to genotoxic stress. p63 has been shown to influence miRNA levels in squamous cell carcinoma (SCC) and a number of other epithelial carcinomas, but little is known about the role of p63 in miRNA regulation in HCC.
Aims and Methods: The aim of this study was to evaluate whether miRNA profiles in HCC cells are regulated by p63. p53-deficient Hep3B cells were transfected with rAd-p63 or rAd-GFP. Expression of miR34a, mir145, miR149, miR192 and miR194 was determined by qPCR. To analyse effects of HCC-relevant therapeutics on p63-dependent microRNA regulation transfected Hep3B cells were treated with HCC-relevant local and systemic therapeutics (doxorubicin, sorafenib, bleomycin, tivantinib and regorafenib) for up to 72 hours in concentrations corresponding to the serum levels of patients undergoing therapy.
Results: Overexpression of p63 resulted in a moderate increase of miR34a (1.9-fold) and miR149 (1.96-fold) and a stronger induction of miR192 (3.85-fold) and miR194 (5.25 fold) after 24h. In untransfected cells, *in vitro* incubation with HCC-relevant therapeutics had no effect on expression levels of the analysed miRNAs. However, in combination with p63 overexpression miRNA was strongly induced by the used drugs. 72h *in vitro* incubation with doxorubicin resulted in an increase of p63-dependent expression of miR34a (2.64-fold), miR149 (2.63-fold), miR192 (2.11-fold) and miR194 (1.91-fold) compared to rAd-transfected controls. Bleomycin increased p63-dependent miR34a expression by 4.29-fold. Sorafenib had a moderate increasing effect on p63-dependent miR34a expression (2.44-fold). Treatment with Tivantinib increased p63-dependent expression of miR192 by 2.42 fold and miR194 by 3.6 fold. Regorafenib displayed a moderate effect on p63-dependent expression of miR34a (2.06 fold) and miR149 (1.64 fold) after 72h. Interestingly, in combination with p63 overexpression systemic drugs showed a stronger impact on miR192 and miR194, while local treatment predominantly increased levels of miR34a and miR149.
Conclusion: This study demonstrates for the first time a p63-dependent induction of tumorsuppressive miRNAs in HCC. Furthermore, these results indicate that p63 interacts with HCC-relevant therapeutics to control expression profiles of specific microRNAs in HCC. This finding provides further understanding of the complex regulatory network by which p53 family members exert their tumorsuppressive functions in HCC.

P1318 P73 AND TIVANTINIB COOPERATE TO ORCHESTRATE EXPRESSION OF TUMORSUPPRESSIVE MICRORNAS IN HEPATOCELLULAR CARCINOMA

L. Kaser, E. Aschenbrenner, K. Pollinger, C. Kunst, M. Müller-Schilling
University Hospital Regensburg, Department of Internal Medicine I, Regensburg, Germany

Contact E-Mail Address: lisa.kaser@stud.uni-regensburg.de
Introduction: Hepatocelluar carcinoma (HCC) is the third leading cause of cancer deaths worldwide. Like in many other tumor entities, the p53 family of tumor suppressor proteins plays an important role in this disease. p53 is the best analyzed member of this family and belongs to the most frequently mutated genes in human tumors. However, besides p53, the p53-family of transcription factors

comprises also p63 and p73 with their different splice variants. Although p63 and p73 share a variety of tasks with p53, such as regulating cellular stress responses, they can also exert independent functions. Depending on their splice variants – with transactivation domain (TA)/dominant negative (DN) – and the characteristics of the particular binding site p53 proteins activate or inhibit specific target genes directly *via* promotor-binding or indirectly, *e.g. via* regulation of microRNAs. microRNAs are small, non-coding RNA-molecules with a length of about 22 nucleotides, which play an important role in gene regulation. They can exert tumor suppressive or oncogenic functions and many of them are known to be induced or repressed by the p53-familiy in different cancer entities. For instance, microRNA 34a can be induced by p53 and – in turn – exerts its tumor-suppressive functions by stabilizing the robustness of p53 responses to genotoxic stress.

Aims and Methods: So far, little is known about p73-controlled microRNAs in HCC. The aim of this study was therefore to analyze regulation of microRNAs in HCC cell lines by TAp73 and DNp73 and effects of the HCC-relevant therapeutic drug tivantinib. p53-deficient Hep3B cells were transfected with adenoviral vectors rAd-TAp73, rAd-DNp73 or rAd-GFP to induce overexpression of p73 isoforms. Cells were stimulated with 5.4 μM of tivantinib or DMSO for up to 72 hours. Expression profiles of microRNA (miR) miR-34a, miR-145, miR-149, miR-192 and miR-194 were examined by qPCR.

Results: In non-transfected cells tivantinib treatment induced an increase of all mentioned tumor suppressive microRNAs by up to 3.6-fold compared to DMSO-treated controls after 48h. Overexpression of DNp73 did not substantially alter microRNA expression profiles in the presence or absence of tivantinib. In contrast, overexpression of TAp73 in the absence of tivantinib had strong inductive effects on the expression of miR-34a (5.0-fold) and miR-149 (8.1-fold) after 72 hours compared to GFP-transfected cells, whereas the expression levels of miR-192 and miR-194 remained unchanged. Notably, a combination of TAp73 overexpression and tivantinib treatment was most effective, resulting in further enhanced microRNA expression rates of miR-34a (9.4-fold) and miR-149 (14.9-fold) compared to rAd-GFP-transfected and DMSO-treated cells after 72h.

Conclusion: TAp73 is an important regulator of tumor suppressive microRNA expression in Hep3B cells. Combined effects of TAp73 overexpression and tivantinib treatment result in a strong induction of miR-34a and miR-149. In contrast, DNp73 did not influence these targets, highlighting the differencial target gene regulation by TA and DN-isoforms.

HCC systemic therapies are rare and characteristics and pathways of most of the used drugs are not well understood. In this study we now provide evidence for regulation of tumorsuppressive microRNAs by a combination of tivantinib and TAp73 overexpression, suggesting novel therapeutic and prognostic options for HCC therapy.

Introduction: Several major risk factors for hepatocellular carcinoma (HCC) have been identified, including chronic infection of hepatitis B virus (HBV) and hepatitis C virus (HCV). Nevertheless, only a fraction of infected patients develops HCC during their lifetime suggesting that genetic factors might modulate HCC development. X-ray repair cross complementing group 1 (XRCC1) participates in the base excision repair pathway of DNA.

Aims and Methods: We aimed to investigate the association of X-ray repair cross complementing group 1 (XRCC1) gene polymorphism with HCC in Egyptian population.

This study was assessed on 40 patients with HCC and 20 cirrhotic patients on top of HCV and 40 age and gender-matched healthy subjects as control group. After collection of relevant clinical data and basic laboratory tests, c.1517G[C SNPof XRCC1 gene polymorphism was performed by (PCR-RFLP) technique.

Results: Our study revealed statistical difference in XRCC1 (CC, GC) genotypes with increased (C) allele frequency in patients with HCC in comparison with cirrhotic patients as well as control group. In addition, patients with CC, GC genotypes showed significant higher number and larger size of tumor foci and significantly higher Child Pugh grades. The multivariate analysis showed that the presence of c.1517G[C SNPof XRCC1 gene is an independent risk factor for the development of HCC in chronic HCV patients with 3.742 folds increased risk of HCC development.

Conclusion: XRCC1gene polymorphism could be associated with increased risk of HCC development in chronic HCV-infected Egyptian patients.

Introduction: Polycyclic aromatic hydrocarbons (PAHs) are among the most carcinogenic, mutagenic and toxic contaminates. Their exposure and metabolism to DNA-reactive metabolites in the body are considered to contribute to the etiology of many types of the human cancers.

We aimed to find out if exposure to polycyclic aromatic hydrocarbons is a risk factor for development of hepatocellular carcinoma among the exposed cases of chronic active hepatitis B and/C.

Aims and Methods: A case-control study was conducted between the periods from the first of March 2015 to end of August 2017. The study was conducted in the outpatient clinic of the Department of Hepatology and Gastroentrology at Theodor Bilharz Research Institute (TBRI), Cairo, Egypt. The minimum sample size required for the present study was calculated using Epi info program, considering the following data: two sided Confidence level = 95%, Power of test = 80%, Ratio of control: cases = 1:1, Percent of control exposed = 21%, Percent of cases exposed = 42% and Odds ratio = 2.8. Estimated number of cases was (77 cases with HCC on top of chronic active hepatitis B and/C) and (77 controls without HCC but suffering chronic active hepatitis B and/C). All subjects of both groups were subjected to the selected interview medical sheet and to biological monitoring of urinary for 1-hydroxy pyrene as a biomarker for PAHs exposure.

Results: 73% of cases of HCC have been found with increased level of 1-hydroxy pyrene in urine with statistical significance difference when compared to the controls, there was significant positive association between exposure to PAHs and development of HCC among cases group (OR = 4.9). There was significant association among the cases group between smoking and abnormal high level of 1-hydroxy pyrene in urine (OR = 1.7). There was significant positive association between exposure to PAHs and development of HCC among males (OR = 1.6). There was a highly positive correlation between 1-hydroxy pyrene and Alfa Feto Protein (AFP) among positive cases of 1-hydroxy pyrene in cases group.

Conclusion: PAHs might be a risk factor for developing HCC among cases of chronic active hepatitis B and/C. 1-hydroxy pyrene in urine could be an early indicator of HCC among cases of chronic active hepatitis B and/C.

Introduction: Alpha-fetoprotein (AFP) is the most widely used serum biomarker for hepatocellular carcinoma (HCC), despite its limitations. Alpha-fetoprotein-L3 (AFP-L3), protein induced by vitamin K absence (PIVKA-II) and Glypican-3 (GPC-3) have been proposed as complementary biomarkers.

Aims and Methods: This study aimed to investigate the diagnostic performance of AFP, AFP-L3 PIVKA-II, and GPC-3 as single or in combination to seek the best biomarker or panel, and to investigate the clinical factors affecting their performance for hepatocellular carcinoma (HCC) diagnosis in patients admitted to a transplant center from Romania.

From March 2016 to October 2017 we prospectively included a number of 153 patients, 101 were with HCC and 52 control patients with liver cirrhosis. Serum levels of AFP, AFP-L3, PIVKA-II and GPC-3 were measured by ELISA and clinicopathological features were determined for all subjects. To compare the diagnostic value in distinguishing HCC from nonmalignant chronic liver disease, receiver operating characteristic (ROC) curves were performed for each biomarker and for every combination of two to four markers.

Results: Of the four biomarkers, AFP-L3 showed the highest area under the curve (0.85). The sensitivity and specificity for each single biomarker was 55.6% and 99% (AFP >18.9ng/mL), 86.1% and 58.3% (PIVKA-II >63 mAU/mL), 86.1% and 72.7% (AFP-L3 >13.5 ng/mL), and 77.8% and 75.0% (GPC-3 >466ng/mL), respectively. The area under the curve was 0.75 for PIVKA-II, 0.79 for AFP and 0.77 for GPC-3 for HCC diagnosis.

Among the combinations of two biomarkers, AFP >18.9ng/mL and AFP-L3 >13.5ng/mL showed the best diagnostic performance with an area under the curve of 0.93. Triple or quadruple combination did not improve the diagnostic performance further. The patient's age, etiology and tumor invasiveness of HCC affected the performance of each marker.

There was a moderate significant correlation between initial PIVKA-II value and maximum diameter of the tumoral nodule ($r = 0.50$, $p = 0.001$), but no correlation between AFP value and tumoral diameter.
Conclusion: AFP-L3 was the most useful single biomarker for HCC diagnosis, and the combined measurement of AFP and AFP-L3 could maximize the diagnostic yield. PIVKA-II has a better correlation with tumor size compared AFP. Clinical decision should be based on the consideration of different factors affecting the diagnostic performance of each biomarker. Efforts to seek novel HCC biomarkers should be continued.

Introduction: Hepatocellular carcinoma (HCC) is a major cause of cancer mortality worldwide. The outcome of HCC depends mainly on its early detection. Alpha-fetoprotein (AFP) is the currently available marker for HCC diagnosis. Talin-1 was previously proposed as a potential novel biomarker for HCC diagnosis but with a limited and inconsistent data.
Aims and Methods: We aimed to study the possible role of Talin-1 in diagnosis and prognostic stratification of patients with hepatocellular carcinoma.
In this prospective study, we recruited 96 patients from Ain Shams University hospitals' clinics and inpatient department, then classified them into three groups; 1) Cirrhosis group: 40 patients with liver cirrhosis without HCC, 2) HCC group: 40 patients with liver cirrhosis and HCC as diagnosed by triphasic CT, 3) Control group: 16 healthy volunteers, with matched age and gender. Talin-1 was detected using enzyme linked immunosorbent assay (ELISA).
Results: The highest level of Talin-1 was observed among HCC group followed by cirrhosis then control groups (25 vs. 12 vs. 1.9 ng/ml; $p \leq 0.001$) respectively. *In cirrhosis and HCC groups*; we found a significant positive correlation between Talin-1 and ALT, AST, ALP, Bilirubin, INR, urea and AFP ($p \leq 0.001$), and a significant negative correlation between Talin-1 and albumin, creatinine, hemoglobin, WBCs and platelets ($p \leq 0.001$), and no significant differences were found regarding sex, anti HCV and HBsAg ($p > 0.05$). *In HCC group*; significant correlation was found between Talin-1 and each of multifocal HCC (29.5 vs. 23 ng/ml; $p = 0.013$), portal vein invasion (27 vs. 21 ng/ml; $p = 0.022$), and presence of ascites (27 vs. 20 ng/ml; $p = 0.001$), no significant correlation was detected with tumor size ($p = 0.605$). ROC curve analysis was used to test the performance of Talin-1 and AFP for cirrhosis diagnosis; Talin-1 at 6.2 ng/ml cutoff level had 90% sensitivity, 93.75% specificity and AUC = 0.980, while AFP at 2.5 ng/ml cutoff level had 92.50% sensitivity, 87.50% specificity and AUC = 0.969. By combining both markers, the sensitivity was 95% with 100% specificity. As regard discrimination between HCC and cirrhosis groups; Talin-1 at 14 ng/ml cutoff level had 100% sensitivity, 65% specificity and AUC = 0.858, while AFP at 15 ng/ml cutoff level had 100% sensitivity, 100% specificity and AUC = 1.000. After combining both markers, sensitivity and specificity were 100%.
Conclusion: Talin-1 is a potential marker for diagnosis and prognostic assessment of both cirrhosis and HCC. Measuring both serum Talin 1 and AFP levels enhance the diagnostic sensitivity in early detection of HCC. Further studies are needed to investigate the ultimate diagnostic and prognostic utility of serum Talin-1.

Introduction: Hepatocellular carcinoma (HCC) is a common cause of worldwide mortality. Sorafenib represents the elective treatment for advanced stage HCC according to the Barcelona Clinic of Liver Cancer classification. However, its tolerability is suboptimal due to adverse effects and liver function deterioration. In the last years, transarterial radioembolization (TARE) with Yttrium-90 microspheres has been proposed for both intermediate HCC poorly responsive to transarterial chemoembolization (TACE) and locally-advanced HCC with segmental or lobar portal vein thrombosis (PVT).
Aims and Methods: The study aim was to evaluate efficacy and safety of TARE in HCC patients. A secondary aim was to confirm the treatment utility in special situation, i.e. tumors complicated by PVT and bridge to liver transplant. From November 2015 to April 2018 20 consecutive patients (M = 19, F = 1, median age 71 [24–85] years) with HCC were selected for TARE by the multidisciplinary HCC board. TARE was performed using 90Y glass microspheres. Tumor response was assessed using computed tomography or magnetic resonance at 3 months evaluated according to modified Response Evaluation Criteria in Solid Tumor.
Results: Among 20 patients treated with TARE, 1 (5%) had early, 10 (50%) intermediate and 9 (45%) advanced stage HCC. HCCs were firstly diagnosed 18 (range 2–96) months before TARE. All patients except three underwent previous treatments for HCC (median number of treatments 2, range 0–6). Other baseline features were: aetiology: hepatitis virus in 7 (35%), alcohol in 7 (35%), multiple in 6 (30%); Child-Pugh class A in 17 (85%), B7 in 3 (15%); median MELD score 7.5 (IQR 6.5–8); pathologic type: unifocal in 7 (35%), multifocal in 13 (65%); PVT in 9 (45%); comorbidities in 17 (85%); performance status: 0 in 7 (35%), 1 in 13 (65%). Only one patient presented side effects: ascites easily controlled with medications. Imaging evaluation at 3 months was performed in 19 patients. Complete response occurred in 13 (65%), partial response in 3 (15%), while progression was seen only in 3 cases (15%). During a median clinical follow-up of 13 months 2 patients repeated TARE due to partial response, 4 underwent TACE and 1 radiofrequency thermoablation due to recurrence of HCC and 2 patients underwent liver transplantation after successful down-staging. Death occurred in 10 patients: 7 died of hepatic failure due to HCC progression, the remaining 3 died of hepatorenal syndrome, heart failure and gastrointestinal bleeding. Median progression free survival and overall survival were respectively 12 and 16 months. HCC patients with or without PVT had no difference in overall survival (median overall survival 14 months in patients with PVT and 25 months in patients without PVT, log-rank test $p = 0.33$).
Conclusion: TARE was a valid and safe treatment option in patients with intermediate-advanced HCC stages even in the presence of PVT. Good median survival and no severe adverse effects were seen in this group. TARE was a suitable procedure for elderly comorbid patients and also led to down-staging, potentially allowing liver transplantation.
Disclosure: Nothing to disclose

P1324 RISK OF AGGRESSIVE/ADVANCED HEPATOCELLULAR CARCINOMA DEVELOPMENT AFTER DIRECT ACTING ANTIVIRAL THERAPY IN PATIENTS WITH HCV-RELATED CIRRHOSIS

Introduction: Hepatocellular carcinoma (HCC) represents a serious complication of HCV-related cirrhosis. Introduction of direct acting antiviral (DAA) agents achieved high sustained viral response (SVR) rates of 90–95%, however, various reports have showed different results regarding risk of HCC development after DAA treatment, moreover data on the risk of developing aggressive or advanced HCC in DAA-treated patients is still unknown and needs to be assessed.
Aims and Methods: Our aim was to compare the patterns of HCC developed after DAA treatment to HCC patterns in patients who did not receive DAA. Methods: we conducted a retrospective study on 137 patients presented to the HCC clinic at our institute over the period of 2 years. 88 patients were included in the study and 49 were excluded due to insufficient DAA treatment details. The patients were divided into 2 groups according to receiving DAA including "DAA-treated" group with patients who received DAA and "DAA-non-treated" group with those who didn't receive DAA. Dynamic contrast enhanced CT/MRI were used to classify HCCs according to their size, number and presence of tumor vascular invasion (TIV) into: I) Early/non-aggressive (NA-HCC) defined as either single lesion < 5 cm or ≤ 3 lesions all of which ≤ 3 cm in diameter and absence of tumor vascular invasion, and II) Advanced/aggressive patterns (A-HCC) defined as either single lesion > 5 cm, ≤ 3 lesions with any > 3 cm, or > 3 coexisting lesions (multicentric), or infiltrative HCC pattern ± presence of TIV.
Results: Our study included 69 males and 19 females, with a mean (±SD) age of 60.2(±8.48). The onset of HCC presentation in DAA-treated group had a median (IQR) value of 7(12.6) months after end of treatment. The DAA-treated group showed significantly higher frequencies of A-HCC patterns on presentation as compared to the DAA-non-treated group ($\chi^2 = 8.17$, $p = 0.004$), with a higher risk of presence of A-HCC patterns after DAA therapy (RR = 0.67, CI 95% = 0.15–1.42). The treated group also showed higher frequencies of presence of TIV as compared to the DAA-non-treated group ($\chi^2 = 7.016$, $p = 0.008$) with a significantly higher risk of presence of TIV after DAA therapy (RR = 3.18, CI 95% = 0.26–12.8). Among the DAA-treated group 27 achieved SVR and 16 were DAA relapsers, yet no significant correlation was found between DAA relapse and presence of A-HCC patterns ($p = 0.948$).

	Study group: n = 88 (100%)		p value
	DAA-non-treated n = 45 (51.1%)	DAA-treated n = 43 (48.9%)	
Gender			
Male	34 (75.6%)	35 (81.4%)	

(continued)

Continued

	Study group: n = 88 (100%)		p value
Female	11 (24.4%)	8 (18.6%)	
Early/low-aggression	25 (28.4%)	11 (12.5%)	**0.004 ($\chi2 = 8.172$)**
Advanced/Aggressive	20 (22.7%)	32 (36.4%)	
TIV	3 (3.4%)	12 (13.6%)	**0.008 ($\chi2 = 7.016$)**
Relapse after treatment		16	
SVR		27	
De novo lesion		41	
Recurrent lesion		2	

[Table (1): Descriptive data of the study group]

Conclusion: In our study we showed a higher relative risk of presence of advanced/aggressive patterns and/or TIV at time of HCC presentation following DAA treatment as compared to DAA-non-treated patients.

Introduction: Hepatocellular carcinoma (HCC) is the third leading cause of cancer-related death worldwide, with most of the patients beeing diagnosed at intermediate to advanced tumour stages, at which therapy options are limited. TACE is the most used palliative treatment modality in this setting.

Aims and Methods: To investigate the predictive factors for complete response (CR) and recurrence after CR in patients with hepatocellular carcinoma (HCC) treated with transarterial chemoembolization (TACE).

From January 2013 to December 2017 we enrolled 168 newly diagnosed patients with HCC who were treated with TACE as a first therapy. We analyzed the predictive factors for CR and the risk factors for local and distant recurrence after CR using Cox proportional hazard model.

Results: The mean age of the patients was 62.2 ± 7.9 years. There were 115 male patients (68.4%) and 53 females (31.5%). Eighty-eight patients had an α-feto-protein (AFP) level >20 ng/mL. The median maximal diameter of the tumors was 3.5 cm. The median follow up period was 27.6 months. Sixty-three patients (37.5%) achieved CR after TACE, and recurrence after CR was detected in 37 patients (58.7%). In univariate analysis elevated serum AFP (>20 ng/mL) level (hazard ratio [HR], 1.985; 95% confidence interval [CI], 1.0477 to 3.7570; $p = 0.0355$), tumor size (>5 cm) (HR, 3.558; 95% CI, 1.3478 to 9.3809; $p = 0.0104$), multinodularity (HR, 5.0682; 95% CI, 2.2703 to 11.3144; $p < 0.001$) were correlated with CR after TACE. In multivariate analyses, tumor size (≤ 5 cm) and single nodularity were predictive factors for CR, with hazard ratios (HRs) of 2.56 ($p = 0.0330$) and 2.87 ($p = 0.002$), respectively. From the total 63 patients with CR, 55 patients had tumor size ≤ 5 cm, and only 8 patients (12.69%) had a tumor size >5 cm. Fifty-one patients (80.9%) had a single nodule and 12 patients (19%) showed multiple nodules. In patients with recurrence after CR, in univariate analysis, multinodularity (HR, 8.226; 95% CI, 0.9353 to 72.3505; $p = 0.475$) and elevated serum AFP (>20 ng/ mL) level (HR, 2.995; 95% CI, 0.4557 to 14.9057; $p = 0.0541$) were associated with HCC recurrence. In multivariate analysis only multinodularity (HR, 3.835; 95% CI, 1.452 to 12.961; $p = 0.0325$) was associated with HCC recurrence after TACE-induced CR. Of the 63 patients with CR, 11 patients (17.4%) had multinodularity and 22 patients (34.9%) had elevated serum AFP (>20 ng/mL) level. The recurrence rate of multinodularity (11/12 patients) was higher than that of single nodularity (26/51 patients) (91.6% vs 50.9%; $p = 0.02$). The recurrence rate of patients with elevated serum AFP (>20 ng/mL) level (18/23 patients) was higher than that of patients with normal serum AFP (≤ 20 ng/mL) level (19/40 patients) (78.2% vs 47.5%; $p = 0.03$).

Conclusion: In patients treated with TACE as a initial therapy, tumor size (≤ 5 cm) and single nodularity were predictive factors for CR. Multinodularity was a predictive factors for recurrence after CR. After achieving CR the median time period to recurrence was 12 months.

Contact E-Mail Address: giulia88.fish@gmail.com

Introduction: The Barcelona Clinic Liver Cancer (BCLC) algorithm, adopted by the EASL (European Association for the Study of the Liver) guidelines, predicts prognosis and suggests treatmernt options in HCC.

Aims and Methods: This study aimed at evaluating the 5 cm cut-off, as adopted in the Milan Criteria, to correctly stage and treat monofocal HCC. Firstly, 2615 patients with a diagnosis of Monofocal HCC were selected from the 6476 patients of the ITA.LI.CA database (2001–2014); following that,1623 Monofocal HCC, excluding the "Very early" subgroup, stratified by diameter (1345 small HCC, $>2/\leq 5$cm, and 278 large HCC, >5cm), were analysed. Among them, 1087 were "Early" Monofocal HCC. The Monofocal (overall) and the "early" HCCs were compared to 1048 BCLC B stage HCC and sub-grouped according to the adherence to the guidelines for resection. Statistics included chi-square, Kaplan-Meier (Log-rank) and Cox multivariate analysis.

Results: Overall median survival was 38 months (Confidence Interval – C.I. – 36–41), with 49 months (C.I.: 45–53) in small "EARLY" HCC and 31 in large "EARLY" HCC (C.I.: 25–44) ($p < 0.0001$). At multivariate analysis size and treatment were the most important indipendent predictors of survival for both Early and Monofocal HCC overall, while CHILD status, performance status and cancer-related events ($>$AFP, PVT, ascites) were the best independent prognostic factors in Monofocal, such as in the original BCLC classification. Resection was associated with the longest survival, regardless of diameter, both in the Monofocal HCC overall and in the subgroup of "Early" single node HCC, with the obvious exception of liver transplant. Among resected patients, the median survival of BCLC B HCC was 44 months (C.I.: 30–55), significantly shorter from the small EARLY HCC survival ($p < 0.0001$), but not from the large EARLY HCC survival ($p = 0.9389$, HR = 1.016 with C.I.: 0.680–1.518). Sameresults were obtained considering Monofocal HCC overall.

Conclusion: The 5 cm cut-off – according to the Milan criteria – stratifies Monofocal ("Early" or not) HCC in two categories different in features, survival, predictors and therapeutic choices. Single HCC >5 cm has a median survival comparable to BCLC B HCC. In Monofocal and "Early" monofocal HCC, surgery correlates with the longest survival; although the best survival is reached in small HCC, resection should be recommended also in the large tumours, due to the best survival achievable, even though these are characterized by much lower survival. Tumor burden has a heavier impact on survival than "adherence to the guidelines".

Introduction: Biliary bacteria play an important role in the pathogenesis of choledocholithiasis, but at present there are very few studies about the biliary microbiota. Our previous studies observed great bacterial community heterogeneity among patients and provided evidence for the potential source of biliary bacteria. However, the sample numbers of both studies were small due to the difficulty of sample collection. Besides, the medication history (i.e. the recent antibiotics treatment) might also lead to bias in the composition of bacterial communities. Thus, the biliary microbiota of a larger scale of choledocholithiasis patients, especially those with no recent antibiotics treatment, still needs further investigations.

Aims and Methods: This study aimed at the biliary microbiota of a larger scale of patients diagnosed with common bile duct stones. Bile samples from the common bile duct of primary choledocholithiasis patients were collected by ERCP. These patients had no other infections and did not receive antibiotics for at least one month before ERCP. They were divided into two groups: group NN, the first treatment ones, no recent antibiotics use with no endoscopic sphincterotomy (EST) history; group NE, the recurrent ones, no recent antibiotics use with a EST history. Eventually, group NN contained 33 patients and group NE contained 19 ones. 16S amplicon sequencing was employed to analyze the biliary microbiota. Predictive functional analysis was also performed.

Results: 1) At the phylum level, *Proteobacteria*, *Firmicutes*, *Bacteroidetes*, *Fusobacteria* and *Actinobacteria* were identified in both groups with a total relative abundance ≥ 0.87. At the genus level, the abundance of *Escherichia/Shigella* was the highest in both groups (NN = 0.27 and NE = 0.17), The average relative abundances of *Pseudomonas*, *Streptococcus*, *Enterococcus*, *Prevotella*, *Neisseria*, *Klebsiella*, *Fusobacterium*, *Granulicatella*, *Veillonella*, *Aeromonas*, *Bacteroides* and *Pyramidobacter* were greater than 0.01, which was consistent with our previous studies.

2) Analysis of similarity using Bray-curtis distance showed that the microbiota dissimilarity of intra-group was significantly lower than that of inter-group. The similarity of the bacterial communities between samples within group NN was

significantly higher than that within group NE ($P = 0.003$). Principal coordinate analysis (PCoA) results revealed that there were differences in the microbial composition between the two groups. Compared with group NN, the relative abundances of *Pseudomonas*, *Neisseria*, *Ochrobactrum*, *Actinomyces* and *Rothia* in NE group were decreased, while the abundances of *Pyramidobacter*, *Akkermansia* and *Porphyromonas* were increased (all $P < 0.05$). These bacteria were also confirmed by our previous studies.
3) The relative abundances of KEGG pathways in the biliary microbiota were predicted by PICRUSt. Compared with group NN, the abundances of pathways such as Peptidases, Energy metabolism and Lipopolysaccharide biosynthesis were increased in group NE, while that of the Glutathione metabolism pathway was decreased (all $P < 0.05$).
Conclusion: 1) Both groups had common kinds of bacterial taxonomic units, which indicates the shared pathogenesis of them. 2) EST may affect the composition of the biliary microbiota. 3) *Pyramidobacter*, *Akkermansia* and *Porphyromonas* may play key roles in the recurrence of choledocholithiasis. 4) The Peptidases, Energy metabolism and Lipopolysaccharide biosynthesis pathways might be involved in choledocholithiasis recurrence.

Contact E-Mail Address: xiaopengt58@126.com
Introduction: Obstructive jaundice (OJ) is a condition that might lead to acute cholangitis and sepsis and multiorgan dysfunction, especially after surgical procedures. Intestinal mucosal barrier dysfunction and intestinal immune function decline might result in endotoxemia and intestinal bacterial translocation, which are important contributors to disease progression or death in patients. As one of the main effector cells of the intestinal mucosal barrier, paneth cell have several natural antibiotic peptides in their endocrine granules. Cell degranulation can be induced under certain conditions. The diversity of stimulants and cell endocrine particles suggests that paneth cell may play important roles in the construction of intestinal mucosal epithelial cells and the defense mechanism of host intestinal tract.
Aims and Methods: We aimed to investigate the functional changes of paneth cell in the intestinal epithelium of mice with OJ and after internal and external biliary drainage.
The experiment was divided into two stages. First stage: a total of 100 male C57BL/6J mice were randomly assigned to two groups: (I) sham operation (SH); (II) obstructive jaundice (OJ). The mice were respectively sacrificed before operation and on the 1st, 3rd, 5th and 7th days after operation to collect blood and terminal ileum specimens. Second stage: a total of 40 male C57BL/6J mice were randomly assigned to four groups: (I) SH; (II) OJ; (III) OJ and external biliary drainage (ED); and (IV) OJ and internal biliary drainage (ID). The animals underwent surgical ligation of the bile duct on day 0. They were reoperated on day 5 for biliary drainage procedure. Blood and terminal ileum specimens were collected on day 10. Various indicators were detected by Real-time PCR, immunohistochemistry, Western blot and other methods.
Results: The number of paneth cell and expression of lysozyme and cryptdin 4 were increased first and then decreased over time in OJ group, and the difference was statistically significant ($p < 0.05$). however, no obvious difference was found in different time points of the SH group ($P > 0.05$). The grade of mucosal injury, the level of plasma DAO and the rate of bacterial translocation increased gradually in the OJ group with the extension of time ($p < 0.05$). In addition, there were negative correlations between the level of plasma DAO and expression of lysozyme ($r = -0.729$, $p < 0.05$) and cryptdin-4 ($r = -0.718$, $p < 0.05$) in OJ group. After the secondary operation in mice to relieve OJ, the number of paneth cell and expression of lysozyme and cryptdin 4 were increased in ID group and ED group than that in OJ group, and more significant in ID group than that in ED group, with statistical differences ($p < 0.05$). In addition, the rate of bacterial translocation and plasma DAO were lower in ID group and ED group than those in OJ group, which were more obvious in ID group than that in ED group, and the differences were statistically significant ($p < 0.05$).
Conclusion: OJ could cause intestinal paneth cell dysfunction in mice, which was mainly manifested in the decrease of paneth cell number, as well as the decrease of cryptdin-4 and lysozyme expression levels. The change of paneth cell in OJ was strongly correlated with intestinal mucosal barrier dysfunction and bacterial translocation. ID was more significant than ED in restoring the function of paneth cell, thereby exerting a role in the functional recovery of the intestinal mucosal barrier. It might be one of the mechanisms that ID was superior to ED.
Disclosure: Nothing to disclose

P1330 EXPRESSION OF TLR4 IN DISTAL ILEUM OF MICE WITH OBSTRUCTIVE JAUNDICE AND ITS ROLE IN INTESTINAL MUCOSA BARRIER DAMAGE

X. Tian[1], H. Zhao[2], W. Li[1]
[1]*Chinese PLA General Hospital, Beijing, China*
[2]*Xingtai People's Hospital, Xingtai, China*

Contact E-Mail Address: xiaopengt58@126.com
Introduction: OJ is a condition that might lead to acute cholangitis and sepsis and multiorgan dysfunction, especially after surgical procedures. Intestinal mucosal barrier dysfunction and intestinal immune function decline might result in endotoxemia and intestinal bacterial translocation, which are important contributors to disease progression or death in patients. Toll-like receptors (TLRs) is a class of transmembrane receptors widely existed in mammalian cells. TLRs can recognize a number of conservative pathogen associated molecular patterns of pathogenic microorganism, initiate signal transduction, eventually stimulate the activation of NF-κB and induce inflammatory mediators expression. TLRs may thus play a key role in innate immune system.
Aims and Methods: We aimed to investigate the role of TLR4 in intestinal mucosa barrier damage and bacterial translocation in mice with obstructive jaundice (OJ).
A total of 100 male C57BL/6J mice were randomly assigned to two groups: (I) sham operation (SH); (II) bile duct ligation (BDL). Mice were sacrificed at different time points (Before operation, as well as 1 d, 3 d, 5 d, and 7 d after operation). The blood, terminal ileum, liver, spleen and mesenteric lymph nodes ((MLNs) were collected under the aseptic condition simultaneously for further usage. The aminotransferase (ALT), total bilirubin (TB), alkaline phosphatase (ALP) and diamine oxidase (DAO) in blood were detected. The morphological changes of distal ileum tissue were observed using haematoxylin-eosin (HE) staining. The expression of Nuclear factor κB (NF-κB), TLR4 in different stage of OJ were observed by Western blot and Real-time PCR. The liver, spleen and MLNs were harvested for the detection of bacterial translocation.
Results: In the SH group, TLR4 protein and mRNA were rarely expressed in the intestinal mucosa of the mice and there were no significant differences at different time points ($p > 0.05$). By contrast, TLR4 protein (0.12 ± 0.06, 0.16 ± 0.08, 0.27 ± 0.10, 0.35 ± 0.12 and 0.41 ± 0.13 respectively) and mRNA (0.49 ± 0.19, 0.62 ± 0.23, 0.98 ± 0.32, 1.42 ± 0.41 and 1.72 ± 0.49 respectively) were increased gradually with the extension of OJ time in the BDL group ($p < 0.05$). The grade of mucosal injury, the level of plasma DAO and the expression of NF-κB increased gradually in the BDL group with the extension of OJ time ($p < 0.05$). In addition, the rate of bacterial translocation was also increasing in the liver, spleen and MLNs in the BDL group. There were positive correlations between the grade of mucosal injury and expression of TLR4 ($r = 0.781$, $p < 0.05$) and NF-κB ($r = 0.828$, $p < 0.05$) in BDL group. In addition, there were positive correlations between the level of plasma DAO and expression of TLR4 ($r = 0.775$, $p < 0.05$) and NF-κB ($r = 0.783$, $p < 0.05$) in BDL group. NF-κB expression was positively correlated with TLR4 expression ($r = 0.744$, $p < 0.05$).
Conclusion: The expression of TLR4 was significantly up-regulated in the distal ileum of mice with obstructive jaundice. Overexpression and activation of TLR4 were involved in the occurrence and development of intestinal mucosa barrier damage and bacterial translocation in mice with OJ.

Introduction: Ursodeoxycholic acid (UDCA) is currently the only drug approved specifically for the treatment of primary biliary cholangitis (PBC), as it can delay histological progression and improve long-term outcome. Patients with inadequate response to UDCA are at increased risk of disease progression, need for liver transplantation, and death. Recently a risk score – the GLOBE score – have been proposed for prognosis of PBC. The aim of this study was to determinate the role of GLOBE score in predicting of response to UDCA in PBC.
Aims and Methods: We conducted a retrospective study of all patients with PBC who were treated with UDCA at the daily dose of 13 to 15 mg/kg between January 2008 and December 2017. The response to UDCA was defined according to Paris criteria after 1 year of therapy. The Globe score was calculated for all patients included in this study.
Results: A total of 71 patients with PBC were included. Sixty-six patients were females and only five were males. The average age was 55.23 years [23–81 years]. Accordingly to Scheur's classification, 28 patients with biopsy-proven were categorized as: stage 1, stage 2, stage3 and stage 4 respectively in 46.42%, 25%, 10.7% and 17.8% of cases. Of 71 patients, 34 were responded to UDCA (48%) and no-response to these therapy was observed in 37 cases (52%) after 1 year of UDCA therapy. The mean value of Globe score was 2.05 [-0.8; 4.68]. This value was found to be significantly elevated in PBC patients with poor response to UDCA comparatively with PBC patients responders to these therapy (2.27 vs 1.64; $p = 0.037$).
Conclusion: Our study showed that Globs score could be a new cheap and easily obtained marker in predicting of response to UDCA in PBC. Our findings need to be confirmed with larger scale prospective studies.

Introduction: Early diagnosis of malignancy in biliary strictures can be challenging given the low rate of diagnostic accuracy of current modalities. Biliary strictures in Endoscopic Retrograde CholangioPancreatography (ERCP) with nondiagnostic brushings and/or biopsies, negative lab (CA19-9) and imaging tests are considered indeterminate. MicroRNAs (miRNA or miRs) are small non-coding RNA molecules that have been associated with pathophysiological processes in different organs and cell types, and are postulated as potential targets for diagnosis and therapy.
Aims and Methods: The aim of the study was to evaluate the potential diagnostic accuracy of a set of 3 miRNAs related to cholangiocarcinoma in indeterminate biliary strictures. We performed a prospective case-control observational study of 18 patients, diagnosed with cholangiocarcinoma, indeterminate stenosis or normal bile duct, who underwent ERCP and cholangioscopy. Biopsies under direct visualization and/or brush cytology were obtained. Specimens were evaluated histologically and miR-21, miR-483 and miR-675 expression was quantified using Reverse Transcription Polymerase Chain Reaction (RT-PCR, relative quantification).
Results: 18 patients underwent cholangioscopy (male 50%, mean age: 67.8). 8 patients had cholangiocarcinoma (mean age: 77.1), 6 had indeterminate biliary strictures (mean age: 63.3) and 4 had normal bile duct (mean age: 56). Normal bile duct cohort results were used as control. MiR-21 expression was upregulated in both cholangiocarcinoma [4.20 times ± 1.87, (1.43–7.06)] and indeterminate cohorts [1.45 times ± 0.28, (1.12–1.92)]. MiR-483 expression was upregulated in cholangiocarcinoma [5.59 times ± 2.09, (2.7–8.19)] and downregulated in indeterminate cohort [33.54 times ± 32.4, (2.32–90.9)]. Similarly, miR-675 expression was upregulated in cholangiocarcinoma [4.4 times ± 2.45, (2.19–9.21)] and downregulated in indeterminate cohort [3.16 times ± 0.99, (2.08–4.54)]. Surprisingly, all cases in cholangiocarcinoma and indeterminate cohorts upregulated or downregulated as above mentioned miR-483 and miR-675 expression, respectively.
Conclusion: Our limited data suggest that there may be a role for miRNAs in differential diagnosis for malignancy in indeterminate biliary strictures. MiRNAs represent a new research area. More trials are required for confirmation of the above results and establishment of cut-off values.

Introduction: Neutrophil-to-lymphocyte ratio (NLR) is an indicator of the systemic inflammatory response, which has been proposed to be used as a prognostic marker in various types of cancers. Cholangiocarcinoma is a common cancer in Thailand. However, data regarding NLR in this cancer is still limited.
Aims and Methods: We would like to verify if NLR could be used as another prognostic factors in cholangiocarcinoma.
We conducted a retrospective study. Data were collected from eligible patients who were admitted to Siriraj Hospital, Mahidol University between January, 2006 and December, 2015. All patients with the diagnosis of cholangiocarcinoma were recruited. The diagnosis of cholangiocarcinoma was proven by pathological and/or imaging confirmation. The exclusion criteria were patients who received less than three cycles of chemotherapy, patients with other malignancy diagnosed within 5 years prior cholangiocarcinoma detected, patients who had active infection during the blood drawn of NLR was collected, and patients who were allocated into palliative care. Patients who received initial treatment at other hospital or unknown diagnosis date, who had been referred for adjuvant or systemic chemotherapy outside the study hospital, patients with missing data from medical record, who lost to follow-up and without definite diagnosis were also excluded. Baseline characteristics, laboratory data, modalities of treatment and therapeutic outcomes were collected. Associations between clinical characteristics, NLR, laboratory variables including tumor markers as well as survival were investigated by regression analysis. The proper cut off level of NLR also identified using sensitivity analysis. Comparison between patients with NLR < 2 and NLR ≥ 2 were performed using logistic regression analysis.
Results: 536 consecutive patients met the inclusion criteria, after considering the exclusion criteria, 171 patients were eligible for the final analysis. The mean age of patients was 59.26 ± 10.88 years. Eligible patients were categorized into 3 groups according to treatment modalities; palliative chemotherapy (N = 77, 45%), adjuvant therapy (N = 37, 21.6%) and surgery group (N = 57, 33%). The cut off NLR value of 2 was selected to predict prognosis with sensitivity of 74% and specificity of 53%. Patients who had NLR < 2 across the study timeline (before, during and after treatment) had the best survival (Median OS = 34.8 and 37.1 months). Patients with initial NLR < 2, had median overall survival (OS) and progression-free survival (PFS)/disease-free survival (DFS) of 34.8 and 50.6 months respectively compared to median OS of 21.6 months ($P = 0.001$) and median PFS/DFS of 16.6 months ($P = 0.004$) in patients with NLR ≥ 2. Multivariate analysis demonstrated that high level of CEA and CA19-9 were significant predictors of poor PFS/DFS with HR = 2.29 and 2.03, $P = 0.016$ and 0.04, respectively). Worse OS were predicted by NLR ≥ 2 (HR 1.76, $P = 0.021$), CA 19-1 > 300 (HR 1.79, $P = 0.009$), and ECOG ≥ 2 (HR 6.24, $P = 0.016$). Only patients in surgical group had significantly survival difference according to the change of NLR.
Conclusion: NLR can be considered as another independent prognostic factor to predict survival in patient with cholangiocarcinoma. As NLR is a cheap and simple, already available test, we proposed to use NLR as a useful biomarker to predict prognosis of cholangiocarcinoma.

Introduction: Real-life treatment and outcomes of distal cholangiocarcinoma in the Western world are largely unknown. This study investigated treatment, outcomes, time trends and predictors for survival in a nationwide cohort of patients with distal cholangiocarcinoma.
Aims and Methods: A population-based cohort derived from the Netherlands Cancer Registry was studied. All patients (resected and unresected) registered to have distal cholangiocarcinoma between 2009–2015 were included. Missing data were handled using multiple imputation. Survival and predictors for survival were analyzed using Kaplan Meier and Cox regression analysis (backward selection).
Results: During the study period, 1152 patients were registered; 537 (46.6%) underwent resection, 376 (32.6%) had unresected non-metastasized disease (M0) and 239 (20.7%) had metastasized disease (M1). In the resected group, 30-day mortality was 5.4% (n = 29) and adjuvant chemotherapy was rarely used (8.4%, n = 45). Palliative chemotherapy was administered in 19 (5.1%) of the patients with non-resected M0 and in 74 (31.0%) of the M1 tumors. Median overall survival for patients with resected, unresected M0, and M1 tumors was 23 months (95% CI 20–25), 7 months (95% CI 6–8) and 4 months (95% CI 3–5) ($p < 0.001$), respectively. Over time, survival did not improve in any of the subgroups. Negative independent prognostic factors for survival in resected patients were increasing age ($p = 0.01$), T3/T4 stage ($p = 0.02$), higher lymph node ratio ($p < 0.001$), poor differentiation ($p < 0.001$), and microscopic ($p < 0.001$) or macroscopic ($p = 0.03$) residual disease.
Conclusion: This largest nationwide Western study on distal cholangiocarcinoma demonstrates a 47% resection rate with acceptable survival despite limited use of adjuvant chemotherapy, and poor survival and limited use of chemotherapy in unresected patients. The study identified predictors for survival which can be useful to stratify future clinical trials with (neo-) adjuvant or palliative treatment.

Introduction: Ampullary tumors may be adenoma, adenocarcinoma or other rare lesions. Although it carries high morbidity, Whipple's pancreatico-duodenectomy is the recommended treatment modality in most. There is an increasing interest in endoscopic snare papillectomy (ESP) as an alternative minimally invasive treatment option. We report long-term results of ESP in a retrospective patient cohort from a single center.

Aims and Methods: Patients with localised ampullary tumors treated by ESP during 10-year period (2007–2017) were identified from a prospectively maintained ERCP database. All underwent pre-ESP endoscopic ultrasonography (EUS) to confirm localized disease and suitability for procedure. Exclusion criteria – tumor infiltration into pancreas, duodenal wall or distal bile duct on EUS. Endoscopic and EUS appearance was adequate to plan ESP and pre ESP histology was not considered mandatory. Enbloc ESP was performed using a diathermy snare followed by biliary and pancreatic stent placement; removed at 4–6 weeks with biopsies to look for residual tumor. Patients with final histology – adenocarcinoma were counselled for either close follow-up or surgical resection & those with benign histology were followed up. Follow up done at 3, 6, 12, 18, and 24 months, yearly thereafter. Duodenoscopy & appropriate imaging at every follow up.
Results: 63 patients underwent ESP. Mean age – 59.2 years (33–72) in adenoma group, 66.8 years (46–88) in adenocarcinoma group. Males – 36. Mean tumour size 20.3mm (5–52). Adverse events – 6 (9.5%) – post ESP bleed – 3 (2 – endotherapy, 1 – angio-embolization), delayed biliary stenosis – 2 (ERCP stenting), fatal pancreatitis after biopsy – 1. Final histology – adenocarcinoma (AC) – 29 (46%), adenoma (AA) – 27 (42.8%), neuroendocrine tumor (NET) – 3, chronic inflammation – 4. Base involved in 6 (9.5%) – underwent surgery. Follow up was as per final histology (Fig. 1). Follow up was available in 49 patients (78%), mean duration – 22.4 months (1–88). Recurrence was documented in 5 patients – 2/13 (15%) in AC (surgery – 1, palliative stenting – 1) & 3/25 (12%) in AA group. After correcting values for patients lost to follow up, 11/22 (50%) patients from AC group and 20/25 (80%) from AA group were disease free during follow up. All recurrences occurred around one-year (10.5 to 14). Therefore for the total cohort, 35/62 patients (56%) remained disease free during follow up.
Conclusion: Results of ESP in this single-center carefully selected patient cohort suggest that ESP may be curative for >50% patients with ampullary tumors. Curative resection may be achieved for 4/5 adenomas and every other localized adenocarcinoma. Given the fact that majority of these patients may be high-risk surgical candidates, these results are encouraging. Histologically confirmed clear resection margin is critical to minimize recurrence risk.

Introduction: A high incidence of thromboembolism (TE) has been reported in patients with malignancy, especially in pancreatic cancer patients. However, few data are available on patients with biliary tract cancer (BTC).
Aims and Methods: The aim of this analysis is to clarify the incidence of TE, risk factors for TE and its clinical impact in Japanese patients with BTC. Data on consecutive patients receiving systemic chemotherapy for advanced BTC between April 2008 and March 2017 were retrospectively studied. Both symptomatic and asymptomatic, arterial and venous TEs were included in the analysis. Risk factors for TE development were analyzed using a proportional hazards model with death without TE as a competing risk. The impact of TE on survival was also evaluated using a time-dependent covariate multiple Cox model.
Results: A total of 174 patients (105 male, a median age of 70 years) with advanced BTC were included in the analysis. Primary sites of cancer were intrahepatic in 66 (38%), gallbladder in 59 (34%), hilar bile duct in 27 (16%), distal bile duct in 17 (10%) and ampulla in 5 (3%). TE was identified in 21 cases (12%): 20 venous TEs and 1 arterial TE. The incidence of TE did not differ by the primary tumor site ($P = 0.66$). The median time to TE was 128 (95% CI; 66–230) days and the median survival from TE was 102 (95% CI; 29–171) days. In a multivariate analysis, female sex was the only significant risk factor for TE (subdistribution hazard ratio 4.10, 95% CI; 1.58–10.7, $P < 0.01$). In a multivariate analysis using a time-dependent covariate multiple Cox model, TE was significantly associated with poor prognosis (hazard ratio [HR] 1.98, 95% CI; 1.17–3.36 $P = 0.01$) as well as CA19-9≥300 (HR 1.55, 95% CI; 1.08–2.21, $P = 0.02$), gallbladder cancer (HR 1.51, 95% CI; 1.03–2.20, $P = 0.03$) and liver metastasis (HR 1.85, 95% CI; 1.27–2.70, $P < 0.01$).
Conclusion: TE was not uncommon in Japanese patients receiving chemotherapy for advanced BTC and was associated with poor prognosis. Female sex was the only risk factor for TE.

P1337 PHOTODYNAMIC THERAPY OF PERIHILAR CHOLANGIOCARCINOMA – A RETROSPECTIVE COHORT ANALYSIS OVER A DECADE

W. Obst, A.E. Canbay, J. Weigt
Otto-von-Guericke University Hospital Magdeburg, Department of Gastroenterology, Hepatology and Infectious Diseases, Magdeburg, Germany

Contact E-Mail Address: wilfried.obst@med.ovgu.de
Introduction: Only a small proportion of patients with perihilar cholangiocarcinoma (hCCC) can be delivered to curative surgical resection. If surgery is impossible, the treatment consists of palliative chemotherapy and biliary drainage. In addition, local ablative therapy such as photodynamic therapy (PDT) can be offered. In previous studies, PDT showed ambiguous results regarding overall survival and clinical profit. Aim of this investigation is to analyse the therapeutic benefit of PDT in a clinical retrospective setting without restriction to combination of PDT with stent or concomitant chemotherapy.
Aims and Methods: We retrospectively analysed the data of 65 patients with histologically confirmed hCCC that were treated from 2003 until 2013. 30 patients received only stent therapy (group A), 35 patients received stent therapy with PDT (group B). PDT was performed with the photosensitzer porfimer sodium and an intraluminal photoactivation (wavelength: 630 nm, light dose: 180 J/cm^2). Survival time, numbers of needed ERCP and complication rate were statically evaluated. Subgroup analyses were done for patients with concomitant chemotherapy.
Results: PDT did slightly improve the survival time (A: 9.27 ± 6.27 months, B: 11.7 ± 8.8 months; $p = 0.348$) and reduced the numbers of needed ERCP within 3 months (A: 1.8 ± 1.2, B: 1.53 ± 0.49; $p = 0.115$). The complication rate per person was equal in both groups (A: $3.17 \pm 2.6\%$, B: $2.69 \pm 1.21\%$). Phototoxic skin reactions occurred in 17.4% of patients with PDT. 32.3% of the patients were able to receive additional chemotherapy which only minimally increased the survival time in both Groups (A: 10.7 ± 4.5 months, B: 16.1 ± 10.7 months; $p = 0.348$).
Conclusion: The impact of PDT on survival time in unselected patients with hCCC is low. The attributed advantages of PDT were not statistically significant and independent of additional chemotherapy.
Disclosure: Nothing to disclose

P1338 TRENDS IN INCIDENCE, TREATMENT AND SURVIVAL OF GALLBLADDER CANCER; A NATION-WIDE COHORT STUDY

Introduction: Gallbladder cancer (GBC) is a rare but lethal malignancy, primarily diagnosed in an advanced stage unless detected incidentally after laparoscopic cholecystectomy for suspected benign gallbladder disease. Scarce data is available on GBC treatment and survival outcomes in Western populations. Consequently, controversy exists regarding surgical and systemic treatment. Aim of this study was to assess trends in incidence and evaluate treatment and survival of GBC patients.
Aims and Methods: Data on all patients with GBC diagnosed between 2000–2015 were retrieved from the nationwide population-based Netherlands cancer registry ($N = 2427$). Age-standardized incidence rates were calculated. Trends in incidence and demographics were assessed. Treatment strategies and associated survival were analysed using Kaplan-Meier methods and propensity score matching.
Results: Age-standardised incidence of GBC varied from 0.6 to 0.9 per 100.000 person years and did not change over time. Most patients were female (72%), over 75 years of age (44%), presented with stage IV (39.8%) disease and were diagnosed pre-operatively (67.2%). The overall median survival was 5.2 months and primarily determined by tumour stage, ranging from 36.2 months in stage I patients to 3.0 months in stage 4 patients. Between 2000 and 2015 overall median survival improved from 4.1 to 6.6 months ($p < 0.001$). After propensity score matching, median survival in surgically treated stage III + IV gallbladder cancer was 7.4 months, compared to 3.3 months for non-surgically treated patients ($p < 0.001$). Stage II GBC patients receiving additional liver bed resection showed superior median survival to those whom did not receive additional surgery (21.7 vs. 46.6 months, $p < 0.001$). Systemic therapy in advanced stage GBC improved median survival from 2.8 to 7.4 months ($p < 0.001$).
Conclusion: Incidence of GBC did not change significantly and overall survival increased slightly in this nation-wide cohort. Median survival was longer in patients with early GBC who underwent an additional resection and patients with advanced GBC who received systemic therapy compared to patients who did not receive these treatments. However, general outcome for GBC patients is still poor.

Introduction: Pancreatic cancer is an extremely lethal malignancy, with a 5-year survival rate of less than 5%. Although chemotherapy is another option of therapy for advanced pancreatic cancer, the response was poor and unpredictable. Preclinical research is recently advanced for in vitro drug testing using cancer cell lines and organoids or xenograft tissue using human tumor tissues. However, obtaining tumor cells from patients with pancreatic cancer are limited because most patients were initially diagnosed as inoperable stage. Recently, methods to culture and/or propagate tumor tissue using specimens obtained from endoscopic ultrasound-guided tissue sampling (EUS-TS) were introduced.
Aims and Methods: The aim of our study was to evaluate the feasibility of a three-dimensional (3D) spheroid culture using EUS-TS in pancreatic cancer. Patients with suspected pancreatic cancer who were referred for EUS-TS were prospectively enrolled. Among them, patients with locally advanced or distant metastasis were included. After the acquisition of tissue specimen for pathologic diagnosis by EUS-guided fine needle aspiration using 20-gauge ProCore needle (Cook medical, Winston Salem, IN, USA), additional EUS-TS was performed for 3D spheroid culture. The acquired specimens were processed to cultivate in culture media and/or Matrigel and observed serially by phase contrast microscopy to evaluate the growth of tumor cells. After appropriate growth of tumor cells, the specimen was examined by Hematoxylin and Eosin staining to compare the similarity of histology between human cancer tissue and 3D spheroid tumor.
Results: Between June 2017 and November 2017, 12 patients were enrolled. Among them, two patients were excluded due to refusal of informed consent and nonpancreatic cancer. Finally, EUS-FNA specimen for 3D culture was obtained from 10 patients (male to female ratio, 2:3; median age of 67, range 54–78), who were diagnosed as ductal adenocarcinoma in EUS-TS. During mean observation period of 41.6 days, 3D spheroid culture was successfully constructed and observed tumor growth in 3 cases. The histology of 3D culture specimen was similar to that of human tumor tissue.
Conclusion: This model, which is successfully and rapidly created by means of EUS-guided core biopsy at the time of initial tumor diagnosis, can be a promising method for construction of in vitro models in the process of drug development and testing for pancreatic cancer.

Introduction: In both chronic and acute pancreatitis (AP), pain is the cardinal symptom and notoriously difficult to managae. In recent studies, we detected a specific enrichment of mast cells around intrapancreatic nerves of patients with painful chronic pancreatitis (CP).
Aims and Methods: In the present study, we analyzed whether administration of mast cell stabilizers can improve the pain due to CP. For this purpose, AP and CP were induced in 8-week-old C57BL/6J mice via repeated i.p. injections of the cholecystokinin analogie cerulein. Mice were either prophylactically, i.e. beginning 2h (AP) or 1 week (CP) prior to disesase induction, or therapeutically, i.e. beginning in the third hour (AP) or at week 2 (CP) after disease induction, with one of the mast cell stabilizers ketotifen or cromoglycate. Metamizol was applied as the comparative agent, and solvent was applied as control. The mast cell stabilizers were applied i.p. during AP, and combined orally and s.c. during CP. The pain-associated behavior of mice was assessed via the von Frey mechanosensitivity test and via the open-field locomotion test.
Results: In dose-finding experiments, the effective analgesic doses for each drug were identified (metamizol: 500mg/kg BW, ketotifen: 10mg/kg BW, cromoglycate 500mg/kg BW). In the final therapy experiment, in AP, the mast cell stabilizers did not exert an anagelsic effect when administered as single therapeutics to the mice. However, in CP, we observed a prominent reduction in the von Frey pain scores and improvement in the locomotion scores of the mice treated with cromoglycate or ketotifen.
Conclusion: The present study showed for the first time a potential analgesic effect of mast cell stabilizers in pancreatic pain. Further preclinical studies analyzing mast cell stabilizers as adjunct analgesics are currently underway. This novel concept also needs testing in early phase clinical trials.
Disclosure: This abstract was also presented at the DGVS 2017 congress.

P1341 DOPAMINE D2 RECEPTOR SIGNALING CONTROLS INFLAMMATORY STATUS OF MACROPHAGES IN ACUTE PANCREATITIS THROUGH INHIBITION OF OXIDATIVE STRESS-INDUCED NF-κB AND INFLAMMASOME ACTIVATION

X. Wang[1], G. Hu[1], X. Han[1], J. Wu[1], B. Li[1], X. Ye[1], J. Dai[1], Z. Wu[1], J. Ni[1], C. Chen[1]

Introduction: Acute pancreatitis (AP) is aninflammatory disease mediated by acinar cell injury andsubsequent inflammation with leukocyteinfiltration.[1,2] Innate immune cells are the first cells to arrive the injured pancreas in AP.[3] Macrophage activation is an important determinant of the severity of AP.[4] In response to different signals, macrophages may undergo two types of activation: M1 (classically activated macrophages) or M2 (alternatively activated macrophages). We have demonstrated the regulatory effects of dopamine and dopamine D2 receptor (DRD2) signaling pathway on AP in our previous studies.[5] Besides, cAMP – the second messenger of dopamine D1 receptor (DRD1) signaling,[6] can prevent macrophages to transform into M1 phenotype.[7] However, the relationship between DRD2 and macrophagepolarization in AP remains to be understood.
Aims and Methods: In the present study, we aimed to investigatethe changes of dopaminergic system in different macrophage phenotypes, the roleof DRD2 on macrophage polarization during AP. We analyzed changes of dopaminergic system both in M1 and M2 macophages, and the effects of DRD2 activation on macrophage polarization in bone marrow derived macrophages (BMDMs) *in vitro* or in caerulein and lipopolysaccharide (LPS) or L-arginine induced AP in wild-type and myoleid-specific $Drd2^{-/-}$mice *in vivo*. Intracelluar oxidative stress, NFκB and inflammasome activation were evaluated.
Results: Dopaminergic system was activated both in M1 and M2 macrophages, but DRD1 and DRD2 were decreased in M1 while increased in M2 macrophages. Compared to normal control, DRD1 and DRD2 were significantly reduced in macrophages from the pancreatic tissue of AP mice. DRD2 activation can significantly downregulate M1 markers (iNOS, TNFα, etc.) but upregulate M2 markers (CD206, etc.) both in LPS and IFNγ-induced BMDMs *in vitro* and in the pancreas of caerulein and LPS-induced or L-arginine-induced AP model *in vivo*. Myeloid-specific Drd2 deficiency aggravated pancreas injury of AP, elevated serum amylase and lipase levels and more M1 macrophages were obsevered in the pancreas. Furthermore, we revealed that DRD2 activation can inhibit the membrane translocation of $p47^{phox}$- one cytoplasmic subunit of NADPH oxidase, and reduce ROS generation, which influence the NFκB and inflammasome activation in the downstream in LPS and IFN-γ-induced BMDMs. And we confirmed these phenomena in the BMDMs isolated from myeloid-specific $Drd2^{-/-}$mice. Our datas showed that DRD2 activation can inhibit NADPH oxidase-mediated ROS generation, NFκB and inflammasome activation in $Drd2^{-/-}$BMDMs.
Conclusion: Our data showed that in the progress of AP, DRD2 can inhibit M1 macrophages, and pherhaps promote them to M2 profile by inhibiting NADPH oxidase-mediated ROS generation and its downregulating NFκB and inflammasome activation. Therefore, therapeutic approaches that activate DRD2 receptor signaling may represent a novel strategy for attenuating inflammation in AP clinically.

P1342 FUNCTIONAL GENOMIC SCREENING DURING SOMATIC CELL REPROGRAMMING IDENTIFIES DKK3 AS A ROADBLOCK OF PANCREATIC REGENERATION

J. Gout[1], M. Breunig[2], L. Perkhofer[1], T. Seufferlein[1], P.-O. Frappart[1], A. Kleger[1]

Introduction: The reprogramming process partly eliminates disease- and aging-associated phenotypes, inducing a ''partial cure'' or ''rejuvenation'' in pluripotent stem cells as shown in studies using somatic cells from centenarians or chronically sick patients as templates. Interestingly, adult stem cells share common features with their pluripotent counterparts, such as differentiation potential and self-renewal, and at least partially share certain molecular programs.
Aims and Methods: We propose that studying somatic cell reprogramming could serve as a tool to gain valuable insights into adult stem cell fitness and organ regeneration. As logical consequence we have successfully applied a straightforward functional genomics approach using RNA-interference techniques during iPS formation.
Results: We identified a set of factors limiting both cellular reprogramming and stem cell fitness in the hematopoietic system. Dkk3 (Dickkopf 3) was found to be a factor limiting these two features. Consequently we aimed to investigate the role of Dkk3 during liver and pancreas regeneration upon injury. To do so, we used Dkk3 null mice to examine its role in a cerulein-induced acute pancreatitis context. First, there was no effect on the acute injury but Dkk3 loss appeared relevant in the regeneration phase of the pancreas. Specifically, we demonstrated that DKK3 inactivation triggers a better pancreatic acinar regeneration four days after pancreatitis induction. Furthermore, DKK3 knockout mice display a significant decrease of acinar-to-ductal metaplasia lesions, correlated with lower

edema and inflammation scores, and a diminished fibrotic content. Additional mechanistical insights are given by organoid cultures derived from wild type and Dkk3 null pancreata. In contrast, partial hepatectomy in Dkk3 null mice revealed just a trend toward better regeneration.
Conclusion: DKK3 appears to act as a brake of acinar regeneration after pancreatic insult in a tissue-specific manner.

Introduction: Acute pancreatitis (AP) progresses to necrotizing pancreatitis in 15% of cases [1]. An important pathophysiological mechanism in AP is third spacing of fluids, which leads to intravascular volume depletion that may progress to hypovolemic shock [2, 3]. This compromises the splanchnic circulation and reduces venous return [4–6]. Smaller diameters of portal system veins (portal, splenic and superior mesenteric) as a result of decreased venous return might contribute to increased morbidity and mortality in acute pancreatitis. Computed tomography (CT) scan enables identification of the diameter of these veins in early acute pancreatitis.
Aims and Methods: We conducted a post-hoc analysis of data from two randomized controlled trials that included patients with predicted severe and mild AP. One trial included patients with a predicted severe disease course at admission [7]. All patients had a CT scan 7–10 days after admission. The other trial included patients with mild biliary pancreatitis [8]. From this trial we included patients who underwent a CT scan within 7 days of admission. We performed additional CT measurements of portal system vein diameters and calculated their prognostic value through univariate and multivariate Poisson regression. In the multivariate regression we corrected for possible confounders. Additionally, we performed an analysis in which we compared the mean vein diameters in patients with predicted mild and severe AP by Student's t-test. The primary endpoint was AP-related mortality. The secondary endpoints were (infected) necrotizing pancreatitis and (persistent) organ failure.
Results: The total sample consisted of 177 patients. Multivariate regression analysis showed a significant inverse association between splenic vein diameter and mortality (RR 0.75 (0.59–0.97)), a smaller diameter was a risk factor for mortality. Furthermore, there was a significant inverse association between splenic and superior mesenteric vein (SMV) diameter and (infected) necrosis. The diameters of all veins were inversely associated with organ failure and persistent organ failure. The results of the univariate and multivariate analysis are displayed in the table. Patients with predicted mild AP had significantly larger diameters of the portal, splenic and SMV compared to those with predicted severe AP.
Conclusion: We observed that a smaller diameter of the splenic vein is a risk factor for mortality and a smaller diameter of all portal system veins is a risk factor for morbidity in AP. These findings could be used in the optimization of radiological scoring systems to predict the severity of pancreatitis.

Mortality	Univariate analysis	Multivariate analysis
Portal vein	0.87 (0.70–1.08)	
Splenic vein	0.78 (0.62–0.98)	0.75 (0.59–0.97)
SMV	0.88 (0.71–1.09)	
Necrosis		
Portal vein	0.90 (0.80–1.01)	
Splenic vein	0.80 (0.71–0.91)	0.78 (0.68–0.89)
SMV	0.84 (0.75–0.94)	0.83 (0.74–0.93)
Infected necrosis		
Portal vein	0.85 (0.72–1.01)	
Splenic vein	0.76 (0.64–0.92)	0.72 (0.59–0.88)
SMV	0.78 (0.66–0.93)	0.76 (0.64–0.91)
Organ failure		
Portal vein	0.83 (0.72–0.95)	0.79 (0.67–0.94)
Splenic vein	0.80 (0.68–0.94)	0.76 (0.64–0.90)
SMV	0.84 (0.73–0.97)	0.81 (0.70–0.94)
Persistent organ failure		
Portal vein	0.81 (0.70–0.94)	0.77 (0.65–0.92)
Splenic vein	0.78 (0.66–0.93)	0.73 (0.61–0.88)
SMV	0.78 (0.67–0.91)	0.75 (0.64–0.87)

Values depict relative risk (95% confidence interval).
SMV: superior mesenteric vein.

Contact E-Mail Address: n.hallensleben@pancreatitis.nl
Introduction: After standard diagnostic work-up, the etiology of acute pancreatitis remains unknown in up to 25% of cases, a condition referred to as idiopathic acute pancreatitis (IAP). Determining the etiology of pancreatitis is essential, as it may direct treatment in the acute phase of the disease and guide interventions to prevent recurrent pancreatitis.
Aims and Methods: We explored the use and yield of additional diagnostic tests (i.e. endosonography, MRI/MRCP, CT, diagnostic ERCP and IgG4). Furthermore, we analyzed the recurrence rate of acute pancreatitis after a first episode of IAP and assessed what the impact was of establishing an etiological diagnosis treatment on recurrence rates.
Between 2008 and 2015, patients presenting with acute pancreatitis were registered prospectively in fifteen Dutch hospitals. Patients who initially had a negative diagnostic work-up with regard to the etiology of their pancreatitis were labelled IAP. This initial work-up included: personal history (signs of a biliary cause, alcohol use, medication use, metabolic disorders, prior abdominal trauma, surgery, or ERCP); family history (chronic or hereditary pancreatitis); transabdominal ultrasound; and laboratory tests (i.e. liver enzymes, calcium, triglycerides) We performed a post-hoc analysis including the type and number of all diagnostic tests performed, the yield of these test to establish an etiological diagnosis, and recurrence rates after treatment.
Results: Out of the 1632 patients that were registered, 191 patients were diagnosed with a first episode of IAP. Out of these 191 patients, 176 (92%) underwent one or more additional diagnostic test: CT (n = 124, yield 8%), EUS (n = 62 patients, yield 35%), MRI/MRCP (n = 56, yield 33%), repeat ultrasound

(n = 97, yield 21%), IgG4 (n = 54, yield 9%), and ERCP (n = 15, yield 47%). In 64 patients (36%) these test revealed an etiologic diagnosis. During a median follow-up of 4 years (IQR 3–6), 50 out of 191 patients (26%) had at least one recurrence, 26 of whom had more than one recurrent episode. There were 101 recurrences in total with a median of 2 per patient (IQR 1–2). Out of 141 patients with only one single episode of idiopathic pancreatitis, 128 patients underwent additional diagnostic testing. In 35 cases (27%) an etiology was found: biliary (n = 22; 1 combined with pancreas divisum), autoimmune (n = 3), pancreatic carcinoma (n = 3), chronic pancreatitis (n = 3), ampullary carcinoma (n = 2), pancreas divisum (n = 1), and a neuroendocrine tumor (n = 1). Of the 50 patients with recurrent episodes of acute pancreatitis, an etiologic cause was identified after additional testing in 29 patients (58%): biliary etiology (n = 17; 1 combined with pancreas divisum), pancreatic carcinoma (n = 6; 1 combined with biliary stones and chronic pancreatitis), autoimmune pancreatitis (n = 3), chronic pancreatitis (n = 2) and an IPMN (n = 1). In 13 out of 176 of patients (7%) additional testing showed an ampullary or pancreatic neoplasm. EUS and MRI/MRCP had a high diagnostic etiological yield, both in the single episode patients (EUS 35%; MRI/MRCP 30%) and the ones with recurrent episodes (EUS 35%; MRI/MRCP 35%).

Conclusion: In over one-third of patients initially labelled as idiopathic pancreatitis an etiological diagnosis is established after additional diagnostic testing. The rate of etiologies detected was twice as high in patients with recurrent IAP (58%) than in patients with only one pancreatitis attack (27%). The etiology found was mostly biliary, but neoplasms were not a rarity which prompts for extra vigilance not to lose an opportunity for timely resection.

Introduction: Recurrent acute pancreatitis (RAP) can occur in 10–30% of patients who recover from first episode, with patients having milder disease and lower mortality. Overall, a handful of studies are available on outcome of RAP, in comparison to first episode of acute pancreatitis (AP).

Aims and Methods: We aimed to provide more complete and updated picture of RAP and how it is different from initial episode of AP.

Consecutive patients admitted with an episode of acute pancreatitis over 8 years were included in study. Patients with prior episodes (≥1) of acute pancreatitis, with atleast a 2-month gap between each episode were labelled as RAP. Patients with underlying chronic pancreatitis were excluded. Blood investigations including fasting triglyceride levels, calcium, parathormone, MRCP and EUS were used to find an etiology. Severity assessment was done using BISAP, APACHE II and revised Atlanta scoring. All patients were managed as per standard guidelines for fluid resuscitation, antibiotics for infection and drainage of infected necrosis using PCD when indicated. Primary outcome measures were need for surgical necrosectomy and mortality.

Results: Of the 724 patients (age 39.22 ± 13.25 years, 68% male) with an episode of pancreatitis, 632 (87.3%) had presented with first episode (AP) and 92 (12.7%) with at least one prior episode (RAP). Regarding the etiology of RAP patients, biliary etiology (32.6%) and alcohol (30.4%) were the two most frequent factors, and no etiology could be identified in 19.6%. SIRS, BISAP and APACHE II scores were less in RAP group. The incidence of severe pancreatitis was significantly less in RAP patients (10.9%) in comparison to AP patients (48.6%). The mean duration of hospitalization (10.5 + 9.5 versus 21.6 + 16.4 days), ICU admission (10.9% versus 43.7%) and need of PCD (38.6% versus 55.1%) were significantly lower in RAP group. Fluid collections were present in 57 (62%) RAP patients and in 573 (90%) patients with AP. The requirement of surgical intervention and mortality were less in patients with RAP (1.1% and 2.2%) in compared to patients with AP (9.3% and 18%, respectively). The mean number of episodes per RAP patients was 2.97 ± 1.66 (range 2–10) and 64.1% had only 2 episodes.

Conclusion: Patients with RAP had milder disease course and lesser mortality when compared to the initial episode of AP. Appropriate evaluation and dealing with etiological factors at the initial episode of AP can prevent a majority of RAP.

Introduction: Percutaneous catheter drainage (PCD) is used as a first step in the management of symptomatic fluid collections in acute pancreatitis (AP). Data is lacking for the ideal time of PCD for fluid collections in AP. We aimed to compare the indication and outcome of PCD in patients with acute necrotic collection (ANC) and walled-off necrosis (WON).

Aims and Methods: Consecutive patients of AP with symptomatic ANC or WON undergoing PCD were evaluated in a tertiary care centre in North India between January 2011 and December 2017. The two were compared for indications and outcome measures (need for additional surgical necrosectomy, mortality, need for up-gradation of first PCD, need for additional drain, total duration of PCD and length of hospital stay). Complications related to PCD were also compared.

Results: Of the 650 patients [mean age was 38.58 ± 12.28 years; 71.5%males; etiology: alcohol (51.5%), gall stone disease (35.5%) with AP, 375(57.6%) underwent PCD as a part of their management. 258 (68.8%) patients underwent PCD for ANC and 117 (31.2%) for WON. The mean time to admission to our hospital was 10.47 ± 9.82 days and 36.79 ± 30.69 days in patients who underwent PCD for ANC and WON respectively (p = 0.001). The commonest indication for PCD in both ANC (n = 135, 52.3%) and WON (n = 79, 67.5%) was suspected infection of pancreatic necrosis. Persistent organ failure as an indication for PCD was significantly more common in patients with ANC than WON (38% vs 16.2%, p = 0.001). Pressure symptoms formed the indication for PCD in 9.7% patients with ANC and 16.2% with WON (p > 0.05). Infection of pancreatic necrosis was proven with culture of drain fluid in 146 (56.6%) patients with ANC and 75 (64.1%) patients with WON (p = 0.104). One PCD was placed in 152 (58.9%) patients with ANC and 72 (61.5%) patients with WON with a mean of 1.50 ± 0.66 and 1.50 ± 0.72 PCDs per patient respectively (p = 0.915). The total duration of PCD in ANC was 28.38 ± 20.72 days versus 30.16 ± 26.20 days in WON (p = 0.479). Surgical necrosectomy was needed in 14% patients with ANC versus 12% patients with WON (p = 0.364). Mortality was 19% in patients with ANC as compared to 13.7% in those with WON (p = 0.132). Complications of PCD included external pancreatic fistula (27.5%), blockade of PCD catheter (12.3%), slippage of PCD catheter (10.9%), and bleed through PCD catheter. External pancreatic fistula which occurred more often in WON than in ANC (24.4% versus 34.2%, p = 0.034).

Conclusion: Outcome of PCD is similar in patients with ANC and WON. However, persistent organ failure formed an indication for PCD in greater number of patients with ANC than WON. External pancreatic fistula occurred more often in WON than ANC.

Introduction: Percutaneous catheter drainage (PCD) is the initial step of step-up approach for management of acute pancreatitis (AP). Currently no reliable criteria are available to predict which patients may benefit from PCD.

Aims and Methods: The aim of this study was to identify factors that lead to surgical intervention or mortality after initial management with PCD. In a prospective observational study, 101 consecutive AP were managed by step up approach. Patients who had worsening after conservative management were subjected to PCD under image (USG/CT) guidance. Patients who did not improve at 72 hours were considered for up gradation of the PCD. Patients who did not improve were considered for surgical necrosectomy. Various factors evaluated were, demographic parameters (age, sex, aetiology, comorbidities), severity parameters (CTSI, APACHE II, CRP and IAP), full morphologic characteristics on USG/MRI/EUS (solid component), characters collection before PCD (infected or sterile, volume, site & number), PCD parameters (indication, initial size, maximum size, number and duration of drainage) and factors after PCD insertion (fall in CRP, fall in IAP, reduction in volume of collection. PCD success (survival without necrosectomy) was correlated with baseline and outcome measures.

Results: Out of 101 patients of AP, 50 patients were treated conservatively and 51 required PCD. A total 87 PCD catheters were placed. The success rate of PCD in our study was 66.66% (34/51) and 4 patients required additional surgical necrosectomy after PCD. Overall mortality rate in our study was 29.4% (15/51, including 2 after surgery). PCD alone improved organ failure in 72.54% patients. Patients were divided into two groups, PCD success group (i.e. survival without necrosectomy) and failure group. Size of first PCD was significantly larger in PCD success group (13.94 ± 2.48 vs 12.58 ± 1.17 Fr, **p = 0.011**). There was a

significant percent volume reduction in PCD success group than in failure group **(74.35±21.35% and 44.49± 31.02% respectively, p = 0.000).** More than 50% reduction in fluid collection after PCD (**p = 0.005**) correlated with the PCD success. Amount of collection (114.21 ± 125.47 vs 388.99 ± 341.03 CC, **p = 0.005**) and percentage of volume reduction after PCD insertion (74.35 ± 21.35% and 44.49 ± 31.02% respectively, **p = 0.000**) were significant between groups. ICU stay was significantly longer in PCD failure group (6.35 ± 7.96 vs 13.23 ± 12.21, **p-0.046**). Higher number of patients had volume of collection more 750 CC before PCD **(p = 0.05)** in PCD failure group

Conclusion: Larger size of the first PCD and more than 50% reduction of collection after PCD were positive predictors of PCD success. Total volume of collection more than 750 CC before PCD was a negative predictor of PCD outcome.

Introduction: A large number of studies have focused on identifying severe forms of acute pancreatitis (SAP) within heterogeneous groups of patients most of whom exhibit non-severe forms. However, the value of such predictors in the identification of patients with the worst prognosis in pre-selected groups, such as the critically ill patient with SAP, has been less studied.

Aims and Methods: We aimed to compare the accuracy of non-specific and specific scores on predicting intra-hospital mortality, need for surgery and complications in SAP. We have also evaluated the accuracy of individual clinical and laboratory parameters.

Single-center retrospective cohort including all adult patients with severe acute pancreatitis admitted between January 2007 and February 2017 at a general intensive care unit (ICU). Severity and local complications were defined according to the 2012 Atlanta classification. Clinical (age, sex, body mass index, vasopressor use, mechanical ventilation, hemodialysis and blood transfusions), laboratory (c-reactive protein (CRP), hematocrit, blood urea nitrogen, serum creatinine, albumin levels) data and Acute Physiologic and Chronic Health Evaluation (APACHE II), Sequential Organ Failure Assessment (SOFA) Simplified Acute Physiology Score (SAPS), Systemic Inflammatory Response Syndrome (SIRS), Ranson's criteria, Bedside Index for Severity in Acute Pancreatitis (BISAP), Pancreatitis Outcome Prediction (POP) were collected on admission. Laboratory parameters were also recorded at 48 hours from admission. Statistical analysis was performed with SPSS v.24 and STATA v.14

Results: 57 consecutive patients were included in the study (59.6% male, median age 71 ± 13 years). 49.1% had cardiovascular comorbidity. 42.1% of the SAP cases were biliary and 43.9% had necrotizing pancreatitis. 49.1% had SAP complications mostly intra-abdominal ischemia. 19 patients required surgery after admission to the ICU. The ICU mortality was 42.1%.

APACHE II, SAPS, POP and SOFA scores were significantly higher in the non-survivor group when compared to the survivor group ($p < 0.0001$, $p < 0.0001$, $p < 0.0001$, $p = 0.004$, respectively). Significantly higher serum levels of creatinine (Cr0) and blood urea nitrogen (BUN0) were also observed in the non-survivor group ($p = 0.048$ and $p = 0.001$ respectively). Other scoring systems and laboratory parameters did not differ significantly. ICU related variables associated with increased mortality included need of hemodialysis ($p = 0.001$), and vasopressor requirement ($p = 0.002$).

POP (AUC: 0.79 [0.68–0.91]), APACHE II (AUC: 0.78 [0.67–0.9]), SAPS (AUC: 0.77 [0.65–0.89]) and Cr0 (AUC: 0.74 [0.61–0.87]), outperformed all other evaluators in predicting ICU mortality

POP score had the highest prediction accuracy for mortality without statistical significance ($p > 0.5$). None of the scoring systems were able to predict with high accuracy the need for surgery or SAP complications. Necrotic pancreatitis correlated significantly with need for surgery during ICU stay and complications as expected ($p < 0.0001$ and $p = 0.047$ respectively) but not with mortality ($p = 0.057$). Age, Body Mass Index, and comorbidities had no statistical correlation with any of the outcomes.

Conclusion: Severe acute pancreatitis is associated with high intensive care unit mortality rates. POP, APACHE II, SAPS and Cr0, were able, in this group of patients, to predict mortality with high accuracy. We believe that an early risk stratification of the critical patient influences subsequent management and outcomes positively and should be used in everyday clinical practice.

Introduction: Acute pancreatitis (AP) due to hydatid cyst is an exceptional complication of hydatid liver cyst (HLC). Its pathogenesis is probably due to pancreatic duct obstruction secondary to fistulization of the HLC in the biliary duct. Its treatment combines the general measures of AP and endoscopic retrograde cholangiopancreatography (ERCP) to unclog the biliary duct andthe cure of the HLC and bili cystic fistula in order topreventrecurrence. We report a first case serie of 16 patients diagnosed and treated at the University Hospital Hassan II to analyze the clinicopathological and evolutionary features.

Aims and Methods: This retrospective study was conducted between January 2013 and April 2018. Sixteen patients were hospitalized in our center for acute pancreatitis associated with biliary fistulating HLC assessed by ultrasound and computed tomography (CT) and ERCP. The data collected were: age, sex, severity of pancreatitis, imaging data, modalities and outcomes of endoscopic and surgical treatment

Results: The average age of our patients was 44.33 years (20–66). We observed a female predominance with a sex ratio F/H of 1.3. All patients had acute pancreatitis associated with angiocholitis. Only 12.5% (n = 2) of the patients had past history of surgical cure of HLC. Nine patients (56.25%) had systemic inflammatory response syndrome (SIRS) at admission. In CT, Balthazar's pancreatitis stages A, B, and C accounted for 87.5% (n = 14) and the E stage for 12.5% (n = 2). The hyatid liver cyst was classified stageIII according to GHARBI classification in 62.5% of patients (n = 10). The size of the cyst varied between 4 and 9cm. The common bile duct (CBD) was dilated in all patients and the cystobiliary fistula was identified in 68.75% patients (n = 11). ERCP showed cystic fistula and lacunar images at the level of VBP followed by evacuation of membranes after sphincterotomy in 87.5% of patients (n = 14) and two of our patients had free CBD with visualization of cystic fistula. All patients had surgical cure of their HLCby the technique of resection of the salient dome and closure of the cystobiliary fistula. After treatment, one patient had anaphylactic shock following intraoperative rupture of the cyst, and another patient had infection of the residual cavity, he benefited from percutaneous drainage afterwards.

Conclusion: Acute pancreatitis is an exceptional complication of hydatic liver cyst. It is often associated with angiocholitis. Imaging allows diagnosis and visualization of cystic fistula in 2/3 of cases. The ERCP combined to surgery of HLC remain the key treatment.

Disclosure: nothing to disclose

P1350 WHOLE-EXOME SEQUENCING TO IDENTIFY GENETIC RISK FACTORS FOR MULTIPLE-ORGAN FAILURE IN SEVERE ACUTE PANCREATITIS

F.F. van den Berg[1], Y. Issa[1], M.G.H. Besselink[1], R.C. Hennekam[2], F. Baas[3], M.A. Boermeester[1], H.C. van Santvoort[4]

Introduction: Acute pancreatitis has a severe disease course in 20% of the patients, often characterized by persistent (multiple-) organ failure. It is largely unknown what factors contribute to this severe complication. Genetic risk factors are thought to enhance severity in complex traits like acute pancreatitis, and this could be an explanation for observed difference in phenotype. However, discovery and validation of novel genetic associations often requires large sample sizes. One strategy to maximize power is to select and compare patients with extreme phenotypes.[1]

Aims and Methods: A case-control study with an extreme phenotype approach was performed to identify genetic risk factors for multiple organ failure in patients with acute pancreatitis. The study population was a Dutch cohort of 387 patients that were potentially eligible for inclusion in a randomized clinical trial that investigated the efficacy of prophylactic probiotics in patients with predicted severe acute pancreatitis (PROPATRIA).[2] Consent was given for the use of stored blood for genetic studies in acute pancreatitis. Nine patients with early multiple-organ failure were case-matched with mild patients in a 1:1 ratio. After DNA isolation and exome capture, the samples were sequenced on an Ion-Proton platform. Candidate variants that are associated with multiple-organ failure were identified using bio-informatics approaches.

Results: Exome sequencing resulted in 161.696 variants that passed quality control, of which 38.333 were synonymous and subsequently selected for downstream analyses. Of these, 153 variants were overrepresented in patients with multiple-organ failure. Gene-set enrichment analyses showed that one gene-set, *KEGG antigen presentation and processing*, harbors more variants than can be expected by chance. Among the highest ranking candidate variants were in the caspase gene family, *CASP8* and *CASP10*, which are key regulators of apoptosis. Other promising variants are in genes involved in the innate immunity, such as *HLA-DQB1*, *KIR2DS4* and *FCGR3A*. Finally, a candidate list of 52 variants was constructed for the validation process.

Conclusion: This is the first study that identifies genetic risk factors of multiple-organ failure in acute pancreatitis using Next-Gen sequencing. Whole-exome

sequencing discovered novel candidate variants that are related to multi-organ failure during acute pancreatitis. These results are currently being validated in a larger international cohort. Discovery of causal genetic risk factors could potentially give insight in the mechanisms that lead to multiple-organ failure and even provide for highly needed, novel targets for drug development.

Introduction: During the early phase of acute pancreatitis (AP), which lasts about one to two weeks, about two-thirds of the patients develop respiratory complications [1]. The pathophysiological mechanisms are complex. Activated pancreatic enzymes are important mediators of severe pancreatic inflammation and systemic toxicity including activation of the complement system, over activation of the leucocyte system, and the involvement of the inflammatory mediators, which in turn lead to pulmonary endothelial and epithelial barrier dysfunction [2]. Pulmonary complications based on gas exchange, chest x-rays and computerized tomography scans have been evaluated [3,4]. Only few studies have attempted to evaluate the pulmonary function in the early phase of AP and with conflicting results [5,6].
Aims and Methods: To evaluate the changes in pulmonary function tests during the early phase of acute pancreatitis (AP). We included patients with their first attack of AP regardless of aetiology or disease severity admitted to our department in the period February 2016 to June 2017. The diagnosis of AP was based on revised Atlanta criteria [7].
Severe AP was defined as C-reactive protein (CRP) >150 mg/l. Patients were evaluated on day 1, 2, 3, 6, and 10, and one month after hospital discharge in our outpatient clinic. We measured plasma values of CRP, white blood count (WBC), amylase and albumin, and performed chest x-rays. Pulmonary function tests included the % predicted: forced expiratory volume during the first second (FEV1), forced vital capacity (FVC), total lung capacity (TLC), diffusion lung capacity (DLCO) and the ratio between DLCO and alveolar volume (DLCO/VA). Patient characteristics were summarized using means with standard errors (SD) or proportions. Groups were compared using t-test or one-way analysis of variance (ANOVA) with Bonferroni's correction for multiple comparisons.
Results: A total of 44 patients (52% men; mean age 52 years; gallstone pancreatitis 66% and alcohol related pancreatitis 20%) admitted with their first attack of AP and 22 healthy controls were included. Eighteen patients (41%) developed severe AP. Six patients (14%) required treatment at the intensive or semi-intensive care unit. Three patients died (7%) during admission. Twenty-eight percent developed pulmonary complications with pneumonia, atelectasis and/or pleural effusion. Thirty-four percent required oxygen therapy, and 34% required continuous airway pressure. None required mechanical ventilation or pleural drainage.
From day one, patients had impaired FEV1, FVC, DLCO, and TLC compared with controls ($p < 0.0001$ in all analyses). The pulmonary dysfunction was greater for patients with lung complications compared with controls ($p < 0.001$) and patients without lung complications ($p < 0.001$). Evidence of pulmonary dysfunction, especially DLCO, was also seen after discharge.
Conclusion: This study suggests that patients with AP develop pulmonary dysfunction, probably due to combination of extra-pulmonary causes and alveolar damage, from the first day after hospital admission and that the dysfunction may last for several weeks after hospital discharge.
Disclosure: L.L.G. acted as investigator in clinical trials funded by Merck, Abbvie, Intercept, and Norgine, got travel expenses covered by Novo Nordisk, and gave lectures funded by Eli Lily and Norgine. The remaining authors declare no conflicts of interest.

Introduction: International guidelines for Acute Pancreatitis (AP) recommend that patients with Acute Biliary Pancreatitis (ABP) should undergo cholecystectomy during index admission or in 4 weeks' time after discharge. However, this recommendation is not consistently followed and the disease recurs in a proportion of patients. A system is needed to determine the risk of recurrence after ABP to prioritize patients for cholecystectomy in the surgical waiting list.
Aims and Methods: We developed a model to determine the recurrence of ABP, based on demographic data, endoscopic procedures and laboratory tests at admission for a first episode of ABP.
A retrospective cohort study of patients admitted at our Department from 2010 to 2015 with a first episode ABP was carried out. All patients were prospectively enrolled in a central electronic medical record (EMR), which is shared by all the hospitals and health centres around the north-west of Spain. Biliary aetiology was defined by the presence of stones, or sludge/microlithiasis in the CBD or gallbladder at abdominal ultrasound, EUS or MRCP, together with the absence of AP relapse over at least 2-year follow-up after cholecystectomy. Liver laboratory tests at admission were recorded. Primary outcome was ABP recurrence during the six-month period after first admission for ABP. Survival analysis was performed using the Kaplan-Meier method. Factors associated with ABP recurrence were scored and patients were classified as low, intermediate and high risk of relapse according to the total score. A Cox regression to compute hazard ratios (HR) and 95% CIs to determine associations between risk of progression and scores were used.
Results: 353 patients with a first episode of ABP were included. The median time for cholecystectomy was 135 days (range 72–199). After exclusion of patients who waited longer than 6 months for cholecystectomy, 221 patients were finally included; 135 (60.5%) were female, mean age 67.6 years (range 51.2 to 77.7). ABP relapsed in 56 patients (25.1%). Serum levels of alkaline phosphatase, endoscopic sphincterotomy (EE) and severity of AP were significantly associated with the risk of ABP relapse. Scores assigned (Table) identified patients at risk of ABP relapse with a c-statistic of 0.63 (95% CI 0.57–0.68), ($p < 0.001$), HR 3.33 (95% CI 1.73–6.40). Patients in the high, intermediate and low-risk group had a rate of ABP relapse of 21.5%, 3.6 and 0%, respectively.
Conclusion: A score system (named Recurrence Acute Biliary Pancreatitis (RABP) score) was developed based on admission serum levels of alkaline phosphatase, EE and severity of AP. The RABP score identified patients with ABP at low, intermediate and high risk of recurrence, allowing patients in the cholecystectomy waiting list to be prioritized.

Serum alkaline phosphatase	Score
0 to 263 (Normal limit)	5
264 to 526 (1–2 ULN)	4
527 to 789 (2–3 ULN)	3
790 to 1052 (3–4 ULN)	2
>1052 (>4 ULN)	0
Severity of AP	
Mild AP	4
Moderate AP	2
Severe AP	0
ERCP + EE	
No	4
Yes	0

ULN, upper limit of normal.
Low risk: 4 to 8 points; intermediate risk: 9 to 11 points; high risk: 12 to 13 points

[Relapsing Acute Biliary Pancreatitis Score.]

P1354 UTILITY OF ERCP IN ACUTE BILIARY PANCREATITIS

K. Jamil[1], **S.S. Latt**[2], S. Folkerts[2], S. Birdi[2]
[1]*BSUH, DDC, Brighton, United Kingdom*
[2]*Brighton and Sussex University Hospitals Trust, Digestive Diseases Department, Brighton, United Kingdom*

Contact E-Mail Address: susulatt.dr@gmail.com

Introduction: The timing of, and indication for ERCP in acute biliary pancreatitis (ABP) is an unresolved issue. Whilst expert opinion suggests early ERCP (<72 hours) should be performed in the setting of cholangitis and ongoing obstruction, lack of consensus guidelines means that practise is variable. Data suggests that often ERCP is not necessary as most ductal gallstones pass spontaneously.

Aims and Methods: The purpose of this study was to assess the use of ERCP in the setting of ABP, specifically evaluating timing and findings at ERCP. We retrospectively reviewed the case notes of all patients admitted to Brighton and Sussex University Hospitals NHS Trust with a diagnosis of ABP between 1st January 2015 and 31st December 2017. Data recorded included age, sex, LFTs on admission, length of stay, and imaging findings. If ERCP was performed, the timing and ERCP findings were analysed, and details of any subsequent cholecystectomy were recorded.

Results: One hundred and fifty seven patients (64 male, 93 female) were admitted with acute biliary pancreatitis during the three-year period with a median age of 63 (Range 14–101). 69 patients (44%) underwent ERCP. 16 patients (23%) had ERCP within 72 hours. The median time to ERCP from admission was 10 days (range 1- 48 days). ERCP was unsuccessful in 4 cases (5.7%). Stones were found in less than half the cases (32/65, 49%). Compared with definite imaging findings, equivocal imaging findings (eg possible stone and biliary dilatation only) was associated with no stone being found at ERCP (66% in equivocal, vs 42% in definite, $p = 0.05$). There was a trend towards lower chance of finding stones at ERCP in those who had the procedure 3–14 days from admission compared with those ERCP'd within 72 hours (46% vs 75%, $p = 0.09$). 26 patients proceeded to cholecystectomy and median number of days before cholecystectomy is 33.5 days (range 4–663 days)

Conclusion: In ABP, ERCP is not always indicated even when stones are seen in the CBD on imaging. Our data suggests that stones often pass spontaneously after the imaging and that unnecessary ERCPs are performed. We suggest that in selected cases (eg those with equivocal imaging), repeat imaging/clinical evaluation is performed at 10–14 days to reassess the need/indication for ERCP.

Disclosure: Nothing to disclose

Introduction: The majority of deaths (60–75%) in patients with chronic pancreatitis (CP) are due to extra-pancreatic consequences of the disease like cardiovascular events, osteoporosis, and infections. Data are lacking regarding the risk of such events and their relation with exocrine (EPI) or endocrine pancreatic insufficiency and the nutritional status during the FU. Recent guidelines recommend the use of the MUST score to assess the nutritional status of CP patients.

Aims and Methods: To evaluate the incidence of extra-pancreatic events in patients with CP during the follow-up and their association with CP features, pancreatic function and nutritional status.

Retrospective analysis of a single-centre cohort of CP patients prospectively enrolled and followed-up. Epidemiological data, risk factors, new hospitalizations were recorded at the diagnosis and at FU visit. EPI assessed by fecal elastase, MUST score evaluated as a nutritional tool. The occurrence of death and of extra-pancreatic events was recorded. Differences in terms of clinical features, risk factors and nutritional factors analysed by fisher and t-test. Hospitalization -free survival was evaluated with Kaplan-Meier and Cox regression analysis.

Results: 110 patients (64% male; mean age 57) enrolled with a median FU of 36 months. 52% had a toxic aetiology and 53% had EPI. 10% of patients had severe CP and 29% had a MUST score ≥2 at diagnosis. During the FU, 2% of patients died, 2% had cardiovascular events, 8% had infections and 16.4% needed endoscopic/surgery treatment. 34% needed hospitalization, in 49% for extra-pancreatic events. There was no association between EPI and extra pancreatic events. A BMI <20 and a MUST score≥2 were borderline significant for being associated with an increased risk of hospitalization (HR 2.1 95% CI 0.7–6 p 0.07; HR 1.8 95% CI 0.8–3.9 p 0.09). Toxic aetiology had a two-fold risk of new hospitalization (HR 2.9 95% CI 0.9–5.7 p 0.001). Patients with severe disease had a higher risk of hospitalization (HR 4.5 95% CI 0.9–22 p 0.0002) and more often needed endoscopic/surgery treatment (55% vs 13% p 0.006).

Conclusion: About 30% of patients were at high risk of malnutrition at diagnosis, and 34% of them were hospitalized during the FU, often for extra-pancreatic events that caused death in 2%. Toxic aetiology and severe disease are associated with hospitalization and MUST score seems to be less useful in predicting these events.

Introduction: Pancreatic steatosis is an uncommon pathological condition caused by adipose ectopic deposition and metabolic disorder. Somatostain, a neuroendocrine hormone, can suppress the release of gastrointestinal peptides, including suppression of pancreatic secretion. Octreotide, a synthetic analogue of Somatostain with a longer half-life, is used as a replacement of somatostain due to the similar effects.

Aims and Methods: This study aims to investigate the underlying mechanisms of pancreatic steatosis and octreotide effects. A total of 60 C57BL/6J mice were randomly allocated to normal chow (NC), high-fat diet (HFD), and HFD + Octreotide groups. Body weight, food intake, pancreatic weight, serum and pancreatic lipid levels, level of serum insulin, glucose tolerance test and pancreatic tissue alteration at histology were investigated. Expression of fatty acid synthesis pathway genes and proteins—adenosine monophosphate-activated protein kinase (AMPK), sterol regulatory element binding protein-1c (SREBP-1c), fatty acid synthetase (FASN), acetyl-CoA carboxylase (ACC), and fatty acid β-oxidation pathway—peroxisome Proliferator activated receptor α (PPAR α), acyl-CoA oxidase-1 (ACOX-1) and carnitine palmitoyltransferase-1 (CPT-1) were measured with RT-PCR and western blot.

Results: Mice with HFD showed increased body and pancreatic weight, serum and pancreatic lipid levels, accompanied by aggregated lipid droplets in pancreatic acinar cells, which were declined with octreotide treatment. In HFD group the mRNA and protein levels of SREBP-1c and its target genes were significantly elevated, while the expression of β-oxidation related genes were decreased compared to NC group. Octreotide reduced fatty acid synthesis pathway, at the same time increased β-oxidation pathway.

Conclusion: Octreotide can improve pancreatic steatosis in high-fat diet mice, probably by inhibiting pancreatic fatty acid synthesis and β-oxidation pathways.

Introduction: Studies reporting on function after endoscopic treatment of chronic pancreatitis are scarce.

Aims and Methods: The aim of the study was to investigate prospectively the evolution of pancreatic endocrine and exocrine function in patients undergoing endoscopic treatment based on endocrine function parameters and fecal tests for exocrine function. Between November 2013 and December 2016, patients

requiring endoscopic drainage for chronic pancreatitis with symptomatic ductal obstruction were enrolled in the study. Endocrine function was evaluated by HbA1c, fasting blood insulin level, C-peptide level and HOMA test before endotherapy and at 1, 3, 6 and 9 months following endotherapy. Exocrine function was evaluated by 72h fecal fat test, fecal acid steatocrit and elastase level. A comparative analysis between follow-up points (1,3,6 and 9 months) and baseline values of variables was performed.
Results: Thirty-four patients (age: 54+12 yr, 67.6% male) were included. Statistically significant improvement in HbA1c was attained at 1 (6.6 vs. 6.2, *p=0.001*), 3 (6.6 vs. 6.1, *p=0.005*) months and at maximum follow-up (6.6 vs. 6.0, *p=0.006*) compared to before drainage. HOMA-B values were statistically higher at 1 (53.0 vs. 67.2, *p=0.002*), 3 (53.0 vs. 68.6, *p=0.001*), 6 (53.0 vs. 75.4, $p < 0.001$) months and at maximum follow-up (53.0 vs. 75.0, $p < 0.001$). Clinical success of endoscopic drainage defined as 50% reduction in VAS score as compared to before drainage was recorded in sixty-eight, seventy-nine, seventy-five and seventy-two percent of patients at 1, 3, 6 and 9 months respectively. Exocrine function was not assessable due to patients' poor compliance to stool sampling.
Conclusion: To our knowledge, our study is the first to evaluate prospectively the effect of endoscopic treatment on the endocrine function of the pancreas as the principal aim. Our study has shown significant improvement in endocrine function at 1, 3, 6 and 9 months following endoscopic drainage. All endocrine function variables (HbA1C, FPG, FBIL, C-peptide, HOMA-B) improved their values at each follow-up point. Similar results were obtained in diabetic patients under insulin therapy or oral antidiabetic medications as well as in non-diabetic patients. In conclusion, endoscopic therapy in chronic pancreatitis improves glycaemic control and pancreatic endocrine function in the short-and mid-term follow-up. We therefore suggest that it might become a new indication for treatment even in non-diabetic patients.

Introduction: Chronic pancreatitis (CP) is a progressive and permanent destruction of the pancreas resulting in exocrine and endocrine insufficiency and often causing chronic disabling pain. Recently, early CP has been recognized by typical pancreatic-type pain, normal conventional imaging examinations, and subtle findings of CP using endoscopic ultrasound (EUS). However, it remains unclear whether the clinical characteristics including EUS findings and symptoms of early CP are reversible. In this study, we retrospectively evaluated the efficacy of treatment for early CP during long-term follow up.
Aims and Methods: Thirty-four patients with early CP were treated with protease inhibitors and pancreatic enzymes for at least two years. They showed typical EUS findings for early CP, presented with repetitive abdominal pain and elevated serum pancreatic enzyme levels. The outcomes measured were changes in abdominal symptoms, serum pancreatic enzyme levels, pancreatic exocrine functions, and EUS findings.
Results: The median treatment duration was 66.5 months, during which 80% of the patients showed decreased pain intensity. The face rating scale significantly improved compared to before treatment (1.1 vs. 2.4 points, $p < 0.01$). Serum pancreatic enzyme levels (amylase, lipase, and elastase-1) significantly decreased compared to before treatment ($p < 0.05$). Although EUS findings revealed some differences compared to before treatment in 4 of the 24 patients, the changed EUS findings were not related to the presence or absence of improvement in abdominal symptoms and serum pancreatic enzyme levels.
Conclusion: Our results indicate that therapeutic intervention for early CP should have clinical significance. However, the changes of early CP may be irreversible because there was no correlation between time-dependent changes in EUS findings and the improvement of clinical parameters.

Introduction: In ESGE guidelines, also in Japanese guidelines, endoscopic treatment and extracorporeal shock wave lithotripsy (ESWL) for symptomatic chronic pancreatitis with/without pancreatic stone is recommended, however, the selection of treatment methods and procedures are not established yet.
Aims and Methods: Evaluating the clinical outcome of the chronic pancreatitis with pancreatic stone patients underwent ESWL in our center.
59 consecutive patients underwent ESWL for pancreatic stone with chronic pancreatitis between January 2010 and December 2014 at our tertiary referral center in Japan.
ESWL was performed under X-ray fluoroscopy using a device of MODULITH SLX (Storz Medical, Switzerland). If it was difficult to recognize stone by X – ray, ENPD tube was indwelled and it was performed under the contrast.
In patients with pancreatic duct stricture, pancreatic stent insertion for 2 to 3 months was applied in addition to ESWL. After the initial treatment, we deployed ENPD tube and clinical success was evaluated by pancreatography via ENPD tube. If the outflow was well confirmed, the patients were observed without additional procedure. If clinical success was not obtained, the patients underwent additional ESWL and/or upgraded the size of the stent or placing of multiple stents.
Primary endpoints were the results of the treatment and the asymptomatic period, and secondary endpoints were the complications of the procedures, and the risk factors for the recurrence.
Results: Of the 59 patients, the median age was 60 years old, 44 males and 15 females. The etiologies of pancreatitis were alcohol (n = 40), idiopathic (n = 12), autoimmune pancreatitis (n = 5) and pancreas divisum (n = 2). The region of the stones were pancreas head (n = 41), body (n = 9), tail (n = 3) and multiple regions (n = 6). 31 patients (52.9%) needed pancreatic stenting for the main pancreatic duct strictures.
In all patients the treatments were successful. The median period of the treatment were 62 days (2–637). The median number of all procedures were four (1–10), ESWL were two (1–6). During the median observation period of 412 days (4–2794), one year asymptomatic duration rate was 76.7%, and three years rate was 55.9% using Kaplan-Meier method.
The risk of recurrence was high in the patients with non-alcoholic pancreatitis and the obstruction/stricture of body-tail. Seven patients (12%) had the complications after ERCP: pancreatitis (n = 3), incompetence of basket catheter (n = 2), guidewire penetration (n = 1), cholangitis (n = 1). They had improvement with conservative or endoscopic therapy.
In order to detect the risk factors for the recurrence of the symptoms we performed univariate analyses, non-alcoholic patients (p = 0.02) and the obstruction/stricture of body-tail (p = 0.009) resulted as significantly correlated with the recurrence.
We also performed a multivariate logistic regression analysis, non-alcoholic patients (OR = 3.71, 95% C.I.: 1.09–12.6, p = 0.036) and the obstruction/stricture of body-tail (OR = 4.42, 95% C.I.: 1.28–15.3, p = 0.019) also resulted as significantly correlated with the recurrence.
Conclusion: ESWL combined with endoscopic treatment for chronic pancreatitis with pancreatic stone is the safe and effective treatment.
The risk of recurrence was high in the patients with non-alcoholic pancreatitis and the obstruction/stricture of body-tail.

Introduction: Previous studies have suggested that chronic pancreatitis (CP) is associated with increased risk of cardiovascular (CV) disease independently of other major risk factors.
Aims and Methods: We evaluated the risk of CV events in a well-phenotyped cohort of patients with CP and its association with pancreatic exocrine insufficiency (PEI) and pancreatic endocrine insufficiency (pancreatogenic diabetes) among other CV risk factors.
Prospective, longitudinal cohort study of patients with CP, followed-up at the Pancreas Unit of the University Hospital of Santiago de Compostela, Spain.
Results: 430 patients were included (mean 47.8 ± 14.4 years of age, 79.1% male). Mean follow-up was 8.6 ± 4.6 years. CP etiology was toxic (alcohol and/or smoking) in 290 patients (67.4%). PEI and pancreatogenic diabetes mellitus (DM) were present in 29.3% and 29.5% of the patients, respectively. A total of 45 cardiovascular events was prospectively recorded (10.5%); 21 patients had a major cardiovascular event (stroke or myocardial infarction) and 27 developed clinically relevant peripheral arterial disease. A higher incidence of cardiovascular events was recorded in patients with PEI than in those without (incidence rate ratio 3.67, 95% confidence interval (CI) 1.92–7.24; p < 0.001). In the multivariate analysis, PEI without DM (OR 4.96; IC95%: 1.68 to 14.65), coexistence of PEI and DM (OR 6.54; IC95%: 2.71 to 15.77), arterial hypertension (OR 3.40; IC95%: 1.50 to 7.72) and smoking (OR 2.91, IC95%: 1.07 to 7.97) were independently associated with increased CV risk.
Conclusion: Together with known major cardiovascular risk factors like smoking and hypertension, PEI is significantly associated with the risk of cardiovascular

events in patients with CP. Coexistence of pancreatogenic diabetes increases the CV risk associated with PEI in CP.

Introduction: Patients with chronic pancreatitis (CP) and pancreatic exocrine insufficiency (PEI) are at increased risk of cardiovascular events. Cardiovascular risk (CVR) assessment leads to proper primary and secondary prevention and may improve the quality of life.

Aims and Methods: To investigate CVR in patients with CP and PEI. Study enrolled 82 patients (48 males, mean age 49.46 years), receiving pancreatic enzyme replacement therapy due to PEI. CVR was assessed by Framingham risk score (FRS) used to predict an individual chance of developing cardiovascular disease in the next 10 years; by routine lipid profile and apolipoproteins (apo): apo A-I (protective against CV events, HDL-associated), apo B and C-III (proatherogenic), Apo B/Apo A-I ratio (associated with myocardial infarction prediction) and by vitamin D levels (using a validated, DEQAS certified ID-LC-MS/MS method with accuracy and precision within 7.5% and linearity range 3.0–300.0nmol/L). Malnutrition risk was evaluated by MUST (Malnutrition Universal Screening Tool). Severity of CP and pancreatic structural changes were assessed by M-ANNHEIM and Cambridge classifications, respectively. Statistics was performed via SPSSv22.

Results: According to FRS 25.61% of the patients were with high CVR, 20.73% – with moderate and 53.66% – with low. We observed a tendency to increase CVR (FRS) as the severity of both morphological changes and CP by M-ANNHEIM worsened. Vitamin D levels were significantly lower in patients with moderate CVR by FRS versus those at low risk, $p = 0.05$. Statistically significant correlations occur between CVR by FRS and HDL ($p = 0.0002$), total cholesterol ($p = 0.02$), LDL ($p = 0.02$), non-HDL ($p = 0.003$), VLDL ($p = 0.0002$), total cholesterol/HDL ratio ($p = 0.0001$). In patients with high CVR by FRS we found significantly higher apo B ($p = 0.02$) and lower apo A-I ($p = 0.007$) levels, as well as an increased risk of myocardial infarction using Apo B/Apo A-I ratio ($p = 0.04$). Dyslipidemia with borderline high and high levels of the atherogenic total cholesterol, triglycerides and/or LDL was evaluated in 50.68% of patients with CP. There was no significant difference in the incidence of dyslipidemia compared to both CP severity and structural changes. Low HDL levels were found in 35 of the studied patients (21 men) and high non-HDL levels – in 71.23%. There was a statistically significant difference in HDL levels between mild and moderate CP, $p = 0.04$. High total cholesterol/HDL ratio (above 5), which is associated with higher CVR, was observed in 41.1% of the patients. A progressive increase in the total cholesterol/HDL ratio was observed as the CP severity increased. Significant lower apo A-I and vitamin D levels were found with malnutrition risk and lipid malabsorption worsening ($p = 0.047$, $p = 0.032$). A significant difference was found in apo A-I levels between mild and moderate CP ($p = 0.007$) and between mild and advanced CP ($p = 0.04$) and in Apo C-III between mild and advanced CP ($p = 0.047$). With morphological changes worsening significantly lower apo A-I levels were found between Cambridge grade I and Cambridge grade III ($p = 0.03$) and between Cambridge grade I and Cambridge grade IV ($p = 0.005$). Similar observation was made for apo C-III between Cambridge grade I, II and Cambridge III, IV ($p = 0.000$).

Conclusion: Overall CVR assessment using FRS, lipid profile and apolipoproteins could identify patients at high risk of cardiovascular events and allows the proper control of the risk factors.

Introduction: Pancreatic Lipase-Related Protein 2 (PNLIPRP2) is a lesser lipase isoform which can digest long chain triglycerides, diglycerides and monoglycerides. In vitro experiments showed that thecommon nonsense variant c.1074G>A (p.W358X) causes the formation of a shorter misfolded protein that is not secreted well but induces endoplasmic reticulum (ER) stress. ER stress is a known susceptibility factor for chronic pancreatitis, suggesting that the p.W358X mutation of the PNLIPRP2 gene might contribute the development of pancreatitis.

Aims and Methods: Our aim was to investigate whether the p.W358X mutation of the PNLIPRP2 gene is associated with idiopathic and alcoholic chronic pancreatitis. In our study we enrolled 115 patients with idiopathic and 142 patients with alcoholic chronic pancreatitis and 200 controls recruited by the Hungarian Pancreatic Study Group (HPSG – www.pancreas.hu). Exon 11 and its flanking intronic regions were analyzed by Sangersequencing. Expression of the PNLIPRP2 gene was studied by RT PCR using human donor pancreas cDNA samples.

Results: When allele frequencies were considered, the p.W358X mutation was not overrepresented either in the idiopathic or the alcoholic chronic pancreatitis groups compared to the controls (54.8% and 50% vs. 52%, respectively). RT-PCR on a homozygous cDNA sample indicated drastically reduced PNLIPRP2 expression at the mRNA level. Additionally, we identified 5 more PNLIPRP2 variants (c.1071–379delG, c.1071–321C>T, c.1084A<G p.I362V, c.1161A>Gp.S387=and c.1181+55C>A) but none were associated with chronic pancreatitis.

Conclusion: The p.W358X mutation of the PNLIPRP2 gene is not associated with chronic pancreatitis. Expression of the truncated protein is inhibited at mRNA level likely by "nonsense-mediated mRNA decay", therefore, this variant does not cause ER stress in the human pancreas.

Introduction: Pancreatic cancer (PC) is one of the most difficult human malignancies to treat with poor outcome. A combination of gemcitabine plus *nab*-paclitaxel (GN) as well as FOLFIRINOX (FFX) is preferentially used for unresectable PC. However, it is not clear which regimen is appropriate for unresectable PC. For practicing evidence-based chemotherapy, we tried to find treatment-predictive markers in PC patients treated with GN and/or FFX.

Aims and Methods: We retrospectively investigated 68 advanced-stage (III and IV) of PC patients treated with GN. Patients backgrounds, hematological and chemical laboratory tests just before the chemotherapies were evaluated to detect the predictive factors for survivals and therapeutic effects with logistic regression analyses.

Results: Statistical differences ($p < 0.15$) were observed in neutrophil/lymphocyte ratio (NLR), platelet/lymphocyte ratio (PLR), neutrophil count, prognostic nutritional index (PNI), platelet count, CA19-9 level, white blood cell count, and serum albumin level between longer OS group (OS ≥1 year) and shorter OS group (OS <1 year) by univariate analyses. Kaplan-Meier analysis revealed that no statistical difference ($p = 0.3144$) on median OS between GN (375 days) and FFX (393 days) treatments. The ratio of PR/SD (disease control rate) was shown to be statistically higher than PD ratio in higher PNI ($p = 0.03$) or higher albumin ($p = 0.05$) group treated with GN, and also in lower CA19-9 group ($p = 0.08$) treated with FFX.

Conclusion: PNI, serum albumin level, and CA19-9 are treatment-predictive markers for disease control rate in patients with unresectable PC treated with GN, GN, and FFX, respectively. Statistical difference in median OS was not determined between GN therapy and FFX therapy.

Introduction: Distinction between the different types of pancreatic cystic neoplasms (PCNs) is essential, since non-mucinous PCNs are mostly benign without need for surveillance, whereas mucinous PCNs are considered premalignant and require either surveillance or surgical resection. We aimed to systematically review the diagnostic accuracy of CEA in differentiating mucinous and non-mucinous PCNs and to determine the optimal cut-off value of CEA using individual patient data meta-analysis.
Aims and Methods: A systematic literature search was performed in PubMed, EMBASE and the Cochrane Library for studies investigating the accuracy of CEA in differentiating mucinous and non-mucinous PCNs. Individual data of patients with histopathological confirmation of the type of PCN were extracted if available from the included studies to determine the optimal cut-off value of CEA.
Results: Nineteen studies were included, with a total of 1477 patients. Meta-analysis of 16 studies with 1298 patients showed that the pooled sensitivity, specificity, positive likelihood ratio, and negative likelihood ratio of the most commonly used cut-off CEA >192ng/ml for the differentiation between mucinous and non-mucinous PCNs were: 63.8% (95% CI 60.6%-67.0%); 85.2% (95% CI 81.3%-88.5%); 90.5% (95% CI 88.2%–92.3%) and 51.7% (95% CI 49.2%–54.0%).
Individual data of 408 patients from seven studies were available and could be extracted to determine the optimal cut-off value of CEA. A cut-off CEA≥20ng/ml achieved the highest accuracy for differentiating between mucinous and non-mucinous PCNs with pooled sensitivity of 91.1% (95%CI 87.5%-93.9%) and 93% specificity (95% CI 84.3%-97.7%). The positive predictive value and negative predictive value were 98.4% (95% CI 96.3%–99.3%) and 68.8% (95% CI 60.9%–75.7%), respectively. With CEA ≥20ng/ml, 5 (1.2%) patients would have been over diagnosed, whilst 30 (7.4%) mucinous cysts (15 IPMNs, 9 MCNs and 6 mucinous ductal adenocarcinoma) would have been missed. Whereas with a CEA >192ng/ml, 0 (0%) patients would have been over diagnosed, but 116 (28.4%) mucinous cyst (69 IPMNs, 35 MCNs and 12 mucinous ductal adenocarcinoma) would have been missed.
Conclusion: In conclusion, pancreatic cyst fluid CEA can accurately differentiate histologically verified mucinous cysts from non-mucinous cysts with an optimal cut-off value ≥20ng/ml,which is much lower than previously reported values. For further validation large prospective studies are encouraged.

Introduction: Pancreatic cancer is a deadly disease that is often detected in late stages due to the unobtrusive nature of its evolution. Various centers around the world are currently investigating the feasibility and yield of surveillance for pancreatic cancer in high-risk individuals. Evidence is beginning to accumulate that surveillance may lead to the early detection of precursor lesions and asymptomatic pancreatic cancer. Proper screening methods and identification of such precursor lesions can allow prophylactic measures and interventions to be administered in order to prevent further fatalities. The primary objective of this project was to check feasibility of identifying precursor lesions in high-risk individuals by endoscopic ultrasound surveillance in attempt to prevent the development of pancreatic cancer or at least detect early cancer.
Aims and Methods: Between 2008 and 2018, a cohort of 123 high-risk individuals came for annual/biannual endoscopic ultrasound screening for pancreatic cancer. Referrals were from both physicians and self-referrals. Inclusion criteria included at least one first-degree relative with pancreatic cancer within 10 years of the age of that first-degree relative, or otherwise within the consensus guidelines recommended criteria. Retrospective and prospectively collected data was obtained, analyzed and compared on the basis of several variables. These variables include age at beginning of screening, gender, smoking, obesity, diabetes and presence of tumor markers. Genetic mutations were taken into account as well as the patients personal and family history of cancer. Each screen date and their respective results and plan were recorded. Pancreatic cancer screening guidelines, based on consensus opinions, have been applied in various centers around the world; however, evidence for effectiveness is lacking. At Rambam Health Care Campus, we have established a cohort of high-risk individuals and herein report our results of screening for pancreatic cancer.
Results: Detection of precursor pancreatic lesions is feasible with endoscopic ultrasound screenings, however adherence remains an important challenge to surveillance of findings. Patients may best be categorized based on specific risk factors, including genetics and family history, as an indication of when to initiate screening.
Average age at first screening was 57. 210 EUS exams have been performed. 22% also submitted to genetic consultations. Overall two patients underwent pancreatic surgery and both have survived long-term. 40% of patients showed any EUS abnormalities.
Conclusion: International Collaborations, such as the International Cancer of Pancreas Screening (CAPS) consorstium, are needed to collate evidence for screening to prevent pancreatic cancer morbidity and mortality, and are essential to achieve proof of concept. Pancreatic cancer is a challenging field and endoscopic ultrasounds alone cannot prevent all cases of pancreatic adenocarcinoma. Screening programs, however, within research protocols may yield actionable results to prevent or at least detect some pancreatic cancers at an early stage. Different countries with varying healthcare systems and budgets may find that variance of screening procedures may be appropriate.

Introduction: Although the incidence of pancreatic cystic lesions has increased, the majority do not progress to pancreatic cancer and the burden of surveillance is significant. In previous studies we and others have identified metabolic parameters, in particular diabetes and obesity, to be associated with pancreatic malignancy. In our cohort of low-risk intraductal papillary mucinous neoplasms (IPMN) surveyed at our institution we sought to evaluate the relationship between progression and the diagnosis of baseline diabetes and new onset diabetes in the presence and absence of obesity.
Aims and Methods: We conducted a retrospective review of prospectively collected data of patients evaluated for a pancreatic cyst between 2003 and 2016. Patients who met clinical criteria for presumed IPMN with no worrisome features or high-risk stigmata at baseline imaging, as defined by the 2012 international Fukuoka guidelines, and ≥12 months of follow-up were included. We collected data on random and fasting glucose values, known clinical diagnosis of diabetes and HbA1C as well as BMI data throughout surveillance. New onset diabetes was defined as a random plasma glucose concentration of ≥200 mg/dl or an HbA1c ≥6.5% at least 3 months after initial diagnosis. Obesity was defined as having a BMI≥30. Statistical analysis was performed with the chi square test and relative risk analysis.

Results: Of 2562 patients who underwent evaluation of a pancreatic cystic lesion, 468 met inclusion criteria. 132 patients (28.2%) had diabetes at index imaging. 32 patients (6.8%) developed diabetes during the period of IPMN surveillance. BMI data was available for 364/468 patients (77.8%). 90/ 364 patients (24.7%) were obese at baseline. 58/468 patients (12.4%) progressed to have IPMNs with worrisome features and 21/468 patients (4.5%) progressed to have IPMNs with high risk stigmata or cancer. Baseline diabetes, with or without obesity, was not associated with a significantly increased risk of progression. New onset diabetes was not associated with a significantly increased risk of developing worrisome features. However, we found new onset diabetes was associated with a significantly increased risk of developing high-risk stigmata or cancer in both the entire cohort (RR 1.14–7.74; p = 0.028) and in non-obese patients (RR 2.16–16.02; p < 0.001).
Conclusion: In this cohort of low-risk clinically suspected IPMNs we found new onset diabetes to be associated with development of high-risk stigmata or cancer. This data further supports the inclusion of new onset diabetes mellitus as a risk factor for IPMN progression.

Introduction: Pancreatic ductal adenocarcinoma (PDA) is the fourth leading cause of cancer-related death with a 5-year survival rate of approximately 7%. While surgery is currently the only potentially curative therapy, only 15–20% of the patients are considered for resection. However, in some 25% of patients the tumor cannot be resected due to unexpected liver or peritoneal metastases. As of now, it is not possible to accurately determine whether PDA patients are suitable for resection and they have to undergo invasive surgery in order to determine the resectability status. Therefore, applying image analysis techniques to routine abdominal CT scans, i.e. quantitative radiomics, could be helpful to predict local resectability of PDA and aid in treatment planning.
Aims and Methods: The aim of our study was to compare the performance of an expert radiologist to that of quantitative radiomics for prediction of local resectability of pancreatic ductal adenocarcinoma on routine abdominal contrast-enhanced CT. We included 50 patients (m:f = 28:22; range 48–79 yrs) with histologically proven pancreatic ductal adenocarcinoma who were operated within 4 weeks of an initial routine portal-venous phase multidetector-row CT examination. An expert abdominal radiologists scored CT data for tumor resectability. Another expert abdominal radiologist drew tumor contours to obtain a volume of interest, from which we computed 90 intensity, shape and texture features. During training the number of features was reduced with a feature selection algorithm and combined with several classifiers to predict local resectability using radiomics.
Results: There were 33 hypo- and 17 iso-attenuating tumors, of which 29 were resectable and 21 non-resectable. The best classification result was obtained with a support vector machine classifier with the feature vector reduced by regularized discriminative feature selection. Accuracy for predicting resectability was 68% for the radiologist, and 74% for radiomics. Sensitivity, specificity, positive and negative predictive value for resectability were 90%, 38%, 67% and 73%, respectively, for the radiologist and 97%, 42%, 70%, and 90%, respectively, for radiomics.
Conclusion: Quantitative CT-based radiomics for prediction of local resectability of pancreatic ductal adenocarcinoma on routine CT, may outperform expert radiologists.

Introduction: An association between ABO blood type and risk of developing cancer is recognized in some cancers such as pancreatic cancer (PC) and gastric cancer. Additionally, long-term effect of ABO blood type on the clinical course of various cancers are reported i.e. PC, renal cell carcinoma, non-small cell lung cancer. Studies with regards to PC from the western countries investigated the effect of ABO blood type on the survival mostly in resected patients. Within Asia, to date, there is a study from China. However, the results are inconclusive and its impact on the Japanese patients with PC, long term outcomes in particular, is poorly understood.
Aims and Methods: The Ehime Pancreato-Cholangiology (EPOCH) Study Group aimed to determine whether ABO blood type influence long-term outcomes of the Japanese patients with PC. Chart review for patients with PC diagnosed between 2011 and 2013 was conducted within the EPOCH Study Group. Data collection includes age, sex, ABO blood type, Union for International Cancer Control (UICC) stage at diagnosis of PC and outcomes. The chi-square test and Student's t-test were used for statistical analysis, where appropriate. Outcomes were analyzed using the Kaplan-Meier method and Cox proportional hazards regression. Differences in survival analyses were determined using the log-rank test. Local ethic boards approved the study but written consent form was waived due to the retrospective manner.
Results: Distribution of UICC stage of the entire cohort (N = 409, mean age 72.9 ± 9.5, male 52.3%) was as follows: stage 0 (N = 7, 1.7%), stage IA (N = 20, 4.9%), stage IB (N = 22, 5.4%), stage IIA (N = 104, 25.4%), stage IIB (N = 50, 12.2%), stage III (N = 63, 15.4%) and stage IV (N = 144, 35.2%). Distribution of ABO blood type were as follows: type A (N = 192, 47.0%), type B (N = 86, 21.0%), type O (N = 91, 22.2%) and type AB (N = 12.2, 12.2%). Mean age did not differ among ABO blood type (71.0 ± 10.6, 72.9 ± 9.5, 72.9 ± 9.2 and 70.5 ± 10.1, respectively). Sex (male rate) did not differ among ABO blood type (53.2%, 52.3%, 60.4%, and 50%, respectively). However, type O was diagnosed at earlier stage than type non-O when UICC stages 0-IIA was considered as earlier stage (47.3% vs. 34.6%, P = 0.027) and the difference was much more significant between type O and type AB (47.3% vs. 26.0%, P = 0.019). Furthermore, median survival time (MST) of type O was longer than that of type non-O (P = 0.058) and statistically significant when compared with type AB (P = 0.045): type A 370 days, type B 408 days, type O 521 days, type AB 301 days.
Conclusion: ABO blood type, type O and type AB in particular, influenced long term outcomes of Japanese patients with PC presumably due to the difference in disease onset.

Introduction: Inflammation plays an important role in pancreatic carcinogenesis. Interleukin-6 promote cell proliferation, migration, invasion and angiogenesis. IL -10 inhibits pro-inflammatory cytokine release from lymphocites via STAT3, downregulates MHCII co-stimulatory molecules CD80/CD60, reducing clonal expansion of T-lymphocytes. Recently several report showed that IL-17 have an important role in initiation and progression of pancreatic intraepithelial neoplasia PanIN and early pancreatic cancer. Family history of pancreatic cancer and several genetic syndromes must be taken into account for early detection of pancreatic cancer.

Aims and Methods: To evaluate IL-6, 10 and 17 profiles in patients with: pancreatic adenocarcinoma (PAC), chronic pancreatitis (CP), risk conditions for PAC (e.g Familial pancreatic cancer, hereditary pancreatitis, Brest ovarian cancer syndrome, HNPCC, FAMMM, PJS, juvenile polyposis, FAP) comparative with a group of controls.

A total of 138 patients (mached by sex and median age), were enrolled in the study. These were grouped in the pancreatic cancer group (n = 77), chronic pancreatitis group (n = 34), risk conditions groups (n = 8) and the control group (n = 19).

The diagnosis of PAC was made histopathologically by biopsy specimen analysis (fine needle aspiration guided by echoendoscopy or surgery resection). The diagnosis of CP was based by medical history, imaging methods and echoendoscopy data according to Rosmond criteria. The control group consisted of healthy volunteers who were matched by gender and age. It was collected 10 mL of peripheral blood from all individuals. Plasma was separated, frozen and stored at −80°C. Systemic concentrations of IL-6, 10 and 17 were measured using ELISA kits.

Results: The seric levels of IL-6 were significant statistically higher in patients with PAC and CP vs. control groups ($P < 0.0001$). There was no statistical significance between IL-10 levels in PAC and risk conditions groups ($P = 0.1777$) and between CP and control groups ($P = 0.1775$). We found statistically significant difference between IL-10 level in PAC group vs CP group ($P = 0.0023$) but no significant statistical between risk conditions group and control group. IL-17 levels were significant higher in PAC patients and in CP vs risk conditions group ($P < 0.0001$) and in PAC group vs CP group also ($P < 0.0001$).

Conclusion: We detected higher serum levels of IL-6, 10 and 17 in patients with CP and PAC suggesting their role in initiation and progression of early pancreatic cancer with implications in diagnostic and therapeutic management. These cytokines can be non-invasive biochemical markers for the screening of PAC in high risk or moderate risk population. Prognostic roles need to be established.

Introduction: Lipoxygenase (LOX)-derived bioactive lipids represent a family of important biological molecules that can be of great importance in the pathogenesis of pancreatic neoplasms. We hypothesized that systemic levels of LOX-derived Hydroxyeicosatetraenoic acids (HETEs) may be associated with clinical presentation of pancreatic neoplasms in humans, as well as with previously reported phenomenon of intensified circulation of various populations of bone marrow-derived stem cells in these patients.

Aims and Methods: In the current study, we comprehensively evaluated the systemic levels of selected HETEs such as 5-, 12-, and 15-HETE in patients with pancreatic adenocarcinoma (n = 36), chronic pancreatitis (n = 39), and in healthy individuals (n = 35).

Results: Compared to healthy individuals, patients with pancreatic adenocarcinoma showed 3–8-fold higher levels of 5-, 12-, and 15-HETE (at least $p < 0.003$). Similar results were observed in patients with chronic pancreatitis, who had elevated concentrations of all examined HETE acids compared to healthy volunteers (in all cases at least $p < 0.03$). Interestingly, the levels of the examined HETEs were not significantly associated with the TNM stage of pancreatic cancer in our patients. However, 12-HETE and 15-HETE concentrations were correlated with peripheral circulation of selected populations of bone marrow-derived stem cells, such as very small embryonic/epiblast-like stem cells and mesenchymal stem cells. Finally, analyses of receiver operating characteristic curves demonstrated that all HETEs examined had relatively low area under the curve values for discriminating pancreatic adenocarcinoma from non-cancerous conditions ($p > 0.05$ in each case).

Conclusion: Our study provides first clinical evidence for the significance of the examined HETEs in the clinical pathogenesis of pancreatic cancer and other pancreatic diseases in humans. Moreover, our study identifies significance of HETEs in the phenomenon of intensified peripheral circulation of selected populations of bone marrow-derived stem cells in patients with pancreatic cancer. Finally, our data demonstrate that the HETEs examined here do not show sufficient clinical potential to be used as independent biomarkers for differentiating pancreatic adenocarcinoma from other non-cancerous conditions in humans.

Introduction: Sarcopenia can be a predictor of complications after pancreatic resections.

Aims and Methods: We performed a retrospective analysis of treatment of 104 patients with pancreatic adenocarcinoma, who underwent pancreaticoduodenectomy in our institution in the period 2012–2017. Preoperative computed tomography (CT) was performed for all patients. Sarcopenia was quantified using Hounsfield Unit Average Calculation (HUAC). They were measured at the level of the third lumbar vertebral body (L3).

Results: Sarcopenia was diagnosed in 44 (42.3%) patients *vs* 60 (57.7%) patients without this diagnosis. Postoperetive complications occurred in 26 (59.0%) patients in the group with sarcopenia and in 17 (28.3%) patients in the group without sarcopenia ($c^2 = 9.9$, $p = 0.0017$). Mortality was 2 (4.5%) and 1 (1.6%) respectively ($c^2 = 0.75$, $p = 0.38$).

In patients with sarcopenia infectious complications occurred in 5 patients, pancreatic fistula Grade B or C in – 14 patients, delayed gastric empting – in 2, haemorrhage- in 5.

In patients without sarcopenia infectious complications occurred in 5 patients, pancreatic fistula Grade B or C in – 4 patients, delayed gastric empting – in 4, haemorrhage- in 4. We did not find any significant difference in the increase in the number of infectious complications ($c^2 = 2.1$, $p = 0.14$), delayed gastric empting ($c^2 = 2.1$, $p = 0.14$) and haemorrhage ($c^2 = 0.11$, $p = 0.7$), but sarcopenia was revealed as an independent, significant risk factor for incidents of postoperative pancreatic fistula Grade B or C ($c^2 = 3.8$, $p = 0.04$).

Conclusion: HUAC could be easily calculated preoperatively in patients with pancreatic cancer. Present results suggest that sarcopenia, determined by HUAC, is a reliable indicator of the surgical outcome and significantly influences on total level of postoperative complications. It is also a strong predictor of clinically relevant postoperative pancreatic fistula occurrence. The assessment of sarcopenia can be used to improve the selection of patients with pancreatic cancer prior resection.

P1374 ANALYSIS OF VOLUME ADJUSTMENT IMPACT, RESULTS AND COMPLICATIONS USING THE SPATZ BALLOON FOR EXCESS WEIGHT TREATMENT: A LARGE BRAZILIAN EXPERIENCE IN FOUR HUGE CENTERS

R.J. Fittipaldi-Fernandez[1,2], A.C. Hoff[1,2]
[1]Endogastro Rio, GI Endoscopy, Rio de Janeiro, Brazil
[2]Angioskope, GI Endoscopy, São José dos Campos, Brazil

Contact E-Mail Address: ricfittipaldi@hotmail.com

Introduction: Intragastric Balloons (IGB) are used for decades worldwide in excess weight treatment with well-established success. SPATZ adjustable IGB approved for 12-month may provide greater weight loss due to a longer period of treatment and reduce early removals in intolerant patients.

Aims and Methods: We aimed to evaluate weight loss and complications in 04 private Brazilian clinics with a high volume of patients; To report whereas download and upward balloon adjustments and longer period of therapy have impact in treatment results regarding weight loss and early removal rates. We included patients that underwent Spatz3 IGB implantation and concluded at least the 1 year treatment. Minimum initial body mass index (BMI) was 27 kg/m2. We analyzed the complications and BMI reduction, percent total body weight loss (%TBWL) and percent excess weight loss (%EWL), weight loss in kilograms, early removal rates between patients submitted to adjustments or not. Data were analyzed using descriptive statistic and the Student t test. The level of significance was set at $p < 0.05$.

Results: 487 patients were analyzed (339 females). Mean age 40.1 years. Mean BMI 36.4 kg/m2; mean weight 101.3 kg, and mean initial balloon volume 620.34 ml (360 -700 ml). Balloon volume adjustments offered for intolerance and weight loss plateau. There were 34(6.98%) early removals (all refused adjustment), 15(3.08%) deflations, 19(3.90%) gastric ulcers (1 requiring balloon removal), 2(0.41%) gastric perforations, 1(0.22%) Mallory-Weiss Syndrome and 2(0.41%) Bezoars, 11(2.25%) gas production inside the balloon. 437 patients completed treatment. Mean weight loss was 18.3 kg; mean EWL 64.33% and mean TBWL 19.1%. The final BMI (29.80 Kg/m2) was significant lower than the initial (36.40 Kg/m2) (mean BMI reduction 6.6 Kg/m2). Success rate (>25%EWL) occurred in 392 (89.7%). Downward adjustments performed in 57(11.7%) cases (mean reduction 280.87 ml ± 64.58) and all continued treatment. Upward adjustment was performed in 232 patients (47.6%) (mean 5.7 ± 1.52 months; mean 230 ± 70.4 ml) and did not show statistically improvement in weight loss (Kg) in comparison to the group that did not adjust (mean weight loss 17.80 Kg vs 18.10 Kg, $p = 0.063$). 71%(mean 12.54 Kg) of the excess weight loss happened in the first 6 months and the other 29% (mean 5.48 Kg) in the subsequent period of treatment.

Conclusion: Spatz3 IGB is a very effective device to induce weight reduction, safe (no mortality), even though with a little higher morbidity when compared to traditional IGBs. The downward adjustment certainly reduces the incidence of early balloon removals in intolerant patients. On the other hand, the upward adjustment seems to be ineffective in providing a greater weight loss, but a longer treatment period probably brings better results when compared to shorter treatments.

P1375 A NOVEL TECHNIQUE FOR ENDOSCOPIC ENBLOC RESECTION FOR LESIONS UP TO 30 MM (EMR+)

B. Meier[1], K. Caca[2]

[2]*Klinikum Ludwigsburg, Abt. für Innere Medizin, Ludwigsburg, Germany*

Contact E-Mail Address: dr.benjamin.meier@gmail.com
Introduction: Endoscopic mucosal resection (EMR) is the most common technique for endoscopic resection (ER) of intestinal mucosal neoplasia. However, successful enbloc resection depends on tumor size and decreases under 40% for lesions >20 mm. In consequence, piecemeal EMR is usually performed for lesions >20 mm. This technique is associated with a higher rate of recurrency and R0 resection is difficult or impossible to determine after piecemeal resection. Endoscopic submucosal dissection (ESD) allows enbloc resection for lesions >20 mm but the technique is difficult, time-consuming and associated with a higher risk for complications. Submucosal injection is well investigated and essential for both resection techniques. The standard solution used for injection is saline solution, but the created submucosal cushion disappears quickly as saline is absorbed by the adjacent mucosa. Frequent re-injections and prolonged procedure times are the consequences.
Aims and Methods: Development of a technique (EMR+) which allows endoscopic enbloc resection of lesions up to 30 mm.
The technique was developed and evaluated in an explanted pig stomach. The stomach was adjusted in a special simulation model to be accessible to endoscopy. An additional working channel was mounted on a standard gastroscope and used for a resection snare. The conventional working channel of the scope was used for an anchor device. For submucosal injection a new developed agent with a temperature-dependent viscosity was used. The agent has liquid consistency at room temperature which allows submucosal injection. At body temperature the agent gels and forms a stable cushion within seconds which allows stable resection (no absorption, re-injections are not necessary). The safety of this agent has already been shown in vivo in domestic pigs. Imaginary lesions of 30 mm were marked by coagulation. After injection the anchor device was used simultaneously with the snare to facilitate resection. After the resection technique was established 22 resections (11 with a frontal and 11 with a tangential approach) were performed and evaluated.
Results: The median size of the enbloc resection specimens was 30 × 26 × 11 mm (maximum 40 × 33 × 14). The procedure times were between 6–7 minutes (Table 1). No perforations occurred.
Conclusion: The technique (EMR+) allows fast enbloc resection and obtains resection specimens of 30 mm. The technique needs to be evaluated in vivo.

Introduction: Although the number of elderly patients with superficial esophageal neoplasms (SENs) has been steadily increasing, there is still an evident lack of studies focused on the clinical outcome of esophageal endoscopic submucosal dissection (ESD) in the elderly. We investigated the feasibility and safety of ESD for SENs in elderly patients.
Aims and Methods: Patients who underwent ESD for SENs between December 2005 to December 2017 were eligible. Clinical features and treatment outcomes according to the three age groups (not-old, <65 years; young-old, 65–74 years; middle and oldest-old, >74 years) were retrospectively reviewed using medical records.
Results: ESD was performed in 426 patients with 475 lesions, including 97 cases (20.4%) of dysplasia, 364 cases (76.6%) of squamous cell carcinoma and 14 cases (3%) of adenocarcinoma. The age was divided into three groups, the not-old (n = 200), young-old (n = 179) and middle & oldest-old (n = 47). Gender, Smoking and characteristics of tumor (circumference, location, lesion size, resected specimen size, histology and depth of invasion) did not differ. Underlying disease such as hypertension (not-old vs. young-old vs. middle & oldest-old; 30.0% vs. 41.9% vs. 40.4%, p = 0.045), chronic kidney disease (0.5% vs. 0.0% vs. 4.3%, p = 0.033) and cardiovascular disease (2.0% vs. 7.8% vs. 4.3%, p = 0.028) significantly differed between the three groups. En bloc resection (96.8% vs. 95.5% vs. 100.0%, p = 0.260), complete resection (88.2% vs. 87.5% vs. 83.3%, p = 0.622) and curative resection rates (77.2% vs. 77.0% vs. 81.5%, p = 0.768) were no significant differences between the three groups. Complications of procedure such as bleeding (2.3% vs. 0.0% vs. 1.9%, p = 0.075), perforation (4.5% vs. 3.0% vs. 5.6%, p = 0.601) and stricture (5.4% vs. 6.0% vs. 11.1%, p = 0.297) also occurred similar in the three groups. During the follow-up period (median, 27.4 months; interquartile range, 7 to 40), among the patients with curative resection, cumulative recurrence rate did not differ significantly between the three groups (local recurrence, 0.7% vs. 0.0% vs. 0.0%; synchronous recurrence, 4.0% vs. 3.7% vs. 2.6%; metachronous recurrence, 5.4% vs. 6.0% vs. 10.3%).
Conclusion: ESD is a feasible and effective procedure for the treatment of SENs in elderly patients as in non-elderly patients which showed favorable outcomes.

prophylactic coagulation of visible vessels on mucosal defect after ESD, the incidence of post-ESD bleeding is not negligible. Furthermore, patients receiving antithrombotic agents are increasing because of population ageing and progress of treatment for cardio-cerebrovascular disease, which may increase the risk of post-ESD bleeding.
Aims and Methods: To prevent postoperative bleeding after gastric ESD of the patients receiving antithrombotic agents, we conducted endoscopic hand suturing (EHS), which was a suturing technique using a through-the-scope needle holder and an absorbable barbed suture attached to a curved needle, for mucosal defects after ESD (Goto O, et al. *Endoscopy* 2017). Eight patients who were receiving antithrombotic agents and underwent ESD for gastric neoplasm (less than 3 cm in size) were recruited. The details of antithrombotic agents were as follows: aspirin in 2 patients, aspirin and clopidogrel in 2 patients, triple antiplatelet agents in 1 patient, warfarin in 1 patient, apixaban in 1 patient, and aspirin and warfarin in 1 patient. In all cases, aspirin were continued and warfarin were replaced to heparin during perioperative period. Other antithrombotic agents were interrupted before ESD and resumed immediately after ESD. We performed EHS for the mucosal defects after successful lesion resection by ESD. Success rate, adverse events, and suture maintenance of EHS and the incidence of delayed bleeding were subsequently investigated.
Results: EHS was successfully completed in 9 lesions in 8 patients without severe adverse events. The tumor locations, the mean size of mucosal defects and the mean procedure time of EHS were U/M/L: 1/4/4, 26.0 ± 9.5 mm and 40.6 ± 12.6 min, respectively. The mean number of stitches for a lesion and the mean time per one stitch were 6.3 ± 1.4 stitches and 6.9 ± 3.0 min, respectively. The sutures of 8 lesions in 7 patients were completely maintained in second endoscopy on third day after ESD. In one patient who had acute myocardial infarction on 2 days after ESD under taking aspirin underwent second endoscopy on 7th day after ESD, which showed that the defect remained closed. In all cases, there was no post-ESD bleeding.
Conclusion: This small-numbered case series showed that the mucosal defects after ESD were successfully closed and no post-ESD bleeding occurred. EHS appears to be feasible and useful for prevention for gastric post-ESD bleeding.
Disclosure: Research funds and supply of devices: Olympus Co. Ltd., Tokyo, Japan

Introduction: The management plan for gastric indefinite for neoplasia is yet to be determined and endoscopic forceps biopsy might be inconclusive to decide to resect or not. The aim of this study was to evaluate the clinical outcomes of endoscopic submucosal dissection (ESD) for gastric indefinite for neoplasia and to know the highly suspicious factors associated with true neoplasia.
Aims and Methods: Between November 2008 and December 2015, a retrospective study was conducted in a single, tertiary, referral hospital. A total of 109 gastric indefinite for neoplasia from endoscopic forceps biopsy which resected by ESD were enrolled. The clinical outcomes and endoscopic factors for prediction of true neoplasia were analyzed.
Results: A total of 99 patients (90.8%) were diagnosed as definite neoplasia after ESD; category 3 ($n = 42$), category 4 ($n = 50$) and category 5 ($n = 7$) according to the revised Vienna classification. The patients' mean age was 65.8 ± 9.8 years. The mean lesion size was 10.7 ± 6.1 mm. The patient population was male predominant (70.6%). The en-bloc and complete endoscopic resection rate were 98.2% and 94.5%, respectively. Associated factors with true neoplastic lesions were male sex (OR 8.596, $p = 0.008$) and lesion size $\geq$ 5 mm (OR 11.355, $p = 0.003$). Associated factors with category 4–5 were male sex (OR 3.165, $p = 0.021$) and erosive change (OR 2.841, $p = 0.031$).
Conclusion: Endoscopic resection for indefinite for neoplasia with larger lesions size with erosive changes especially in male sex should be considered when possible.

Introduction: Symptomatic epiphrenic diverticula are mostly treated with laparoscopic diverticulectomy. Recently, submucosal tunneling endoscopic septum division (STESD) has been used for the treatment of esophageal diverticulum. Our study aimed to demonstrate the safety and efficacy of STESD for treatment of symptomatic epiphrenic diverticula and elucidate the possible of STESD combined with POEM for treating patients with epiphrenic diverticula and achalasia.
Aims and Methods: Data of patients with symptomatic epiphrenic diverticula who underwent STESD between October 2016 and January 2018 at Jiangsu Province Hospital (Jiangsu, China) were retrospectively reviewed. The parameters analyzed were the modified Eckardt score, total procedure time, hospital stay, the number of clips used, the incidence of complications and patient satisfaction.
Results: A total of 7 patients were enrolled in our study. There were 4 men and 3 women with the mean age of 66.42 ± 6.68 years. The most common symptoms were dysphagia, heartburn and regurgitation. The mean size of epiphrenic diverticula was 3.70 ± 1.95cm. One patient had Zenker's diverticula while the others had supradiaphragmatic diverticula. One patient had multiple diverticula. In four patients with co-existent achalasia, peroral endoscopic myotomy (POEM) was simultaneously performed by the same tunnel. The mean procedure time was 56.42 ± 24.10 minutes. The median number of clips applied was 6 (range: 3–16). The modified Eckardt score significantly decreased after STESD ($P = 0.002$). The mean hospital stay was 5.57 ± 0.79 days. No complications were observed during the median follow-up of 7.83 months.
Conclusion: STESD is an effective and safe procedure for the treatment of epiphrenic diverticula. STESD can be combined with POEM for treating patients with epiphrenic diverticula and achalasia.

P1380 THE YIELD OF BIDIRECTIONAL ENDOSCOPY IN YOUNG MALES WITH IRON DEFICIENCY ANAEMIA

S. Baillie, A. McNair, A. Loganayagam
Queen Elizabeth Hospital, Gastroenterology, London, United Kingdom

Contact E-Mail Address: s.baillie1@nhs.net
Introduction: Current British Society of Gastroenterology (BSG) guidelines advise bidirectional endoscopy in all males and postmenopausal women with iron deficiency anaemia (IDA). Endoscopy findings are reported to be significant in anywhere between 42 and 85% of patients in this group. The aim of this study was to investigate the yield of bidirectional endoscopy specifically in males 18–55 with iron deficiency anaemia (IDA).
Aims and Methods: The endoscopy database was searched for all synchronous bidirectional endoscopies undertaken at Queen Elizabeth Hospital in males aged 18–55 in 2017 with the indication of IDA. Endoscopic findings were retrieved for each procedure and the hospital results system provided levels of haemoglobin (Hb), mean corpuscular volume (MCV), ferritin, iron and haemoglobin electrophoresis, if performed, at the time of referral. Histology samples from endoscopy were also assessed. Significant findings were defined as malignancy, grade C/D oesophagitis (Los Angeles scoring system), coeliac disease, colitis, polyps >1cm, oesophageal stricture, Barrett's oesophagus, ulcers, arteriovenous malformation and Giardia infection.
Results: Forty six patients fit the inclusion criteria, with an average Hb of 109 g/L and average MCV of 77 fL. Fourteen patients (30%) were found to have significant findings. These included 3 diagnoses of malignancy (7%) and 2 diagnoses of IBD (4%). Eight of the significant findings (57%) were on oesophagogastroduodenoscopy, with the remaining 6 findings (43%) being on colonoscopy.
Conclusion: These results indicate that bidirectional endoscopy has a high yield in young men with IDA. While the yield is lower than that reported in all males and post menopausal women, significant findings, including malignancy, indicate that bidirectional endoscopy should continue to be recommended in this population.

Introduction: Angiogenesis is a hallmark of cancer development inducing the formation of new vasculature to support its growth. Probe based confocal laser endomicroscopy (pCLE) is an advanced technique which provides imaging of gastrointestinal mucosa at subcellular resolution and of microvasculature during endoscopic examination. The evaluation of the tumoral vascular pattern could predict response to chemo-antiangiogenetic-radiotherapy.
The aim of our study was to evaluate tumor neoangiogenesis through pCLE imaging in locally advanced gastric patients, before and after neoadjuvant radio-chemotherapy (RT/CT).
Aims and Methods: 50 consecutive patients with Gastric Cancer (GC, 24F, 26 M mean age: 65 years) underwent endoscopy with pCLE-GastroFlex UHD probe (Mauna Kea Technologies) and i.v. fluorescein infusion in order to evaluate intratumoral vascularization and to evaluate the efficiency of blood flow. After RT/CT treatment, 12 GC (5F, 7M) patients were revaluated using pCLE. Vascular assessment was based on vessel shape and size, vessel permeability and blood flow, and allowed the creation of an angiogenic score ranging from 0, for normal vasculature, to 4: Cannizzaro-Spessotto (CS) scale. A first evaluation of angiogenic status was given in real time by the endoscopist during the pCLE analysis. Images were stored digitally and then reviewed with a dedicated software package.
Results: 5 out of 12 (41.6%) GC patients showed an improvement of angiogenesis index, while in the remaining 7 GC (59.4%) no substantial changes were documented. The unchanged vascular alterations in gastric cancer patients correlated positively with stable or progressive disease. Since a small remission was detected in only 25% of gastric cancer patients it was possible that the unaltered angiogenic score could be ascribed to the lack of treatment efficacy.
Conclusion: In GC patients median angiogenesis index remained unmodified, without positive changes in vascular morphology, probably due to the presence of fibrosis.
The evaluation of tumor vasculature may provide vital information for predicting the efficacy of treatments and for achieving tailored interventions for individual patients. The analyses performed on gastric cancer patients suggest that these patients could especially benefit from neoadjuvant angiogenetic tailored therapy, thereby improving also the efficacy of the standard therapy. The results of our work demonstrate that pCLE is a valid method for real-time analysis of the vascular density and efficacy in gastric cancers.
This work was supported by the following grant Ministry of Health RF -2016–02361525

Introduction: Barrett's Esophagus (BE) represents an early stage in carcinogenesis leading to esophageal adenocarcinoma (EAC), but current screening and surveillance strategies are limited by the absence of specific molecular markers highly predictive of increased risk for EAC. In our previous translational study, we provided new insights into the kinetics and pathogenesis of esophageal cancer, and introduce CXCR4-based imaging of the tumor microenvironment as a potential approach for diagnosis and surveillance of EAC[1]. In the present study, we investigate the attractive molecular targets such as fluorescent labelled neutrophils, CXCR4 expressing cells and HSP70 expressing cells for endoscopy imaging.
Aims and Methods: We utilized a IL-1b transgenic mouse model of BE and EAC[2] for fluorescent endoscopy imaging to analyse the importance of immune cells, CXCR4 expressing cells and Hsp70 expressing cells during esophageal carcinogenesis. The dual channel murine upper endoscopy is performed with a highly sensitive fluorescence/color endoscope imaging system[3] with a design to offer video-rate simultaneous color and near-infrared (NIR) fluorescence endoscopy.
Results: Our Immunohistochemistry (IHC) and flow cytometry (FACS) data show that specific recruitment of neutrophils and CXCR4-positive (CXCR4+) immune cells correlated with dysplasia progression, suggesting that the immune population may be a key contributor to esophageal carcinogenesis. Furthermore, stronger CXCR4 signal intensity was accumulated in ex vivo fluorescence imaging in advanced dysplasia mice. Moreover, fluorescent endoscopy studies showed that fluorescently labelled CD45 immune cells and fluorescently labelled CXCR4 cells could be detected in low grade and high grade dysplasia in L2-IL-1b mice. Most importantly, elevated CXCR4-fluorescence signal intensity was observed in high grade dysplasia in L2-IL-1b mice. In addition, IHC data showed that HSP70 was expressed in BE regions of dysplasia in L2-IL-1b mice. These findings support that immune cells, CXCR4 and HSP70 are suitable molecular markers for endoscopy imaging of the tumor microenvironment during esophageal carcinogenesis.
Conclusion: The recruitment of neutrophils, CXCR4+ immune cells in esophageal dysplasia highlight the potential of immune cells and CXCR4 as molecular targets for diagnostic imaging of the tumor microenvironment in BE and EAC. We hypothesize that the early detection of a tumorigenic niche by fluorescence endoscopy based imaging could define a novel modality that allows to define a population at risk to develop EAC. Therefore, we are currently developing a dual channel murine upper endoscopy that can detect and overlap 2 molecular markers for parallel evaluation of early dysplasia surveillance. A series of case studies are under investigation to confirm the ability to detect early dysplastic lesions.
Disclosure: Nothing to disclose

Introduction: Anastomotic leak is one of the most common complications of esophagectomy. The endoscopic vacuum-assisted closure (EVAC), which is based on continuous negative pressure applied to the wound with a sponge, has advantages of effective drain of infected fluid and accelerating would healing by inducing formation of granulation tissue over fully covered self-expanding metal stent (SEMS) treatment.
Aims and Methods: We aimed to evaluate the efficacy and to identify factors associated with longer ($\geq$ 21 days) treatment duration of EVAC for esophageal anastomotic leak following esophagectomy for cancer. We retrospectively analyzed 20 esophageal cancer patients who had undergone EVAC for esophageal leak after esophagectomy between October 2016 and December 2017 at the Samsung Medical Center.
Results: All 20 patients were male. Of these, 10 (50.0%) received neoadjuvant treatment and 6 (30.0%) had one or more comorbidities. The median size of fistula opening was 1.75 cm. During a median of 14.5 days of EVAC treatment, a median of 5 interventions were performed. Treatment success was achieved in 19 patients (95.0%). Neoadjuvant treatment was significantly associated with longer EVAC treatment. There was a non-significant trend toward the need for longer treatment duration for a larger fistula opening size.
Conclusion: EVAC treatment is a good non-surgical option for anastomotic leak following esophagectomy. Long duration of treatment is associated with neoadjuvant treatment and a large leakage opening.

Introduction: The procedure of Per Oral Endoscopic Myotomy (POEM) is becoming standardized for treatment of Achalasia. Recently, the new Triangle tip (TT) knife is equipped with water-jet function which could hasten the operative time. We retrospectively compared the use of TT knife with and without waterjet function on the clinical outcomes of POEM for treatment of Achalasia
Aims and Methods: This is a retrospective cohort study comparing use of TT knife against TT knife with water jet function (TTJ) for performance of POEM. All patients who received POEM using TT knife for treatment of Achalasia at our institution were recruited. The POEM procedures were all performed under general anesthesia by single endoscopist. The outcomes including baseline demographics, operative time, hospital stay and efficacy were compared.

Results: From 2010 to 2017, 91 patients received POEM performed by using TT knife (81 patients with conventional TT and 10 patients with TTJ). There was no difference between two groups in the age, gender and baseline demographics. The preoperative Eckhardt score was 5 (1–11) for TTJ group and 6 (1–12) for TT group ($p = 0.875$). The mean myotomy length was 9.8 ± 0.9cm for TTJ group and 10.8 ± 2.4cm for TT group ($p = 0.223$). The operative time was significant shorter for the TTJ group as compared to the conventional TT group (79.3 ± 21.6 vs 101.6 ± 34.3 mins; $p = 0.05$). There was no difference in the hospital stay between the two groups (2.7 ± 0.5 (TTJ) vs 3.1 ± 1.1 (TT); $p = 0.409$). There was no perioperative mortality, and no difference in the morbidities between two groups (1 (TTJ) vs 6 (TT); $p = 1.0$). The postoperative Eckhardt score was 0 (0–1) for TTJ group and 0 (0–6) for TT group (n.s).
Conclusion: In this retrospective cohort study, we showed that the use of TT knife with waterjet function significantly reduced operative time of POEM while achieving similar length of myotomy, clinical efficacy as well as safety for treatment of Achalasia.

Parameters	TT Jet (10)	TT (81)	p value
Gender: M (%)	5 (50)	29 (35.8)	0.492
Age	47.3 ± 18.6	49.3 ± 17.2	0.735
Duration of symptoms (months)	42.8 ± 35.3	61.0 ± 83.9	0.548
Comorbidities	1 (0–1)	0 (0–5)	0.839
Previous therapy (%)	2 (33.3)	14 (17.7)	0.315
Baseline Eckhardt score (Median)	5 (1–11)	6 (1–12)	0.875
Mean OT time	79.3 ± 21.6	101.6 ± 34.3	0.05
Mean total Myotomy length (cm)	9.8 ± 0.9	10.8 ± 2.4	0.223
Mean Hospital stay (days)	2.7 ± 0.5	3.1 ± 1.1	0.409
Complications (%)	1 (10)	6 (7.4)	1.0
Postop Eckhardt score	0 (0–1)	0 (0–6)	n.s.
FU (months)	13.7 ± 15.4	37.8 ± 21.4	0.002

P1385 UPPER GASTROINTESTINAL CAPSULE ENDOSCOPY AS AN ALTERNATIVE TO OESOPHAGOGASTRODUODENOSCOPY

F.W.D. Tai, A. Healy, V. Thurston, R. Sidhu, M. Mcalindon
Royal Hallamshire Hospital, Dept. of Gastroenterology, Sheffield, United Kingdom

Contact E-Mail Address: david.tai@nhs.net

Introduction: Conventional oesophagogastroduodenoscopy (OGD) is uncomfortable, unpopular with patients and may result in non-attendance. When mean examination time using this invasive modality exceeds 7 mins, the chance of detecting neoplasia increases by 3-fold compared to mean examination times of less than 7 minutes (1). Capsule endoscopy (CE) is better tolerated than OGD (2) and upper gastrointestinal capsule (UGIC) endoscopy has been evaluated in the screening and surveillance of varices in liver disease (3) and screening for Barrett's oesophagus (4).
Aims and Methods: We aim to examine patient's tolerability of UGIC and outcomes following UGIC in those who refused or did not tolerate OGD.
Consecutive patients undergoing UGIC were prospectively recruited between December 2016 and 2017. UGIC was performed by two specialist nurses using a novel simple positional interchange technique as previously described (5). The UGIC (Medtronic Ltd., Dublin, Ireland) is a novel device with cameras at both ends taking up to 35 frames per second (FPS) for 10 minutes and up to 18 FPS for the remaining 80 mins. Clinical records and endoscopy findings were reviewed and data on patients expected and actual discomfort and pain scores were collected before and after UGIC respectively.
Results: Thirty-four patients who refused (88.2%) or did not tolerate OGD (11.8%) had UGIC with a median follow up period of 119 days (19–670 days). Indications for UGIC were variceal screening ($n = 20$), dyspepsia ($n = 6$), reflux ($n = 3$), iron deficiency ($n = 3$), Barrett's screening and gastric ulcer healing ($n = 1$ each). Half the patients had previous OGDs. In patients for variceal screening, 45% were index examinations and the remainder surveillance procedures, of which 10% have had variceal haemorrhage.
UGIC was successful in 91% with 3 patients being unable to swallow the capsule. The capsule spent a mean time of 26 (±9.7) secs in the oesophagus, 1 hour 25 mins (±16.6 min) in the stomach, entered the duodenum in 87% in whom it spent 12 (±2.2) mins. Normal exams were found in 35.4% ($n = 11$). Pathologies detected on UGIC include oesophageal (OV; $n = 6$) and gastric ($n = 1$) varices, portal hypertensive gastropathy ($n = 4$), gastric erosions ($n = 7$), oesophageal erosions or ulcers ($n = 1$ each), hiatus hernia ($n = 2$) and benign fundic cystic gland polyps ($n = 4$).
Only 6.5% ($n = 2$) had a further gastroscopy during their follow up period. They were performed to confirm OV in one and in another to rule out malignancy in a patient with a suspicious lymph node found on imaging, who had earlier UGIC for variceal surveillance. No additional findings were seen on OGD.
Mean procedural distress, discomfort and pain were excellent (scores from best to worse = 0–10; 0.3, 0.1, 0.1) despite patients expecting more discomfort and pain prior to investigation (2.9 and 2.3 respectively). Overall, 96.6% of patients with successful UGIC would have a repeat examination.
UGIC changed patient management in 25.8% ($n = 8$). In patients with liver disease, 2 were placed on variceal surveillance (with UGIC), 2 patients had beta blockers started or increased and in one omeprazole initiated for incidental erosive gastritis. In 9 patients with dyspepsia and/or reflux, a third had their PPIs changed or doses altered.
Conclusion: UGIC is extremely well tolerated and highly acceptable to patients, almost all of whom would agree to having repeat procedures. A range of oesophageal and diffuse gastric pathologies were identified. No focal gastric lesions were identified in this small study, but the longer examination duration suggest that a blinded comparison with OGD is warranted.
Disclosure: Nothing to disclose

Introduction: Because of thin anatomical structure and high risk of complication including perforation, endoscopic resection (ER) for non-ampullary duodenal lesions (NADLs) is technically more difficult than lesions of stomach. However, with development of therapeutic endoscopy, endoscopic treatment of duodenal lesions has been performed recently.
Aims and Methods: The aim of this study was to evaluate the efficacy and safety of endoscopic resection for NADLs. Retrospectively, patients who underwent ER for NADLs between December 2004 and June 2017 were included. We analyzed clinical and pathologic features of the lesions including the clinical outcomes and adverse events.
Results: The study included fifty-two patients (57.7% male) with NADLs. The median age of patients was 55.5 years (range 22 to 80 years). The mean NADL size was 10.19 ± 7.72 mm and the mean procedure time was 14.55 ± 12.08 min. After resection, final histological data showed 39 adenomas (61.5%), 10 Brunner's gland tumors (19.2%) and 3 pyloric gland tumors (5.8%). The en-bloc resection rate was 92.3% (48/52), and the complete resection rate with clear margins was 86.5% (45/52). According to the location of NADLs, half (26/52) of the lesions were located in duodenal bulb including superior duodenal angle. Even though micro-perforation occurred from 2 out of 52 patients, it was treated only with conservative treatment.
Conclusion: ER for NADLs might be an effective treatment method with favorable long-term outcomes. However, it should always be performed with the possibility of perforation complication in mind.
Disclosure: Nothing to disclose

P1387 OVER-THE-SCOPE CLIPS (OTSC) FOR THE TREATMENT OF STOMACH AND DUODENAL ULCERS WITH HIGH-RISK STIGMATA OF BLEEDING – ONE AND DONE?

S. Gölder[1], L. Neuhaus[1], J. Stückle[1], D. Freuer[2], G. Braun[1], A. Ebigbo[1], A. Probst[1], T. Weber[1], H. Messmann[1]

[2]*Chair for Epidemiology, of the LMU Munich, at the UNIKA-T, Augsburg, Germany*

Contact E-Mail Address: stefan.goelder@klinikum-augsburg.de

Introduction: The risk of treatment failure as well as short-term recurrence of bleeding after standard endoscopic therapy of high-risk peptic ulcer bleeding (HRUB) is high even after successful primary control of bleeding. We evaluated the use of OTSC in patients with HRUB.
Aims and Methods: Between 04/2014 and 03/2018, N = 100 patients (pts) with peptic ulcer bleeding and HRUB (Forrest Ia – IIb), who received primary treatment with OTSC or secondary treatment after unsuccessful standard endoscopic therapy, were recorded in a database.
The primary endpoint of the study was either uncontrolled bleeding or recurrence after primary control (within 30 days). Furthermore, we examined factors that influenced the clinical success of OTSC treatment.
Results: OTSC as a single procedure for bleeding control was possible in N = 76 (76%) of all cases. OTSC as the primary and only treatment was performed in 64 pts, with clinical success in 50 pts (78.1%). Another 36 pts received the OTSC as a rescue treatment after failed initial standard endoscopic treatment. In 26 pts (72.2%) the treatment by OTSC alone was successful.
In 8 pts the bleeding could not be controlled by OTSC. 5 pts received a successful angiographic treatment, one pt underwent surgery and two pts died during active bleeding.
In 16 pts the bleeding was initially controlled by OTSC but recurrent bleeding occurred after 1–12 days. 11 pts received subsequent endoscopic retreatment, 5 pts angiography, one pt underwent surgery and one pt died.
OTSC failure occurred more often in large ulcers (> 3 cm $p = 0.03$), in the duodenal bulb ($p = 0.03$) and in ulcers with negative helicobacter test ($p = 0.045$). The patients with OTSC failure received more blood transfusions ($p = 0.002$). We found no statistically significant difference for the Rockall Score (median 7.5), the Glasgow Blatchford score (median 15.5), NSAID use or anticoagulation.
Conclusion: OTSC has a good clinical success rate in primary and secondary bleeding control in peptic ulcers with high-risk stigmata of bleeding. Potential risk factors for treatment failure are large ulcer size, location in the duodenal bulb and a negative helicobacter status.

Introduction: Sporadic duodenal adenomas (SDA) are rare lesions, accidentally diagnosed during endoscopy. Larger lesions (≥15mm) are usually referred to tertiary centers because of the challenging endoscopic resection and the reported high complication.
Aims and Methods: The aim of our study was to evaluate efficacy and safety of endoscopic mucosal resection for the treatment of SDA in two tertiary centers. This is a retrospective analysis of a cohort of patients with SDA referred to 2 tertiary centers (Humanitas Research Hospital, Milan; Queen Alexandra Hospital, Portsmouth), for resections of SDA between 2013 and 2017. Patients with familial adenomatous polyposis or ampullary lesions were excluded. All patients were included in a prospectively maintained database. Data regarding size of the lesion, site, morphology (Paris classification), type of endoscopic resection (en-bloc endoscopic mucosal resection (EMR), piece meal (PEMR), endoscopic submucosal dissection (ESD), histological findings, intra and post-procedural adverse events were recorded and analyzed. Lesions were divided into: small (<15 mm), large (≥15–30mm) and giant (≥30mm). Outcomes considered for this study were technical success, adverse events, and recurrence. Statistical analysis included descriptive statistics, Chi square tests (p. values of <0.001 was considered statistically significant) and Kaplan-Meier with survival estimation.
Results: A total of 120 patients (mean age 66 ± 11.9 years, 53 male) were enrolled in the study. Mean size of the lesions was 23.3 mm (range 5–80). Most common morphology (54.7%) was flat elevated (type IIa) with almost 1/3 of the lesions located in the second part of the duodenum (68.3%). En-bloc EMR was performed in 56 (46.6%) cases, PEMR in 41 (34.1%), 23 patients (19.1%) underwent ESD. LGD was the most common histology type (65.8%). HGD was found in 23 cases (19.1%). Five lesions were neuroendocrine tumors. We found 10 hyperplastic lesions and 3 amartoma. No cancer was detected. Ninety-eight (81.6%) lesions were resected uneventfully with no intra or post-operative complications. Intraprocedural perforation was observed in 4 patients (3.3%) all successfully treated by clips. Fourteen post-procedural (11.6%) complications were recorded: 11 bleedings (78.5%) (4 self-limited not requiring treatment, 3 endoscopically treated, 1 requiring transfusion). Four delayed perforations (3.3%) needed surgery. One patient who underwent surgery for perforation died. Considering the size of the lesions, 3/4 of intraprocedural perforations and all post-procedural perforations occurred in giant lesions. We found a significant correlation between giant lesions and development of complications ($p < 0.001$). 119 patients were still alive at last follow-up. Recurrence was observed in 11 patients (9.5%) during a median follow-up of 29 months: HGD was found in 6 patients. All recurrences but one were successfully managed endoscopically. Only one patient required surgically.
Conclusion:
1. Histological analysis found no cancer in any of the resected specimen demonstrating that the optical diagnosis alone can help exclude polyps with cancers from endoscopic resection.
2. Endoscopic resection can be successfully carried out in majority of patients
3. Adverse event rate of duodenal resection is high at just below 20%.
4. Size >3 cm seems to be the predictor of high risk polyps as most complications happened in this group.
5. Most of the complications can be managed endoscopically in expert hands. We recommend that such polyps should only be resected at expert centres.
Disclosure: Nothing to disclose

P1389 SAFETY OF ENDOSCOPIC FULL-THICKNESS RESECTION OF SUPEPITHELIAL TUMORS IN THE STOMACH AFTER PRIOR FULL-THICKNESS SUTURING

A. Wannhoff[1], A. Schmidt[2], K. Caca[1]
[1]*Klinikum Ludwigsburg, Ludwigsburg, Germany*
[2]*University Of Freiburg, Medical Center, Abt. Gastroenterologie, Freiburg, Germany*

Contact E-Mail Address: andreas_wannhoff@gmx.de
Introduction: Endoscopic resection of gastric supepithelial tumours after application of full-thickness sutures with a device originally designed for endoscopic anti-reflux therapy was proven to be feasible and efficient in a recent study on 31 patients (Schmidt A, et al. *Endoscopy*. 2015)
Aims and Methods: The aim of this study was to extend the above-mentioned study and further analyse safety of endoscopy full-thickness resection of gastric supepithelial tumours in a larger cohort. The above-mentioned study was extended until January 2018 and patients were identified retrospectively. The tumour was resected as following: after prior full-thickness suturing underneath the tumour with either the Plicator device or the GERDX device, the tumour was then resected with a snare. Besides basic demographic and health characteristics we as well included information on peri- and post-interventional complications.
Results: 50 patients were finally included in the study. The tumour was located in the gastric antrum in 12, the corpus in 26, the fundus in 7 and the cardia in 5 patients. Median tumour size as measured by endoscopic ultrasound prior to resection was 20 mm (range: 7–60). In 27 patients the resection was done with the Plicator and in 22 with the GERDX device. A median of 3 (range: 1–12) sutures was applied in total, of which a median of 2 were applied before resection; in 23 patients at least one further suture was applied after snare resection. Endoscopic resection was feasible in all patients. Bleeding during resection occurred in 29 patients and could be managed endoscopically in all patients; peri-interventional transfusion of red blood cells was necessary in only 1 patient. A perforation or dehiscence of the gastric wall after resection occurred in 14 patients and could be closed by application of furthers sutures or clips in all cases. A control endoscopy the following day was routinely performed. Treatment of bleeding was necessary in 7 patients during control endoscopy and in 3 patients treatment of perforation was performed. An episode of further bleeding after control endoscopy occurred in 7 patients and could again be managed endoscopically. During follow-up the most severe complication was noted in one patient who died 8 days after resection due to delayed perforation and peritonitis. One patient experienced oesophageal perforation and pleural empyema, who finally could be discharged 36 days after resection. Median hospital stay in all patients was 4 days (range: 2–36).
Conclusion: The endoscopic resection of subepithelial tumours in the stomach after prior full-thickness suturing is safe. Bleeding or perforations commonly occur during resection, but can be managed sucessfully endoscopically in all cases. The most important postinterventional complication is bleeding, which again can be treated endoscopically. Severe complications are rare.

P1390 DELAYED REMOVAL INCREASED THE COMPLICATION OF SHARP FOREIGN BODY IN THE UPPER GASTROINTESTINAL TRACT: AN EXPERIENCE FROM MULTIPLE CENTERS IN CHINA

L. Wang, M. Ma, Y. Guo
Second Affiliated Hospital of Zhejiang University School of Medicine, Department of Gastroenterology, Hangzhou, China

Contact E-Mail Address: wangljzju@zju.edu.cn
Introduction: Foreign bodies (FBs) ingestion is a common medical emergency accounting for 4% of all emergency endoscopies, secondary only to the GI bleeding.[1] 70∼75% of FBs are located in the esophagus[2]. The need of endoscopic management reached up to 63∼76%[3–5] with 3%∼20% of incidence of complications[6]. According to the latest guidelines from ESGE, emergent endoscopy is recommended for the impaction of sharp-pointed objects within 24 hours[5]. However, there were still different opinions on the endoscopic methods with different FBs.
Aims and Methods: The study was performed from October 2015 to August 2016 among 595 patients with clinical suspicion of foreign body ingestion from 18 general hospitals in China. The patient data including age, gender, clinical features, and data about endoscopic management including types and locations of

foreign bodies, retrieval devices, outcomes and complications were collected and analyzed.
Results: 1) The most common types of foreign bodies were sharp ones (75.9%), including fish bones (34.0%), chicken bones (22.1%), and fruit nucleus (17.1%). A few were non-sharp ones (24.1%), such as food bolus (14.6%). The majority of them were short objects (<2.5cm, 74.0%), subsequently followed by middle objects (2.5~6.0cm, 24.5%) and long objects (>6cm, 1.5%). Most objects were lodged in the proximal esophagus (75.9%), followed by the middle segment (15.2%) and the distal segment (8.9%) of esophagus. 2) Complication rate was as high as 34.0%, which was increased with long retention time and sharp objects ($P < 0.001$). The rate was increased by 2.2- and 6.1- folds after impacted for over 24 hours or 48 hours as compared to in 12 hours. Logistic regression analysis indicated that sharp objects had obviously more complications than non-sharp ones (OR 3.36, 95% CI: 1.97–5.74). In particular, the incidence of perforation was 5.6%, which was strongly related with long retention time and sharp objects ($P < 0.01$), but not with locations or lengths of the objects ($P > 0.05$). For sharp objects (75.9%), complication rate was increased by increased retention time ($P < 0.001$).
Conclusion: Foreign bodies, especially sharp ones, should be removed as soon as possible within 24 hours, to further decrease severe complications.
Disclosure: Nothing to disclose

Introduction: Esophageal caustic stricture is the stubborn disease and postoperative restenosis limits clinical efficacy for endoscopic dilation. Some refractory cases with frequent recurrence or anatomic abnormality may require surgical intervention. Autologous mucosa graft has been successfully applied for treating urethral stricture and preventing stricture after extensive mucosal resection. We aimed to use mucosal autograft endoscopically to treat the refractory esophageal stricture.
Aims and Methods: Three patients with intractable corrosive esophageal stricture were treated endoscopically via combining dilation with autologous mucosal transplantation. For donor graft, the autologous normal esophageal mucosa was firstly chosen considering with tissue homology. The standard ESD was successfully performed as described. The isolate normal mucosal patch was spread in 37°C 0.9% saline, then rapidly delivered to the defect region endoscopically following gastric intubation. The basolateral side of mucosal patch should orient towards the defect surface. The graft was fixed by clips (Olympus, Japan). All patients received postoperative anti-acid and anti-infection intervention, and were fasted for 5–7 days.
Results: All procedures were successful without severe complications. Mucosa regeneration were shown at the transplanted segments. One patient maintained normal diet with complete remission after one-year follow-up. Intraluminal stenosis and dysphagia were significantly improved in another two cases.
Conclusion: Our preliminary human experience achieved the amazing success for refractory caustic stricture. The findings need to be verified in more controlled trials. The standard modality of operation and post-operational care are urgently required for clinical practice. If effective and reproducible, this strategy might substantially benefit patients suffering from corrosive esophageal stricture.

Introduction: Biermer's Disease is an auto immune affection that is a preneoplasic situation and can lead to carcinoid tumors and gastric adenocarcinoma. Thus, the endoscopic screening of patients with Biermer's disease is necessary should be evenly performed. The aim of our work is to relate the experience of our gastroenterology and endoscopy unit concerning the endoscopic screening of Biermer's disease.
Aims and Methods: This study was run from January 2006 to January 2018 and reported all the cases of Biermer's disease admitted to the unit. All patients underwent an upper gastrointestinal endoscopy with antral and fundic biopsies and biopsies of the lesions if any. We reported the clinical, endoscopic and histological and therapeutic aspects.
Results: Within 18165 upper gastrointestinal endoscopies run during this period, 251 Biermer's disease were reported, with a frequency of 1.38%. The age of patients was from 21 to 80 with an average of 40 years. There was a slight male predominance of 56.5%. The upper gastrointestinal endoscopy found a fundus congestion in 67% of the cases, polypoid lesions in 25% of the cases, they were located in the fundus in 21% of the cases and the antrum in 4% of the cases. The endoscopy was normal for 6% of the patients.
Histological analysis revealed a chronic atrophic fundal gastritis in 32% of the cases, an intestinal and pyloric metaplasia with ECL cells hyperplasia was associated to the gastritis in 40% of the cases, a neuroendocrine tumor with ECL cells hyperplasia was described in 15% of the cases, hyperplasic polyps were present in 9% of the cases, and polyadenoma in low grade dysplasia were found in 3% of the cases. Hp infection was found in 75% of the hyperplasic polyps, and in 50% of the gastric adenomas, and in 50% of neuroendocrine tumors.
Conclusion: Biermer's disease is a preneoplasic state that can degenerate into neuroendoscrine tumors and gastric adenocarcinoma. In our series, 18% of the patients had a tumoral evolution, and none presented a gastric adenocarcinoma. The gastric screening through upper gastrointestinal endoscopy and histology for pernicious anaemia is necessary.

Introduction: Mid-esophageal and epiphrenic diverticula are frequently associated with esophageal motility disorders [1, 2]. Optimal treatment of mid-esophageal and epiphrenic diverticula is still debated. Of note, in case of esophageal motility disorder, several authors suggest to perform a surgical myotomy of the lower esophageal sphincter associated to diverticulectomy [2, 3]. In the absence of esophageal motility disorder, instead, diverticulectomy alone may be considered [3].
Per-oral endoscopic myotomy (POEM) has become an accepted treatment for major esophageal motility disorders and has been recently used to perform a diverticulotomy [4], a technique similar to the one used for the treatment of Zenker's diverticulum [5].
Aims and Methods: The aim of this study is to report our experience with POEM for the treatment of patients with mid-esophageal or epiphrenic diverticula with or without underlying esophageal motility disorder.
Data were prospectively collected from a cohort of patients with mid-esophageal or epiphrenic esophageal diverticula treated with POEM between April 2017 and March 2018. Preoperative evaluation included in all patients barium contrast radiographic study, high-resolution manometry (HRM) and esophagogastroduodenoscopy. Eckardt score was used to report the severity of patient symptoms before POEM and at each postoperative evaluation [6]. POEM was performed under general anesthesia by two expert endoscopists following the procedural steps described by Inoue et al [7]. In case of esophageal motility disorder, myotomy of the circular muscle bundle was performed on the opposite side of the diverticulum using a triangular tip knife. When no motility disorder was observed, myotomy was then performed homolateral to the diverticulum to achieve diverticulotomy, as previously described by Mou et al [4]. Barium contrast radiographic study was performed on postoperative day 1. Postoperative HRM was performed 3 months after endoscopic treatment. Follow-up visits were scheduled every 3 months.
Results: Four patients were treated with POEM for mid-esophageal or epiphrenic diverticula with or without underlying esophageal motility disorder. One patient suffered from distal esophageal spasm, one from jackhammer esophagus, one from esophago-gastric junction outflow obstruction. In one case no esophageal motility disorder was detected. Patients' age ranged from 65 to 77 years. Diverticulum size was 3 cm in one case and 6 cm in the others three cases. Pre operative Eckard score ranged from 6 to 8. No procedural related adverse events were reported. Patients with esophageal motility disorders were asymptomatic at 6–8 months follow-up except from one case of pathological reflux that was

treated with proton pump inhibitor. The patient without motility disorder had an Eckard score of 2 at 1 month follow up.
Conclusion: Mid-esophageal and epiphrenic diverticula may be associated with esophageal motility disorders. In this case, POEM performed contralateral to the diverticulum allows to treat the cause underlying the diverticulum and seems to achieve good early clinical outcomes. In the absence of a motility disorder, endoscopic diverticulotomy appears feasible in experienced hands with promising early clinical outcomes, and might be offered as an alternative to surgical diverticulectomy in selected patients.

Introduction: Non cardiac chest pain (NCCP) is recurrent angina pectoris like pain without evidence of coronary heart disease in conventional diagnostic evaluation. The treatment options and therapeutical results for patients with hypercontractile esophageal motility disorders are disappointing so far. Recently, peroral endoscopic myotomy (POEM) was established as treatment option in achalasia. However, limited data exist on the effectivity of POEM in NCCP with hypercontractile esophageal motility disorders.
Aims and Methods: In this prospective study 18 patients (female = 8, mean age 63.2 ± 13.2 years) with NCCP and hypercontractile esophageal motility disorders (type III achalasia n = 8, Jackhammer esophagus n = 9, distal esophageal spasm n = 1) were included. All patients underwent standardized diagnostic work-up including esophagogastroduodenoscopy with esophageal biopsies, high-resolution esophageal manometry and combined intraluminal impedance and pH testing before and 3 weeks after procedure. The POEM procedure was executed standardized (Hybridknife®, t-type, electric generator VIO 300D®, Erbe, Tuebingen, Germany) with myotomy of the lower esophageal sphincter and the manometrically identified hypercontractile segments in the esopahgeal body. A standardized symptom questionnaire was disposed before POEM, 3 weeks after and every 6 months after the intervention.
Results: 15 patients (clinical success rate 83.3%) showed significant symptom relief after POEM (pre-Eckardt-score: 7.9 ± 1.4, 3 weeks post: 1.8 ± 1.8, 6 months post: 2.3 ± 2.9 and 1.9 ± 2 after a mean follow-up of 10.5 ± 10.0 months). High-resolution-manometry showed significant reduction in IRP (pre-POEM: 22.8 ± 17.8 mm Hg, post-POEM: 12.9 ± 14.7 mm Hg) and DCI (pre-POEM: 4208 ± 3334 mmHg*s*cm, post-POEM: 1133 ± 1017 mmHg*s*cm). Two moderate adverse events classified with ASGE lexicon severity grading system were handled endoscopically. One case of gastroesophageal reflux disease (Type B, LA-Classification) occurred after intervention and was handled successfully with PPI. Two patients required secondary intervention because of persisting hypercontractile segments in HR-manometry.
Conclusion: The results suggest that POEM is an effective and safe therapeutic option for patients with NCCP and hypercontractile esophageal motility disorders.

Introduction: The incidence and prevalence of oesophageal foreign body (OFB) is on the rise. However, its impact on the rate of inpatient admissions, utilization of endoscopic and surgical interventions and healthcare outcomes is poorly understood. We conducted a study to analyze these outcomes using the national inpatient sample (NIS) database.
Aims and Methods: Data on all adult (≥18) patient admitted with OFB was extracted from the NIS database from 1998 to 2013. ICD-9-CM code, 935.1 was used to identify patients with a primary discharge diagnosis of OFB. The temporal trends in discharge rates as well as in length of stay (LOS), hospital charges and in-hospital mortality rates were assessed by linear and polynomial regression. A p value of <0.05 was considered as statistically significant.
Results: Average age, gender and race of inpatients with OFB were not significantly different between 1998 and 2013. Patients were more likely to be smokers, alcoholics with higher Charlson comorbidity index in 2013 as compared to 1998. The rate of OFB admissions increased significantly from 1998 to 2005 followed by a decline thereafter ($p = 0.01$). LOS and hospital charges increased by 0.02 days/year ($p = 0.015$) and \$1547/year ($p < 0.001$) respectively. Patients undergoing oesophago-gastro-duodenoscopy (OGD) within 24 hours of admission were higher in 1998 as compared to 2013 ($p = 0.026$). The rates of surgical intervention and inpatient mortality did not change significantly over the study period.
Conclusion: The rate of inpatient admissions for OFB is on the decline in recent years, suggesting the modern-day practice of cost-effective medicine. LOS and hospitalization cost have increased, whereas rates of surgical intervention and inpatient mortality have not changed significantly over the study period.

P1397 EFFECT OF VONOPRAZAN ON THE TREATMENT OF POST-ENDOSCOPIC SUBMUCOSAL DISSECTION ARTIFICIAL GASTRIC ULCER

Y. Kusumoto[1], T. Yamada[1], R. Nakanishi[2], S. Nagahama[2], E. Kimura[2], T. Tanimoto[2], K. Ohnishi[1], Y. Sueyoshi[1], T. Yamaguchi[1], K. Matsumoto[1], M. Hirao[1], A. Hosui[1], N. Hiramatsu[1]

Introduction: Proton pump inhibitors (PPI) are effective for the treatment of gastric ulcers (GU) after endoscopic submucosal dissection (ESD). Vonoprazan, a potassium-competitive acid blocker, has a strong inhibitory effect for gastric acid secretion. However, the efficacy of Vonoprazan is unclear in this field.

Aims and Methods: The aim of this study is to clarify which factors are more important for healing of GU after ESD procedure. We compare the healing status of ESD-induced GU and incidence of post-ESD bleeding between subjects treated with Vonoprazan and Rabeprazole.

Two hundred twenty-two patients who were performed ESD for the treatment of gastric neoplasms between April 2014 and April 2017 at our hospital were enrolled in this study. Twenty mg per day Vonoprazan (V group) or 10mg per day Rabeprazole (R group) for 4 weeks after ESD. Endoscopic images on 30th day after ESD were used for the evaluation of the shrinking rate of ESD ulcers. For the assessment of healing effect, age, sex, past history, smoking, drinking, drugs, the status of *Helicobacter pylori* (HP) infection, tumor location (Upper/Middle/Lower), tumor size, tumor depth, and tumor histopathology were analyzed by multivariate analysis.

Results: The ulcer healing was only related to the tumor size ($P < 0.01$) and drugs. The ratio of treated lesions with scar-stage was significantly higher in the V group than in R group (30.1% < 40 of 133 > vs 16.9% < 15 of 89 >, $P = 0.027$). In the V group, patients got good healing regardless of HP infection although patients with HP infection had the low rate of ulcer scar-stage as compared with patients without HP infection in the R group ($P = 0.021$). The factors affecting post-ESD bleeding incidence were the patients who has a diabetes and renal failure past history ($P < 0.05$). There were no statistically significant differences between the two group with regard to use of anticoagulants, antiplatelet agents, steroid, and non-steroidal anti-inflammatory drugs (NSAIDs).

Conclusion: Vonoprazan was significantly superior to Rabeprazole for the healing of post-ESD artificial ulcer. Post-ESD bleeding did not have the significant difference between drugs, but the contraction rate is significantly faster in Vonoprazan and may be a medical care drug to contribute to economically at the point. Therefore Vonoprazan may supersede PPI in treating post-ESD artificial ulcers.

P1398 FLEXIBLE ENDOSCOPIC MYOTOMY IN ZENKER'S DIVERTICULUM: NO CORRELATION BETWEEN OUTCOME AND DIVERTICULUM SIZE OR PRETREATMENT AFTER COMPLETE SEPTOTOMY

D. Albers[1], D. Dakkak[2], B. Schumacher[2]
[1]*Elisabeth-Krankenhaus Essen, Gastroenterology, Essen, Germany*
[2]*Elisabeth -Krankenhaus Essen, Gastroenterology, Essen, Germany*

Contact E-Mail Address: david.albers@t-online.de

Introduction: Flexible endoscopic myotomy offers several advantages over competing techniques like surgery or rigid endoscopic myotomy because of less invasiveness. Nevertheless different studies displayed a declining success rate with rising diverticulum size or in pretreated patients.

Aims and Methods: This is a single-center retrospective study including 42 patients with symptomatic Zenker's diverticulum between 4/2014 and 12/2016. Patient characteristics showed a male-female ratio of 3:2, mean age was 73 years (range 43–94). 26% of patients were pretreated (flexible endoscopic myotomy (5), open surgery (2), rigid endoscopic diverticulotomy (4). Mean size of diverticulum was 3.3 cm (range 1.5–6.5 cm). The intervention was performed following a standardized protocoll. On first day routine endoscopy and barium esophagogram was performed.

On day 2 mucomyotomy under conscious sedation took place using a needleknife (Zimmon knife, Cook medical, Winston-Salem, NC) with a diverticuloscope (Cook medical, Winston-Salem, NC) or a standard transparent cap. The complete incision of the septum was intended in one session. On first postinterventional day water-soluble contrast-esophagogram excluded perforation and oral intake was started. Clinical success was defined as complete resolution of clinical symptoms and disappearance of diverticulum in esophagogram.

Clinical success rate was interpreted in relation to the variables diverticulum size and pretreatment. Level of significance was evaluated with fisher's exact test.

Results: Overall clinical success rate was 88%. Adverse events occurred in 3 patients: bleeding (2), microperforation (1), all treated conservatively (complication rate 7.1%).

Mean follow-up was 19 ± 10 months, 6 patients developed recurrance of disease (14%), 4 of them were treated successfully with second endoscopic intervention. Mean time until recurrance was 8 ± 5 months. There were no significant changes in outcome in relation to the variables diverticulum size or pretreatment.

Conclusion: Flexible endoscopic myotomy is a safe and effective treatment in Zenker's diverticulum.

Our retrospective data suggest that clinical success rate is indepent of diverticulum size or state of pretreatment when complete septotomy is performed.

Contact E-Mail Address: vinbove@alice.it

Introduction: Enlargement of gastrojejunal anastomosis is associated with weight regain in patients with Roux-en-Y gastric bypass (RYGB). Endoscopic transoral outlet reduction (TORe) has proven safe and effective for treatment of weight regain. The objective of this study was to evaluate the safety and the efficacy in weight loss and quality of life after TORe.

Aims and Methods: Patients with at least 50% of weight regain and enlarged gastric outlet after RYGB treated at our centre were retrospectively identified from a prospectively collected database. Endoscopic outlet reduction was performed with Overstitch (Apollo Endosurgery), a full-thickness endoscopic suturing device. Before suturing the outlet rims were cauterized with pulsed Argon Plasma Coagulation on 40 Watts, 1l/min (VIO 300D, ERBE Elektromedizin GmbH). Telephonic follow-up was done at 1, 3, 6 and 12 months. The quality of life was evaluated according to the Quality Of Life Scale (QOLS).

Results: Thirty-three patients (29 female, mean age 43.7) underwent TORe from January 2015 to April 2017. Baseline mean BMI was 37.9 (range 31–50) and weight was 107.9 kg (range 77–132). Mean procedure time was 34 minutes (range 15–60) and a mean number of 2.3 stitches per patient were placed (range 2–4) on the level of the gastric outlet. After suturing the patency of the redone outlet was tested with a standard gastroscope. There were 2 (6%) complications: one patient developed fever due to a small retrogastric collection and was treated with antibiotics, while one patient had a gastric perforation that required urgent surgery. Mean hospital stay was 2.4 days (range 1–10).

Thirty patients completed the follow up at 1, 3, 6 and 12 months. Three patients were lost during the follow-up. Mean weight loss at 1-month was 8.7 kg, at 3 months was 11.7 kg, at 6 months was 14.1 kg while at 12 months was 14.8 kg. Mean BMI was 32 and the %EWL was 34.5 at 1 year. Only two patients regained weight compared to baseline during the follow up. All the patients reported satiety after 1 month, which was confirmed by 56% of patients after 6 months and by 37.5% after 12 months of follow-up. In addition, over 50% of the study population had an improvement quality of life in terms of physical activity, relationships and dietary habits at 1 year follow-up.

Conclusion: In our experience TORe was a safe and effective procedure in patients with weight regain after RYGB, with stable promising results even in the long-term follow-up.

Moreover, our study showed an improvement in patients' quality of life, in terms of satiety, relationships, dietary habits and aerobic physical exercise.

Further clinical trials are needed to confirm these results and to establish the role and correct timing of TORe after RYGB in the multidisciplinary strategy.

Disclosure: Nothing to disclose

P1400 LONG-TERM OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR UNDIFFERENTIATED EARLY GASTRIC CANCER, BEYOND EXPANDED CRITERIA

C.B. Ryu[1], J.Y. Bae[2], M.S. Lee[1], Y.S. Lim[1]
[1]*Soon Chun Hyang University School Of Medicine, Department of Internal Medicine, Bucheon, Korea (Republic of)*
[2]*Seoul Medical Center, Internal Medicine, Seoul, Korea (Republic of)*

Contact E-Mail Address: ryuchb@gmail.com
Introduction: Expanded indication of endoscopic submucosal dissection (ESD) for intramucosal undifferentiated early gastric cancer (EGC) up to 2 cm without lymphovascular invasion have been accepted because of negligible lymph node metastasis.
However, preoperative measurement of the tumor was completely not as same as postoperative one and if the postoperative tumor size would be a little more than 2 cm with R0 resection, additional surgery recommaded.
Aims and Methods: The aim of this retrospective study was to analyze the long-term outcomes of ESD carried out to treat undifferentiated EGC in two groups (group A: up to 2 cm, group B: 2–3 cm)
Between January 2001 and March 2015, 104 patients with undifferentiated early gastric cancer (EGC) including poorly differentiated adenocarcinoma (PD, $n=66$) or signet ring cell carcinoma (SG, $n=38$) on preoperative biopsy underwent ESD (group A: 71 cases, group B: 33 cases),
Total ESD speciemens were evaluated en bloc resection, R0 resection, and curative resection (CR) and to evaluate long-term outcome, annual endoscopic surveillance with biopsy and CT scan were done.
Results: M/F was 40/31 and 17/16. Mean follow-up period in group A and B were 61.10 ± 38.12, 60.79 ± 47.75. Mean age in group A and B were 52.90 ± 13.62, 57.00 ± 12.25. En bloc in group A and B were achieved in 92.9%, 90.9% of patients, respectively *(NS)*. R0 resection in were achieved in 87.3%, 51.5% of patients, respectively *($p < 0.05$)*.
Curative resection was 83.0% in group A and group B was not include this definition.
Postoperative bleeding, perforation during the procedure, and delayed perforation were no significantly different in both groups, respectively.
Recurrence rate in group A and B were 5.6%($n=4$), 18.1% ($n=6$), retrospectively *(NS)*.
Recurrence rate with R0 resection in group A and B were 1.7% (1/59), 6.25% (1/16) *(NS)*.
All cases with lateral margin positive required additional ESD ($n=2$), desctructive therapy ($n=3$), or surgery ($n=4$) and no recurrence happened.
No patient died of gastric cancer.
Conclusion: In group B, R0 resection rate was lower than group A. However, long term follow up showed en bloc resection, recurrence rate, and with R0 resection in both group were not different. Carefully, undifferented EGC with 2 to 3 cm in a size recommended ESD and long-term close follow-up.

Introduction: Gastric per-oral endoscopic myotomy (G-POEM) of the pylorus has emerged as a novel endoscopic technique for refractory gastroparesis (GP). However, limited data on the efficacy and safety of G-POEM are available. Therefore, a systematic review was conducted to evaluate the efficacy of G-POEM in refractory GP.
Aims and Methods: We performed a thorough literature search using PubMed, EMBASE, Cochrane library, Medline, Google scholar and Science citation index for studies related to G-POEM between January 2010 to January 2018. Search terms included MeSH and non-MeSH terms relating to gastroparesis, refractory gastroparesis, gastric per-oral endoscopic myotomy, endoscopic techniques in gastroparesis and delayed gastric emptying. Additional case-reports, case series, and abstracts were retrieved by searching from references of relevant studies. Pooled technical success, clinical success, and adverse events were calculated.
Results: Based on our search criteria 23 studies were identified and 7 were excluded after careful review. 16 studies which included 189 patients were analyzed. The overall technical success rate, clinical success rate, and frequency of adverse events were 88.5, 83.2, and 10.8%, respectively. The common adverse events associated with G-POEM were pneumoperitoneum (4.7%), ulcer (1.6%), bleeding (1.5%) and stricture (1.01%). Overall mean procedure duration was 61.2 +/− 11.4 minutes.
Conclusion: G-POEM is a technically feasible and effective therapeutic option for gastroparesis with good clinical responses. However, larger data is still required to determine the subgroup of patients who would benefit from this novel procedure.

Introduction: Zenker's diverticulum (ZD) is an uncommon disorder. Therapy of symptomatic ZD has evolved from an open surgical approach to less invasive transoral endoscopic techniques.
Flexible endoscopy allows to use vessel-tissue sealer to perform diverticulotomy. An overtube protects both diverticulum and esophageal wall with a well-view of the septum. This procedure has demonstrated to be safe for high-risk surgical patients in small previous case series with a lower morbidity rates and quick patient's recovery. Very little has been published with this approach in ZD treatment.
Aims and Methods: 1. To evaluate the effectiveness and safety of flexible endoscopy treatment assisted by vessel-tissue sealer technique. 2. Describe epidemiology data of ZD patients.
One-single-centre prospective and descriptive study including ZD patients treated with flexible endoscopy, using vessel-tissue sealer technique for the resection of ZD.
Patients were included consecutively from March 2009 to April 2018. Patients were censored until the end of the follow-up or death. We analysed complications, symptoms before treatment, sex, age, type of sedation and number of interventions needed for resolve ZD. Bleeding complication was considered when cases required a second endoscopy.
Results: 46 symptomatic ZD patients were included in the final analysis. Women were 41.3%, median-age of 73.7 ± 11 years. Median follow-up period was 37.21 ± 28 months. 58.7% ZD were considered small (<3 cm). Solid or semi-solid food related dysphagia was present in 55.6% of patients, whereas liquid-food and total dysphagia were observed in 34.8% and, 6.7% respectively. There were 4.3% complications with this technique. Bleeding was the most frequent adverse event in relation to endoscopy procedure (2.2%).
Technique was successful in 76.1% in one single procedure. However, it increased until 89.1% with a second procedure. No statistically significant differences were found between complications rates according to diverticulum length, or number of interventions needed. Likewise, we did not find differences between the need of re-intervention and diverticulum length or symptoms. The majority of patients (80.7%), were managed as out-patient or short admission less than 24 hours.
Conclusion: In this large case series study, ZD treatment based on flexible endoscopy assisted by vessel-tissue sealer is an effective and safe procedure with a high successful rate in a few endoscopy sessions and low complications rate. This procedure can be recommended as a solid alternative in ZD endoscopic treatment.

Introduction: Post-surgical fistulae involving the upper digestive tract (UDT) are associated with significant morbidity and mortality. Endoscopic management is a minimally invasive alternative option to surgical repair in this situations.
Aims and Methods: We aimed to access efficacy and safety of a primarily endoscopic approach for management of post-surgical fistulae involving the UDT. Retrospective multi-centric study, involving 71 consecutive patients that were managed endoscopically for post-surgical fistulae of the UDT, between March 2009 and December 2017, in 3 endoscopic centers. Possible factors associated with fistula closure, fistula recurrence and mortality including age, indication for surgery, fistula orifice size and time to fistula diagnosis/ treatment were evaluated. Complications related to endoscopic therapy were classified as early ($\leq$1 week) or late ($>$ 1week). Statistical analysis was performed with IBM SPSS®22 and a p value <0.05 was considered significant.
Results: The mean age was 52.3 ± 16.2 years and 63.4% (45) were women. Indications for surgery were: obesity 57.7% (41); neoplasia 32.4% (23); others 9.9%(7). Median time between surgery and fistula diagnosis was 8(2–62) days. The average size of fistula orifice was 7.74 ± 5.06mm. Endoscopic interventions included: Metallic stents in 86% (61) patients (totally covered 29; partially covered 32), clips in 21.1% (15) patients (OTSC 7, TTS 8) and intraluminal drainage with plastic stents in 2.8% (2) patients.
Early complications ($\leq$1 week) occurred in 7.0%(5) patients: stent migration (n = 3); mucosal dissection (n = 1); anastomotic dehiscence (n = 1) and late complications ($>$1 week) in 29.6%(21) patients: dysphagia related to mucosal ingrowth/overgrowth (n = 8), stent fracture (n = 4), stenosis after stent removal (n = 3), migration (n = 3), other (n = 3).
Overall clinical success (fistula closure) was documented in 76.1%(54) patients. Fistula closure was obtained with a single endoscopic intervention in only 38%(27) patients. The median number of endoscopies until fistula closure was 2(1–8). Median time until confirmation of fistula closure was 8(4–63) weeks. Surgical re-intervention was performed in 21.9%(13) patients. The main reasons for surgical re-intervention were: Abdominal fluid collection drainage and peritoneal lavage (n = 7), esophageal exclusion (n = 3), fistula suture (n = 2), fistula-jejunostomy (n = 1).
After a median follow-up of 8(1–98) months, the mortality rate was 22.5% (16) being significantly higher in patients who underwent surgery for neoplastic compared to non-neoplastic etiologies (56.5% vs 8.3%, $p < 0.001$). None of the evaluated variables were found to be significantly associated with endoscopic treatment failure, fistula recurrence or mortality.
Conclusion: Endoscopic treatment of post-surgical fistulae involving the upper digestive tract is associated with high clinical success with an acceptable safety profile.

P1404 SURVEILLANCE AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION FOR SUPERFICIAL COLORECTAL TUMORS

T. Okumura, S. Kudo, T. Hayashi, Y. Kouyama, T. Sakurai, Y. Maeda, Y. Ogawa, K. Ichimasa, S. Matsudaira, H. Nakamura, Y. Yagawa, T. Ishigaki, N. Toyoshima, Y. Mori, M. Misawa, N. Ogata, T. Kudo, T. Hisayuki, K. Wakamura, F. Ishida
Showa University Northern Yokohama Hospital, Digestive Disease Center, Yokohama, Japan

Contact E-Mail Address: javier.thierry@gmail.com
Introduction: Endoscopic mucosal resection (EMR) is currently the most used technique for resection of large colorectal polyps. However, in large lesions EMR can often only be performed in a piecemeal fashion resulting in relatively low radical (R0)-resection rates and high recurrence rates. Endoscopic submucosal dissection (ESD) is a newer procedure that is more difficult resulting in a longer procedural time, but is promising due to the high en bloc resection rates and the very low recurrence rates. There are few reports on surveillance for patients with superficial colorectal tumors after ESD. The aim of this study is to evaluate surveillance after ESD for superficial colorectal tumors.
Aims and Methods: Endoscopic submucosal dissection (ESD) was performed on 558 colorectal tumors in 500 consecutive patients at Showa University Northern Yokohama Hospital between September 2003 and March 2013. Tumors larger than 20mm were indicated for ESD. We investigated the following variables: patient characteristics, the American Society of Anesthesiologists score, tumor location, tumor size, growth type, pit pattern, histology, en bloc resection rate, achievement of curative resection, procedure time, and adverse events. Curative resection was defined when the pathological specimen had tumor-free resection margins, without submucosal deep invasion ($\geq$1000μm), lymphovascular involvement, or a poorly differentiated adenocarcinoma component.
Results: We identified 496 tumors in 446 patients who were confirmed follow-up data for more than 5 years. Based on the postprocedural pathologic reports, 17 lesions were excluded because they showed positive vertical margines and they were indicated for additional surgery. The rest of lesions were categorized as follows: lesions with piecemeal resection (n = 9), lesions with en bloc resection (n = 470). The 5-year cumulative recurrence rate was 22.2%(2/9) in piecemeal resection group and 0.6%(3/470) in en bloc resection group ($P = 0.003$). Further, En bloc resection group were divided as follows: lesions with positive lateral margins of en bloc resection (n = 15) and lesions with R0 resection (n = 455). The 5-year cumulative recurrence rate was 6.7%(1/15) in the non-R0 group and 0.4%(2/455) in the R0 group. The risk of recurrence after complete en bloc resection of ESD is definitely low, but two recurrence tumors were encountered.
Conclusion: The local recurrence rate was higher in lateral margin-positive cases than in R0 resection cases. En bloc resection of ESD could reduce recurrence. However there were a few cases to recur even if R0 resection was achieved, surveillance after ESD for superficial colorectal tumors are significant necessary for R0 resection.
Disclosure: Nothing to disclose

P1405 "DIAGNOSE-AND-LEAVE" STRATEGY FOR DIMINUTIVE LEFT COLORECTAL POLYPS

C. Palmela, M.P. Costa Santos, C. Gouveia, C. Gomes, J. Nunes, E. Barjas, J. Torres, M. Cravo, A.O. Ferreira
Hospital Beatriz Ângelo, Gastroenterology, Loures, Portugal

Contact E-Mail Address: palmela.carolina@gmail.com
Introduction: The "diagnose-and-leave" strategy is based on the decision of leaving in situ diminutive ($\leq$ 5mm) rectosigmoid hyperplastic polyps, based on optic chromoendoscopy assessment. ASGE recommends this strategy only if endoscopic diagnosis provides a 90% or higher negative predictive value for adenomatous histology when used with high confidence.
Aims and Methods: Our aim was to assess the feasibility of this strategy in our centre. We performed a prospective observational study of patients submitted to colonoscopy with optic chromoendoscopy (narrow-band imaging – NBI) during 2017. Pathological and endoscopic characteristics of diminutive left colorectal polyps (location, size, NICE classification and degree of confidence in this assessment) were collected. We compared NICE classification using optic chromoendoscopy and histology for each polyp.
Results: 107 colonoscopies and 199 diminutive left colorectal polyps were included: 48% from the descending/sigmoid colon and 52% from the rectum. Mean size was 3.4 ± 1mm. According to the NICE classification, 74% of polyps were type I and 26% type II. Pathology revealed that 58% were hyperplastic polyps, 33% were adenomas, 1% were sessile serrated polyps and 8% were inflammatory changes. The endoscopic diagnosis using NICE classification for adenomatous histology had an 82% accuracy, 51% sensibility, 95% specificity, 80% positive predictive value and 82% negative predictive value.
Conclusion: Optic chromoendoscopy assessment of diminutive left colorectal polyps did not reach the ASGE recommended cut-off. We will need to improve our optic chromoendoscopy performance, for instance trough the implementation of NBI training programs, before the "diagnose-and-leave" strategy can be used in our centre.

Contact E-Mail Address: zahra.bouhnoun@gmail.com
Introduction: Crohn's disease (CD) and ulcerative colitis (UC) are the most common chronic inflammatory bowel disease (IBD) and may be associated with spondyloarthropathy (SPA). The aim of our work is to specify in a group of patients suffering from any form of SPA having benefited from systematic ileocolonoscopy the frequency of macroscopic lesions found at endoscopy.
Aims and Methods: This is a prospective study, during a period of 8 years and 7 months [January 2009 – July 2017]. All patients with a selected SPA according to ESSG criteria with or without gastrointestinal manifestations were included.
Results: One hundred seventy-three patients had undergone systematic ileocolonoscopy in the setting SPA, 33% had diarrhea as gastrointestinal manifestations. The average age of our patients was 38 years [16 years-76 years]. Male predominance was noted (91H/82F). The results of the endoscopy were as follows:
- Normal endoscopy without macroscopic lesions in 63% of cases, the histological study of systematic staged rectocolic biopsies confirmed these results except in 2 patients returning in favor of IBD.
- In 35% of patients endoscopy revealed an endoscopic appearance of ileal localized Crohn's disease in 34% of cases, colic in 36% of cases and ileocolic

localization in 30% of cases. However, there was no endoscopic aspect of UC. The endoscopic lesions described were: congestion with erythematic, aphtoid ulcerations, and erosions. The histological results in this group of patients were in favor of IBD in 31% of cases (N = 19) including 18 cases of CD and 1 case of UC, ileal and/or colic lesions were non-specific in 30 patients.
- Revealed the presence of colonic the presence of colonic polyps in 4 patients without lesions of the mucosa and the histological study was in favor of tubular adenoma in low-grade dysplasia in 2 cases and normal in the 2 others.
Colonoscopy was associated with a single case of complication represented by colonic perforation.
Of the patients in whom endoscopy was in favor of IBD, 49% were asymptomatic in the digestive tract.
Conclusion: In our study, systematic ileocoloscopy performed in patients with ASA revealed macroscopic and microscopic evidence of lesions in favor of IBD in 36.4%. This systematic screening is therefore recommended for early management of IBD.
Disclosure: Nothing to disclose

P1407 DO HYPERMOBILE JOINTS PREDICT A PAINFUL COLONOSCOPY?

A. Beckers[1], L. Vork[1], R. de Ridder[1], Q. Aziz[2], A. Masclee[1], D. Keszthelyi[1]

Contact E-Mail Address: ab.beckers@maastrichtuniversity.nl
Introduction: Patient perception of colonoscopy varies greatly; young slender women and irritable bowel syndrome (IBS) patients appear to be at risk for peri-procedural pain. Recent evidence suggests a high prevalence of connective tissue disorders referred to as ''Hypermobility Spectrum Disorders'' (HSD) in this population. Therefore, HSD might be associated with increased pain during colonoscopy.
Aims and Methods: In this study we aimed to compare pain perception during colonoscopy between HSD and non-HSD patients. We prospectively included patients undergoing a standard colonoscopy. Patients with a history of major abdominal surgery, inflammatory bowel disease, or who were taking part in the national cancer screening program, were excluded. Subjects were assessed for HSD using the Brighton criteria, and IBS and functional dyspepsia (FD) using the ROME III criteria. After colonoscopy and recovery from sedation, patients were asked to report pain scores on a 100mm visual analogue scale (VAS). In addition, cecal intubation time was measured, and endoscopists scored the difficulty of the procedure (100mm VAS).
Results: Of 201 included patients, 22 (10.9%) met criteria for HSD. HSD patients were more often female than subjects without HSD (86.4% vs. 48.6%, $p = 0.001$). A crude linear regression model demonstrated that pain scores were 13.30mm higher (95%-CI 0.07–26.53, $p = 0.049$) in HSD vs. non-HSD patients. When subsequently correcting for possible confounding factors, however, this difference in pain scores could be explained by a confounding effect of female gender. Indeed, female gender was the strongest predictor of a higher pain score (B: 18.51mm, 95%-CI 10.56–26.47, $p < 0.001$). No other factors were found to be associated with patient pain score. Cecal intubation time and perceived procedural difficulty did not differ significantly between HSD and non-HSD subjects.
Conclusion: HSD is not an independent predictor of painful colonoscopy, since female gender as a confounding factor explains the higher pain scores in HSD patients compared to non-HSD patients. In addition, performing colonoscopy is not more complicated in HSD vs. non-HSD. Endoscopists should consider offering higher dose sedo-analgesia to female patients, but not to HSD patients per se.

[3]*ICube, CNRS, University of Strasbourg, Illkirch-Graffenstaden, France*

Contact E-Mail Address: pietro.mascagni@ihu-strasbourg.eu
Introduction: Interventional procedures performed by means of flexible endoscopy have been considerably increasing thanks to recent technical and technological advances. Endoscopic submucosal dissection (ESD) is as effective as technically demanding. Robotic assistance and endoscopic translation of surgical principles could shorten the learning curve of existing endoluminal interventions and help establish innovative procedures. Our group previously described a master-slave robotic flexible endoscopic platform allowing for intraluminal surgical triangulation[1].
Aims and Methods: The aim of this study was to evaluate preclinical feasibility of robotic colonic ESD in a porcine model.
A mobile robotic cart and a detachable flexible endoscope compose the slave unit. The endoscope has 2 working channels for telemanipulated flexible instruments (graspers, a hook, and an isolated tip knife) and a third working channel for conventional endoscopic instruments. The jaw-like opening of the tip of the scope allows for the spacing of operative instruments offering surgical triangulation. The whole system has 10 degrees of freedom. The ergonomic master unit allows a single operator to control all movements of the endoscope and instruments through two control handles.
A surgeon without prior exposure to ESD had to perform 20 robotic colonic ESD in 6 pigs. Pseudotumors were delineated with coagulation marks on the bottom, lateral, and upper walls of the colon at a distance from the anal verge ranging between 15 and 35 cm. The assistant at the patient's side performed a lifting submucosal injection when required by the operator. Total time (from mucosal marking to complete excision), ESD time (from the first incision to complete excision), ''en bloc'' resection of the marked area, specimen size, excision speed (specimen size/ESD time) and complications were recorded.
Results: All 20 pseudotumors, with the mean size of $15.18 \pm 8.66 cm^2$, were resected ''en bloc''. One perforation (5%) occurred during the first experimental session and was managed intraoperatively, without interference with the planned procedure. Mean total time, ESD time, and excision speed accounted for 33.36 ± 14.20 min, 29.42 ± 14.29 min and $57.05 \pm 29.42 mm^2$/min respectively, regardless of the ESD location. Comparative analysis between the first 10 and the second 10 ESDs showed a significant increase in dissection speed (43.72 ± 30.74 vs. 70.37 ± 22.09; $p = 0.007$).
Conclusion: Robotic colonic ESD is feasible in a preclinical model. The robotic platform and flexible instruments responded well to the stress test. Comparing current results with previous studies performed by our group, robotic assistance outperforms conventional and mechanical platforms while carrying out colonic ESD[2]. These preclinical results suggest that robotic assistance could be a shortcut to endoscopic expertise. The described robotic flexible endoscopic platform is ready for the first clinical case.

Contact E-Mail Address: entcho.klenske@gmx.de
Introduction: Apart from mucosal healing as an established treatment goal in inflammatory bowel diseases (IBD), recent evidence suggests that histologic healing is another key prognostic parameter in IBD patients. I-scan optical enhancement (OE) is a novel endoscopic pre-processing optical filter technology, in which the spectrum of the emitted wavelengths is reduced, thereby leading to enhanced visualization of the mucosal and vascular pattern and first studies suggest that magnification endoscopy in combination with virtual chromoendoscopy can render the endoscopic diagnosis in IBD more precisely.
Aims and Methods: Our aim was to evaluate whether i-scan OE in combination with high-resolution optical magnification endoscopy can accurately assess histologic inflammation in IBD patients. The *in vivo* assessment of histologic inflammation was made with optical magnification endoscopy in conjunction with i-scan OE by a total of four endoscopists. Targeted biopsies of the imaged areas were obtained and results were compared against established and validated histology scoring. Moreover, interobserver agreement was calculated.
Results: 82 IBD patients (29 CU, 53 MC) were consecutively enrolled (40 men, median age 43, range 19–72). A newly developed I-scan OE magnification score showed high accuracy, sensitivity and specificity for assessing the histologic level of inflammation and correlated strongly with histopathologic scoring ($r \geq 0.7$, $p \leq 0.05$). Further, a prevailing amount of patients with mucosal healing on standard endoscopy showed signs of microinflammation on optical magnification endoscopy in combination with i-scan OE. Interobserver agreement for assessing microscopic inflammation with optical magnification endoscopy and i-scan OE with Cohen's kappa was substantial (≥ 0.7).
Conclusion: Optical magnification in combination with i-scan OE allows for a precise assessment of histologic inflammation during real-time endoscopy in IBD patients. Therefore, this approach holds the potential to reduce the need of physical biopsies for monitoring of inflammatory activity in patients with IBD during colonoscopy.

Introduction: Even if Split-dose regimen (SpD) [and Same-day regimen (SaD) for afternoon colonoscopies] is recommended by international guidelines[1,2], its adoption is still suboptimal.

Aims and Methods: Our aim was to survey and improve adhesion to SpD through a Plan-Do-Study-Act (PDSA) approach and to identify factors predicting its adoption.

This multicenter cross-sectional study consisted of 3 phases. Cycle1: survey of current practice; Interventional phase: local spontaneous corrective measures after analysis of Cycle1 data; Cycle2: survey of modified practice. Every outpatient or inpatient scheduled for a complete colonoscopy was eligible.

Differences were compared using a Student's T or a Chi Square test as appropriate. Multiple stepwise selection logistic regression models were built.

Results: 8213 patients (mean age 60.29 (SD 13.58), men 54%, outpatients 88.4%) were enrolled in 74 Endoscopy Units between 2013 and 2016 (4189 in Cycle1 and 4024 in Cycle2; no difference except a slightly higher rate of comorbidities in Cycle2). The SpD and SaD adoption raised from 29.1 and 3.1% of Cycle1 to 51.1 and 4.4% of Cycle2 ($p < .0001$ and.0039) respectively, while the Day-before regimen adoption declined from 67.8% to 44.5% ($p < .0001$). SpD advanced in all time slots ($p < .0001$ for each, including colonoscopies scheduled <9:30 am), but it became the preferred regimen only after 11:30 am (reaching 66.3% of late morning and 73.5% of afternoon colonoscopies); improvement in SaD adoption was detected only for afternoon colonoscopies ($p < .0001$), reaching 19% in Cycle2.

Significant changes detected in Cycle2 were: a higher use of 4L polyethylene glycol and a lower use of sodium picosulfate/magnesium citrate or sodium phosphate ($p < .0001$); a higher use of private transportations to reach the hospital ($p < .0001$); median delay between the end of bowel preparation and colonoscopy reducing from 12.42 to 7 hours ($p < .0001$), this delay being >6 hours in 75.3% of Cycle1 versus 56.4% of Cycle2 patients ($p < .0001$); fewer colonoscopies scheduled under deep sedation ($p = .0005$) and before 9:30 am ($p = .0019$); a higher rate of 100% product drinkers ($p = .007$). In Cycle2 adequacy of bowel cleansing was higher both in right ($p = .0274$) and left colon ($p < .0001$) and more patients would like to repeat the same regimen for future colonoscopies (83.1 vs 80.4%; $p = .021$).

At multivariate analyses, variables predicting SpD adoption (afternoon colonoscopies excluded) were: the colonoscopy scheduled 9:30–11:30 (OR 2.66) and after 11:30 am (OR 7.08; $p < .0001$); regimen communicated by the Endoscopy Unit and by more than one modality ($p < .0001$); colonoscopy being the first (OR 1.28, $p < .0001$), prescribed for screening instead of surveillance (OR 1.27, $p = .007$) and by a gastroenterologist instead of a general practitioner (OR 1.3, $p = .0001$). Colonoscopy planned under deep sedation (OR 0.51, $p < .0001$), a higher patient educational level ($p = .0063$) and being enrolled in Cycle1 vs 2 (OR 0.359; $p < .0001$) were negatively associated with SpD adoption.

SpD adoption independently predicted the willingness to repeat the same preparation ($p = .0001$), endoscopist satisfaction ($p = .0175$) and an adequate preparation of left ($p < .0001$) and right colon ($p < .0001$).

Conclusion: Notwithstanding barriers limiting the spread of Split-dose regimens (e.g. early morning colonoscopies, anesthesiological concerns, information providers, patient characteristics), corrective measures through a PDSA approach result in higher adoption of SpD (even in early morning colonoscopies), higher colonoscopy quality and higher patient and physician satisfaction.

Introduction: Endocytoscopy (EC) is a brand-new contact-type endoscope commercially available in Japan and the European Union. It allows in vivo evaluation of cellular atypia with 520-fold magnification. Thus, EC provides diagnostic accuracy comparable to pathological diagnosis[1]. However, it is uncertain whether the EC image can be easily obtained, compared with conventional magnifying endoscopy.

Aims and Methods: The aim of this prospective study was to determine whether EC images can be acquired as easily as images in conventional magnifying endoscopy. This was a single-arm, prospective study conducted at Showa University Northern Yokohama Hospital. Consecutive 278 diminutive polyps (≤5 mm), all of which were observed by endocytoscope (CF-H290ECI, Olympus Corp.), were enrolled between June and December 2017. Inclusion criteria were follows: i) patients >18 years old, ii) patients who were not treated with anticoagulants, iii) patients who agreed with study participation. Exclusion criteria were histories of inflammatory bowel disease, chemotherapy, or radiation therapy for colorectal cancer. CF-H290ECI can acquire both conventional power magnification image (100×) and ultra-magnifying image (520×) by adjusting the zoom lever of the endoscope. During examination, detected polyps were observed by both narrow band imaging with conventional magnification (NBI-ME) and NBI with ultra-magnification (EC-NBI). To evaluate the degree of difficulty for obtaining an EC image, we measured the time that the physician could maintain an image in focus, by using both NBI-ME and EC-NBI as surrogate markers. We defined the image acquisition rate as the rate of lesions that the physician keeps continuously in focus for more than 3 seconds. In this study, physicians were told to maintain in-focus images, in both NBI-ME and EC-NBI, as long as possible. All procedures were recorded as movies and the in-focus times were measured by a research assistant and a single expert endoscopist in the recorded movies.

Results: Consecutive 278 polyps were analysed. Mean size was 3.4 ± 1.0 mm and the subsets of polyp locations were as follows: right sided, 119 polyps; left sided, 93 polyps; rectum 63 polyps. One-hundred and seventy-eight polyps were diagnosed as tubular adenoma, while the remaining 100 polyps were diagnosed as hyperplastic polyps. The image acquisition rate (the rate of lesion that physician maintain the image in focus more than three seconds) of EC-NBI was 94% (261/278), whereas NBI was 41% (113/278) ($P < 0.001$, Fisher's exact test).

Conclusion: This study showed that EC-NBI was able to take focused images for longer periods than NBI-ME. Thus, we conclude that EC-NBI images can be taken easily. We suspect that this is because EC is a contact-type endoscope. Once the physician can contact the polyps, a contact-type endoscope allows the physician to fix a focused image for longer than a conventional endoscope.

Introduction: The aim of endoscopic polyp characterization is to predict histopathological diagnoses on the basis of optical polyp features. Clinical data suggest that the quality of optical diagnoses of colorectal polyps differs markedly among users. Technical support is therefore demanded in order to improve accuracy of optical predictions. Computer-assisted optical biopsy (CAOB) approaches have recently been published but these apporaches have focussed on high-magnification endoscopy techniques [1–2]. The latter endoscopes and processors are not available in Europe. An automated computer-based decision suppurt based on standard solution picturer is not avialable until now.

Aims and Methods: The aim of this study was to develop a computer program that was able to differentiate neoplastic from non-neoplastic polyps using unmagnified endoscopic pictures.

During 250 colonoscopy procedures polyp photographies were performed using the unmagnified high-definition white light (HDWL) and Narrow Band Image (NBI) mode. All detected polyps (n = 275) were resected and sent to pathology. Histopathological diagnoses served as the ground truth. Machine learning was used in order to generate a computer-assisted optical biopsy (CAOB) approach (machine learning phase). In the test phase pictures of 100 polyps were presented to CAOB in order to obtain optical diagnoses. Altogether 788 pictures were available (602 for training the machine learning algorithm and 186 for CAOB testing. All test pictures were also presented to two experts in optical polyp characterization. The primary endpoint of the study was the accuracy of CAOB diagnoses in the test phase.

Results: A computer program for automated optical polyp characterization was sufficiently developed. Accuracy of the CAOB approach was 78.0%. Sensitivity and negative predictive value (NPV) were 92.3% and 88.2%. In the high

confidence setting (n = 89) accuracy of CAOB predictions was 80.9%. High confidence CAOB predictions showed a sensitivity of 93.9% and a NPV of 89.7%. Overall accuracy obtained by two expert endoscopists was 84.0% and 77.0%. Regarding accuracy of optical diagnoses CAOB predictions did not differ significantly compared to experts (p = 0.307 and p = 1.000 respectively).
Conclusion: Computer-assisted optical biopsy showed good accuracy on the basis of unmagnified endoscopic pictures. Performance of CAOB predictions did not differ significantly from experts' decisions. The concept of computer assistance for colorectal polyp characterization needs to evolve towards a real time application prior of being used in a broader setup.

Introduction: Endoscopic mucosal resection (EMR) is a minimally invasive technique used for the treatment of superficial neoplasms of the gastrointestinal tract, including early carcinomas. There is limited data on the safety and efficacy of this technique for large colorectal lesions in elderly patients.
Aims and Methods: The aim of this study was to evaluate the efficacy and safety of EMR of large colorectal lesions (≥20 mm) in the elderly (≥75 years) and to compare the outcomes with those of younger patients (<75 years).
Retrospective study of all patients who underwent EMR of colorectal lesions ≥20mm at our institution between January 2013 and December 2016. Patients were divided in two age groups considering 75 years as cut-off: ≥75 years (Group 1) *vs* <75 years (Group 2). The demographics of the patients, size and location of the lesions, technical aspects of the procedure, rate of endoscopic recurrence and complications were considered.
Results: A total of 136 colorectal lesions were removed in 123 patients. Fifty-one EMR were performed on 44 patients ≥75 years and 85 EMR were performed on 79 patients <75 years. The median age in Group 1 was 80 years (range 75–89 years) and 67 years in Group 2 (range 47–74 years). There was no significant difference in sex ratio, lesion size and lesion distribution between the two groups. En bloc resection was performed in 29.4% (15/51) of the lesions in Group 1 *vs* 31.8% (27/85) in Group 2 ($p = 0.774$). There were 2 cases (3.9%) of perforation in Group 1 and 3 cases (3.5%) in Group 2 ($p = 1.00$). There were no cases of delayed bleeding. The rate of endoscopic recurrence was 21.3% (10/47) in Group 1 and 23.6% (17/72) in Group 2 ($p = 0.766$). The overall endoscopic success rate was 84.3% (43/51) in Group 1 and 84.7% (72/85) in Group 2 ($p = 0.951$).
Conclusion: EMR is a safe and effective procedure for the treatment of large colorectal neoplasms in the elderly, with outcomes similar to those obtained in younger patients.

Introduction: Underwater endoscopic mucosal resection (UEMR) for colorectal (CR) lesions has been described for overcoming the technical drawbacks of standard mucosectomy (EMR). This approach takes advantage of the behavior of mucosal lesions floating away from the muscular layer, once immersed in liquid. Thus, luminal water infusion allows to achieve an alternative way to have the lesion lifted before being resected, without any submucosal injection. We performed a systematic review with meta-analysis to evaluate the efficacy of UEMR for the resection of CR lesions.
Aims and Methods: Electronic databases (Medline, Scopus, EMBASE) were searched up to March 2018. The search was restricted to english language full articles. Studies including patients with CR lesions resected by the UEMR technique were eligible. The complete resection (primary outcome), en-bloc resection, recurrence and adverse event rates were pooled by means of a random- or fixed-effect model according to the degree of heterogeneity to obtain a proportion with a 95% confidence interval (CI).
Results: Ten studies were eligible for inclusion providing data on 508 lesions endoscopically removed in 433 patients (m/f = 239/194; means ages ranging from 62.2 to 75 years). Six studies were performed in United States and the other in Europe; seven studies were prospective. The specific indications for performing UEMR, instead of standard EMR, varied widely across the studies: large (defined as above 20 mm in 2 studies, above 15 mm in 1 and above 10 mm in the others) lesions (5/10 studies, 248 lesions), recurrence after EMR (1/10, 36 lesions), scarce accessibility (1/10, 27 lesions). Three studies included mixed cases and aimed either to evaluate the feasibility of the new technique (2/10, 124 lesions) or to compare it to the standard approach (1/10, 73 lesions). Most of the lesions were located proximally to the splenic flexure (309 lesions, 61%). The means of the lesion size ranged from 15 mm to 33.8 mm.
Complete resection rate was 96.36% (CI:91.77–98.44) with a rate of en-bloc resection of 57.07% (CI:43.20–69.91%). The recurrence rate was 8.82% (CI:5.78–13.25) in a mean endoscopic surveillance period of 7.7 months (range 4–15 months). The intra and post-procedural bleeding rates were 3.14% (1.65–5.88%) and 2.85%(CI:1.64–4.90), respectively and were always endoscopically managed. Intra procedural bleeding were always mild and were considered as part of the procedure in all series. The overall adverse events rate was 3.31% (CI: 43.20–69.91%). No cases of perforation were reported.
Conclusion: Underwater endoscopic mucosal resection (UEMR) is an effective and safe technique for resecting colorectal lesions. The rates of complete resection, recurrence and adverse events are at least comparable to the ones recorded in literature for standard EMR. These data are even more relevant considering that most of the studies aimed to remove recurrent, large or difficulty accessible lesions.
Disclosure: Nothing to disclose

P1416 DOES ENDOSCOPIC SUBMUCOSAL DISSECTION REALLY DIFFER BETWEEN COLONIC AND RECTAL LESIONS? A WESTERN EXPERIENCE BY A SINGLE ENDOSCOPIST ON 505 PROCEDURES

Introduction: In the treatment of early stage malignant and pre-malignant lesions, endoscopic submucosal dissection (ESD) is an effective, minimally invasive treatment modality which can provide en bloc and complete resection, when compared to other treatment modalities such as endoscopic mucosal resection and polypectomy.
Aims and Methods: In this study, we aimed to compare the effect of localization on ESD treatment success, in patients with pre-malignant and early-stage malignant colorectal lesions. Up to date, the number of lesions included in this study is higher than any single-institutional publications in the Western literature.
Between April 2012 and April 2018, patients with a total of 2458 colorectal lesions were referred to our clinical unite to be treated with advanced endoscopic techniques. Colorectal ESD was performed on 541 lesions. Data were recorded prospectively and analyzed retrospectively by utilizing t-test and chi-square methods. 8 patients with subepithelial lesions, 7 patients with tumors located on anastomosis line and 21 patients who didn't have post-operative evaluation were excluded from the study. According to the localization of the lesions, ESD procedures were categorized as rectum (R-ESD) and colon (C-ESD). The perioperative results of these two groups were compared.
Results: For pre-malignant and early-malignant lesions, 505 colorectal ESD procedures were performed in 486 patients. The overall en bloc and complete resection rates were 95.1% and 92.3% respectively for colorectal lesions. Numbers of lesions localized to rectum and colon were, 253 and 252 respectively. Between two groups, no differences were observed for age, gender, en bloc and complete resection rates, severity of dysplasia, rate of invasive carcinoma, utilization of snare or other knife, procedure times. ($p > 0.05$).
Lesions localized to rectum were larger than lesions localized to colon. Although procedure times were similar between groups, dissection rate was faster in rectal lesions. For controlling bleeding and providing pre-coagulation during the procedure, hemostatic forceps use were utilized more in rectal lesions. There were significant differences in classifications of lesions ($p < 0.05$): Lateral spreading tumor non-granular (LST-NG) type lesions were more common in colon group, while LST granular mixed type (LST-GM) lesions were more common in rectal group. Rate of malignancy was higher in rectal lesions; however no significant differences were observed ($p > 0.05$).
During procedure, utilization of clip was required for 14 lesions with mucosal damage. Delayed perforation was observed in 1 lesion. Except for the late perforation, all complications were treated with endoscopy. Usage of clip was higher in lesions located to colon ($p < 0.05$). Patients with Sm2 invasion were referred for surgical treatment. During follow-up, no residual or relapsing lesions were identified in patients who underwent endoscopic and radiological evaluation.

Conclusion: According to the results of our study, ESD is faster and safer for lesions localized to rectum, compared to the other segments. But rectal lesions are larger and more prone to bleeding, thus more pre-coagulation is needed to control bleeding in these lesions. For lesions localized to colon, especially at the flexures, ESD is slower due to decreased maneuverability of endoscope and anatomic limitations; rate of complications is higher compared to lesions localized to rectum. With respect to our short and long-term follow-up results, we conclude that ESD can be safely and effectively used in the treatment of colorectal lesions.

Introduction: Magnifying narrow band imaging (NBI) is useful for examination of colorectal lesions, for differentiating neoplasms from non-neoplasms, and for predicting the histopathological diagnosis. Endocytoscopy (EC) is performed with a new type of endoscope that is commercially available in Japan and the EU. It allows visualization of glandular structure and cellular atypia *in vivo* with ×520 magnification. EC has visualized living tumor cells *in vivo* and obtained ultra-magnified pathological images simply by applying the scope to the target mucosa during endoscopic examination. However, in order to visualize cell nuclei, dye staining (i.e., methylene blue) is mandatory. Since dye staining complicates the procedure, a new observation method without use of dye has been needed. On the other hand, EC with NBI (EC-NBI) allows ultra-magnified microvessel observation without using any dye solution.
Aims and Methods: The aim of this study was to determine whether the observation of surface microvessels using EC-NBI was useful in predicting the histopathology of colorectal lesions. The study included 460 patients who underwent complete colonoscopy and endoscopic or surgical treatment between April 2006 and February 2016. A total of 623 lesions (54 non-neoplastic polyps, 340 adenomas, 73 intramucosal cancers, 21 slightly invasive submucosal [SMs] cancers, and 135 massively invasive submucosal [SMm] cancer) were retrospectively evaluated. We defined ultra-magnified microvessel findings as an endocytoscopic vascular (ECV) pattern and classified the findings into the following 3 groups: EC-V1, surface microvessels were very fine or obscure; EC-V2, surface microvessels were more clearly seen, with a regular vessel network, and uniform caliber and arrangement; and EC-V3, surface microvessels were thick, with non-homogeneous caliber and arrangement.
Results: EC-V1 was observed in 90.7% of non-neoplastic polyps, with EC-V2 in 97.1% of adenomas. Mucosal and SMs cancers tended to present as EC-V2 (91.5%). However, most SMm cancers presented as EC-V3 (82.2%). The sensitivity, specificity, and accuracy of EC-V1 for diagnosis of hyperplastic polyps were 90.7%, 98.6%, and 98.0%, respectively. Similarly, the sensitivity, specificity, and accuracy of EC-V3 for diagnosis of SMm were 82.2%, 98.2% and 94.7%, respectively.
Conclusion: Endocytoscopic vascular pattern was useful for predicting the histopathology of colorectal lesions.

[2]*Pinderfields ganeral hospital, Gastroenterology, Wakefield, United Kingdom*

Contact E-Mail Address: oka.priya@gmail.com
Introduction: Endoscopic mucosal resection (EMR) is a widely recognised, safe and minimally invasive technique for the removal of large, non-polypoidal colorectal lesions without resorting to surgery. In spite of high complete resection rates, local recurrence is not uncommon. Most studies have reported on short-term recurrence post EMR. We analysed our experience to determine long-term outcomes at 3 and 5 years post EMR.
Aims and Methods: A retrospective analysis was performed of all patients who underwent an EMR at lower GI endoscopy during a 2-year period, from January 2010 to January 2012, at a large non-tertiary endoscopy unit. Data was collated from endoscopy reports accessed from the hospital endoscopy reporting system (HICSS). Reports were analysed for details of the EMR performed and follow-up endoscopies for recurrence at the site of the initial EMR. The size and morphology of polyp, location and histology was recorded along with EMR details including completeness of excision and use of argon plasma coagulation (APC). Polyp recurrence at subsequent endoscopies up to 5 years was also recorded.
Results: A total of 437 patients underwent EMR during the study period. After exclusion for malignancy requiring surgery, incomplete follow-up, polyp size <1cm and index EMR outside the study period, 241 cases were analysed. Of the 241 polyps, 63% (153) were 1–2cm, 33% 2.1–5cm (79) and 4% (9) >5cm. Of the 241 polyps, 61% were located in the left colon and 39% right-sided. Most polyps irrespective of size were sessile (79%) with the remainder being flat (15%) or sub-pedunculated (6%). Duration of follow-up ranged from 3 to 60 months with a mean follow-up of 31 months (median 33 months). Residual/recurrent adenoma was successfully treated with further endoscopic resection and/or ablation. Histologically, there was no progression of severity of dysplasia/grading of adenoma in those patients who developed recurrence at long-term follow-up.
Conclusion: This study confirms EMR is a safe alternative to surgery for the management of large or difficult colonic polyps with good long-term outcomes. Our short-term recurrence rates are comparable to previous studies[1]. These low recurrence rates are maintained at long-term follow-up with good histological outcomes as well.
Disclosure: Nothing to disclose

Introduction: Endoscopic resection is usually the first-line treatment for colorectal adenomas and superficial adenocarcinomas. In case of pejorative histology: submucosal invasion >pT1 sm1 or pT1sm1 with pejorative qualitative criteria (poorly differentiated or with lymphovascular invasion or budding grade 2 or 3) a surgical resection is necessary because of the risk of lymphatic invasion despite complete resection (R0). In case of microscopically incomplete resection (R1) without any pejorative histologic criteria a surgical approach is the gold standard because the risk of lymph node metastasis is unknown. In order to try to avoid unnecessary surgeries we evaluated the efficiency and the safety of a second attempt to complete the resection in selected patients and in agreement with the surgical team. To many physicians this strategy appears to be an acceptable option; nevertheless few series studied specially this option. Indeed, second endoscopic approach is safe and effective (but less) after macroscopic incomplete resection (R2) and we wanted to prove with our case series the interest of endoscopic scare resection for R1 resection.
Aims and Methods: Between 2009 and 2018 we included retrospectively patients who underwent a second endoscopic resection in our center (Paoli-Calmettes institute Marseille) after R1 resection in another center. Macroscopic incomplete resection (R2) during the first endoscopy were excluded. The primary endpoint was the rate of avoided surgeries. Secondary endpoints concerned the morbidity rate and the recurrence rate.
Results: Between 2009 and 2018 we included 14 patients (mean age 73 years [64–88], men = 8, women = 6) who underwent a second endoscopic resection after a first resection R1 for colorectal adenocarcinomas. The technique resection was endoscopic submucosal dissection (ESD) in 6/14 patients (42%), endoscopic mucosal resection (EMR) in 7/14 patients (50%) and a hybrid method (hybridESD) in 1/14 patient. 7 patients had rectal lesion (50%) and 7 colonic lesions (50%). 10 patients (71%) had a en bloc resection (5 EMR, 5 ESD) and 4 patients had a piecemeal resection (2 EMR, 2 ESD and 1 hybrid ESD). In 12/14 patients (86%) complementary surgery has been avoided: in 8/12 cases (66%) because the lesion was less than a pT1sm1R0 on the second endoscopic resection,

in 2/12 cases (17%) because the lesion was pT1sm1R0 with no pejorative qualitative criteria and in 2/12 cases (17%) we confirm pT1sm2 lesion as on the initial resection but with negative positive deep margins on the second resection (one patient refused initially rectal surgery, rectal surgery was not possible for the second one) and we wanted avoid more than pT1sm2 lesion. In 2/14 patients (17%), surgery was recommended: 1 patient for R1 resection on the second procedure and 1 patient for pT1sm2R0 on the second procedure (pTis on the first) Regarding the secondary endpoints, only 1 patient presented a side effect which was a post polypectomy syndrome quickly controlled by an antibiotic treatment and by this time no recurrence was notified. The median follow-up time was 569 days and no local recurrence has been observed in our patients.
Conclusion: In case of R1 resection for superficial adenocarcinomas without pejorative histology a second endoscopic resection in an expert center may be a safe way to evaluate the real risk of metastatic lymph node in order to avoid unnecessary surgery.

P1420 PIECEMEAL ENDOSCOPIC MUCOSAL RESECTION OF COLORECTAL SUPERFICIAL LESIONS ≥20 MM IN SIZE: SHOULD WE TATTOO MORE?

P. Marcos, L. Eliseu, C. Leal, H. Vasconcelos
Centro Hospitalar de Leiria, Hospital de Santo André, Gastroenterology, Leiria, Portugal

Contact E-Mail Address: pedromarcos1ster@gmail.com
Introduction: Piecemeal endoscopic mucosal resection (P-EMR) of large colon superficial lesions (≥20 mm in size) raises several concerns, including the possibility of inadequate/incomplete polypectomy and future recurrence. It is desirable to locate with precision the site at which a lesion was removed in piecemeal fashion at the follow-up colonoscopy, even if the resection was apparently complete based on endoscopic criteria. However, the resection scar is not always easy/possible to locate in the surveillance colonoscopy, reason why some authors and guidelines suggest colonoscopic tattooing of the mucosa adjacent to all resection sites of lesions ≥20 mm (other than those in the cecum, adjacent to the ileocecal valve or in the low rectum) to allow optimal localization of the scar at future endoscopic exams. This is important because incomplete resection rates are higher for larger lesions removed piecemeal, the risk of recurrence after P-EMR of >20 mm lesions has been described as so high as 50% and some interval cancers may develop as a result of incompletely resected neoplastic lesions.
Aims and Methods: Evaluation of the scar identification rate post P-EMR at the first follow-up colonoscopy.
Retrospective unicenter analysis of all colorectal lesions ≥20 mm removed by P-EMR during the previous 7 years. Lesions located in the cecum, adjacent to ileocecal valve or in the low rectum were excluded, as well as pedunculated and semipedunculated lesions, lesions whose resection was considered incomplete at the moment of resection, invasive carcinomas and which didn't have follow-up colonoscopy in ≤12 months. All the remaining were included and divided in 2 groups: lesions in which tattooing of the mucosa adjacent to the resection site was not performed (group 1) and lesions in which tattooing was performed (group 2).
Results: In total, 177 P-EMR were included (group 1: n = 132; group 2: n = 45). The scar identification rate post P-EMR at first follow-up colonoscopy was 70.5% and 100% in group 1 and 2, respectively ($p = 0.000$). In group 1, lesions ≥30 mm and adequate bowel preparation were predictive factors of scar identification in the surveillance colonoscopy. In group 2, the colonic tattoo enabled precise scar location at all cases independently of factors as: lesion size, bowel preparation and timing of first follow-up colonoscopy. Globally, considering the cases in which the resection site was identified, the incomplete resection/recurrence rate (after P-EMR) was 31.2% (48/138).
Conclusion: Tattooing the mucosa adjacent to resection sites of large colonic lesions (other than those located in the cecum, adjacent to the ileocecal valve or in the low rectum) promotes accurate and efficient surveillance after P-EMR. The high rate of incomplete resection/recurrence observed in this study and described in the literature reinforces the conclusion of our analysis. Tattooing more after P-EMR may prevent some interval colorectal cancers.

Introduction: Literature supports that endoscopic resection and surveillance of malignant polyps is feasible and with low short term local recurrence rates and metastasis especially in patients with well/moderately differentiated cancer with invasion depth >1mm and no lymphovascular invasion, but data are limited.[1,2]
Aims and Methods: Aim of our study was to evaluate short and long-term clinical outcomes of malignant polyps that underwent endoscopic resection as the initial intervention under the Bowel Cancer Screening (BCS) programme during 2006–2011.
We performed a retrospective analysis of all patients attending BCS in Wolverhampton bowel cancer screening hub. Cases were identified after interrogation of BCS software database and verified using endoscopy and histology databases. Long-term outcomes were derived from patient case notes. Recurrence was defined as no mucosal, local lymhnode disease or metastatic spread.
Results: 34 polyps were identified initially in 33 patients. 32 patients were analysed due to missing follow up data. Mean age was 64.5 and 26 were male. Post endoscopic resection, follow-up was endoscopic surveillance (28%, n = 9), surgery (69%, n = 22) but 2 declined, palliation (3%, n = 1). One of the surgically managed patients had transanal endoscopic microsurgery. 30-day mortality rates were 10% (n = 2) in surgical group vs. 0% in others. No complications were reported in the endoscopy group.
Table 1 presents the number and type of polyps identified, mode of endoscopic removal, mean polyp size as assessed in endoscopy, histological clearance margins and follow-up pathway for each group.
In the endoscopic surveillance group, 1-year recurrence was 0%. 22.2% of (n = 2) patients had recurrence at 5 years (3 years and 4 years). In the surgical cohort, 15% (n = 3) of patients were found to have residual cancer in the resected specimen. No patients were found to have positive lymph nodes. 5-year recurrence in the surgical group was 0%.
Two patients declined surgery. One underwent endoscopic surveillance with no 5-year recurrence. The other received chemoradiation and died within a year. One patient had metastatic disease on staging after endoscopic resection and followed a palliative approach.
6 patients had a poorly differentiated adenocarcinoma on histology with 2 following endoscopic follow up and 4 having subsequent surgery. The 5-year recurrence was 0%. Mucinous adenocarcinoma was seen in 2 patients in 3 pedunculated polyps. At 1 year the recurrence rate was 0% but 100% at 5 years. Lymphovascular invasion was seen in 5 patients and associated with local or metastatic spread on initial staging in 40%. One further patient died post operatively (day 3). 40% of patients had no recurrence at 5 years.
Conclusion: Patients undergoing surgical follow up had lower recurrence rates compared with endoscopic follow up although no recurrent disease was found in the surgical cohort at resection. Patients with mucinous adenocarcinoma and lymphovascular invasion at initial histology appeared to have poorer outcomes. There was no difference in prognosis between en block and piecemeal endoscopic resection but margin clearance was not accurately identified in piecemeal polypectomies. Further data from the 2012–2016 cohort will follow.
Disclosure: Nothing to disclose

Introduction: In recent years considerable progress has been made to establish formal frameworks to ensure that quality services are delivered safely to patients. This was accompanied by considerable progress of the equipment available to deliver endoscopic services. While there are some studies assessing the procedural performance of specific equipment innovations, very little is known about the reliability of equipment and subsequent changes of reliability over time as well as the availability of equipment when time between repairs and repair time were taken into considerations.

Aims and Methods: We reviewed endoscopic service records of endoscopic equipment for a seven year time-period of a large tertiary teaching hospital delivering annually >12.000 endoscopic procedures. We aimed to capture the number of procedures done per scope, the number of repairs, costs per repair and time required for repair.

Results: In total 56 scopes (all from one supplier) were in use at the time of data capturing. While in 2011 on average scopes had a useability of 453 days until next repair (95% CI 312–593), this dropped to 80 days (95% CI 56–103) in 2017. This was associated with a significant increase of repair costs per 1000 procedures. At the same time the number of procedures per scope or the average age of the endoscopes did not significantly change. Moreover the time required for repairs provided by the manufacturer increased from an average of 27 days (±23 SD) to 75 days (±35 SD). Interestingly, repair times of a third party supplier engaged for some of the repairs since 2015 remained consistently below 40 days. There were significant differences in the number of repairs per 1000 procedures if the two most recent generations of scopes were compared. It appears that the mean failure rate per 1000 procedures has substantially increased with the latest scope generation, from 4.10 (±1.73 SD) to 5.47 (±4.46 SD).

Conclusion: Over a seven-year time period the reliability of standard endoscopic equipment appears to have substantially deteriorated. At the same time the turnaround time for repairs of a major supplier has doubled. In combination this substantially impacts on the availability of endoscopic equipment and equipment costs. Appropriate monitoring of the reliability of endoscopic equipment and the performance of service partners should be part of the quality framework of endoscopic providers.

Introduction: Identification and accurate characterisation of colonic polyps is important in the prevention of colo-rectal cancer. Currently, the well validated classifications for colon polyps are based on image enhancement technology (IEE). Magnification endoscopy is also required for some of the proposed algorithms. The uptake of such technology is not universal and learning curves are variable. High-definition white light endoscopy (HD-WLE) is used routinely by endoscopists. We developed a new classification and clinical algorithm using HD-WLE and proceeded to an initial validation.

Aims and Methods: The aim of our study was to develop and validate a classification and algorithm for colonic polyps using HD-WLE. In the first step, 10 experts developed the UNICORN classification by a series of consensus statements. Polyps were divided into Type 1a or hyperplastic polyps (HP),Type 1b or Sessile serrated polyps (SSP)),Type 2a or low-risk adenomas, Type 2b or high-risk adenomas and Type 3 or deep submucosal invasive cancer. In the next step, participants in 9 Endoscopy centres underwent training with a specially designed tutorial. Subsequently, 35 polyp images collected on HD-WLE from the 3 major endoscopic systems were provided. These included 16 images of Type 1, 18 images of type 2 polyps and 1 type 3. Participants were divided into experts and non-experts based on their level of experience and were asked to predict polyp type. Level of confidence of prediction was also recorded. Accuracy of prediction was calculated by measuring sensitivity, specificity, negative predictive value (NPV) and positive predictive value (PPV) as well as diagnostic effectiveness or accuracy.

Results: 12 experts and 15 non-experts participated in the validation using polyp images. Both groups achieved negative predictive values (NPV) >90% for HP, SSP and high risk adenomas. NPV was 86 and 81% respectively for low-risk adenomas. The expert group achieved diagnostic accuracy of 0.92 for HP, 0.93 for SSP, 0.87 for low risk adenomas and 0.92 for high-risk adenomas. The corresponding values for the non-experts were 0.91 for HP, 0.90 for SSP, 0.84 for low risk adenomas and 0.90 for high-risk adenomas. PPV was low for high-risk adenomas in the expert and non-expert group.
Detailed results are in the table.

Conclusion: HD-WLE is used routinely by endoscopists for detection and initial decision making on the management of colo-rectal polyps. Existing classifications based on IEE are associated with challenges in translation to routine clinical practice. The newly proposed UNICORN classification is based on HD-WLE. The classification proposes the use of IEE and or chromoendoscopy and magnification endoscopy for low certainty and for high-risk adenomas. Our initial results suggest that HD-WLE can be used for initial characterisation of a majority of polyps with use of IEE in specific scenarios. In our study, non-experts were able to achieve similar results to experts after a brief tutorial. High specificity and NPV for SSPs was also achieved in both groups using newly proposed criteria. Further analysis is planned looking at levels of confidence of prediction and polyp sizes. Further validation of the UNICORN classification in real-time endoscopy and involving community based endoscopists is also planned.

Introduction: Endoscopic characterization of colorectal neoplasia is a key point to choose in real time the best therapeutic option to treat effectively and safely each lesion. This characterization is based on 5 classifications, difficult to combine and to learn for non-experts. Thus, we mixed all the validated criteria in a single classification called CONECCT to facilitate prediction and therapeutic choice. This study aimed to evaluate CONECCT benefits in endoscopic characterization of colorectal neoplasia.

Aims and Methods: It is a prospective multicenter study involving all French gastroenterology interns and seniors who participated to usual bi-annual teaching session. Each participant performed a pre-test with 20 colorectal neoplasia (High quality pictures with chromoendoscopy) with 2 questions for each about histology prediction and adequate treatment to propose. Then, they followed a 30 min teaching session about CONECCT and repeated a post-test with same 20 lesions in different order. In order to check that their progressions are sustainable in long time, we asked them to participate in a second session, 3–6 months later, during which they performed a test (T3M) with 40 colorectal (the last 20 lesions and 20 news) neoplasia with the 2 same questions.

Results: 419 persons (280 interns and 139 seniors) participated at first session and we analyzed 206 participants for T3M (96 persons were excluded because of matching problems). Mean rate of good answers progressed from 60.6% at pre-test versus 76.4% at post-test ($p < 0.05$) versus 70.5% at T3M ($p < 0.05$).
Between pre Test and post Test, 345 (86.9%) participants progressed and mean progression per participant was 21.0%. Depending on histology, prediction results were significantly improved ($p < 0.05$) with 61.0% at pre Test and 78.5% at post Test. After the teaching program, overtreated patients reduced significantly from 30.1% to 15.4% ($p < 0.05$).
Between pre Test and T3M, 121 (76.6%) participants progressed and mean progression per participant was 12.9%. Depending on histology, prediction results were significantly improved ($p < 0.05$) with 61.0% at pre Test and 70.5% at T3M. Overtreated patients reduced significantly from 30.1% to 20.0% ($p < 0.05$).
Other interesting results are that among all french participants, 86.4% considered CONECCT as helpful for prediction and 88.5% for treatment. 51.3% already used that classification.

Conclusion: CONECCT classification teaching is effective to improve histology prediction and treatment choice regardless of lesion histology in gastroenterology interns and seniors. Overrated patients reduced significantly thanks to CONECCT.

Introduction: Endocuff -a plastic device with flexible projections- mounted on the distal tip of the colonoscope, promises improved colonic mucosa inspection

Aims and Methods: Since data from individual studies are controversial, we aimed to elucidate the effect of Endocuff on adenoma detection rate (ADR) and on advanced ADR (AADR). We performed literature searches in MEDLINE and Cochrane Library for randomized-controlled trials (RCTs) published as full papers in English language evaluating Endocuff-assisted (EAC) versus conventional colonoscopy (CC) in terms of ADR and AADR. The effect size on study outcomes was calculated using fixed or random effect model, as appropriate, and it is shown as OR[95%CI].

Results: We identified 6 studies; five parallel groups design and one tandem. Five studies evaluated the first-generation and the sixth one the Endocuff-Vision device. One study included screening examinations, another one evaluated FOBT-positive screening and surveillance examinations and four studies evaluated colonoscopies with mixed indications (screening, surveillance and symptomatic). ADR was reported in all 6 studies (3460 examinations). As compared to CC, EAC significantly increased ADR [OR(95%CI) = 1.30(1.00–1.69); $I^2 = 67\%$]. Meta-analysis of data from 5 studies (2971 examinations) did not detect any difference between EAC and CC regarding AADR [OR(95%CI) = 0.92(0.74–1.16); $I^2 = 0\%$]. There was no evidence of publication bias.

Conclusion: Meta-analysis of RCTs data provide evidence that EAC increases ADR compared to CC, without increasing AADR. Heterogeneity among the included studies calls for cautious interpretation of the results

P1426 COMPARISON OF ENDOSCOPIC SUBMUCOSAL DISSECTION USING THE POCKET CREATION METHOD AND THE CONVENTIONAL METHOD FOR COLORECTAL LESIONS

Y. Fujii, M. Nishimura
Tokyo Metropolitan Geriatric Hospital, Gastrointestinal Endoscopy, Tokyo, Japan

Contact E-Mail Address: fjyuko00@gmail.com

Introduction: Endoscopic submucosal dissection (ESD) is a widely used procedure for colorectal neoplasms. However, especially for fibrotic colorectal lesions or flat colorectal lesions, it is still technically difficult because of the lack of counter-traction. Recently, the pocket creation method (PCM) was developed to overcome these technical difficulties, which facilitating ESD for such colorectal lesions by creating a large submucosal pocket under the lesion. However, it is still unclear whether the PCM is superior to the conventional method (CM) for colorectal lesions.

Aims and Methods: The aim of this study was to compare the clinical results of the PCM and CM for colorectal lesions. Between January 2016 and October 2017, a total of 87 colorectal ESD cases were performed at our institution. Retrospectively, they were divided into the PCM group (n = 40) and CM group (n = 47). All procedures were conducted using a water-jet colonoscope (PCF-290ZI; Olympus, Tokyo, Japan) and DualKnifeJ (KD-655; Olympus, Tokyo, Japan). A small-caliber tip transparent hood (DH-29CR, Fujifilm, Tokyo, Japan) were appropriately used so as to keep nice visualization between PCM. MucoUp (Seikagaku, Tokyo, Japan) was used as the injection solution.
For PCM, initial mucosal incision is made approximately 20mm in length at the distal side of the tumor after submucosal injection. Then, submucosal pocket under most of the tumor was created with Dual-J knife. The lower side of the pocket was opened in a step-by-step manner toward the proximal side, and the tumor is resected.
For conventional method, mucosal incision and submucosal dissection was performed from the proximal edge of the tumor. Then, additional mucosal incision was performed circumferentially, and submucosal dissection was made in the same manner.
For both groups, lesion size, procedure time, total amounts of midazolam, and ESD-related complications (hypotension, hypertension, hypoxia, and arrhythmia) were compared. SPSS version 14 (IBM, Armonk, NY, USA) was used for statistical analysis.

Results: Forty patients in the PCM group (16 male; 24 female; age range, 44–87 years; mean age, 75.5 years) and 47 patients in the CM group (21 male; 26 female; age range, 65–98 years; mean age, 77.3 years) were treated with ESD and analyzed. The mean resected size was 33.7 mm in the PCM group and 33.3 mm in the CM group ($p < 0.05$). ESD times for the PCM and CM groups were 51.7 and 54.6 minutes ($p = 0.14$), respectively. Midazolam doses for the PCM and CM groups were 2.87 and 2.5 mg ($p = 0.23$), respectively. En bloc resection rates for the PCM and CM groups were 97.5% and 97.9% ($p = 0.45$), and R0 resection rates were 88.2% and 75.0% ($p = 0.17$), respectively. Complications occurred in the PCM and CM groups as follows: hypoxia, 5.0% and 10.6% ($p = 0.31$); bradycardia, 2.5% and 10.6% ($p = 0.17$); tachycardia, 0% and 2.1% ($p = 0.17$); hypotension, 37.5% and 70.2% ($p < 0.05$); and hypertension, 32.5% and 23.4% ($p = 0.18$). Postoperative bleeding occurred in one case (1/40; 2.5%) of the PCM group; however, no perforations occurred in either group. Of note, even if the

lesion had submucosal fibrosis caused by a previous biopsy, en bloc resection was possible for four cases without any difficulty in the PCM group.
Conclusion: PCM is feasible, safe, and simple compared with the CM for colorectal lesions. Furthermore, it might be hugely advantageous during ESD for patients with fibrotic/scarred colorectal lesions. However, further studies using updated devices to perform the PCM are needed.

Introduction: Accurate diagnosis of colorectal precancerosis and early carcinoma is crucial for cancer prevention and prognostic improvement. Various endoscopic technologies were developed to increase the diagnostic accuracy, and the biopsy-dependent pathology remains the golden standard. During routine endoscopy, real-time optical biopsy diagnosis is desired as the new imaging technology. Without fluorescent label, multiphoton microscopic (MPM) imaging directly reveals live cellular morphology and tissue microenvironment based on intrinsic two-photon excited fluorescence (TPEF) and second harmonic generation (SHG) signal. As reported, its resolution and performance *in vivo* are comparable to the *ex vivo* histopathology. We thus aimed to initially investigate the original features of colorectal diseases under MPM, and evaluate its potential for real-time diagnosis in vivo.
Aims and Methods: Experimental and diagnostic cohorts were designed in this study. The multiphoton images of 40 fresh tissues were collected and confirmed pathological performance of colorectal normal tissues, hyperplastic polyps, adenomas and adenocarcinomas. Both morphological and quantitative features were recorded and analyzed to establish diagnostic standards with MPM. For the second cohort with 86 tissues, we distinguished the various colorectal diseases with conclusive MPM features.
Results: Through the investigation, the colorectal normal, hyperplastic polyps, adenoma and adenocarcinoma were presented difference in the crypt opening, gland structure, epithelial cells and collagen fibers. The epithelial nuclear area of normal cases were similar to hyperplastic tissues ($31.36 \pm 3.18\mu m^2$ and $32.14 \pm 3.12\mu m^2$, respectively, $P = 0.062$) but apparently smaller than adenoma and cancer ($57.41 \pm 4.88\mu m^2$ and $86.62 \pm 10.61\mu m^2$, $P < 0.001$). Cellular asymmetry were 0.79 ± 0.08, 0.77 ± 0.09, 0.39 ± 0.07 and 0.76 ± 0.10, respectively, indicating the nuclear elongation of adenoma evidently, while relative round in normal, hyperplastic and cancerous cells. Compared with normal tissues, the TPEF/SHG intensity ratio for collagen content was also similar in hyperplastic cases (0.27 ± 0.04 and 0.26 ± 0.02, $P = 0.736$) but decreased in adenoma and adenocarcinoma samples (0.22 ± 0.01 and 0.17 ± 0.02, $P < 0.001$). With the typical features, we preliminarily tested the diagnostic efficiency of real-time MPM, and found its sensitivity for distinguishing normal, hyperplastic polyps, adenoma and adenocarcinoma was 90.63%, 75%, 85.94%, 97.92%, while the specificity was 99.29%, 95.14%, 95.37%, 94.36%, respectively.
Conclusion: The real-time multiphoton microscopic imaging can be effective to identify colorectal diseases with high resolution. Via integrating with the endoscopes in the future, it could promote optical precise diagnosis in clinics.

Introduction: Bowel preparation is an essential step for successful colonoscopy in order to achieve complete visualization the whole colonic mucosa, detection of abnormalities. four liters of polyethylene glycol (PEG) is widely used, associated with a poor tolerance of the patients seen the drink of a large amount of liquid, the reduction of this quantity associated with others agent is better accepted and tolerated by the patients, however its effectiveness on the quality of the preparation necessitates studies.
Aims and Methods: A prospective comparative randomized study comparing the tolerance, acceptability and efficacy of bowel preparation using four liters of PEG (Group A) versus two Liters of PEG plus 15 mg of Bisacodyl (Group B) as bowel-cleansing agents, Using the Boston Bowel Preparation Scale (BBPS) to evaluate the bowel-cleansing efficacy.
Results: One hundred and thirty-three patients were included (68 in group A and 65 in group B), with a sex ratio = 0.85. The average age of patients was 52 +/−14.2 years [18–75]. The indication of colonoscopy was gastrointestinal bleeding or anemia in 50.3%, constipation in 17.2% of cases.two groups were comparable for sex, history of constipation, taking all of the preparation**.** the duration after the last taking. but there was a significant difference for age classes and adherence to the Low-residue diet.
There was significant difference in the rates of side effect (Group A: 49.5%, Group B: 23.1%) (p:0.008) and acceptability (70.5% Versus 90.7% respectively) (p:0.01).
In term of effectiveness, the Group B had a better mean BBPS compared with Group A (7.05 +/− 1.5 versus 6.43 +-1.8.) (p:0.039), the BBSP greater than or equal to 6 was recorded in 89.2% versus 70.6% of patient respectively (p = 0.008). After adjustment for age classes and adherence to Low-residue diet, BBSP at Group B remained better than Group A.
Conclusion: According to our study, the efficacy of bowel preparation for colonoscopy can be improved by reducing the volume of Polyethylene glycol to two liters associated with Bisacodyl, this protocol is best tolerated and tolerated by the patients
Disclosure: Nothing to disclose

P1429 WATER-AIDED COLONOSCOPY IS AS EFFECTIVE AS CONSCIOUS SEDATION IN CONTROLLING PAIN

E. Giambruno[1], M. Furnari[1], P. Zentilin[1], M. Brunacci[1], A. Parodi[2], G. Coccia[2]

Introduction: Colonoscopy is gold standard of colorectal cancer screening by detecting precancerous lesions. Air insufflation to distend lumen can cause pain and discomfort to the patient that often requires sedation. Indeed, colonoscopy is an invasive "operator-dependent" technique requiring a learning curve and the rate of missed lesions is still not satisfying. Sedation increases quality and tolerability but also costs and timing of the procedures.
The use of water infusion in lieu of gas insufflation seems to improve colonoscopy performance decreasing insertion pain and the need for sedation, increasing cecal intubation rate and facilitating completion of difficult colonoscopy without reducing the adenoma detection rates.
Aims and Methods: Aim of the study was to evaluate tolerability of warm water infusion technique (WWI) compared to carbon dioxide (CO_2) insufflation in terms of pain and need for sedation. Secondary aim was to compare the performance of the two techniques.
Prospective randomized controlled trial in which consecutive patients referred to undergo colonoscopy over a 4-month period were recruited. Pregnancy, age <18 yrs, bowel resection, malignant stenosis, emergency were exclusion criteria. After the inform consent, patients were randomized into two arms: a) warm water infusion with no sedation b) CO_2 insufflation with minimal patient's weight based sedation. Patients completed a questionnaire regarding tolerability of the procedures and the level of pain after the colonoscopy expressed on a visual scale. Cecal Intubation Rate (CIR), Cecal Intubation Time (CIT), Total Procedure Time (TPT), Adenoma Detection Rate (ADR), Adverse Events (AEs) and bowel preparation and amount of sedation required were assessed. Procedures were performed by one doctor in training under supervision.
Results: One-hundred sixty-four patients were enrolled in the study (101F, 63 M; age 63 range 21–92; BMI 24.5, range 15.5–39.5): 82 in the WWI group (44F, 38M; age 64 yrs, 21–92; BMI 24.8 15.5–39.5) and 82 in the CO_2+sedation group (57F, 25M; age 62, 21–82; BMI 24, 16–34). There was no difference in terms of pain perception, CIR, CIT, TPT and bowel cleansing between the two groups (Tab. 1). Higher ADR was achieved in the WWI arm (p 0.02). Moreover, adverse events were significantly lower with water infusion compared to CO_2+sedation (p 0.03). Finally, 3 patients required sedation during WWI to complete the procedure.

	WWI	CO_2 + sedation	P value
Cecal Intubation Rate n (%)	78/82 (95.1%)	81/82 (98.8%)	0.99
Cecal Intubation Time min means (SD)	8.67 (3.59)	8.46 (3.47)	0.66
Total Procedure Time min means (SD)	18.31 (4.9)	18.21 (6)	0.89
Bowel Preparation BBPS	7	7	0.2
Adenoma Detection Rate n (%)	20/82 (24.4%)	8/82 (9.8%)	0.02
Pain means (SD)	2.33 (2.02)	2.74 (2.71)	0.12
Sedation adjustment n (%)	3 (3.7%)	13 (15.9%)	0.01
Adverse events n (%)	1/82 (1.2%)	8/82 (9.8%)	0.03

[Table 1. Results]
Conclusion: Water Infusion colonoscopy was well tolerated and equally to intravenous sedation in terms of pain perception, procedure time and cecal intubation rate. Moreover, underwater colonoscopy in our study provided lower occurrence of adverse events and higher Adenoma Detection Rate (ADR).

The WWI technique seems to be a valid alternative to colonoscopy with sedation to achieve quality and painless colonoscopy when sedation is not available or executable and is a valuable aid to endoscopy trainees.

Introduction: As 90% of Colorectal cancer (CRC) cases occur in individuals over 50, screening programs have focused on this population. However more often adenomas and colorectal carcinomas were detected within younger (<50y), averaged risk adults, especially in the rectum. A study by Brenner et al reported rates of progression from advanced adenomas (AA) to CRC of approximately 2–5% per year. Therefore our aim is to assess incidence rates of adenomas, advanced adenomas and CRC according to age to determine when we should start screening colonoscopy.
Aims and Methods: 246,857 screening colonoscopies within the Austrian quality assurance program were retrospective analyzed between November 2007 and February 2018. Patients were categorized according to age and we determined ADR, AADR and CRC-rate for each group, also comparing male and female sex.
Results: Overall in 22.40% (n = 55381) of all patients, adenomas were detected, 27.8% within men and 17.2% (n = 33789) within women. Advanced adenoma detection rate (AADR) was 4.6% (n = 11266), Male-AADR (MAADR) was 5.7% and female-AADR (FAADR) 3.5%. In 0.77% (n = 1894) colorectal carcinomas were detected, 0.98% within male and 0.56% within female patients
According to age, ADR was 5.6% (♀: 3.3%; ♂: 7.5%) within group of 30–34 year old individuals; 7.0% [(♀: 8.4%; ♂: 5.8%) 35–39y], 11.7% [(♀: 14.5%; ♂ :9.2%); 40–44y], 15.0% [(♀: 17.8%; ♂ :12.1%); 45–49y] and 17.1% (♀: 21.2%; ♂ :12.9%) in patients aged 50–54, where screening is already recommended.
AADR was 1.2% [(♀: 1.0% ♂: 1.4%) 30–34y], 1.2% [(♀: 1.0%; ♂: 1.4%) 35–39y], 2.6% [(♀: 3.3% ♂: 1.8%) 40–44y], 2.8% [(♀: 2.6% ♂: 2.9%) 45–49y] and 3.1% [(♀: 3.8% ♂: 2.4%) 50–54y]. Incidence of CRC was 0.30% [(♀ :0.33%; ♂: 0.29%);30–34y], 0.37% [(♀: 0.19% ♂: 0.53%);35–39y], 0.54% [(♀ :0.77%; ♂: 0.32%);40–44y], 0.38% [(♀ :0.32%; ♂: 0.45%); 45–49y] and 0.33% [(♀ :0.40%; ♂: 0.25%); 50–54y]. Regarding localization, 50% of CRC in the group 30–34 years, 50% (35–39y), 47% (40–44y) and 44% (45–49y) were located in the rectum, compared to 0.38% in patients older than 50.
From 2008 to 2017, the overall incidence rates of adenomas in adults age 45–49 increased from 15.9% in 2008 to 20.9% in 2017; AADR 2.3% to 4.9% and incidence rate of CRC increases from 0.39% to 0.65%. In female patients, ADR was 12.6% vs. 20.7% (2008 vs. 2017); AADR 1.4% vs. 7.6% and incidences of CRC 0.70% vs. 1.38%. Within male individuals, ADR changes from 20.0% to 21.1%; AADR 3.5% to 2.5% and no cases of CRC were documented in 2008 as well as in 2017.
Conclusion: In this large cohort of screening colonoscopies, we noticed quite similar incidence rates in patients aged 45–49, compared to those, whom screening colonoscopy is already recommended (50–54years): Incidences of adenomas (15.0% vs. 17.1%), advanced adenomas (2.8% vs. 3.1%) and colorectal carcinomas (0.38% vs. 0.33%). Compared to 2008, higher incidence rates of adenomas, advanced adenomas and colorectal carcinomas were documented in 2017, especially in female patients from 45 to 49, while we found no big changes within male individuals at the same age comparing 2008 and 2017.
Regarding this and to prevent more cases of colorectal cancer we should start screening colonoscopy at the age of 45, especially in female patients.
Disclosure: Nothing to disclose

P1431 USEFULNESS AND EFFICACY OF RETROFLEXION IN THE ASCENDING COLON DURING COLONOSCOPY FOR POLYP AND ADENOMA DETECTION

S. Michopoulos[1], G. Axiaris[2], P. Baxevanis[2], M. Stoupaki[2], V. Gagari[2], G. Leonidakis[2], E. Zampeli[2], I. Serafentinidis[2], K. Petraki[3], M. Sotiropoulou[4]

Contact E-Mail Address: michosp5@gmail.com
Introduction: Missing polyps in the ascending colon during colonoscopy is considered to be an important factor for interval cancer.
Aims and Methods: The aim of our study was to evaluate the feasibility of retroflexion in the ascending colon and its contribution to polyp and adenoma detection. Patients-Methods: 440 consecutive patients with a complete colonoscopy under conscious sedation (midazolam and/or propofol) were prospectively evaluated for retroflexion achievement after reaching the caecum – (only 3 attempts were permitted for achieving retroflexion). Polyp detection was divided in 3 phases: Insertion into the caecum (1st phase), withdrawal up to the hepatic flexure and then reinsertion into the caecum with forward view (2nd phase) and then retroflexion in the caecum and inspection of the ascending colon up to the right flexure and reinsertion into the caecum (3rd phase). Phases 1 and 2 were considered as forward view while phase 3 as retroflexion. Polyps were removed after the whole mapping of the ascending colon when the 3 phases were completed according to the protocol.
Results: 440 patients with complete colonoscopy, 218 (48.6%) men, mean age = 62.6 ± 11.2 years, BMI = 26.8 ± 4.4. Indication for colonoscopy: Screening (32.3%), Follow-up (31.1%), Diagnostic assessment (36.6%). Mean colonoscope length to the caecum: 89.9 ± 14.6 cm. Only 1% had poor cleaning preparation. Retroflexion was successful in 97.73% [1st attempt (78.18%), 2nd (12.95%) and 3rd (6.59%)]. No major adverse events were reported during the study. Adenoma detection rate (ADR) for the entire colon was 51% [Screening (39%), Follow-up (59%), Diagnostic (55%)]. Mean time for forward view (phases 1+2) was 69.7 ± 21.4s and for retroflexion (phase 3) 60.4 ± 16.7s. In total 199 polyps and 151 adenomas were detected in the ascending colon. Forward view (phases 1+2) identified 104 polyps and 84 adenomas yielding a polyp and adenoma detection rate (ADR) in the ascending colon of 16.7% (95% CI: 13.2–20.3) and 13.7% (95% CI: 10.5–17.0) respectively. Retroflexion identified a further 95 polyps and 67 adenomas improving the polyp and ADR in the ascending colon to 29.1% (95% CI: 24.8.2–33.3) and 22.5% (95% CI: 18.6–26.5) respectively, ($p < 0.01$). Adenoma miss rate was 44.4% (67/151) and per patient adenoma miss rate was 8.8%. Multivariate analysis showed that factors influencing the detection of adenomas with retroflexion were age >60 years (OR: 2.63, 95% CI: 1.25–5.50 p = 0.011), male gender (OR: 1.88, 95% CI :0.99–3.58 p = 0.055), previous surgery (OR: 2.74, 95% CI:1.42–5.27 $p < 0.01$), the existence of adenomas in forward view (OR: 3.06, 95% CI:1.48–6.30 $p < 0.01$) and indication ''Follow-up'' (OR: 2.12, 95% CI:0.94–4.8 p = 0.07).
Conclusion: 1) Retroflexion in the ascending colon is safe and feasible in the vast majority of patients 2) It has an added value for polyp and adenoma detection in the ascending colon provided that forward view missed an important number of lesions. Retroflexion, a simple maneuver during colonoscopy, without additional cost, may decrease interval cancers in the right colon if added in the standard practice.

P1432 DOES THE ENDOSCOPIST'S GENDER INFLUENCE QUALITY PARAMETERS OF SCREENING COLONOSCOPY?

B. Majcher, D. Penz, E. Waldmann, A. Hinterberger, A. Szymanska, A. Asaturi, M. Trauner, M. Ferlitsch
Medical University of Vienna, Department of Internal Medicine III, Division of Gastroenterology & Hepatology, Vienna, Austria

Contact E-Mail Address: barbara.majcher@meduniwien.ac.at
Introduction: Gender differences were shown in relation to less career satisfaction and lower career advancement for female gastroenterologists (Gerson LB et al, *Gastroenterology* 2007).
Not much association was found so far between gender of endoscopists and outcome of their performance. Thus, the aim of the study was to assess differences in quality measures and incidence of complications according to endoscopist's gender.
Aims and Methods: Data from 174 848 screening colonoscopies between 2007 and 2018 from private practices were analyzed within Austrian Certificate in Quality for Colorectal Cancer Screening. We evaluated the adenoma detection rate (ADR), advanced adenoma detection rate (AADR) and cecal intubation rate (CIR), sedation rate (SR), complication rate and compared these quality measures between male and female endoscopists.
Results: From 189 endoscopists included in this study, 18.52% were female (27 370 screening colonoscopies, mean patient's age = 61.07) and 81.48% were male (n = 147 478, mean patient's age = 61.3). Female endoscopists had significantly more female patients (57, 56% (SD = 6.39) vs. 49, 43% (SD = 5.16), $p < 0.001$) while male endoscopists more male patients (50.57% (SD = 5.16) vs. 42, 44% (SD = 6.39), $p < 0.001$).
No statistical significance was found in median ADR among female and male participants (25.68% (IQR = 17.06) vs. 21, 41% (IQR = 13.55), U = 2 277, p = 0.152). Median male ADR and female ADR did not show significant difference in relation to endoscopist's gender (male ADR: 32.15% (IQR = 17.31) vs. 27, 47% (IQR = 14.75), U = 2 297.5, p = 0.174; female ADR: 20.0% (IQR = 13.65) vs. 15.87% (IQR = 10.92),: U = 2 240, 5, p = 0.120).
There was no statistical significance in median AADR among both groups of endoscopists (6.98% (IQR = 6.26) vs. 6.90% (IQR = 5.28), U = 2 443, p = 0.388). According to the CIR, SR and complication rate no significant difference was found (median CIR: 97, 54% (IQR = 4.08) vs. 97.47% (IQR = 4.27), U = 2 824, p = 0.659; median SR: 97, 37% (IQR = 10.33) vs. 95.45% (IQR = 13.58), U = 2 499, p = 0.502; median complication rate: 0.05% (IQR = 0.35) vs. 0.02% (IQR = 0.3) U = 2 554, p = 0.607).
Conclusion: The study showed that more female patients were examined by female endoscopists while more male patients were examined by male endoscopists but it did not show any significant difference in the quality parameters in

relation to gender of participants. Both female and male endoscopists participating in the Austrian quality certificate performed screening colonoscopy with high quality.
Disclosure: Nothing to disclose

P1433 UNDERWATER ENDOSCOPIC MUCOSAL RESECTION SHOWS TO BE MORE EFFECTIVE THAN EMR IN WORSE SCENARIOS WITH LESS ADVERSE EVENTS

M. Sánchez Alonso[1], A. Sobrino López[1], H. Uchima Koecklin[2], B. López Viedma[1], F. Domper Bardají[1], E. De la Santa Belda[1], P. Olivencia Palomar[1], J. Olmedo Camacho[1], J. Rodríguez Sánchez[1]
[1]*Hospital General de Ciudad Real, Gastroenterology Department. Endoscopy Unit, Ciudad Real, Spain*
[2]*Josep Trueta Hospital, Gastrointestinal Endoscopy Unit, Gerona, Spain*

Contact E-Mail Address: monica.san.al@gmail.com
Introduction: Nowadays, endoscopic mucosal resection (EMR) is the usual technique for treatment of flat colorrectal polyps, however underwater-EMR (U-EMR) has appeared as an atractive alternative. Despite its preliminar suitability, the real indication of U-EMR remains unclear. The aim of this study is to compare the feasibility, adverse events and recurrences of both techniques in a multicentric fashion.
Aims and Methods: We performed a prospective cross-sectional study in two referral hospitals from December 2016 to November 2017 in which lesions >15 mm resected by EMR or U-EMR were included. Both cohorts were matched using a propensity matching score (ratio 2:1) to avoid a selection bias using as reference the score in SMSA score. The margins of the scars were assessed to detect residual adenomatous tissue. A follow-up colonoscopy in 3–6 months and 12 months was scheduled.
Results: A total of 162 lesions were resected and analysed from 137 patients (59% male, 66% y.o), with an average size of 25 mm and 60% of them located in proximal colon. Histological assessment revealed carcinoma in 33/162 (20%), detecting in 8 of them (5%) deep mucosal invasive cancer (referred to surgery). Regarding to the procedures, en bloc resection was achieved in 68% U-EMR versus 49% EMR ($p > 0.05$), and less number of slides to reach complete resection were detected in U-EMR (2.59+/− 2.43 vs 1.74 +/− 1.10, $p < 0.001$). There were no significant differences between efficacy comparing size of the lesions, however U-EMR might trend to be more feassible in achieving en bloc and complete resection compared to EMR, in addition to more efficient (less time spent per procedure). In terms of adverse events, post procedural bleeding (10% EMR vs 2% U-EMR; $p > 0.05$) and one perforation (EMR group) were described. In the follow up endoscopies (early-3-6moths and late-12months), no differencies were described between both techniques.
Conclusion: In real clinical practice U-EMR showed to be as effective and safer than traditional EMR especially in difficult cases. Furthermore, U-EMR yielded a feasible approach to prevent cautery artefact, allowing an accurate pathologic assessment.
Disclosure: Nothing to disclose

P1434 CHROMOENDOSCOPY WITH INDIGO CARMINE VERSUS ENDOCUFF FOR ADENOMA DETECTION RATE IN COLONOSCOPY: A RANDOMIZED CONTROLLED TRIAL

J.A. Fernandez Rivero[1], Y. Gutierrez-Grobe[1], F. Rojas-Mendoza[1], J. Oria-Hernandez[2], **N.E. Aguilar-Olivos**[1]
[1]*Medica Sur Hospital and Clinical Foundation, Gastroenterology and Gastrointestinal Endoscopy Research Unit, Mexico City, Mexico*
[2]*National Institute of Pediatrics, Biochemistry and Genetics Lab, Mexico City, Mexico*

Contact E-Mail Address: dra.nancy.aguilar@gmail.com
Introduction: Colorectal cancer (CCR) is one of the leading causes of death in the world. These deaths could be avoided by early detection of adenomas. There are some techniques to increase the adenoma detection rate (ADR) during colonoscopy, such as the chromoendoscopy with indigo carmine or the use of endocuff device. Indigo carmine highlights the surface topography of the mucosa while endocuff is a flexible long cap that is integrated into the tip of the colonoscope to flat the folds of colon. Both techniques seem to increase the ADR, but there is not direct comparison between the two methods.
Aims and Methods: The aim was to compare ADR of chromoendoscopy with indigo carmine versus endocuff. This is a randomized controlled trial performed in a single center from March 2016 to November 2017. The Institutional Ethical Committee approved the study and written informed consent was obtained in all cases. The inclusion criteria were patients over 50 years old with average risk for colorectal cancer and adequate Boston bowel preparation (≥6). Patients were randomly selected in a 1:1 ratio by a computer generator in blocks of four. Colonoscopies were performed using 10 mL of indigo carmine 0.8% in 250 mL of water or endocuff™ (Arc Medical Desing Ltd). ADR was defined as the proportion of patients with at least one adenoma (per-patient analysis). Mean adenomas per patient (MAP) was also calculated as the total number of detected adenomas in each group divided by the total number of patients in that group (per-adenoma analysis). ADR and MAP were compared for both groups using chi^2 test and Student's T-test respectively; $P < 0.05$ was considered statistically significant. The preliminary results of the 30% of the total calculated sample size (n = 150 per group) are shown here.
Results: A total of 92 patients were included but 6 were eliminated because they did not meet inclusion criteria. The selected 86 patients were randomized into the two groups, chromoendoscopy (n = 44) vs endocuff (n = 42). There were no differences in gender, age or quality of colonic preparation. The withdrawal time for chromoendoscopy was 15 ± 4 minutes whereas for endocuff was 12 ± 4 minutes ($p = 0.002$). Ileocecal valve cannulation was 91% in chromoendoscopy versus 89% in endocuff without statistical differences. The results of ADR and MAP analysis are described in the table below.

	Indigo carmine n = 44	Endocuff n = 42	P value
Adenoma detection rate, ADR (%[95% CI])			
Total	50 (35–65)	31 (16–45)	0.07
Right	32 (18–46)	10 (0.7–19)	**0.02**
Transverse	16 (5–27)	13 (2–23)	0.69
Left	25 (12–38)	15 (4–27)	0.28
Rectum	11 (2–21)	5 (1–12)	0.31
Mean Adenomas per Patient, MAP (mean [95% CI])			
Total	1.20 (0.56–1.84)	0.51 (0.19–0.83)	0.07
Right	0.40 (0.19–0.62)	0.10 (0.00–0.20)	**0.01**
Transverse	0.25 (0.05–0.45)	0.12 (0.01–0.24)	0.29
Left	0.39 (0.11–0.66)	0.23 (0.00–0.46)	0.39
Rectum	0.16 (0.01–0.30)	0.05 (0.00–0.12)	0.20

[Table1]
There were no significant differences between chromoendoscopy with indigo carmine versus endocuff for ADR (50 vs 31, $p = 0.07$) or MAP (1.20 vs 0.51, $p = 0.07$) in total colonoscopy. ADR and MAP were significantly higher in the chromoendoscopy group for the right colon segment (32 vs 10, $p = 0.02$ and 0.40 vs 0.10, $p = 0.01$, respectively). There were not complications in any of the two groups.
Conclusion: Chromoendoscopy with indigo carmine was superior to endocuff for ADR and MAP for the right colon. We did not find statistical significant differences in the total colon evaluation.

Introduction: Colonoscopy with polypectomy of adenomas reduces the incidence and mortality of colorectal cancers (1). With recent increment of the number of screening colonoscopies, it is reported that eradication of adenomas during colonoscopy can be a big burden for endoscopists (2). According to the Japanese Society of Gastroenterology guidelines (3), diminutive adenomas which has no evidence of carcinoma in their appearance are allowed to be left in situ, provided strict surveillance colonoscopies within 3 years (="leave-in-situ strategy") are conducted, which is different initiative from the European or American guidelines (4,5). However, the safety and efficacy of the "leave-in-situ strategy" of diminutive adenomas are unknown.
Aims and Methods: The aim was to retrospectively assess the safety and compliance of the "leave-in-situ strategy" of diminutive adenomas. Patients whose diminutive adenomas were not resected at the initial colonoscopies between April 2001 and November 2014 at a referral center were chosen as the subjects. All the subjects were asked to receive surveillance colonoscopies within 3 years. The primary outcome measure is the incidence rate of index lesions (ILs) at the surveillance colonoscopy within 3 years. The ILs were defined as follows: adenomas ≧10 mm, high grade dysplasias, villous adenomas, and invasive cancers. The secondary outcome measures included the rate of patients who received the 3-year surveillance colonoscopies and the number of the diminutive polyps which were detected at both the initial and surveillance colonoscopies.
Results: A total of 4816 patients were left untreated of diminutive adenomas (n = 2502) at the initial colonoscopies. The incidence rate of index lesions at the surveillance colonoscopies was 2.3%(36/1543; 12 adenomas ≧10 mm, 22 high-grade dysplasias, and 2 invasive cancers). The rate of patients who underwent 3-year surveillance colonoscopies was 32.0% (1543/4816). The same

diminutive adenomas were detected in the surveillance colonoscopies in 63.2% (1582/2502).
Conclusion: "Leave-in-situ strategy" of diminutive adenomas can be acceptable whose rate of ILs in the surveillance colonoscopies is limited to 2.3% which is similar to those in the National Polyp Study (6). However, strict instruction to the patients is indispensable considering the low receiving rate of surveillance colonoscopies.

Introduction: The predictive effect of a quality of a single negative screening colonoscopy on long-term risk of colorectal cancer (CRC) remains uncertain.
Aims and Methods: This study aims to determine the predictive effect of quality of negative screening colonoscopy on long term CRC incidence and mortality. We retrospectively analysed subjects with a single negative screening colonoscopy defined as absence of any neoplastic lesions. Data was obtained from the Polish CRC screening program database. All colonoscopies performed between October 1st 2000, and December 31st 2011 were included. Analysed subjects were followed for CRC occurrence and death through the National Cancer Registry over median of 9.2 years up to 16.4 years. High-quality colonoscopy was defined as examination with cecal intubation, adequate bowel preparation ('very good, good or suficientaccording to Aronchick scale) performed by an endoscopist with an adenoma detection rate $\geq$20%. Standardized incidence and mortality ratios (SIRs and SMRs) were calculated by comparison with values for general Polish population according to sex and 5-years age groups.
Results: Of the 156.633 individuals included into analysis, 365 CRC after 1,449,733 person-years of follow up were observed (25.2 per 100,000 person years). CRC related deaths totalled 96 over 1,450,761 person-years (6.6 per 100,000 person years). SIRs and SMRs for individuals after single negative colonoscopy, irrespective of its quality, were 0.41 (95% CI, 0.37–0.46) and 0.22 (95% CI, 0.18–0.27), respectively. Negative high-quality colonoscopy was associated with SIR of 0.22 (95% CI, 0.16–0.28) and SMR of 0.1 (95% CI, 0.05–0.17), whereas low-quality colonoscopy yielded SIR of 0.49 (95% CI, 0.44–0.55) and SMR of 0.28 (95% CI, 0.22–0.34). Table 1 shows SIRs and SMRs after single negative colonoscopy according to the duration of follow-up. Individuals observed longer than 10 years after single negative colonoscopy had still significantly reduced risk of CRC and CRC mortality compared to general population (SIRs and SMRs were 0.53 (95% CI, 0.39–0.71) and 0.40 (95% CI, 0.23–0.63), respectively). High-quality single negative colonoscopy yielded SIR of 0.35 (95% CI, 0.13–0.77) and SMR of 0.13 (95% CI, 0.0–0.7) after more than 10 years of follow-up.

Quality of screening colonoscopy	Time from screening colonoscopy (years)	SIR (95% CI)	SMR (95% CI)
Low	0.1–3.0	0.30 (0.23–0.39)	0.11 (0.05–0.21)
	3.1–5.0	0.46 (0.35–0.60)	0.12 (0.05–0.24)
	5.1–10.0	0.62 (0.52–0.72)	0.42 (0.31–0.55)
	>10	0.58 (0.41–0.78)	0.46 (0.26–0.74)
High	0.1–3.0	0.12 (0.06–0.22)	0.05 (0.01–0.18)
	3.1–5.0	0.23 (0.12–0.39)	0.07 (0.01–0.26)
	5.1–10.0	0.28 (0.18–0.40)	0.15 (0.06–0.31)
	>10	0.35 (0.13–0.77)	0.13 (0.00–0.70)

[Table 1. SIRs and SMRs of colorectal cancer after negative screening colonoscopy according to quality according to time from screening colonoscopy.]

Conclusion: Single high-quality negative colonoscopy was associated with significantly lower CRC incidence and mortality as compared to low-quality negative colonoscopy. The predictive effect of single negative high-quality colonoscopy extended beyond 10 years of follow up.

Introduction: Colorectal cancer ranks third among the most commonly diagnosed cancers worldwide. Colonoscopy has been shown to reduce morbidity and mortality in screening programs. Colonoscopy due to sedation procedure has several complications being the most frequent the cardiorespiratory complications. The overall complication rate ranges from 0.1 to 0.2%, with a mortality of 0.0014%.
Aims and Methods: To determine which factors are related to the risk of developing a sedoanalgesia complication (SAC) during a colonoscopy with the objective of reduces the post-colonoscopy complications. All screening colonoscopies after a positive faecal immunochemical test were analyzed related to 2009–2018 invitations. 87 SAC were identified. SAC was considered: chest pain, bradycardia, tachycardia, hypoxia, reflex reactions, respiratory distress, hypo-hypertension. SAC were classified in mild and serious. Considering mild as complication that obligate the interruption of the colonoscopy and serious if a hospitalization is required. A multivariate model was performed and Independent Predictors (IP) of SAC after a colonoscopy were identified through a logistic regression.
Results: After 67,946 colonoscopies, SAC rate was 0.12%. 64.4% were men. Most of the patients had 2 points in the Charlson Index (49.4%) and ASA II (42.1%). 65–69 range age was which presents he highest rate of complications. 79 mild and 8 serious SAC were identified.
Mild SAC: 30.4% was smoker and 24.1% had a moderate consumption of alcohol. The 14.1% and the 20.5% of the cases had cardiopathy and neumopathy history respectively. The 16.9% of patient were treated with benzodiazepines, 6.4% with antipsychotic and 2.6% with opioids. 49.3% of the patients had polypectomy. Serious SAC: 50% had a moderate consumption of alcohol and the 12.5% were smoker. 25% had cardiopathy and neumopathy history. 25% were treated with benzodiazepines and the 12.5% with antipsychotics. 49.3% of the patients had polypectomy.
Firstly we made a univariate analysis. Patients-variables for the analysis were: age, sex, ASA, cardiopathy and neumopathy history, patient's toxic habits (tobacco and alcohol), IMC, Charlson Index, chronicity index, polypectomy and antipsychotic, benzodiazepine or opioids therapies. Colonoscopy technique variables: patient position, type of insufflation, type of sedation, type of oxygenation, colonoscopy assist or not by an anesthetist, hours until the patient recuperation, nurse's sedation training and type of hospital. The variables with a significant result in the univariate analysis were; tobacco, alcohol, neumopathy history, polypectomy, colonoscopy assist or not by an anesthetist, hours until the patient recuperation and nurse's sedation training.
After a multivariate analysis SAC IP were: tobacco (OR:2.8; 95%CI:1.1–7.4), alcohol (OR:8.0; 95%CI:2.1–30.0), polypectomy (OR:0.4; 95%CI:0.2–0.8) and nurse's sedation training (OR:0.4; 95%CI:0.2–0.9). The logistic model explained 73% of the complications (CI95% 0.65–0.80, $p < 0.001$).
Conclusion: The colonoscopy is a procedure with a small but not insignificant risk of SAC, so it is crucial to know which factors predict the risk of those complications in order to implement countermeasures. The study that we present shows that both variables related to the patient (toxic habits and polypectomy) and related with colonoscopy technique (nurse's sedation training) are independent factors to consider while performing a colonoscopy.

Introduction: The diagnostic accuracy of colorectal cancer screening colonoscopies (CRCSCs) depends on the adherence to quality indicators.
Aims and Methods: We aimed at evaluating the effects of an educational intervention on quality indicators of CRCSCs at a tertiary center.
CRCSCs performed between 2005 and 2009 at a tertiary center were analyzed and an educational intervention regarding the results of CRCSCs evaluation and optimal quality indicators was given to the team of gastroenterologists and nursing staff in January 2011. 2118 CRCSCs performed between 2011 and 2015 were evaluated and compared to 1545 CRCSCs performed between 2005 and 2009. Descriptive statistical analysis was performed and Chi-Square test was applied to compare quality indicators of CRCSCs between 2005 to 2009 and 2011 to 2015.
Results: 2118 CRCSCs were performed between 2011 and 2015. The mean age was 62.5 ± 10.7 years and 57% (1205) were women. Sedation was performed in 77% (1634) of the procedures. The cecal intubation rate (CIR) was 85.5% (1833). Most common reasons for incomplete CRCSCs were: patient intolerance 46.3% (132), inadequate bowel preparation 20.4% (58) and technical difficulties 15.1% (43). Good or adequate bowel preparation was noted in 1786 (84%) patients. Photodocumentation of cecal landmarks (PCL) was performed in 97.3% (1783) of the cases. Polyp detection rate (PDR) was 34.3% (726) and polyps ≥1cm were detected in 13.4% (97) patients. Colorectal cancer (CRC) was detected in 0.5% (11) patients.
1545 CRCSCs were performed between 2005 and 2009. The mean age was 60.4 ± 10.7 years and 62% (958) were women. Sedation was performed in 32% (499) of the exams. The CIR rate was 91% (1336). Most common reasons for incomplete CRCSCs were: patient intolerance 40% (84), inadequate bowel preparation 35% (73) technical difficulties 18% (37).
Good or adequate bowel preparation was noted in 1345 (87%) patients.
PCL was performed in 93% (1248) of the cases. PDR was 33% (503) and polyps ≥1cm were detected in 16% (82) patients. CRC was detected in 0.3% (5) patients.
Conclusion: Although there was a significant improvement in the quality of the PCL indicator after the educational intervention, there was no improvement in cecal intubation rates despite a significant increase in use of sedation during colonoscopy. Additionally, our results suggest a need for better patient educational programs to improve the quality of bowel preparation.

Indicator	2005–2009	2011–2015	P
CIR	1336 (91%)	1833 (87%)	0.950
Incomplete SC:			
– Intolerance	84 (40%)	132 (46%)	0.175
– Inadequate bowel preparation	73 (35%)	58 (20%)	<0.001
– Technical difficulties	37 (18%)	43 (15%)	0.436
PCL	1248 (93%)	1783 (97%)	0.001
PDR	503 (33%)	726 (34%)	0.276
Polyp measuring ≥ 1cm	82 (16%)	97 (13%)	0.313
Colorectal cancer	5 (0.3%)	11 (0.5%)	0.375
Good/reasonable bowel preparation	1345 (87%)	1786 (84%)	0.021
Poor preparation	200 (13%)	332 (15.7%)	0.02
Sedation	499 (32%)	1634 (77%)	<0.001

Introduction: Measuring colon polyp size is crucial in choosing an appropriate therapeutic option. However, currently available measurement procedures are not necessarily accurate. Depth and spatial information, which is lacking in conventional two-dimensional (2D) endoscopy, has become available with the use of 3D technology. In collaboration with a medical device company, by using a flexible three-dimensional (3D) endoscope currently in development, we conducted an ex vivo study to evaluate the utility of 3D endoscopy in measurement of colon polyp size.
Aims and Methods: We prepared models of colon polyps (protruding and flat lesions) ranging in size from 2 mm to 10 mm in 1-mm increments. A total of 220 measurements were made among 10 doctors (6 specialists and 4 non-specialists). A prototype 3D endoscope was used to measure polyp size either in 3D mode in combination with 3D glasses or in 2D mode. Randomization was performed by using envelopes containing the size of a model polyp and the mode of measurement to be used. Accuracy rate and measurement error (i.e., actual polyp size minus measured size) were compared between 3D and 2D endoscopy.
Results: Among the 220 measurements, 103 were by 2D endoscopy and 117 by 3D endoscopy. Accuracy rate was 23.3% (24/103) by 2D endoscopy and 25.6% by 3D endoscopy (30/117); the difference was not significant. On the other hand, measurement error by 2D endoscopy (1.81 ± 1.88 mm) was significantly larger ($p < 0.05$) than that by 3D endoscopy (0.92 ± 2.27 mm). Errors in measurements of flat polyps and protruding polyps were 2.25 ± 1.97 mm and 1.34 ± 1.69 mm, respectively, by 2D endoscopy, and 1.68 ± 1.62 mm and 0.2 ± 2.56 mm, respectively, by 3D endoscopy. Accuracy rate was 33.8% (27/80) with a measurement error of 0.96 ± 2.10 mm among non-specialists, and 19.3% (27/140) with a measurement error of 1.55 ± 2.14 mm among specialists; accuracy rate was significantly higher and measurement error was significantly smaller among non-specialists than among specialists.
Conclusion: Accuracy rate of colon polyp size measurement was not high, and there was no significant difference between 2D and 3D endoscopy. Measurements tended to be larger and measurement errors were significantly smaller in 3D endoscopy than in 2D endoscopy. Also, measurement of protruding polyps tended to be large and have smaller error than those of flat polyps. Accuracy rate was significantly higher and measurement error was significantly smaller among non-specialists than among specialists.

Introduction: Colonoscopy is considered the gold standard screening method for colorectal cancer (CRC), it allows the detection and resection of the adenomatous lesions. There are different markers which define colonoscopy-quality indicators, these have shown to decrease the CRC incidence. One of the most important is the adenoma detection rate (ADR).
Aims and Methods: We aimed to know the ADR in colorectal cancer screening colonoscopy in an average risk population for CRC, at the Gastroenterology Service of HIGA San Martin La Plata, WGO advanced endoscopy training center, from January 2012 to December 2017.
This was an observational study. The global ADR was analyzed, adjusted to sex, morphological features, lesions topography and high-risk adenoma frequency. Colonoscopy were performed by fellows and supervised by experts. Fellows ADR was evaluated at different training stages. Statistical analysis was performed by using the $\chi 2$ test. Patients with Boston Bowel Preparation Scale ≥5 and cecal checkpoint were included.
Results: 12,106 procedure were performed, 1,111 (9.2%) of which were CRC-screening. 935 procedures met the inclusion criteria, with a mean age of 60 years (range 50 to 75y). In 256 at least one adenoma was found; 98(38.3%) showed some high-risk features. Global ADR was 27.4% and, adjusted to sex, 23.3% in women and 34.3% in men. During the first formation stage (1 to 150 procedure), ADR was of 27.8% while during the second stage (150 to 300 procedure) was 26.8% ($p = 0.78$). 398 adenomas in total were resected, corresponding to a 42.6% adenoma detection index (ADI). 337 (84.6%) were polypoid lesions. When analyzed by segments, it was found that 114 patients showed at least an adenoma in the right colon, 107 in the left colon, 57 in the transverse colon and 38 in rectum.

In the left colon, 55 (51.4%) showed at least one high risk characteristic, 26 (22.8%) in the right colon, 11 (19.3%) in the transverse colon and 17 (44.7%) in rectum. A statistically significant difference was found between the adenoma location and their high risk findings. Compared and corrected by the p-value through the Bonferroni method, statistically significant differences were found in the high-risk adenoma proportions found in the left colon compared with the transverse colon ($p = 0.0024$) and the right colon ($p = 0.0013$).
Left colon and rectum localization of adenomas, increases by 3 ($p < 0.0001$, OR = 3.73, IC 95%: 2.19–6.34) and 2 ($p < 0.0001$, OR = 1.99, IC 95%: 0.99–3.99) times respectively the possibilities that the adenomas found at any other segment of the colon or rectum may have at least a high-risk characteristic. No significative association between risk adenomas and sex was found ($\chi 2 = 1.971$, $p = 0.160$).
Conclusion: Our global and adjusted by sex ADR are comparable to those recommended by the international guidelines. Formative stages under the supervision of an experienced observer do not influence on ADR. Despite right-sided adenomas were the most frequent, left colon and rectum adenomas showed a significant association with the presence of at least one high-risk features in the adenomas founded. Therefore, the measurement of colonoscopy quality indicators in the colorectal cancer screening programs must be a goal from the earliest formative stages.

Introduction:. Intubation of caecum is foundation for general impression of colon. Cecal intubation rate (CIR) <80% correlates with higher risk of post colonoscopy colorectal cancer (PCCRC), (Baxter et al., *Gastroenterology* 2011).
Aims and Methods: Aim of the study was to investigate if surgeons, internists or gastroenterologists have higher rates of incomplete colonoscopies. Further to identify reasons for incomplete colonoscopy (complication, stenosis, pain, inadequate bowl preparation, others) and analyze the quality of bowel preparation (data collected since 2012). Therefore 264,116 screening colonoscopies performed by 294 physicans between 2007–2018, within the Austrian certificate of screening colonoscopywere analysed within the study.
Results: 32% of endoscopists were surgeons, 52% internists 16% gastroenterologists. Mean CIR was 96.45% (SD = 4.12). 3.81% (SD = 4.17) of colonoscopies within surgeons, 3.31% (SD = 4.06) within internists ($p = 0.4616$) and 3.79% (SD = 4.19) within gastroenterologists were incomplete (compared to surgeons $p = 0.9821$, compared to internists $p = 0.4772$). Mean age of patients who had incomplete procedure was 63.13 (SD = 10.23) vs. age of 61.12 (SD = 9.17) in patients who had complete procedure ($p = 0.0001$).
In group of internists adequate rate for bowel preparation was 95.52% (SD = 4.30), in surgeons rate was 96.70% (SD = 3.09) ($p = 0.0297$) and 96.20% (SD = 4.02) in group of gastroenterologists (compared to surgeons $p = 0.4281$, compared to internists $p = 0.3416$).
Conclusion: There was no significant difference between surgeons, specialists for internal medicine and gastroenterologists according rate of incomplete colonoscopies. Regarding reasons for termination of examination, surgeons claimed stenosis more often than specialists for internal medicine or gastroenterologists. Patients who underwent colonoscopy performed by surgeons had a better bowel preparation than patients of internists and gastroenterologists. Patients in which caecum was not intubated were older than patients in which caecum was intubated.

Introduction: Videocolonoscopy (VCC) is the gold standard for colorectal cancer (CCR) screening. Removal of adenomatous polyps during VCC decreases CCR mortality by 50%. CCR incidence occupies the third place worldwide. Although the screening VCC efficiently prevents distal colon cancers, its efficacy to prevent right colon cancers is less clear. Interval cancer is associated with injuries lost in the right colon.
Our aim was to decide whether the performance of a second evaluation of the right colon would increase the adenoma rate (TDA)
Aims and Methods: A prospective study from September 2016 to May 2017 was performed.
All patients who underwent a CCR screening videocolonoscopy were included, with prior informed consent.
Every patient having a Boston Scale store of 2 or 3 in the right colon segment underwent a second evaluation of the right colon[C1].
Injuries found in the right colon were described according to location, size and Paris Classification; they were resected during the procedure.
The time required to perform the second evaluation of the right colon was evaluated
Results: A total of 130 patients were included in the study between September 2016 and May 2017. 21 patients (16%) were excluded according to the Boston Scale <than 2 in the right colon; and 109 patients (84%) met the inclusion criteria, 69 (63%) men and 40 (36%) women, with an age range of 45–75 years. A total of 42 (38%) patients had an injury in their right colon, 27 of them (24%) during the first evaluation and 15 (13%) during the second one.
Injuries found were 23 (21%) <5 mm, 12 (11%) of 5–9 mm and 7 (6%) >to 10 mm. According to the Paris Classification, there were 16 (14%) 0-Is, 24 (22%) 0-IIa and 2 (1%) 0-IIb injuries. Histopathological examination showed 36 (32%) adenomatous injuries and 6 (5%) corresponded to sawing injuries.
TDA during the first evaluation was 22% and increased around 7.3% during the second evaluation, thus reaching a 29.3% TDA, with a statistically significant difference according to the Chi square Test.
Average time before a second evaluation in the right colon was 1.36 minutes (1.15- 2 min)
Conclusion: The performance of a second evaluation of the right colon increases the adenoma detection rate (TDA). It consists of a simple technique, which is carried out within a period of less than 2 minutes, with favourable results for the patient
Disclosure: Nothing to disclose

P1445 DOUBLE BALLOON-ASSISTED ESD VERSUS STANDARD ESD FOR SIGMOID LESIONS

K. Momose[1], Y. Kono[1], J. Milsom[2], **S. Sharma**[1]

Introduction: Endoscopic submucosal dissection (ESD) for colorectal lesions requires a higher skill level to complete. In particular, sigmoid colon lesions are thought to be amongst the hardest anatomical location for ESD. This is due to the sigmoid colon being more mobile with lack of peritoneal fixation. From this standpoint, we hypothesized that a double balloon-assisted technique could facilitate sigmoid colon ESD through stabilizing of the sigmoid colon.
Aims and Methods: A bespoke 3D-printed abdomino-pelvic anatomical housing was developed and an ex-vivo colon model mounted within it. A commercially available double balloon sheath on endoscope was used in this study. A 3.0cm pseudo-polyp was created on the fresh porcine distal colon mucosa with electrocautery. Six ESDs were performed against this 3.0cm pseudo-polyp without the double balloon sheath as control group, and with the double balloon sheath on the scope as intervention group. The total procedure time, the number of perforation and the number of muscle layer damage were collected and compared. A single operator performed every procedure.
Results: There were no perforation in all of the procedures. The total procedure time and the number of the muscle layer damage in each ESD were shown in the table. The mean total procedure time in Double balloon ESD group was 23.29 minutes and this was significantly shorter than 46.45 minutes in control group ($p = 0.007$). There was no significant difference in the number of the muscle layer damage (1.5 vs 1.0, $p = 0.599$).
Conclusion: Double balloon technique may facilitate sigmoid colon ESD by reducing the procedure time and difficulty. We postulate that this is performed by 'splinting' that section of the sigmoid intestine reducing movement and increasing stability.

Introduction: SpyGlassDS has been used as diagnostic or therapeutic tool for biliary tract lesions, and the feasibility of this device was reported in several studies. We investigated the utility of the SpyGlassDS for patients with biliary tract lesions.
Aims and Methods: We evaluated success rates of observation and sampling using SpyGlassDS for 34 patients who were performed cholangioscopy for the purpose of examine the biliary tract lesions at our hospital between November 2015 and December 2017. Successful observation was defined as the case in which SpyGlassDS reached the biliary tract lesion and obtained high-quality images

enough to evaluate. Successful sampling was defined as the case in which sufficient amount of specimen was collected by SpyBite biopsy forceps. For 18 patients with cholangiocarcinoma who had undergone surgical treatment, we evaluated the concordance rate of horizontal extension of cancer between diagnosis using SpyGlass and SpyBite, and resected specimens. Horizontal extent of cholangiocarcinoma was diagnosed by SpyGlass as the presence of irregular papillary or granular mucosa or irregularly dilated and tortuous microvasculature that continuously spread from the main lesion.
Results: The rates of successful observation and successful sampling were 97.5% (119/122) and 88.5% (69/78), respectively. Biopsy using SpyBite were not informative due to insufficient amount for pathological review in 9 cases. To evaluate horizontal extension in 18 (?) cholangiocarcinoma patients, 91 checkpoints were observed using SpyGlass and 50 samples were obtained using SpyBite. Comparison between the SpyGlass images and the histological diagnosis in resected specimens revealed the diagnostic accuracy of 86.8% (79/91). The false positive rate was 11.0% (10/91), and the main cause of false positive was misdiagnosis for the inflammatory mucosa as carcinoma. Comparison between the SpyBite biopsy specimen and the resected specimen revealed the accuracy of 90.0% (45/50) and the false-positive rate of 6% (3/50), namely the diagnostic ability of the biopsy specimen was higher than that of visual images.
Conclusion: The ability to approach for the biliary tract lesion which we aimed to evaluate was good and feasible, especially in the advanced technique, evaluation for the second branch of the intrahepatic biliary tract was possible. That was very meaningful to decide the therapeutic option or the surgical form. Considering the results of visual images or the biopsy specimen, the accuracy was mostly satisfactory.

Introduction: Recently ERCP Guided RF probes were designed. This device has been already used in cholangiocarcinoma and pancreatic cancer with biliary obstruction.
This new treatment induces local coagulative necrosis by delivering thermal energy from high frequency current via bipolar probes and induced an immunomodulation.
We report our experience in ampullomas treated by combination of endoscopic resection and radio frequency ablation (RFA).
We aim to evaluate the feasibility, clinical efficacy and safety of biliairy RFA a new minimally invasive approach.
Aims and Methods: In this study 9 patients (2 males and 7 females) average 70 (41–93) underwent prior endoscopic ampullectomy. Indications of biliary RFA were deep margins not free in 8/9 patients and a relapse in 1 case. Surgery was contra indicated due to comorbidities in 3/9 patients, but mainly because the residual tissue was adenoma with low-grade dysplasia (n = 5). We used dedicated RFA probe manufactured by Taewong Compagny (ELRA^{TM}) of 18 mm length and 7 F. From July 2015 to September 2017 we performed 12 sessions of ampullary RFA (7 patients with a single session 1 patient with 2 sessions and 1 patient with 3 sessions for recurrence).
Technique: Finally a cholangiogram was obtained to clearly determine the location of the lesion and to access its length. The most often there was none defect or stricture visible. The RFA probe was then introduced over the guide wire on the low part of common bile duct.
RFA energy was delivered over the selected period by the device usually 2 mn 10W; We used selected power and time settings recommended by manufacturers based on the results of preclinical studies After withdrawing the probe a biliary stent fully covered metallic stent (n = 8) or accessory plastic stent (n = 4) was placed to ensure biliary drainage and avoid a delayed stricture. The most often a small plastic pancreatic stent (5F) was also placed to avoid acute pancreatitis and migrated spontaneously a few days after (X ray control checked their spontaneous migration after 1 month). Biliary stents were usually removed after 2.5 months (1–5 months) on average during a new ERCP to control the result and perform new biopsies on site.
Results: Feasiblity: technical success was 100%. No complication such as angiocholitis or pancreatitis occured immediatly after RFA ablation. All patients, except two, were discharged one day after procedure. Regarding late complications 2 biliary benign strictures in 2 patients at 4 and 7 months easily treated by a new stent. None pancreatic stricture with an average follow up of 12 month occurred. All patients are alive at the end of this study.
Clinical efficacy was accessed on absence of reccurence of ampuloma on biopsy with an average follow up of 11 months in 6/9 patients. 1/9 patient was lost because was very old (93 years old). 2 patients presented recurrence. 1 with a recurrence after 22 months treated by a second RFA ablation and actually free of disease for 17 months. Last patient presented 2 recurrences after 2 and 7 months treated by RFA ablation with a good result for 4 months.
Conclusion: ERCP with RFA ampullary is safe and seems to be an effective alternative in patients with a high risk for surgery (important co-morbidities) or patients who refuse surgery.
Further studies are mandatory to confirm these preliminary results.

P1448 POST-ERCP PANCREATITIS (PEP): MINIMIZING ROLE OF PANCREATIC DUCT (PD) STENTING WITH NON-INVASIVE COMBINATION THERAPY IN DIFFICULT CASES

J.L. Ho, C.T.W. Chia, K.B. Chuah
Tan Tock Seng Hospital, Department of Gastroenterology & Hepatology, Singapore, Singapore

Contact E-Mail Address: jingliang.ho@mohh.com.sg
Introduction: Selective biliary cannulation can be challenging during endoscopic retrograde cholangiopancreatography (ERCP). Double-guidewire technique (DGT) is one of the various salvage techniques utilized to improve success rate of selective deep biliary cannulation. Instrumentation of the PD has been associated with increased risk of PEP. Safety of DGT in difficult ERCP access needs to be better defined to determine if it truly affects PEP.
Aims and Methods: ERCP data was retrospectively retrieved from our electronic database between July to December 2017. Approval of the local review board was sought. A total of 258 ERCP cases were reviewed with regards to patient demography, successful standard biliary cannulation (SBC), cases requiring DGT, periprocedural rectal non-steroidal anti inflammatory drug (NSAID), intravenous hydration with lactated Ringer's (LR), PD stenting and common complication rates including PEP, infection, bleeding and perforation. Aim was to determine PEP rates in DGT cases and role of PD stenting in these situations. Data was analyzed using SPSS v20.
Results: From a total of 258 ERCP cases conducted, 13.5% (35 cases) failed SBC and required DGT to facilitate successful biliary access. Of all DGT cases, rectal NSAID was administered in 65%, PD stenting was performed in 23%, and hydration with intravenous LR was initiated in 83% as PEP prophylaxis. DGT cannulation rate following failed SBC was 83%. The incidence of PEP, infection, significant bleeding and perforation were 2.9%, 17.1%, 0% and 0% respectively. The rate of PEP in the subgroup without PD stent placed was only 3.7%. Impact of PEP prophylaxis was found to be significant for rectal NSAID ($p < 0.01$), PD stenting ($p = 0.039$) and LR hydration ($p < 0.01$). There was no PEP witnessed when at least 2 PEP prophylactic measures were instituted (either rectal NSAID and/or PD stent and/or LR drip).
Conclusion: Our data demonstrated PEP rates remained low despite performing DGT for difficult biliary access and PEP risk may be minimized even without PD stenting if at least 2 other PEP prophylactic measures are undertaken such as using rectal NSAID and LR drip. This suggests PD stenting may not be critical in the setting of DGT if deemed challenging. A larger prospective study is indicated to evaluate this finding.
Disclosure: Nothing to disclose

P1449 COMPARISON OF THE DIAGNOSTIC SENSITIVITY OF A NOVEL PERORAL CHOLANGIOSCOPY-GUIDED TARGET BIOPSY TO THAT OF CONVENTIONAL ENDOSCOPIC TRANSPAPILLARY FORCEPS BIOPSY IN PATIENTS WITH SUSPECTED BILE DUCT CANCER

K. Sekine[1], I. Yasuda[1], K. Sato[1], S. Doi[1], M. Mabuchi[1], Y. Takano[1], T. Tsujikawa[1], N. Kuniyoshi[1], T. Iwashita[2], T. Miyazaki[3], M. Kawamoto[4], M. Takahashi[4]

[4]*Teikyo University Mizonokuchi Hospita, Diagnostic Pathology, Kanagawa, Japan*

Contact E-Mail Address: hawaiiantuberider@gmail.com
Introduction: Endoscopic transpapillary forceps biopsy has been used for the histopathological confirmation of bile duct cancer. However, its sensitivity has been reported to be around 50%. To improve the sensitivity, peroral cholangioscopy (POCS)-guided target biopsy has been attempted as an alternative. However, its fragility and impaired maneuverability have hindered its popularity. Recently, a new disposable-type peroral cholangioscope with better maneuverability, SpyGlass DS^{TM}, was developed. Some studies have shown that this cholangioscope has a high sensitivity.
Aims and Methods: To compare the diagnostic sensitivities of POCS-guided target biopsy and conventional endoscopic transpapillary forceps biopsy in patients with suspected bile duct cancer.
This retrospective cohort study included 1) patients with suspected bile duct cancer and 2) patients who underwent both the biopsy methods at our institutions between November 2010 and November 2017. The primary endpoint of this study was the diagnostic sensitivity for malignancy. The specificity, positive predictive value (PPV), negative predictive value (NPV), accuracy, and sample size of both methods were also compared.
Results: A total of 40 patients were included. Their final diagnoses were bile duct cancer (n = 32), gallbladder cancer (n = 2), and benign or inflammation stricture (n = 6). The sensitivity, specificity, PPV, NPV, and accuracy of the conventional method were 71%, 100%, 0%, 32%, and 80% and the SpyGlass-guided targeted biopsy were 50%, 100%, 0%, 47%, and 60%, respectively. The mean sample sizes for the conventional method and for SpyGlass-guided targeted biopsy were $1.69 \pm 2.10\,mm^2$ and $0.43 \pm 0.47\,mm^2$, respectively ($P < 0.01$).
Conclusion: The diagnostic sensitivity was rather high for conventional endoscopic transpapillary biopsy compared with SpyGlass-guided target biopsy,

which was probably because of insufficient volume of the biopsy specimen for SpyGlass-guided target biopsy.
Disclosure: Nothing to disclose

P1450 ASSESSMENT OF ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY (ERCP) IN THE ELDERLY -IS ERCP REALLY SAFE IN THE ELDERLY?-

Contact E-Mail Address: cshibata69@gmail.com
Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is important for diagnosis and therapeutics for cholangiopancreatic disease. Several studies demonstrated its safety in the elderly. But most of those reports assessed only complication rates of ERCP.
Aims and Methods: We retrospectively analyzed the clinical records of consecutive patients (n = 299) undergoing ERCP between November 2016 and December 2017. We divided them into two groups: group A ≥75 years old and group B <75 years old. Patient attributes, ERCP success rate, complication rate, hospitalized days and changes of PS were compared between two groups using chi-square test or t-test. The multivariate regression model was applied to find the risk factors of the prolonged hospitalization and the worsening of PS.
Results: A total of 299 patients was divided into two groups: group A (n = 123, mean age: 82.5 ± 5.3), and group B (n = 176, mean age: 62.3 ± 9.6).
Patients in Group A were more likely to have hypertension, chronic kidney disease and poor PS. Findings for other characteristics were similar between two groups.
All patients underwent ERCP successfully. No significant differences were observed between two groups regarding major ERCP-related complications (pancreatitis, bleeding, cholangitis and so on), while only the rate of pneumonia was higher in group A (p = 0.037).
Hospitalization for 20 days or more was needed in 33 patients (26.8%) in group A and in 24 patients (13.6%) in group B (p = 0.0043). The worsening of PS was observed in 19 patients (15.4%) in group A and in 4 patients (2.3%) in group B (p < 0.0001).
The multivariate regression model identified that the complications (Odds Ratio [OR] :3.81, 95% Confidence Interval [CI] :1.69∼8.57, P = 0.0012) and the older age (OR:2.02, CI: 1.09∼3.72, P = 0.024) were independent risk factors for the prolonged hospitalized days, and it also identified that the older age (OR:5.86, CI:1.89∼18.2, P = 0.0022), complications (OR:3.33, CI:1.03∼10.8, P = 0.045) and malignancy (OR:2.75, CI:1.03∼7.32, P = 0.043) were independent risk factors for the worsening of PS. Especially, Combinations of the older age and complications placed patients at increasingly higher risk of the prolonged hospitalization (OR:4.02, CI:1.40∼11.5, P = 0.0097) and the worsening of PS (OR:9.89, CI:2.81∼34.8, P = 0.00036).
Conclusion: We found that the risk of pneumonia, the prolonged hospitalization and the worsening of PS after ERCP are significantly higher in the elderly. We should perform ERCP carefully in the elderly.

P1451 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY OF ACUTE CALCULOUS CHOLANGITIS IN PATIENTS WITH LIVER CIRRHOSIS

S.-H. Dong, **H.J. Ha**, C.H. Oh, S.K. Lee
Department Of Internal Medicine, Kyung Hee University College of Medicine, Seoul, Korea (Republic of)

Contact E-Mail Address: haa0912@naver.com
Introduction: Endoscopic Retrograde Cholangiopancreatography (ERCP) has become standard treatment of choice for treating acute calculous cholangitis, but little is known about its outcome and safety in patients with liver cirrhosis (LC).
Aims and Methods: The objectives of this study were to analyze outcomes, efficacy and safety through a retrospective study of ERCP in patients with liver cirrhosis. A cross-sectional retrospective analysis of 59 ERCPs of 51 patients with LC performed at tertiary academic hospital over 5years period was conducted. The patients (LC group) were subdivided into two groups based on their Child-Pugh classification (CP-class): 32 with CP-class A (LC-A), 14 with CP-class B (LC-B) and 5 with CP class C (LC-C).
Results: Procedural outcomes and post-procedural complications (bleeding or perforation) did not differ significantly among three groups. The 30-day, procedure-related adverse events included post-ERCP pancreatitis (n = 5, 8.47%), hemorrhage (n = 2, 3.39%), cholangitis (n = 5, 8.47%), and death (n = 2, 3.39%). There was a higher rate of adverse events in patients with LC-C when compared with those with LC-A and LC-B (11.4%, 5.3%, and 6.1%, respectively; P = .034). There was no correlation between the risk of significant hemorrhage and CP class, even in those who underwent an endoscopic sphincterotomy. No patients experienced worsening of the CP score 1 month after ERCP compared with the baseline score. During a median observation period of 44 months, the recurrence rates of cholangitis were similar between the three groups (recurrence rates: 8.1 vs. 7.5 vs 6.4%, p = 0.625). The overall mortality rate was increased in the LC-C group (1-year mortality rates: 4.3 vs. 6.3 vs. 12.7%, p = 0.021).
Conclusion: The adverse events seen in patients with liver cirrhosis are not different from those seen in the general population of patients undergoing ERCP, although patients with Child C have higher adverse event rates compared with those with Child A and B.
Disclosure: Nothing to disclose

P1452 RADIOFREQUENCY ABLATION (RFA) FOR INTRABILIARY EXTENSION OF ADENOMA OF THE PAPILLA OF VATER: PRELIMINARY RESULTS

Introduction: Endoscopic snare papillectomy (ESP) of adenoma of the papilla of Vater is an effective technique which can be curative in more than 85% of the cases. Intrabiliary extension of the adenoma can limit the curative intent of the endoscopic resection.
Aims and Methods: Radiofrequency ablation (RFA) of the intraductal extension was evaluated in consecutive patients with adenoma of the papilla of Vater after papillectomy.
ESP was performed with an intent for en-bloc-resection without submucosal injection and placement of a 5 french prophylactic pancreatic stent. Possible intra-biliary extension was assessed on cholangiogram and after traction with an inflated extraction balloon: in case of suspected intrabiliary extension, biopsies were performed and a biliary stent was placed. RFA was planned during a subsequent procedure 1 month later. RFA was performed with the VIVAcombo™ generator (STARmed, South Korea) and an 18 or 33 mm long bipolar catheter (ELRA), power setting 10 W, 80°, 2 minutes. A 7 french pancreatic stent was placed before RFA and 2–3 biliary plastic stents were inserted to prevent stenosis. All the stents were removed 3 months later and intrabiliary biopsies performed. In case of positive biopsies RFA was repeated.
Results: Between March 2016 and April 2018, 7 patients (6 F, mean age 67.3 years) underwent ESP for adenoma of the papilla of Vater with intrabiliary extension. Liver function tests were normal in all the cases. Final histology resulted in 1 case of adenocarcinoma; the patient refused surgery and accepted RFA. RFA was performed one month after ESP (6 cases with a pancreatic stent in place, 1 without due to failure in replacement). The patient without the pancreatic stent developed severe post-RFA pancreatitiswhich resolved with conservative treatment. After a mean follow-up 13 months, 4 patients have no evidence of residual intrabiliary adenoma on biopsies, 2 patient are under treatment, while the patient with adenocarcinoma accepted duodenopancreatectomy due to repeated biopsies positive for adenocarcinoma (**table 1**).
Conclusion: RFA ablation of intrabiliary extension of adenoma of the papilla of Vater after papillectomy appears feasible and effective. According to our small experience, RFA should be performed with a pancreatic stent in place to reduce the risk of pancreatitis. Further data and extended follow-up are needed.

7	25	HGD	CBD	3	LGD	1	APC	3	–

P1453 ASSOCIATION BETWEEN PREDICTIVE FACTORS AND RADIATION EXPOSURE DURING ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY

S.-H. Dong, C.H. Oh, H.J. Ha, S.K. Lee
Department Of Internal Medicine, Kyung Hee University College of Medicine, Seoul, Korea (Republic of)

Contact E-Mail Address: gidrdong@hanmail.net

Introduction: The objectives of this study were to analyze the dose of radiation to which the physician is exposed during endoscopic retrograde cholangiopancreatography (ERCP) and to identify predictive factors of radiation exposure during the procedure. Further, we evaluated the characteristics of patients and procedural factors associated with prolonged fluoroscopy time.

Aims and Methods: A cross-sectional retrospective analysis of 780 ERCPs performed at tertiary academic hospital over 48-month period was conducted. The primary outcome of interest was the radiation exposure during ERCP as determined by fluoroscopy time and additionally to determine the association between variables and radiation exposure. And we correlated them with age, sex, body mass index (BMI), diagnosis, duration of procedure, procedure name, and procedure complexity.

Results: As a result of analysis of the 780 ERCPs performed for 2 years, the mean fluoroscopy time was 5.07 minutes (95% confidence interval (CI), 4.87–5.26). The mean radiation durations were as follows: cholelithiasis was 5.76 minutes (95% CI, 4.75–6.80); malignant biliary obstruction was 6.13minutes (95% CI, 5.91–6.35); pancreatic disease was 5.28 minutes (95% CI, 4.45–6.28); benign biliary stricture was 5.32 minutes (95% CI, 5.02–5.94). There was no significant difference between the two expert endoscopists in present study. Multivariate analysis revealed that prolonged duration of fluoroscopy was related to specific factors of patient including higher BMI (BMI > 27.5 kg/m2) (+ 4.1 minutes; 95% CI, 2.56–5.63), mechanical lithotripsy (+ 4.85 minutes; 95% CI, 0.45–9.25), needle knife (+ 4.5 minutes; 95% CI, 2.15–6.86), and malignant biliary obstruction (+ 2.34 minutes; 95% CI, 0.15–4.53).

Conclusion: ERCPs are associated with significantly higher radiation exposure of patients on the specific procedure. The endoscopists should be aware of the determinantal factors including patients who were obese, mechanical lithotripsy, malignant biliary obstruction and the use of a needle-knife, affected the fluoroscopy time during ERCP.

Introduction: The treatment of ampullary carcinomas is based on duodenopancreatectomy (DP). However, in the absence of poor prognostic factors (submucosal invasion, lymphovascular embols (LV), budding, poorly differentiated tumors), the risk of lymph node metastasis is low, justifying endoscopic local resection. However, data on the performance of endoscopic ampullectomy in the treatment of ampullary cancer remain limited. Aim of this monocentric retrospective study was to evaluate the rate of curative endoscopic resection of ampullary carcinoma.

Aims and Methods: We included all consecutive patients presenting with ampullary carcinoma treated by endoscopic resection (ER) between January 2006 and September2017 in our department. Data were retrospectively extracted from electronic medical database. Endosonography was performed before resection to exclude T2 or N+ lesions. Endoscopic ampullectomy (EA) was performed following the previously published technique. Prevention of acute pancreatitis (AP) was achieved by the placement of a 5 Fr pancreatic stent, and for 8 years in combinaison with rectal indomethacin. Tumoral invasion was staged using the Japanese classification: Du0 was defined as invasion limited to the duodenal mucosa or sphincter of Oddi, Du1 to the submucosa, Du2 to the duodenal muscularis propria. Complementary surgery was proposed in case of submucosal invasion, low differentiation, R1 resection or LV. In another situation, clinical and endoscopic follow-up was recommended.

Results: During the study period, 153 EA were performed including 29 carcinomas (7 neuroendocrine tumors, 22 adenocarcinomas). Twenty-two patients (16 males) were treated endoscopically for 22 ampullary adenocarcinomas. Mean diameter was 20 mm (7–30mm). All lesions, except one related to familial adenomatous polyposis, were sporadics. Monobloc resection was achieved in 77%. A prophylactic pancreatic stent was inserted in 72% (divisum pancreas = 2, insertion failure = 4) . Morbidity was 18% (delayed bleeding = 3, severe AP = 1). No procedure-related death was observed.
Histopathological examination showed well or moderately differentiated carcinoma in respectively 45% and 13%. LV and budding were observerd respectively in 9% (n = 2) and 4.5% (n = 1). Pathological subtype was classified into intestinal and biliopancreatic subtypes respectively in 13 (59%) and 5 (23%), 4 (18%) cases being unclassifiable. Microscopic deep margins were positive in 50%. Carcinomas was staged Du0, Du1 and Du2 respectivement in 20 (91%), 1 (4.5%) and 1 (4.5%). Eleven patients with R0 resection of Du0 cancers without lymphovascular invasion were followed-up a mean of 24 months, with only 1 local recurrence. This relapse in low grade dysplasia was successfully treated by intraductal biliary radiofrequency. Eleven resections had positive deep margins (Du0 = 9, Du1 = 1, Du2 = 1. Among these 11 patients, 3 patients had PD (pT0N0 = 1, pT1N0 = 1, pT0N1 = 1) and 8 patients were followed-up. Of these patients, 5 had local recurrence which were treated by surgery (n = 1), chemoradiotherapy (n = 1), radiofrequency (n = 1) or best supportive care (n = 2). Local recurrence rate after endoscopic resection of Du0 adenocarcinoma with negative deep margins (R0) was 9% (n = 1). Endoscopic approach provides curative treatment for adenocarcinoma in 64% in intent to treat but in 100% for R0 Du0 carcinoma.

Conclusion: EA is a validated treatment for cancers that do not invade beyond the oddi sphincter. This technique makes it possible to avoid surgery in almost 60% of cases. A positive deep margin is associated with a higher risk of local recurrence, justifying surgery.

Introduction: Ampullary adenomas represents 5% of the neoplasia of the gastrointestinal tract. The premalignant nature of ampullary adenoma justify their radical excision.
Aim of this study is to evaluate the results and the long-term follow-up of endoscopic snare papillectomy (ESP) of ampullary tumor.

Aims and Methods: Consecutive patients undergoing ESP between October 1999 and February 2018 were identified from an electronic database.
The following data were recorded: size of the ampullary lesion, pre- and post-endoscopic resection histology, complications, local recurrence rate and survival. Endoscopic follow-up was scheduled after 1, 3, 6 and 12 months for the first year, and then yearly for the following 5 years.

Results: ESP was performed in 173 consecutive patients (89 M, mean age 60.5). En bloc resection was possible in 88% of patients. 28 patients (16.2%) had familiar adenomatous polyposis (FAP).
Biliary sphincterotomy with or without insertion of a plastic stent was performed after papillectomy in 77 patient (44.5%); a pancreatic stent or a naso-pancreatic drain, with or without pancreatic sphincterotomy was inserted in 95 (54.9%) patients, 14 had a pancreas divisum and in 8 cases pancreatic stent placement failed.
The following adverse events were recorded:
- delayed bleeding (n = 16, 9.2%) treated endoscopically except 2 cases that required angiography;

- retroperitoneal perforations (n = 5, 2.9%), successfully treated by percutaneous (n = 3) or surgical (n = 2) drainage;
- pancreatitis (n = 4, 2.3%, 3 without pancreatic stent).
There was 1 case (0.6%) of mortality due to pancreatitis.
Follow-up (mean 51.9 months, range 1 -108) was available in 146/173 patients (84.4%). Results are summarized in **table 1**.
Residual and recurrent adenomas were diagnosed in 30 (17.3%) and 29 (16.8%) cases, respectively but were successfully retreated endoscopically in all the cases except 5 patients who underwent surgery (duodenopancreatectomy) due to failed resection.
Conclusion: The present series reports the results of ESP after more than 4-year median follow-up.
ESP is effective with favorable long-term outcomes; multidisciplinary is team needed to manage complications. The high incidence of residual/recurrent adenoma is balanced by the successful endoscopic re-treatment in 91.5%. Compliance to the follow-up is important for the early detection and re-treatment of recurrences; a recall system is therefore mandatory.

	n (%)
Alive, performed endoscopic follow-up	119 (81.5)
Alive after duodenopancreatectomy	13 (8.9)
Death for unrelated reasons	14 (9.6)
Post-ESP histology in 119 pts	**Recurrence (n = 29) %**
Adenoma /Tis	23/99 (23)
Adenocarcinoma	5/13 (38)
Neuroendocrine tumor	1/7 (14)

[Table 1. Follow-up results in 146/173 (84.4%) after endoscopic snare papillectomy (ESP).]

Introduction: Bile duct injuries (BDI) occur most often after biliary tract surgery, with laparoscopic cholecystectomy representing the leading cause. Reconstructive biliary surgery is considered standard treatment for the most severe form of biliary injuries, also known as complex BDI. Recent studies have suggested a role for an endoscopic or combined endoscopic/percutaneous approach in selected patients.
Aims and Methods: We report our experience with a variety of endoscopic or combined endoscopic/percutaneous techniques to re-establish biliary drainage in patients with complex BDI and biliary exclusion.
Results: We identified 15 symptomatic patients with complex BDI and biliary exclusion who were treated by various endoscopic or combined endoscopic/percutaneous methods to recreate a communication with the excluded bile ducts. In 6 patients, BDI occurred after cholecystectomy. In 5 patients, biliary reconstruction was performed using a TIPSS-200 set, initially developed for insertion of transjugular intrahepatic portosystemic shunts (TIPSS) Successful drainage of the excluded biliary ducts with resolution of symptoms was possible in 14 patients, either through recreation of bilio-biliary continuity (10 patients) or by creating a bilio-enteric drainage tract (3 patients) or by both techniques (1 patient). Mean duration of the biliary repermeabilisaiton procedure was 107 min (range 59–180). No immediate severe complication occurred. Complete internalization of biliary drainage was possible in 14 patients. An average of 7.4 additional ERCP procedures per patient were performed after the initial repermeabilisation procedure and an average of 7.5 biliary stents were placed per patients (range 1–19). Mean duration of follow-up was 53.5 months (range 5–195). During the follow-up period, 8 patients developed a biliary stricture at the level of the initial BDI, three patients developed episodes of cholestasis and/or cholangitis secondary to biliary stent occlusion, biliary stones or sludge, and one patient developed a recurrent biloma. These late complications were all successfully treated endoscopically. All patients are free of external drainage at follow-up. Biliary surgery was necessary in 1 of the patient. During the follow-up period, 3 patients died of causes unrelated to the repermeabilisation procedures.
Conclusion: In patients with complex BDI and biliary exclusion, various endoscopic or combined endoscopic/percutaneous procedures may be successfully performed to recreate bilio-biliary or bilio-enteric continuity. In experienced hands, these techniques seem safe and can prevent reconstructive biliary surgery in the majority of the cases

Introduction: Biliary cast syndrome (BCS) is a rare complication after liver transplantation (LT) defined as material molded into the bile ducts and associated with ischemic cholangitis. Knowledge on cholangiographic features and endoscopic management of BCS is scarce. We sought to review the radiologic and cholangiographic features of BCS.
Aims and Methods: Records of the prospectively collected database of patients having been treated by liver transplantation in Erasme hospital from 12/2004 to 12/2014 were analyzed to identify patients having biliary complications (BC). After the exclusion of those having altered anatomy or no stricture, their cholangiograms and magnetic resonance cholangiography (MRCP) were systematically reviewed identifying patients with BCS. It was defined as intrabiliary material associated to filling defect during cholangiography in the supra-anastomotic portion of the biliary tree with features of biliary injury. Three types of BC were identified: BCS, anastomotic (AS) and non-anastomotic strictures (NAS). Clinical, endoscopic and radiological data of those patients were reviewed.
Results: BC were present in 86 (27%) of the 313 patients (70% male; mean age, 61 ± 7 years). Forteen cases (4.6%) identified to have a BCS were treated by ERCP. There was no statistical difference in patient demographics, delay between LT and BC in the three groups.
Pre-therapeutic MRCP was available in 12/14 cases with none having been described as BCS. The revision of these MRCP disclosed the following features: T1 hypersignal material filling the duct was present in 11, a "duct-in-a-duct" picture in 8 and an aneurysm-like saccular dilation of the bile duct in 3 of the 12 cases, respectively. On initial ERCP, 8 of the 14 patients had no stricture. A saccular aneurysmal or moderate biliary dilatation containing cast was present in 6 and 5 patients respectively.
It was possible to obtain a complete cast extraction by ERCP in 12 of the 14 cases in a median of 2 (1–7) ERCP sessions in a median period of 3 (1–22) months. Only one of the 12 patients with cast completely extracted presented with cast recurrence in the follow-up (8%). Eleven of the 13 patients (85%) for who ERCP follow-up was available presented an evolution with secondary biliary strictures treated with multiple plastic stents. Stricture calibration was obtained in 10 of them (90%) after a median of 5 (4–9) ERCP sessions on a median of 12 (5–19) months treatment period.
In 4 of the 10 patients, we observed stricture recurrence at 14 (1–84) months of stent retrieval. New stenting sessions for stricture recurrence calibration were performed by a median of 6 (4–10) ERCP in 22 (12–42) months for those patients with 3 of them (75%) obtaining stricture calibration and one partial hilar calibration and left excluded bile ducts without clinical counterpart.
At the end of a median follow-up of 58 months, we observed a lower overall survival (42.9% (BCS) Vs 83.3%(AS) Vs 68.8% (NAS), p value of log rank test = 0.035) and a lower re-transplant-free survival (42.9%(BCS) vs 80.6% (AS) vs 56.3%(NAS), p value of log rank test = 0.025) for patients with BCS compared to those without.
Conclusion: Biliary cast syndrome is a rare complication of liver transplantation and is associated to specific radiological features. Complete cast extraction is possible by ERCP. The prognosis of those patients is poorer compared to the overall patients presenting biliary complications after LT.

Introduction: In tertiary centres 5–10% of bile duct stones are difficult to clear with conventional ERCP techniques. Similarly, most pancreatic stones cannot be removed.
Recently it has been possible to treat complex calculi under direct vision with peroral single operator cholangiopancreatoscopy (POC) using Holmium (Ho) laser lithotripsy.

Aims and Methods: Prospective observational study of data collected between July 2015 and November 2017 from a single endoscopist's experience. In patients with difficult stones, POC was performed using Spyglass DS ® (Boston Scientific) in all procedures.
Stone lithotripsy was performed with a VersaPulse Powersuite Holmium laser (Lumenis) and a ScopeSafe 200-µm fibre (Optical Integrity). Patients underwent standard ERCP and cholangiopancreatoscopy. Once the stone was visually confirmed, the laser fibre was placed onto the stone and short bursts of energy were applied to achieve fragmentation. Stone fragments were then removed with ERCP-directed balloon or basket. If required, treatments were repeated to achieve complete ductal clearance.
Results: 26 patients underwent POC – guided laser lithotripsy.
25 patients underwent technically successful procedures, with one unsuccessful attempt. This was for pancreatic stone lithotripsy with inability to access the stone due to pancreas divisum. The patient underwent subsequent pancreaticojejunostomy.
Patients had required a mean 1.6 (range 1–4) earlier attempts to remove stones at ERCP including preceding endoscopic sphincterotomy +/− sphincteroplasty. Five patients required multiple lithotripsy sessions to remove the stones, otherwise a mean of 1.3 sessions was required for ductal clearance. 17 patients had multiple stones at time of procedure (15 biliary and 1 pancreatic). Median number of stones per patient was 3 (range 1 -7). The mean largest biliary stone was 13mm (range 3–30mm) and pancreatic stone 9mm (range 8–10mm). Mean procedural time was 48 minutes for bile duct stones and 29 minutes for pancreatic stone cases.
Laser power settings were higher for pancreatic stones (pancreatic 8–30 and biliary 8–10 W). Complications were mild, aspiration pneumonia (2) and pancreatitis (1) from 21 procedures. There were no ductal injuries.
Stones were cleared in all patients undergoing lithotripsy.
Conclusion: Cholangiopancreatoscopy-guided Holmium laser lithotripsy appears to be safe and very effective at treating difficult biliary and pancreatic stone disease, with pancreatic stone disease being more challenging to manage. Further studies are required.

Introduction: Brush cytology is systematically performed during endoscopic retrograde cholangiopancreatography (ERCP) to characterize biliary stenosis. However, it has a low sensitivity in detection of malignant strictures.
Aims and Methods: The aim of this retrospective study was to verify if biopsies improve the characterization of malignant biliary strictures.
We reviewed 186 patients with biliary strictures who underwent endoscopic brush cytology with or without biopsies, between January 2010 and December 2017. Brush cytology was performed at the site of biliary stricture at least ten times and at least two fragments were obtained for histopathological diagnosis. Final diagnosis was based on cytology/biopsy, percutaneous biopsy, surgery, or clinical follow-up.
Results: The mean age was 69.6 ± 14.2 years and 111 (59.7%) of patients were males. Single stricture of the main bile duct was documented in 96.8% (n = 180). The majority of stenosis was located in the proximal and distal thirds of the biliary duct (51.1% e 27.4%, respectively). Malignant strictures were identified in 76.9% of patients with pancreatic cancer (n = 66) and cholangiocarcinoma (n = 61) being the most frequent aetiology. Biopsies were performed in 97 (52.2%) patients.
For detection of malignancy, brush cytology alone had a sensitivity of 34.27% (95% IC: 26.54–42.66), a specificity of 97.67% (95% IC: 87.71–99.94) and an accuracy of 48.92%. For pancreatic cancer specifically, brush cytology presented a sensitivity of 34.85% (95% IC: 23.53–47.58) and specificity of 100%, and for cholangiocarcinoma a sensitivity of 36.07% (95% IC: 24.16–49.37%) and specificity of 100%. Biopsy alone had a sensitivity of 30.43% (95% IC: 19.92–42.69), specificity of 96.43% (95% IC: 81.65–99.91) and accuracy of 49.48%. A combination of brush cytology and biopsies yielded a slight increase in sensitivity to 38.46% (95% IC: 30.45–46.96). ERCP was repeated in 72 (38.7%) patients and cytology repeated in 22 (27.3%), 6 of which detected malignant stricture that was not previously identified.
Conclusion: Combination of brush cytology and biopsies during ERCP can increase detection of malignant biliary strictures when compared to cytology alone. Cholangioscopy-guided biopsies may improve the characterization of these malignant strictures.

Introduction: Introduction: Endoscopic retrograde cholangiography (ERC) is an endoscopic procedure that is applied worldwide for the examination and treatment of biliary stones. However, the success rates for the use of conventional endoscopic devices for the treatment of biliary stones had been unsatisfactory in patients with surgically altered gastrointestinal (GI) anatomy. Recently many papers proved that the development of the balloon-assisted endoscope (BAE) radically made endoscopic approaches feasible, however, those studies objected varieties in sizes of total number of object patients and the success rate was overall wide ranging.
Aims and Methods: The aim of this study was to evaluate a large case series of ERCP using short type DBE for common bile duct stones in postoperative patients.
From February 2006 to October 2017, ERC using short-type DBE (DB-ERC) was performed in 210 postoperative patients (325 procedures). We retrospectively studied the success rate of reaching the blind end, the mean time to reach the blind end, the success rate of complete ERC related interventions, the mean procedure time, and adverse events.
Results: The success rate of reaching the blind end was 98.5% (320/325). By type of reconstruction methods, the success rate of reaching the blind end was 98.1% (202/206) in Roux-en-Y(R-Y) reconstruction, 99.1% (106/107) in B-II gastrectomy, 100%(106/107) in jejunal interposition. The mean time to reach the blind end was 16.5 minutes. By type of reconstruction methods, the mean time to reach the blind end was 19.5 minutes in Roux-en-Y(R-Y) reconstruction, 11.4 minutes in B-II gastrectomy, 10.5 minutes in jejunal interposition. The success rate of complete ERC related interventions were 97.5% (312/320). By type of reconstruction methods, the success rate of complete ERC-related interventions was 98.5% (199/202) in Roux-en-Y(R-Y) reconstruction, 96.2% (102/106) in B-II gastrectomy, 91.7%(11/12) in jejunal interposition. The mean procedure time was 76.9 minutes. By type of reconstruction methods, the mean procedure time was 86.0 minutes in Roux-en-Y(R-Y) reconstruction, 61.6 minutes in B-II gastrectomy, 55.1 minutes in jejunal interposition. The occurrence of adverse events was 9.2% (30/325). By type of reconstruction methods, the occurrence of adverse events was 8.7% (18/206) in Roux-en-Y(R-Y) reconstruction, 10.3% (11/107) in B-II gastrectomy, 8.3%(1/12) in jejunal interposition.
Conclusion: Conclusions: ERC using a short-type DBE for biliary stones is highly effective and safe in patients with altered gastrointestinal anatomy. DB-ERC is a promising therapeutic modality in such patients and should be selected as the first-line policy.

Introduction: Biliary anastomotic strictures (AS) occur in 5–15% of liver transplant (LT) recipients and cause graft dysfunction and morbidity. The main alternative to surgical reconstruction is stenting at endoscopic retrograde cholangiopancreatography (ERCP), using plastic polyethylene or fully-covered self-expanding metal stents (fcSEMS). We retrospectively reviewed outcomes after ERCP for biliary AS, aiming to assess rates of success and complications.
Aims and Methods: We retrospectively reviewed outcomes after ERCP for biliary AS, aiming to assess rates of success and complications.
Records for all patients undergoing ERCP post LT between 2013–16 were reviewed. AS were classified as early or late (<3 or ≥3mths post LT) and cases of diffuse cholangiopathy excluded. Data collected included graft characteristics, timing/nature of ERCPs and complications. Stricture resolution was determined from graft function, imaging and ERCP findings.
Results: In total 252 ERCPs were performed (median 4/patient, range 2–10) in 62 patients, 72.6% male, age at LT 54yrs (range 20–71). 48 grafts (77.4%) were donations after brain death, 13 (21.0%) after cardiac death and 1 live donor. At first endoscopy 53 (85.4%) had a native papilla. Median time from LT was 28days (4–75) in early AS (n = 29, 46.7%, 9 presenting with bile leak) vs 11.5mths (3.4–251) in late AS (n = 33, 53.2%). Biliary stents were placed in 172 ERCPs (63.4% plastic vs 36.6% fcSEMS) and AS dilated in 68 (27.0%; 60 in conjunction with stenting).
Stricture resolution was achieved endoscopically in 47/55 patients with complete outcome data (85.5%). Plastic stents were placed at index ERCP in 23/26 of early AS, in whom sequential plastic 'upstenting' was ultimately successful in 9

(39.1%) and 12 (52.2%) proceeded to fcSEMS (stricture remodelled in all). Of late AS, 9/29 were managed with fcSEMS (88.8% successfully), 8 plastic 'upstenting' (75% success), 8 fcSEMS after initial plastic stent (all successful) and 2 resolved with dilatation only.
The overall rate of post-ERCP pancreatitis (PEP) was 7.1% (none severe by Cotton criteria) and was higher after fcSEMS (15.9%) than plastic stenting (5.5%, $P = 0.024$), despite similar use of NSAID prophylaxis. Compared with plastic stents, fcSEMS were more likely to migrate (36.5% vs 12.8%, $P < 0.001$) and embed (6.3% vs 0%, $P = 0.008$) but stent occlusion was numerically lower (0% vs 4.6%, $P = 0.084$). Of 8 endoscopic failures (14.5%), 3 (5.5%) required percutaneous stenting and 2 (3.6%) biliary reconstruction, one after duodenal perforation by a migrated plastic stent.
Conclusion: Endoscopic management is effective in treating 85% of biliary AS. fcSEMS appear superior to sequential plastic 'upstenting' but are associated with higher rates of PEP and migration.

P1462 BASKET VERSUS BALLOON EXTRACTION FOR CHOLEDOCHOLITHIASIS: A SINGLE-CENTER PROSPECTIVE RANDOMIZED STUDY

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) has become an integral part in the therapeutic armamentarium when dealing in patients with choledocholithiasis. However, when choosing the proper extraction device, data are inconsistent, with selection being, often, a matter of the endoscopists' preference.
Aims and Methods: We conducted a single-center prospective randomized controlled study to access success rates for basket versus balloon catheters for small stones for the first time in Europe.
In our non-inferiority study, 180 patients with bile duct stones were randomized in a basket and a balloon catheter group. Inclusion criteria were fluoroscopically bile duct stones ≤10mm in diameter and a common bile duct (CBD) diameter ≤15mm. The primary endpoint was the rate of complete bile duct clearance for each extraction method used. Secondary endpoints included time completed and the amount of radiation dose recorded in each ERCP session, as well as any reported adverse events.
Results: Balloon was non-inferior to basket stone extraction (OR 3.35, 95% CI 1.12–10.05, $p = 0.031$). Complete clearance was achieved in 69 out of 82 patients (84.1%) in the basket catheter group versus complete clearance in 79 out of 84 patients (94%) in the balloon catheter group ($p = 0.047$); this seems to hold especially true for patients with few stones and of small size (≤2 stones, $p = 0.043$ and stone diameter ≤5mm, $p = 0.032$). Complete stone clearance in the basket group patients took longer than complete stone clearance in the balloon group (4.52 and 4.06 min, respectively, $p = 0.015$). Higher median radiation doses for stone clearance were recorded in the basket versus the balloon catheter group (1534.43 Gy versus 1245.45 Gy, $p < 0.015$).
Conclusion: In conclusion, our study showed that balloon was non-inferior to basket stone extraction. More prospective future studies with proper methodology will enhance our knowledge and provide us with more robust data regarding complete stone clearance and catheter type.

Introduction: The use of rectal NSAIDs, the intravenous administration of Lactated Ringer (LR) and pancreatic duct stenting are recommended measures that demonstrated a positive impact in preventing PEP.
Aims and Methods: Our objective was to evaluate if the association of LR with NSAIDs in average-risk or high-risk patients undergoing ERCP is effective in reducing PEP when compared to the usually recommended use of NSAIDs in high-risk patients.
We conducted a retrospective, observational and cross-sectional study. Patients undergoing ERCP for biliary diseases between January 2013 to December 2017 were included. Patients diagnosed with any pancreatic disease (pancreatic cancer, chronic pancreatitis, previous acute pancreatitis) and post-surgical altered biliopancreatic anatomy were excluded. Patients were divided in three cohorts depending on the type of PEP prophylaxis used in different periods of time. Group I: rectal diclofenac 100mg in high-risk patients of PEP; group II: rectal diclofenac + LR 500 mL in high-risk patients of PEP; group III: rectal diclofenac + LR 500 mL in every patient undergoing ERCP. All patients were monitored for pain and serum pancreatic enzymes over 24h after ERCP. The incidence of PEP was analysed by ANOVA and risk factors by binomial logistic regression.
Results: A total of 613 patients were included, mean age 77 yrs, 329 females; 251 in group I, 152 in group II and 210 in group III. The global incidence of PEP was 2.6% (2.4% in group I, 2.0% in group II and 3.3% in group III; $p = 0.70$). Factors associated with a higher risk of PEP were bile duct stenting (OR 8.2, CI 95% 1.46–46.14) and incomplete biliary drainage (OR 6.4, CI 95% 1.24–33.18) in group I, the presence of cholagiocarcinoma (OR 17.87, CI 95% 1.53–208.93) and smoking (OR 12.19, CI 95% 1.06–140.28) in group II. There was no evidence of associated risk factor in group III.
Conclusion: The combination or LR with rectal NSAIDs in high-risk and average-risk patients is not associated with a lower incidence of PEP when compared to the administration of rectal NSAIDs alone in high-risk patients. While attempting to further prevent PEP in patients receiving rectal NSAIDs, some new risk factors that should be taken into consideration have been identified.

P1464 SAFETY AND EFFICACY OF EUS-GUIDED GALLBLADDER DRAINAGE (EUS-GBD) COMBINED WITH ERCP IN THE SAME SESSION

R. Torres-Yuste, F.J. Garcia-Alonso, M. Cimavilla, A.Y. Carbajo Lopez, N. Mora Cuadrado, I. Penas-Herrero, **R. Sanchez-Ocana**, S. Sevilla-Ribota, C. De La Serna Higuera, M. Pérez-Miranda
Hospital Universitario Rio Hortega, Gastroenterology, Valladolid, Spain

Introduction: ERCP is increasingly being combined in a single-session with other endoscopic procedures such as EUS (staging, screening for CBD stones, rendezvous for failed cannulation) duodenal stenting or cholangioscopy. EUS-guided gallbladder drainage (EUS-GBD) is an emerging option for acute cholecystitis in non-surgical candidates. Patients with acute cholecystitis often need CBD stone removal. Combination of ERCP for CBD stones and EUS-GBD might be appealing in some patient subsets, but there is virtually no objective evidence to support this combined approach to gallstone disease.
Aims and Methods: To assess the safety and efficacy of EUS-GBD combined with ERCP in the same session.
Single-center retrospective cohort study comparing outcomes of EUS-GBD alone to those of ERCP combined with EUS-GBD in the same session between June 2011 and May 2017. Lumen-apposing metal stent (LAMS, Axios®) were used in both groups. Exclusion criteria: ERCP or EUS-GBD used for salvage of one another (ie, transcystic GB drainage after failed EUS-GBD or EUS-GBD for failed biliary drainage at ERCP), EUS-guided biliary drainage (EUSBD) in the same session, and ERCP within 5 days (before/after) EUS-GBD. Epidemiologic, procedural, and clinical outcome data were analyzed with Wilcoxon, Chi-square and Fisher tests where appropriate. Primary endpoints were rates of technical success, clinical success and adverse events.
Results: Sixty four consecutive patients underwent EUS-GBD between June 2011 and May 2017. 19 Patients were excluded: in 11 the indication for either ERCP or EUS-GBD was salvage of a failed tandem procedure, 5 had EUS-guided biliary drainage in the same session and a further 3 had another ERCP within 5 days of the index procedure. Forty-five patients met inclusion/exclusion criteria: 24 EUS-GBD and 21 EUS-GBD combined with ERCP. Baseline characteristics were comparable in both groups. There were no significant differences in technical (100% vs 91.7%) and clinical success rates (90.5% vs 91.7%) of EUS-GBD in the combined versus the single procedure groups. The rate of adverse events (23.8% vs 20.9%) and the rate of technical issues (14.3% vs 37.5%; $p = 0.10$) during LAMS deployment were also comparable. Results are detailed in Table 1. Technical success of ERCP was 100% and 81% of patients required sphincterotomy and stone extraction.
Conclusion: While ERCP combined with EUS-GBD maintains similar rates of technical and clinical success to EUS-GBD alone, a combined procedure does not appear to increase adverse events. Despite the limitations of our study, these findings are encouraging and warrant further evaluation before this therapeutic approach can be generalized.

	EUS-GBD+ERCP (n = 21)	EUS-GBD (n = 24)	p
Median Age (IQR)	85.3 (78–89)	83.9 (78.6–89.9)	0.70
Male, n (%)	10 (47.6%)	13 (54.2%)	0.66
Baseline disease -Benign, n (%) -Malignant, n (%)	18 (85.7%) 3 (14.3%)	20 (83.3%) 4 (16.7%)	1
Indication – Cholecystitis, n (%) -Choledocolithiasis, n (%) -Biliary decompression, n (%)	19 (90.5%) 1 (4.8%) 1 (4.8%)	24 (100%)	0.21
Technical issues during LAMS deployment, n (%)	3 (14.3%)	9 (37.5%)	0.10
Adverse events, n (%)	5 (23.8%)	5 (20.9%)	1
Clinical success, n (%)	19 (90.5%)	22 (91.7%)	1
Technical success, n (%)	21 (100%)	22 (91.7%)	0.49

Introduction: The swine model has been described as a realistic tool for EUS training [i]. Papers extensively describing EUS swine anatomy are lacking in the current literature, though.
Aims and Methods: The aim of the article is to describe both linear and radial EUS pancreatobiliary swine anatomy.
We report the animal lab experience of the WEO (World Endoscopy Organization) International School of EUS (WISE) group at ASAN Medical Center in Seoul. 2 adult mini pigs were scoped under general anesthesia, endotracheal intubation and mechanical ventilation. Both radial and linear array echoendoscopes were used for delineation of pancreatobiliary anatomy and videos were recorded.
Results: It was possible to image aorta, crus of the diaphragm, celiac trunk, superior mesenteric artery, pancreas, common bile duct, gallbladder, portal vein, kidneys, spleen and hepatic hilum. Images obtained were comparable to human EUS findings, even if with some remarkable differences.
Conclusion: Swine model confirmed to be a highly realistic teaching model for EUS. To the best of our knowledge swine EUS anatomy has not been reported to date. We believe that this image-provided description of swine pancreatobiliary anatomy can be a useful tool for EUS training in the setting of in-vivo hands-on sessions.

Introduction: Endoscopic ultrasonography (EUS)-guided puncture is the standard of care for tissue sampling of pancreatic masses. For pancreatic neuroendocrine tumors (P-NET), obtaining material that allows a complete anatomopathological examination with Ki-67 index quantification is essential for its adequate characterization. However, the factors that enable it are unclear, namely the advantage of fine needle aspiration (FNA) versus fine needle biopsy (FNB).
Aims and Methods: The aim of this study is to evaluate in patients with P-NET diagnosed by EUS the factors that potentially influence the ability to obtain adequate samples allowing complete anatomopathological examination with assessment of the Ki-67 index.
Retrospective study of all patients with P-NET with histological diagnosis by EUS at our institution between January 2013 and December 2017. The size of the lesion, location of the lesion, tissue acquisition technique (FNA vs FNB) and needle gauge were analysed.
Results: Twenty-one procedures were performed in 20 patients: 11 women (55.0%) and 9 men (45.0%) with a median age of 54 years (range 27–82 years). The median lesion size was 25mm (range 8–70 mm). In 61.9% (n = 13) of the procedures an adequate sample allowing a complete anatomopathological examination (with Ki-67 index quantification) was obtained. The Ki67 index assessment rate according to the analysed variables was: 72.7% in lesions $<$20mmm (8/11) vs 50.0% in lesions $\geq$20mm (5/10), p = 0.290; 64.3% in body/tail lesions (9/14) vs 57.1% in head/uncinate lesions (4/7), p = 0.751; 53.8% of the cases with FNA (7/13) vs 75.0% with FNB (6/8), p = 0.339; 70.0% with 22G needle (7/10) vs 54.5% with 25G needle (6/11), p = 0.469. There were no complications associated with the procedure.
Conclusion: Characteristics of the lesion and puncture technique did not significantly influence the ability to obtain material for complete anatomopathological examinations in P-TNE. However, the size of the sample does not allow a definitive conclusion. The authors recommend that this study be replicated in a larger sample of patients, possibly in a multicenter study.

P1468 DIAGNOSIS AND OUTCOME OF MEDIASTINAL FOREGUT DUPLICATION CYSTS: THE ROLE OF EUS

A. Tenca[1], M.A. Färkkilä[1], P. Arkkila[1]
[1]*Clinic of Gastroenterology – Helsinki University Hospital, Helsinki, Finland*

Contact E-Mail Address: ante14@hotmail.it
Introduction: Mediastinal foregut duplication cysts (FDC) are rare dysembriogenic lesions originating from the ventral portion of the endodermal primitive foregut. The diagnosis, follow-up and outcome of these lesions have been reported in only few case series and small retrospective studies.[1,2]
Aims and Methods: Aim of this study was to assess the role of endoscopic ultrasound (EUS) in the diagnosis and follow-up of FDC.
Forty-five patients who had been referred for EUS for mediastinal lesions suspected of being FDC between 01.01.2009 and 01.02.2017 were identified by using the ICD-10 code Q39.8 from the patient registry of EUS of Helsinki University Hospital. All patients' baseline characteristics (gender, age, symptoms and signs), gastroscopy, computer-tomography (CT) findings (density, localisation), EUS findings (echogenicity, localisation, final diagnosis), surgical intervention, histologic findings and complications were reviewed. Data are presented as number with percentage when categorical and as median and range when continuous.
Results: All the patients (n = 45, 17 males, median age 55 years; range: 27–79) underwent EUS for a suspected FDC after endoscopy and/or chest-CT. In 31 patients (69%) the lesion was an occasional finding. Gastroscopy was performed in 22/45 (49%) showing a submucosal lesion in 19/22 (86%). Chest-CT was performed in 36/45 (80%) and the final diagnosis was consistent with a fluid lesion in 15/36 (42%) and with a solid lesion in the remaining 19 patients; normal finding was found in 2 patients. In CT images, lesions were localized outside the oesophageal wall in 22/36 (61%) of the patients and inside in the remaining 12. After EUS, the final diagnosis was consistent with a FDC in 44/45 (98%) and normal in 1. Biopsy was not routinely performed because of the risk of infection. Thirty-four lesions (77%) were localised inside the oesophageal wall and 10 outside. Lesions were anechoic in 23 cases (52%) and hypoechoic with inner hyperechoic material in 21. Nineteen out of 45 patients (42%) underwent surgical enucleation. Finally, FDC was confirmed in 12/19 (63%) and normal finding in 1/19 (5%). Leiomyoma was diagnosed in 3 cases (in EUS 2 findings were hypoechoic and localized in the third layer and one anechoic and localized in the fourth layer), enlarged lymph node with sarcoidosis in 1 (in EUS finding was anechoic and localized in the fourth layer), mesenchymal benign tumour in 2 (in EUS one finding was hypoechoic and localized outside of the oesophagus and one was anechoic and localized in the third layer). Nine out of 45 patients (20%) underwent follow-up (median 3.4 years; 5 months–6.7 years) with EUS, being the number of controls 4 in one, 3 in one and 2 in seven. The lesion was stable in 7 patients, but two were operated because of the growth of the lesion: histology was consistent with FDC and with leiomyoma (in EUS finding was anechoic and localized in the fourth layer), respectively.
Conclusion: EUS plays still an important role for the diagnosis and the follow-up of FDC. However, differential diagnosis, mostly with leiomyoma might be difficult. No cases of malignancy occurred. FNA should be considered in selected cases to improve the diagnostic accuracy.
Disclosure: Nothing to disclose

Introduction: Gastrointestinal stromal tumors (GISTs) represent the largest group of subepithelial tumors (SETs) of the upper gastrointestinal tract. The differential diagnosis of GISTs is important because of malignant potential, in contrast to other SETs. Endoscopic ultrasound (EUS) and contrast-enhanced endoscopic ultrasound (CE-EUS) is frequently used to diagnose GISTs, however, the characteristic features to distinguish GISTs from other SETs are still unknown.

Aims and Methods: The aim of this study is to find specific features on CE-EUS in differential diagnosis of GIST with other SETs. We retrospectively reviewed the findings of CE-EUS of 25 hypoechoic tumors, located in gastric proper muscle layer in 25 patients from January 2014 to December 2016. The presence and degree of tumor vessel in the SET on CE-EUS was evaluated. In addition, the SETs were classified also according to enhancement pattern as hypo-enhancement, iso-enhancement, and hyper-enhancement. The results were compared to histological diagnosis, in which obtained by EUS-guided fine needle aspiration with biopsy or /and surgical resection.
Results: 17 of 25 SETs were diagnosed as GIST by histological results. 6 SETs were diagnosed as leiomyoma and 2 SETs were schwannoma. In 14 of 17 GISTs tumor vessel was observed and In 8 non-GISTs tumor vessels were not observed. On statistical analysis, the presence of tumor vessel was significantly related to GIST (Odds ratio, 4.250; 95% confidential interval, 1.8–10.0; $P < 0.001$); 1 or 2 tumor vessels (1+) in 5 cases, 2 or 3 tumor vessels (2+) in 6 cases,more than 3 tumor vessels (3+) in 3 cases and no tumor vessels in 3 cases. The sensitivity, specificity, accuracy and positive predictive value with vessel enhancement were about 100%, 66.7%, 77.4% and 84%. In 17 of GISTs hypoenhancement was observed in 5 cases, isoenhancement in 11 cases and hyperenhancement in 1 case. In 8 of non-GISTs, hypoenhancement was observed in 5 cases, isoinhancement in 2 cases, unenhancement in 1 case. The results showed that the tendency of correlation between iso-enhancement pattern and GISTs, but there was no statistical significance (OR, 7.78l; 95% CI 1.165–51.915; $P = 0.061$).
Conclusion: The findings of tumor vessel enhancement in CE-EUS is useful for differential diagnosis between GIST and non-GIST in gastric hypoechoic tumor of proper muscle layer. The echo patterns of contrast enhancement were insufficiency for differential diagnosis between GIST and non-GIST.

Introduction: Standard endoscopic ultrasound-guided fine-needle biopsy (EUS-FNB) of solid pancreatic lesions involve the use of no-suction or suction aspiration techniques. A new aspiration method, the stylet slow-pull technique, consists in the slow withdrawal of the needle stylet to create minimum negative pressure. New generation of stylets could facilitate the slow-pull technique.
Aims and Methods: We compared EUS-FNB performed with the stylet slow-pull technique versus the standard suction technique in patients with solid pancreatic lesions. We evaluated blood contamination and adequacy of the samples, FNB diagnostic accuracy and complications. All EUS-FNB were performed with a 20-gauge needle (EchoTip ProCore with ReCoil Stylet^{TM}). The ReCoil Stylets has an automatic recoiling capability designed to help users to manage more easily the stylet minimising the risk of contamination.
After completion of the endosonographic examination, the pancreatic mass was evaluated with color Doppler to avoid the involvement of vessels. The needle was sharpened by withdrawing the stylet approximately 2 mm, and then was advanced into the lesion. In patients randomized to the stylet slow-pull technique, 15 to-and-fro movements within the lesion were performed, with simultaneous minimal negative pressure provided by pulling the needle stylet slowly and continuously. In patients randomized to the standard suction technique, 15 to-and-fro movements within the lesion were performed with the use of a 10-mL suction syringe. A visible core was defined as an architecturally intact-looking piece of tissue deemed sufficient for histological evaluation. Samples positive for malignancy were considered diagnostic. In patients with negative EUS-FNB, surgical specimen evaluation, results of other diagnostic investigation and/or long-term clinical follow-up (6 months) were used to establish the definitive diagnosis.
Results: In the interim analysis of the study we included 46 patients with an adequate follow-up (25 in the slow-pull group and 21 in the standard group). Patients' characteristics were reported in table 1. Among these 46 patients with an analyzable retrieved sample, blood contamination of the samples was poor in 33 patients (72%) and the final sample was adequate in the 70% of patients (32/46); no difference between the two techniques were observed. A diagnosis of malignancy was obtained in 40 cases (87%, "true positive"): 23 in the slow-pull group and 17 in the standard group. In 6 patients (2 in the slow-pull and 4 in the standard group) the suspected final diagnosis was chronic pancreatitis, but the clinical history suggested for a prudential approach, considering the final diagnosis as possible "false negative" in 4 of these patients (1 and 3 respectively). Based on these results, comparing the slow-pull group and the standard group, the sensitivity, specificity, negative likelihood ratio, positive likelihood ratio, and diagnostic accuracy were respectively of: 86 vs. 85%, 100% in both, 0.04 vs. 0.15, "infinity" in both, and 96 vs.85%. No adverse events were recorded.
Conclusion: Our preliminary data show as both slow-pull and standard suction techniques are comparable offering high diagnostic sensitivity and accuracy. Slow-pull technique seems to improve final diagnostic accuracy but it would be necessary to analyse all patients of our multicentric cohort. Up to now the endosonographer may choose either technique during FNB.

P1471 DO WE NEED ENDOSCOPIC ULTRASONOGRAPHY IN THE WORKUP OF PATIENTS WITH ACHALASIA?

S. Oumrani[1], M. Barret[1,2], G. Roseau[1], B. Brieau[1], S. Leblanc[1], F. Prat[1,2], S. Chaussade[1,2]

Introduction: The etiology of primary achalasia of the lower esophageal sphincter is unknown. Endoscopic ultrasonography (EUS) is advised in the workup of achalasia patients to rule out secondary achalasia or pseudoachalasia, and search for a typical esophageal wall thickening. The purpose of this study was to assess the clinical contribution of EUS findings in achalasia.
Aims and Methods: We conducted a single-centre retrospective study at a tertiary referral center. We included all patients with an endoscopic ultrasonography for the workup of a suspected esophageal motility disorder from January 2012 to December 2017.
Results: Seventy-one patients were included, 54% were men, with a mean (±SD) age of 61 ± 14 years. Mean (±SD) Eckardt score at time of the EUS was 7 ± 2. EUS was strictly normal in 27 (38%) patients, and showed an esophageal wall thickening in 44 (62%) patients. The inner circular muscle layer was the most frequently affected, with a mean (±SD) thickness of 2.9 ± 2 mm. Three cases of secondary achalasia were diagnosed: 2 esophageal carcinomas and one eosinophilic esophagitis, all three diagnosed at mucosal biopsies. Sixty percent of the patients had never received a treatment at the time of EUS and 82% were treated after EUS. The most frequent treatment was an esophagogastric myotomy in 48% of the patients (per oral endoscopic myotomy in 45% and Heller myotomy in 3%), while 20% and 13%of patients were treated with pneumatic dilatation and botulinum toxin injection, respectively. The occurrence of a wall thickening was not significantly associated with the type of esophageal motility disorder or achalasia subtype, the Eckardt score, the integrated relaxation pressure at manometry, or a previous treatment. There was no statistical correlation between the presence of a wall thickening at EUS and therapeutic outcomes after any of the achalasia treatments.
Conclusion: In our work, the contribution of endoscopic ultrasound findings was limited. The presence of an esophageal wall thickening was not predictive of achalasia subtype or treatment outcome.

Introduction: Real-time endoscopic ultrasound elastography (EUS-E) allows for the quantification of tissue stiffness and has proven to be useful to better characterize lymph nodes and pancreatic masses. Strain ratio (SR) measurement has been introduced as a method to minimize the operator bias by providing semi-quantitative data. Studies on EUS-E with SR in gastrointestinal subepithelial lesions (SELs) are lacking.
Aims and Methods: Aim of this study was to assess the efficacy of EUS-E with SR in differentiating SELs. Retrospectively collected data from consecutive patients with SELs evaluated by EUS-E with SR at three centers were analyzed. EUS-E was carried out using the Olympus compact ultrasound processor EU-ME2. Two different areas were selected for SR. Area A included the biggest possible area of the lesion without surrounding tissue, while area B was selected in the peritumoral healthy gastrointestinal wall. The SR was calculated as the quotient of B/A. Every time, 3 measures of SR were recorded and the mean value for each was calculated and used as final SR. The reference standards for the final diagnosis were histology on EUS-FNB, surgical specimen or clinical follow-up.
Results: A total of 57 SELs were included. The mean lesion size was 36.4 mm (SD 20.8 mm). The lesion locations were esophagus (n = 7), stomach (n = 38), duodenum (n = 10) and rectum (n = 2). The final diagnosis of SELs included 27 (47.3%) GISTs, 14 (24.5%) leiomyomas, 7 (12.2%) lipomas, 3 (5.2%) ectopic pancreas, 2 (3.5%) schwannomas, 2 (3.5%) neuroendocrine tumors, and 2 (3.5%) cancers. The median SR was 27.2 (IQR 9.2–52.3) for GIST, and 6 (IQR 3.2–17.6) for leiomyomas. Receiver operating curve analysis of SR for the detection of GISTs vs. leiomyomas yielded an area under the curve of 0.741 (95%CI: 0.587–0.895) (Figure 1). The best cut-off level of SR to differentiate GIST from leiomyoma was 13.3 with a sensitivity of 74.1% and specificity of 71.4%.
Conclusion: The results indicate that EUS-E with SR may improve differential diagnosis of SELs, being SRs of GIST higher than those of leiomyoma. The cut-off of 13.3 may be helpful to differentiate between GIST and leiomyoma.

Introduction: Acute severe pancreatitis can be necrotizing and frequently complicated by Pancreatic Fluid Collections (PFC). These PFC contains necrotic contents which has important implications on management and outcome. However, the effect of these pancreatic necrotic contents in PFC on treatment strategy and more importantly on the subsequent pancreatic ductal anatomy not clearly known.
Aims and Methods: The objective of this study is to evaluate whether the severity of necrotic contents in pancreatic fluid collections impacts the treatment strategy and pancreatic ductal anatomy
Subjects of acute pancreatitis with symptomatic PFC were included after an informed consent from Jan 2013 to December 2017. PFCs were classified into 3 distinct groups based on severity of necrotic contents, Group A) <15% SD; Group B) 15–40% SD; Group C) >40%. Subsequently EUS-guided drainage done using either short covered bi-flanged metal stent or plastic stents. After drainage, subjects were reassessed at 48–72 hours & Re-intervention including, Naso-cystic tube (NCT) placement with irrigation and Direct Endoscopic Necrosectomy were performed if required. All subjects underwent MRCP followed by ERCP between 4–8 weeks after the complete resolution of PFC to define the abnormalities in Pancreatic duct (PD) & were compared between 3 PFC subgroups. A p value <0.05 was considered statistically significant.
Results: A total of 408 subjects (350 males, median age 32 years, range 5–68 years) were included in the study group. Group A included 211 (51.7%), Group B included 155 (38%), Group C included 42 (10.3%) subjects. During EUS guided drainage, 270 underwent metal stent, 138 underwent plastic stents placement. Overall, Re-intervention was required in 110 (27%) subjects. The need for Re-intervention was significantly higher in Group C (SD >40%) compared to Group B & A (40.4% vs. 29.8% vs. 22.2%, $p = 0.03$). 340 out of 408 subjects had both MRCP and ERCP and included in final analysis. Of these, 42 (12.4%) subjects had normal PD, 35 (10.3%) had leak in PD, 20 (5.9%) had PD stricture & 11 (3.2%) had dilated PD with calculi & majority of subjects (n = 232, 68.2%) had cut-off in PD (Disconnected pancreatic duct). Normal PD was present significantly higher in Group A(SD <15%) compared to Group B & C(61.9% vs. 23.8% vs.14.2%). Similar trends were observed among Group A, B,& C for PD leak (71.4% vs. 28.5% vs. 0%), PD stricture (75% vs. 25% vs. 5%). However, PD cut off (Disconnected pancreatic duct) was observed significantly higher in Group C (SD>40%) compared to Group A (80.5% vs. 57.7%, $p = 0.001$).
Conclusion: Pancreatic necrotic contents in PFC significantly impacts management strategy and subsequent Pancreatic ductal anatomy. PFCs with severe necrotic contents require aggressive treatment strategy including Re-intervention. Normal Pancreatic duct can be seen in majority of subjects with PFC containing minimal necrotic contents. Whereas disconnected pancreatic duct is significantly higher in PFC containing severe necrotic contents.

Introduction: Different type and size of histological needles for Endoscopic Ultrasound guided Fine Needle Biopsies (EUS-FNB) have been developed, however the appropriated clinical setting in which they should be used has to be defined. The diagnosis of mesenchymal tumors (MT) often requires tissue for molecular studies (i.e. ISH. FISH, NGS) beside H&E and immunohistochemistry.
Aims and Methods: The aim of the study was to evaluated clinical performance of a new three points 19 G core needle with opposing bevels design in the setting of MT.
Prospectively collected data from consecutive patients who underwent EUS-FNB with a 19 G core needle characterized by a three-points design for suspected abdominal and pelvic MT at a single referral center were analyzed. Procedures were performed by a single operator between July 2017 and February 2018.
Results: Fifteen patients were managed. The procedure was technically feasible in all patients. Biopsy was performed through the rectum, the duodenum, and the stomach in 3, 2, and 10 patients, respectively. No major adverse events have been observed, although hemostatic clips were used to control mild gastric bleeding at the point of the needle passage for 2 patients. Biopsies showed in 2 cases malignancies other than MT one being a lymphoma and one a pelvic metastases from ovarian cancer. The remaining 13 patients were diagnosed MT (10 M, mean age 54 ± 16.7 years) and FNB lead to a diagnosis in 12 cases (accuracy, 92.3%); 2 sarcomas, 1 leiomyoma, 1 schwannoma, 6 GISTs, 1 glioma, and 1 desmoid-type fibromatosis. The mean size of the target lesion was 79 mm (range: 25–190). FNB was non-diagnostic in a patient with a large mass located behind the gastric wall with lipomatous radiological features. Quality of biopsy was examined showing that, although a mean number of 1.4 passes (range: 1–2) were performed based on gross visual inspection, adequate core tissue was available after the first pass for all patients. In 10 out of 12 diagnostic cases additional molecular studies were performed
Conclusion: This is the first report, to the best of our knowledge, on 19 G histological EUS needle with a novel three points design and showed both feasibility and safety of the procedure. This study showed a high rate of biopsied core tissue which was adequate for a full histological and molecular evaluations, supporting this new device as a promising tool when a pathological diagnosis is needed for patient management such as the case of MT.

Introduction: In the last decade a paradigm shift in the treatment of necrotizing pancreatitis from more invasive surgical strategies toward less invasive percutaneous and endoscopic techniques took place.
Infected necrosis is a dreaded complication requiring an intervention. Nevertheless the optimal timing of first intervention is unclear and consensus data are sparse.
This retrospective two-center study evaluates immediate direct endoscopic necrosectomy using lumen-apposing metal stents in case of proven or suspected super-infection.
Aims and Methods: 60 patients with a mean age of 53.1 years were included between 6/12 and 2/18. Etiology of pancreatitis was alcoholic (n = 18), biliary (n = 23), after surgery (n = 1), hypertriglyceridemia (n = 1), post-ERCP-pancreatitis (n = 3) and unknown (n = 14). Pancreatic necrosis was diagnosed by contrast-enhanced computed tomography. Infection of necrosis was confirmed by presence of gas in the CT-scan or suspected based on clinical or biochemical markers of infection or sepsis. In case of infection a lumen apposing metal stent (hot-Axios™-Stent, Boston scientific, Marlborough, Massachusetts, USA or NAGI™-Stent, Taewoong medical, wolgot-myeon, South Korea) via transgastral or transduodenal access was implanted and sequent direct endoscopic necrosectomy was performed until resolution of the necrotic debris. The patient-cohort was divided in an early group receiving first necrosectomy within the first 30 days and a late group obtaining the intervention more than 30 days after first proof of necrosis. The C-reactive-protein as marker of inflammatory activity was recorded.
Results: The mean CRP was 219.2 ± 134.9mg/l and 56 ± 74 mg/l before and after intervention, respectively. The mean time between first proof of necrosis and first intervention was 20 ± 33.1 days, all-over mortality was 9.7%, clinical resolution was achieved in 86.7%. 4.9 ± 3.4 necrosectomies were performed per patient. The mean stay on the intensive-care-unit was 5.4 ± 11.5 days, on intermediate-care-unit 3.2 ± 6.1 days. Mean follow-up was 19 ± 12.4 months.
49 patients were assigned to an early intervention group (stent placement before 30 days after acute episode). Patients received 4.7 ± 3.2 necrosectomies after 8.9 ± 7.8 days, mortality was 8.2%, clinical resolution 87.8%. Days in intensive-care-unit were 5.0 ± 9.8, in intermediate-care-unit 4.4 ± 7.1.
11 patients were treated at least 30 days after onset of pancreatitis receiving 5.4 ± 3.3 necrosectomies after 67.6 ± 52.2 days with a mortality of 18.2%, clinical resolution of necrosis was 81.8%. ICU-days were 11.4 ± 18.3 days, stay in intermediate-care-unit was 0.8 ± 1.3 days.
Conclusion: Our retrospective data reveal an advantage of early timed endoscopic intervention over a delayed approach in necrotizing pancreatitis. Direct endoscopic necrosectomy in combination with lumen apposing metal stents shows a trend to less mortality and saving in ICU-capacity when its performed in an early stage of disease. Further randomized investigations should concretise the optimal timing of intervention.
Disclosure: Nothing to disclose

P1476 ADEQUACY AND DIAGNOSTIC YIELD OF A NOVEL CORE BIOPSY NEEDLE (SHARKCORE FNB NEEDLE) IN THE DIAGNOSIS OF SUBEPITHELIAL LESIONS: OUR SERIES

I. Barbuscio[1], A. Fantin[2], C. Mescoli[1], F. Farinati[3]

Introduction: Subepithelial lesions of the gastrointestinal tract are commonly encountered during routine upper and lower endoscopy, diagnosticated incidentally because of their asimptomaticity. They are frequently located in the stomach, but also found in the esophagus and duodenum. Endoscopic ultrasound (EUS) plays a fundamental role in the detection and management of these

lesions, both for the ability to identify the original layer and the ultrasound pattern, but especially for the possibility to provide a histological, immunohistochemical and molecular diagnosis, through Fine Needle Biopsy (FNB).
Aims and Methods: The aim of the study is to assess adequacy and diagnostic yield of a novel core biopsy needle (Sharkcore FNB needle Medtronic). We retrospectively analized all EUS performed at our Center between September 2015 and March 2018, to further investigate suspicious subepithelial lesions found at upper and lower endoscopy.
Results: Out of 923 EUS, 123 were performed with suspicious of submucosal lesions, finally identifyng 109 (average size 16 mm, range 1–35 mm). FNB (Sharkcore FNB needle Medtronic, 22G, average of 3 passages), was performed in 22 cases (average dimension 30 mm, 12 female), only one patient experimented mild and self-limiting intralesional bleeding during FNB. The material resulted adequate in 20 cases, resulting diagnostic in 19 cases (10 GIST, 8 leiomyomas and 1 gastric splenosis). Therefore in 16 cases the sample allowed the immunohistochemical analysis, in 7 cases molecular tests. In only 4 cases surgery was performed, with a concordant diagnosis with FNB in 3 of them.
Conclusion: Our series demonstrates FNB (Sharkcore FNB needle Medtronic) adequacy of 90% and diagnostic yield of 86%.
Disclosure: Nothing to disclose

Introduction: Diagnostic yield of endoscopic ultrasound fine needle aspiration (EUS-FNA) in solid pancreatic masses depends on the lesion characteristics, needle diameter, presence of aspiration, number of passes and presence of rapid on site evaluation. We aim to prove that high needle acceleration through tissue significantly increases EUS FNA diagnostic yield.
Aims and Methods: We designed a prospective multicenter study to assess the impact of needle acceleration on the EUS FNA tissue acquisition rate, diagnostic accuracy, cellularity and quality of the acquired material (NCT03303352). Patients with larger than 20mm pancreatic solid masses with unknown histology were included. Using a 22-gauge needle, two "fast" and "slow" passes were performed, with accelerations higher and lower than 1g respectively. The two passes were performed in a randomized order, each with ten "to and fro" fanning movements. Acceleration was measured with a Pocketlab device attached to the aspiration syringe. Aspired material was fixed in alcohol and processed by the Cytoblock procedure. Slides for each pass were scored for accuracy by the Papanicolau Pancreatobiliary Terminology classification scheme and by two four-points cellularity and quality scales (minimum 0 to maximum 3). For a 25% increase in accuracy the calculated sample size was 51.
Results: 21 patients with locally advanced or metastatic pancreatic cancer on CT scan/MRI were included so far. 18 patients were evaluable, 3 patients were excluded from analysis (one withdrawn informed consent, one groove pancreatitis, one Pocketlab dysfunction). The mean acceleration values were 1.06g and 0.39g for "fast" and "slow" pass respectively ($p < 0.0001$). The tissue acquisition rate was 88%. The "fast" pass yielded a significantly better Papanicolau class ($p = 0.016$) and higher rate of positive diagnosis when compared with "slow" pass (66.6% versus 44.4%, $p = 0.638$). The mean cellularity scores were 1.56 and 1.28 for "fast" and "slow" passes ($p = 0.059$), while the mean quality scores were 2.17 and 1.67 for "fast" and "slow" pass respectively ($p = 0.083$).
Conclusion: Preliminary data proves that diagnostic accuracy was significantly influenced by a higher than 1g EUS FNA needle acceleration. There was a tendency towards better accuracy, cellularity and quality of EUS FNA specimens.
Disclosure: Nothing to disclose

P1478 THE PREVALENCE OF SMALL BOWEL AND COLONIC POLYPS IN PATIENTS WITH SPORADIC DUODENAL AND/OR AMPULLARY ADENOMAS – A PROSPECTIVE CASE CONTROL STUDY

H. Awadie[1], A. Klein[1], D.J. Tate[1], B. Jideh[1], I. Bar-Yishay[1], K. Goodrick[1], G. Ahlenstiel[1], M.J. Bourke[1,2]
[1]*Gastroenterology and Hepatology department, Westmead Hospital; Sydney, NSW, Sydney, Australia*
[2]*University of Sydney, Sydney, Australia*

Contact E-Mail Address: halimawadieh@yahoo.com
Introduction: Sporadic duodenal and/or ampullary adenomas are found in 1–3% of patients referred to upper endoscopy. Patients with duodenal adenomas have a 3-7-fold increased risk of colonic neoplasia above the normal population. It is unknown whether these patients have a clinically significant increased risk of small bowel neoplasia. Video capsule endoscopy (VCE) identifies Small bowel (SB) polyps in up to 75% of familial adenomatous polyposis (FAP) patients. Our aim was to investigate the prevalence of SB polyps occurring in association with large (≥10mm) sporadic duodenal or ampullary adenoma patients using VCE
Aims and Methods: A single-center, prospective case control study was performed. Patients with ≥10mm duodenal and/or ampullary adenoma were approached to participate in the study (Adenoma group). Patients with FAP were excluded. The control group comprised patients undergoing VCE for the evaluation of obscure gastrointestinal bleeding (OGIB) or Iron deficiency anemia (IDA) within the same study period.
Results: Over 20 months, 194 patients were enrolled in the study. The mean age was 65 (IQR 24–91) and 49% were male. There were 94 control patients and 99 adenoma cases (Duodenal adenomas n = 74 (75%), mean size 33mm (IQR 10–80mm); Ampullary adenomas n = 25 (25%), mean size 25mm (IQR 10–80mm)). 91% of duodenal adenomas were in the second part of the duodenum.
Five patients (adenoma group) were excluded from analysis due to inadvertent aspiration of the capsule (1), technical failure (2), inability to swallow the capsule (1) and non-adenomatous lesion (1).
There were no SB polyps in either group. One adenoma patient had an incidental finding of active bleeding, most likely from an angiodysplasia, but otherwise no significant small bowel findings were obtained.
Colonoscopy was performed in 82% and 84% (p-0.705) of the adenoma and control groups, respectively. Colonic polyps were found more frequently in the adenoma group than controls (61% vs 41%, respectively (p-0.009)). Overall, 43% of patients in the adenoma group had at least one colonic adenoma vs. 21% in the control group (p-0.002). The polyps were < 10mm in 87% and 95%, conventional adenoma in 76% and 71% (p-0.537) and sessile serrated polyps in 10% and 2%, respectively (Table-1). Advanced colonic polyps (HGD, > 10mm, Villous histology) were found in 21% of the adenoma group and 5% of the control group (p-0.02).
Conclusion: This is the first prospective case control study to show the negligible risk of synchronous SB polyps in large sporadic duodenal and/or ampullary adenoma patients. We have also confirmed the increased risk of colonic adenoma in this population, even in comparison to a control group at potentially greater risk of colonic pathology. Our data indicate that VCE for SB polyp screening in this group of patients is not necessary. However, colonoscopy is mandatory due to the high prevalence of colonic adenomas including advanced polyps.

	Adenoma (n = 106)	Controls (n = 41)	P value
1–5mm	61 (57%)	16 (39%)	
6–10mm	31 (30%)	23 (56%)	
> 11mm	14 (13%)	2 (5%)	
Conventional adenoma	81 (76%)	22 (71%)	NS
SSP	11 (10%)	1 (2%)	NS
Villous component	10 (9%)	0	
Advanced polyp	22 (21%)	2 (5%)	0.02
Patients with at least one adenoma	35 (43%)	16 (21%)	0.002
Polyps > 10mm	14 (13%)	2 (5%)	0.017
Proximal colon	51 (48%)	20 (49%)	NS
Distal colon	55 (52%)	21 (51%)	NS

[Table-1: Colonic polyp size, histology and location in both groups]

[2]*Tel Aviv University, Sackler Faculty of Medicine, Tel-aviv, Israel*

Contact E-Mail Address: liatml@tlvmc.gov.il
Introduction: Video capsule endoscopy (VCE) is a non-invasive procedure that evaluates the small bowel (SB). The use of VCE in the elderly is rising mainly due to an increased rate of investigations for obscure gastrointestinal bleeding. While previous studies in the elderly have demonstrated delayed gastric transit time (GTT) with normal SB transit time (SBTT), detailed data is lacking regarding motility and diagnostic yield in these age groups.
Aims and Methods: To evaluate the diagnostic yield and transit times in different age categories among elderly patients.
All consecutive VCEs performed from 01/2010 to 12/2017 in a single tertiary center were reviewed. Inclusion criterion was age≥65 years. Exclusion criteria were technical malfunction or inability to swallow. The cohort was divided into two age groups: 65–79 years (young-elderly, YE) and ≥80 years (old-elderly, OE). Complete SB visualization was defined by cecal documentation. GTT and SBTT were calculated and expressed as median (range min-max). Indications, TTs and diagnostic yield were compared between groups.

Results: A total of 1765 VCEs were performed, 535 (30.3%) in patients ≥65 years including 90 (5.1%) in patients ≥80 years (12 patients were excluded). YE included 445 VCEs in 425 patients, mean age 71.3 ± 4.2 years and 51.9% male. OE included 90 VCEs in 83 patients, mean age 83.9 ± 3.2 years (range 80–93) and 47.8% male. The most common indication for referral in both groups was iron deficiency anemia (YE = 69.7% vs. OE = 73.3%, p = 0.529), followed by chronic diarrhea/suspected Crohn's disease, which was 3-fold higher in YE (17.8%) compared to OE (5.6%, p = 0.002). Complete visualization of the SB was equally achieved by both groups (YE = 96.4% vs. OE = 93.3%, p = 0.236). GTT and SBTT were comparable as well (YE = 20 (0–356) minutes vs. OE = 22 (1–184) minutes, p = 0.240 for GTT; YE = 243 (24–642) minutes vs. OE = 242 (35–581) minutes, p = 0.706 for SBTT). No correlation was found between age and GTT (p = 0.425) or age and SBTT (p = 0.334). The rate of significant visual impairment resulting from food mixing, allowed at 4 hours after capsule swallowing, with a capsule retained in the stomach for > 4 hours did not differ between groups (YE = 1.3% vs. OE = 1.1%, p = 1.000). The rate of positive VCEs was higher in OE compared to YE (68.5% vs. 51.7%, p = 0.005), as was the rate of clinically significant findings (58.4% vs. 41.1%, respectively, p = 0.003). Angioectasias were observed more frequently in OE (36.8% vs. 22.9%, p = 0.010). Active bleeding was observed in 12.8% in OE compared to 6% in YE (p = 0.037). Moreover, in sub-analysis of patients referred solely due to iron deficiency anemia, the prevalence of evident active bleeding was more than two-fold higher in OE compared to YE (14.3% vs. 6.7%, respectively, p = 0.058).
Conclusion: One third of our VCE studies are performed in the elderly while 5% are performed in patients≥80 years. "Old-elderly" patients have a higher rate of clinically-significant findings with similar rates of technical success. The high diagnostic yield in the old- and young-elderly, together with low rates of extended GTT and high SB completion rates, justify VCE studies in these populations.

Introduction: Fecal immunochemical tests (FIT) have been used as an initial test in CRC screening programs. However, majority of patients do not have advanced neoplasia on colonoscopy. Colon capsule endoscopy (CCE) has the potential to reduce the need for optical colonoscopy (OC) in FIT positive individuals.
Aims and Methods: In this multicenter (3 tertiary referral centers) feasibility study, second generation of colon capsule endoscopy (CCE2) has been prospectively compared with OC in persons with positive semi-quantitative FIT with cut-off level 75 ng/ml. The primary outcome was negative predictive value (NPV) of the CCE2 for large polyps (≥ 10 mm). The accuracy of detection of all polyps (polyps ≥ 6 mm and ≥ 10 mm) and cancers was assessed. Colonoscopy was performed within 10 hours after capsule ingestion. CCE2 videos were viewed independently by a nurse and a physician, both blinded to the results of OC. Complications were assessed as serious (bleeding, perforation) or mild to moderate. The methods of acceptance were evaluated based on the questionnaire completed after both procedures (CCE2 and CC) were finished. The interim analysis of results is presented.
Results: From April 2016 until April 2018, 111 individuals (mean age 61 years) have been enrolled; data from 54 persons have been analyzed. During optical colonoscopy, polyps were diagnosed in 37 persons (69%), polyps ≥ 6 mm and ≥ 10 mm in 22 (41%) and 12 (22%) persons, respectively. The sensitivity of CCE2 for polyps ≥ 6 mm and ≥ 10 mm was 82% (95% confidence interval [CI]: 60–95%) and 75% (95% CI: 43–95%), respectively. The specificity for polyps ≥ 6 mm and ≥ 10 mm reached 88% (95% CI: 71–96%) and 93% (95% CI: 81–99%), respectively. Two cancers were diagnosed at both CCE2 and OC. The negative predictive value of CCE2 for polyps ≥ 10 mm was 93% (95% CI: 81–99%). Nurses identified 30 polyps of 37 (81%) found on OC compared to 36 polyps (97%) identified by physicians. A total of 40 patients (74%) preferred CCE2 as the primary screening method.
Conclusion: A second generation of colon capsule has appeared to have a high negative predictive value for clinically relevant colorectal neoplasia in screening population. This method might be considered as an adequate tool for colorectal cancer screening.

P1481 RISK OF SMALL BOWEL BLEEDING ASSOCIATED WITH USE OF ORAL ANTICOAGULANTS OR ANTIPLATELET AGENTS: A RETROSPECTIVE COHORT STUDY

A. Mussetto, A.T. Garribba, S. Gasperoni, F. Cantoni, O. Triossi
Gastroenterology Unit, Santa Maria delle Croci Hospital, Ravenna, Ravenna, Italy

Contact E-Mail Address: alessandromussetto@gmail.com
Introduction: Antiplatelet and anticoagulant therapy is increasingly being used for cardiovascular prevention. Novel direct-acting oral anticoagulants (NOAC) represent a recent, alternative, family of drugs. Rate of bleeding complications by NOAC seems to be comparable to those of warfarin but a previously assumed increase in gastrointestinal bleeding complications was meanwhile confirmed. The risk of bleeding in the setting of suspected small bowel bleeding (SSBB) in patients taking antiplatelets or anticoagulants has been poorly investigated.
Aims and Methods: Aim of this study was to evaluate diagnostic yield using video capsule endoscopy in OGIB patients taking antiplatelets or anticoagulants.
This is a retrospective review of chronic users of anticoagulants or antiplatelet agents who underwent VCE for SSBB. Small bowel findings were evaluated using Mirocam VCE (Intromedic, Korea).
Results: 264 patients (134 women, mean age 72.3 years, 55% occult SSBB) underwent VCE from January 2014 to March 2018 for SSBB. 162 out of 264 patients were taking antiplatelets or anticoagulants agents. 44 patients were taking 100 mg of enteric-coated aspirin, 24 taking thienopyridine (ticlopidine or clopidogrel), 39 taking aspirin combined with thienopyridine (combined group), 27 taking warfarin and 28 patients taking NOAC (20% dabigatran, 32% apixaban, 48% rivaroxaban). Diagnostic yield in this specific cohort was 52.5%. Relevant lesions were most frequently detected in the "combined" group (74.3%) among the five groups (aspirin group 52.2%, NOAC group 50%, warfarin group 48.1%, thienopyridine group 41.6%) (p = 0.037).
Conclusion: The risk of small bowel bleeding related to antiplatelet / anticoagulant therapy seems to be increased in patients taking the combination of aspirin and thienopyridine and preventive strategies in this group should be established. The risk related to novel oral anticoagulants seems to be similar to that for warfarin and aspirin alone.

Introduction: The capsule endoscopy (CE) is a high yield diagnostic procedure for evaluating small bowel (SB) with low invasiveness. One of the limitations is the incomplete studies' rate, generally, due to a delay in gastric evacuation and limited useful life of the batteries. Consequently, a final segment of the SB could not be visualized and the study should be repeated. Prokinetics, laxatives, patients' position and the use of chewing gum to accelerate the transit were evaluated with discordant results.
Aims and Methods: 1. Establish if gastric transit time (GTT) and SB transit time (SBTT) were lower in patients who consume chewing gum than in those who do not. 2. Evaluate if the use of chewing gum decreases the rate of incomplete studies. 3. Describe the clinical characteristics of patients with incomplete studies. Adults referred for CE who accepted to enter the study were included. Retained CE, CE repositioning by upper endoscopy and impossibility to chew were exclusion criteria. Setting: Outpatients gastroenterology center, between 05, 2014 and 09, 2017.
Experimental, prospective, comparative, randomized, single blind and cross sectional. The patients were divided as follows: Ch group: received chewing gum (20 minutes every 2 hours from CE ingestion until the end of the procedure) and control group. Indications and procedures were performed according to usual practice, with CE. GTT and SBTT in minutes, reaching the ceccum, incomplete studies, outpatient-admitted condition, and co morbidities were registered. Ethics: the protocol was approved by the local Committee. Statistical analysis: SPSS 19, Student, $X^{2,}$ Kaplan Meier.
Results: 365 patients: 52.6% females; average age in men and women, 59.4 ± 16.13 years and 56.41 ± 15.83 years, respectively (p = 0.07);average BMI in men and women: 27.27 ± 4, 23 and 26.51 ± 5.10 kg/m2, respectively (p = 0.125); average GTT: 42.47 ± 44.86 min; average SBTT: 238.55 ± 105.16 min; Group Ch: 48, 2% (176/365), outpatients (98.5% (357/365); Co morbidities 17% (61/365) 1. a) Average GTT for Ch and control group were 46.11 ± 47.30 vs. 39.08 ± 42.31 min, respectively (T = 2.07; p = 0.13). b) Average SBTT for Ch and control group were 236.37 ± 108.70 and 240.58 ± 102 min, respectively; (T = −0.38, p = 0.70). 2. Incomplete studieś rate in Ch and control group was statistically no different (2.3% (95% CI 0.6–5.7; 4/176) vs. 1.6% (0.3–4.6; 3/189; p = 0.92) 3. Sex, hospitalization, at least one co morbidity, BMI and age were not associated with not reaching cecum.
Conclusion: GTT, SBTT and the proportion of incomplete studies were no different between consumers of chewing gum and non-consumers during CE.

Introduction: A typical capsule endoscopy case generates several thousand images, with abnormalities often confined to a just few frames. The use of rapid reading software has become common place in an attempt to reduce reading times. There is concern that use of such software may result in an unacceptable number of missed lesions. Omni Mode is novel EndoCapsule software algorithm, which aims to intelligently remove duplicate images whist maintaining lesion detection. Here we present the interim results of a multi-centre European study of the use of Omni Mode in daily clinical practice.
Aims and Methods: This study took place across 9 European centres, using real life cases. Patients undergoing a clinically indicated capsule endoscopy had their case read at their local centre using standard reading, with every captured frame reviewed. A pragmatic 'real life' approach was adopted, with readers using their usual viewing mode and speed. These cases were then anonymised and randomly allocated to another centre where this was read using Omni mode. Detected lesions and reading time was recorded, with findings compared between both viewing modes. All lesions were reviewed and classified according to lesion type and severity using the P- Classification. Where lesions were missed, a review of the Omni Mode reading stream was conducted at 10fps, to determine whether they were missed by the viewer or had been excluded by the software.
Results: Here we report the preliminary results for the first 210 cases analysed. The patient population undergoing capsule endoscopy had a mean age of 60.8 years (range 18- 91), with a Male to Female ratio of 1.1:1. The investigation of anaemia or overt gastro-intestinal bleeding accounted for 68% of cases. A total of 1732 lesions were identified, which were classified according to the P-Classification as P0 (927), P1 (550) and P2 (255). Lesions were identified using both reading modes in 48.3% (n = 836). 320 lesions seen in normal mode were missed using Omni Mode, of which 229 were P0, 66 were P1 and 25 were P2. When the viewing stream in Omni mode was evaluated, it was noted that only 4% (n = 13) of the missed lesions were removed from the reading stream (P0 5, P1 8, P2 0). A greater proportion of lesions were missed during standard reading, than when using Omni Mode (n = 516).
The average small bowel transit time was 4 hours and 22 mins (range: 23 mins-13h and 36 mins). Reading cases with the use of Omni Mode was significantly faster ($P < 0.0001$), with an average time saving of 29.1 mins. Cases read without the use of rapid reading software took an average reading time was 45.6 mins (6 to 181 mins), compared to 16.3 mins (3–63 mins) using Omni Mode.
Conclusion: These preliminary results suggest that Omni mode has an acceptable accuracy and is associated with a significant reduction in reading time. Missed lesions using the standard reading mode may be attributable to loss of concentration due to time spent and the tendency to use faster reading speeds.

Introduction: The visualization of the upper gastrointestinal tract with capsule endoscopy was not possible because of the large cavity of the stomach and the lack of controlled movements. The Ankon robotically controlled magnetic capsule endoscopy (MACE) system has been developed to investigate the stomach disorders. Our current prospective study aimed to evaluate the feasibility and safety of the Ankon MACE system in the visualization of the upper gastrointestinal (GI) tract in humans.
Aims and Methods: Our current prospective study enrolled 75 consecutive patients under the age of 40, with upper GI complaints or dyspepsia, but without any alarm symptoms. All subjects swallowed the Ankon MACE after drinking of one liter of clear water for gastric distension. An external robotic system with automatic preset programs applied to maneuver the MACE in the upper GI tract and generate a targeted magnetic field. The primary outcomes were the feasibility and safety of the MACE, including the quality of gastric preparation (excellent:4 good:3, moderate:2, poor:1), the level of visualization (complete, partially complete, none) of the Z line, the entire gastric mucosa (cardia, fornix, corpus, angulus, antrum), the duodenal bulb and the Vater papilla. We also assessed the feasibility of the esophageal withhold and active pyloric passage of the MACE with the targeted magnetic field.
Results: MACE was successful in all 75 patients with good to excellent visualization (mean score: 3,37) of the stomach and the entire small bowel without any complication or capsule retention. The visualization of the Z line was possible in 67/75 patients (89%), which was assessed as complete in 23 and partially complete in 44 patients. The mean stationary time for MACE in the esophagus was 1 min and 32 sec. Complete visualization of the cardia, fundus, corpus, angulus, antrum, and duodenal bulb was 95,4%, 100%, 100%, 100%, 100% and 100%, respectively. We were able to visualize the Vater papilla in only 20 patients. The possibility of successful pyloric passage of the MACE with the targeted magnetic field without administration of intravenous metoclopramide was possible in 55 patients (73%) within 60 minutes. Following MACE 10 patients underwent upper GI endoscopy to take histology due to the following pathologies detected by MACE, such as one patient with gastric lymphoma, three patients with hyperplastic polyps, five patients with severe erosive gastritis and one patient with peptic ulcer.
Conclusion: Our present study proved that robotically controlled MACE is easy to perform, non-invasive, safe method with excellent maneuverability in the upper GI tract, and has a future potential to detect and diagnose upper gastrointestinal disorders including oesophageal, gastric and small bowel pathologies.

P1485 INVESTIGATING IRON-DEFICIENCY ANEMIA WITHSMALL BOWEL CAPSULE ENDOSCOPY: IS HAEMOGLOBIN A RELIABLE PREDICTOR OF POTENTIALLY BLEEDING LESIONS?

M. Freitas, R. Magalhães, B.J.F. Rosa, J. Cotter
Gastroenterology Department, Hospital Senhora da Oliveira, Gastroenterology, Guimarães, Portugal

Contact E-Mail Address: martaspfreitas@gmail.com
Introduction: Capsule endoscopy (CE) is a first-line diagnostic tool for iron-deficiency anemia (IDA) evaluation after a negative bidirectional endoscopic study. Whether haemoglobin level is a predictor of potentially bleeding lesions (P2) in small bowel capsule endoscopy (SBCE) remains controversial.
Aims and Methods: Determine the influence of haemoglobin levels on diagnostic yield of SBCE for P2 lesions in patients with IDA.
Retrospective single-center study including consecutive patients submitted to SBCE over 12 years for IDA. The minimum value of haemoglobin observed between the diagnosis of IDA and the performance of the exam was considered. The lesions were described using Saurin et al. classification[(1)]
Results: 289 patients were included, 211 females (73.0%), mean age of 61.6 ± 18.7 years. The overall diagnostic yield was 60.6%, with identification of 100 P2 lesions (34.6%)
A statistically significant association was found between the presence of P2 lesions and age (68.3 ± 17.6 vs 58.1 ± 18.3, $p < 0.001$), male gender (36.0% vs 22.2%, $p = 0.02$), haemoglobin levels (8.6 ± 2.0g/dL vs 9.3 ± 1.7g/dL, $p = 0.003$), smoking habits (23.0% vs 12.7%, $p = 0.03$), alcoholism (10.0% vs 3.7%, $p = 0.04$), Charlson index (5.2 ± 3.2 vs 3.5 ± 3.4, $p < 0.001$), arterial hypertension (70.0% vs 49.7%, $p = 0.001$), chronic kidney disease (31.0% vs 19.6%, $p = 0.04$), heart failure (39.0% vs 20.1%, $p = 0.001$), chronic obstructive pulmonary disease (16.0% vs 7.4%, $p = 0.03$) and proton pump inhibitors use (62.0% vs 48.7%, $p = 0.04$). At logistic regression analysis only haemoglobin levels ($p = 0.02$) were independently associatedwith the diagnosis of P2 lesions. Although haemoglobin levels showed a weak discriminative capacity for the diagnosis of P2 lesions ($AUC = 0.60$, $p = 0.005$), values ≤ 7.7 g/dL were associated with a higher likelihood detection of P2 lesions.
Conclusion: Haemoglobin values may help guiding the decision to study the small-bowel in patients with IDA, since values ≤ 7.7g/dL are predictive of potentially bleeding lesions.
Disclosure: Nothing to disclose

P1486 BULKING AND LAXATIVE EFFECTS OF KIWIFRUIT DIETARY SUPPLEMENTATION: NOVEL MRI IMAGING INSIGHTS

N. Dellschaft[1], V. Wilkinson-Smith[2], C. Hoad[1], L. Marciani[2], P. Gowland[1], R. Spiller[2]

[2]*University of Nottingham, Digestive Diseases Centre and NIHR Nottingham BRC, Nottingham, United Kingdom*

Contact E-Mail Address: neele.dellschaft@nottingham.ac.uk
Introduction: Chronic constipation affects approximately 17% of the population worldwide and remains an important unmet need as patients are often dissatisfied with treatment. Kiwifruit may offer an alternative to traditional laxatives and have been shown to increase stool volume and frequency (1). Using novel validated non-invasive MRI techniques (2,3), we assessed fluid distribution in the small and large intestine and colon volumes.

Aims and Methods: A two-period crossover trial of kiwifruit versus control in adults without bowel disorders. Participants consumed two kiwifruit twice daily or an isocaloric control (28 gm maltodextrin drink) twice daily for 3 days. Participants underwent MRI scans on the third day, including a fasted scan, consumption of the two doses of test products and of two standardised test meals, altogether 9 hourly scans (baseline to 420 min after first meal). Participants attended visits 3 weeks apart.
Outcomes were small bowel water content (SBWC) and ascending colon T1 relaxation time (T1AC), volumes of the ascending, transverse and descending colon, gut transit time measured by the weighted average position score (WAPS) of markers ingested 24h before, stool frequency and Bristol stool form score and symptoms. All images were analysed blinded to intervention.
All data are reported as mean ± standard deviation. Paired tests were applied to area under the curve (AUC) summary measures.
Results: The study was completed by 14 participants, 6 male, 8 female, with a mean age of 26 (range 21–33) years.
SBWC AUC was markedly increased in participants consuming kiwifruit, 85.5 ± 34.9 l*min, as compared to control, 35.0 ± 15.6 l*min; $P < 0.001$.
T1AC was significantly higher after kiwifruit ingestion AUC (137 ± 39 s*min) as compared to control (108 ± 40 s*min, $P = 0.029$) when calculated for the period (T240-T420), representing the time period when the test product and first meal started reaching the colon.
Total colon volume AUC (baseline to T420) was increased in the kiwifruit arm (283.6 ± 59.4 l*min) as compared to the control arm of the study (243.2 ± 46.2 l*min, $P = 0.004$). This was primarily due to increased volumes of the ascending colon (kiwifruit 110.3 ± 26.1 l*min; control 92.4 ± 24.9 l*min; $P = 0.003$).
Transit time did not change ($P = 0.11$). Stool frequency was significantly increased during the kiwifruit week (1.60 ± 1.04 stools per day) compared to the control (1.22 ± 0.61 stools per day; $P = 0.02$), and baseline (1.26 ± 0.78; $P = 0.02$). The stool consistency scores were different between groups (X^2, $P = 0.005$), with looser stool consistency scores in the kiwifruit compared to both control ($P < 0.0001$) and baseline ($P = 0.002$).
There was no significant difference in scores for all symptoms (gas, nausea, abdominal pain, bloating) between the kiwifruit, control and/or baseline study periods.
Conclusion: The MRI data suggest that consumption of kiwifruit in healthy participants increases water retention in the small bowel and ascending colon, as well as increasing colonic bulk. The data is consistent with the observations of an increase in stool frequency and looser stool consistencies, suggesting that kiwifruit could be used as a dietary alternative to laxatives in mild constipation.
Disclosure: This study and Dr Dellschaft's post have been funded by Zespri, a consortium of kiwifruit growers.

[3]*Mater Dei Hospital, Gastroenterology, Msida, Malta*

Contact E-Mail Address: trevor.tabone@gov.mt
Introduction: The optimal surveillance protocol for incidental branch-duct intraductal papillary mucinous neoplasm (BD-IPMN) remains controversial to this day. Various international authorities have produced guidelines (such as the Fukuoka guidelines in 2017 and the more recently published guideline in 2018 by the European Study Group on Cystic Tumours of the Pancreas) with differing recommendations regarding frequency and duration of repeat imaging. This is partly because the risk of growth of BD-IPMNs lacking complex features and their association with concomitant development of pancreatic adenocarcinoma (PADC) is not yet fully understood due to the paucity of data available.
Aims and Methods: This retrospective study aims to establish the risk of growth of BD-IPMNs which lack features of complexity, according to baseline size on incidental imaging. All BD-IPMNs incidentally identified on cross-sectional imaging between 2007 and 2017 in a single-centre in Malta were included and subdivided according to size according to the revised international consensus Fukuoka guidelines: <10 mm, 10–19 mm, 20–29 mm and >30 mm. For those which had follow-up imaging, size comparison was carried out and the risk of concomitant development of PADC (distinct from BD-IPMN malignant transformation) was noted and compared with the Maltese general population.
Results: A total of 328 patients with BD-IPMNs were identified and categorised according to size as detailed in the table below.

	IPMN Size (mm)			
	<10	10–19	20–29	>30
Incidental number on imaging (n)	127	151	37	13
Follow-up imaging performed (%)	41.7 (n = 53)	41.7 (n = 63)	48.7 (n = 18)	53.8 (n = 7)
Average radiological follow-up period (months)	11.9	15.4	18.3	24.9
Increase in IPMN size on follow-up imaging (%)	7.5 (n = 4)	15.9 (n = 10)	5.6 (n = 1)	28.6 (n = 2)
Development of concomitant PDAC (%)	0.0 (n = 0)	3.2 (n = 2)	5.6 (n = 1)	0.0 (n = 0)

[Radiological follow-up outcomes in BD-IPMNs lacking complex features]
BD-IPMNs measuring <10 mm on incidental imaging increased in size in 7.5% of cases to a maximum of 2 mm during an average follow-up period of 11.9 months. This did not change patient management. The rate of growth in BD-IPMNs measuring 10–19 mm was 15.9% over a 15.4 month average follow-up period. The average increase in size was of 5.2 mm, with the largest difference being of 12 mm at 24-month follow-up. 3.2% (n = 2) of those radiologically followed-up developed concomitant PADC (at 17 and 24 months respectively), whilst 1.6% (n = 1) progressed into a mixed-type IPMN. Only 5.6% of BD-IPMNs measuring 20–29 mm increased in size during an average 18.3-month follow-up period.
Concomitant development of PADC was observed in 5.6% of radiologically followed-up patients. BD-IPMNs measuring >30 mm increased in size in 28.6% of followed-up cases. The lifetime risk of developing concomitant PADC in our cohort of 141 BD-IPMN patients with surveillance imaging was of 2.1% (1 in 48) whereas the general population-matched lifetime risk in Malta is 1.5% (1 in 68), resulting in a relative risk of 1.4. The risk increases further to 3.4% (1 in 29) when BD-IPMNs measuring <10 mm are excluded, with a relative risk of 2.3.
Conclusion: BD-IPMNs lacking complex features still harbour the potential for interval growth. The risk increases further with larger BD-IPMNs. The relative risk of concomitant development of pancreatic adenocarcinoma in our patient cohort was found to be higher than the general population. Given these findings, active long-term surveillance is warranted in all incidental BD-IPMNs, even in the absence of complex features, especially if over 10 mm in size.

Introduction: Patients presenting to the Emergency Room with abdominal pain frequently undergo urgent CT scans, often revealing bowel wall thickening (BWT). In the absence of guidelines to address the issue, endoscopic evaluation is carried out in most of them, while only a proportion of patient have significant pathology. The study aims to evaluate the clinical relevance of such BWT and assess predictors of significant pathology on endoscopic evaluation.
Aims and Methods: Patients referred to Gastroenterology Service from the Emergency Department at Hamad General Hospital with Bowel Wall thickening on CT scans between July 2015-July 2017 were retrospectively analyzed. Apart from the CT features, correlation of endoscopic findings to clinical presentation, laboratory parameters and histopathology were studied.
Inclusion Criteria:
1. Patients who underwent endoscopic evaluation were included in final analysis.
2. In the case of a negative endoscopy, patient had follow up of at least 6 months to exclude GI Condition.
3. Age > 16 years.
Exclusion Criteria:
1. Patients who have had endoscopy or biochemical markers done after 4 weeks of CT scan reporting of LGIO thickening were excluded from the analysis.
2. Patients with known GI Pathology (IBD, malignancy).
3. Evidence of luminal obstruction, stricture or mass on CT scan.
Results: 109 of 160 referred patients satisfied criteria for study inclusion. Endoscopic appearance was normal in 37/109(33.9%). Significant findings

confirmed as chronic pathology were found in 41/109(37.6%) patients. Of these 21(19.1%) had IBD {13 Crohn's Disease (11.9%), 8 Ulcerative Colitis (7.3%)}, 9(8.3%) had Tuberculosis, 11(10.1%) had malignancy. Mucosal abnormalities but normal or acute inflammation on histopathology were observed in 31/109(28.4%) patients. Segment based diagnosis and distribution in Table 1.
Age or gender had no correlation with significant findings. Symptom duration was the strongest predictor of significant endoscopic findings (> 2 weeks 25/35, 71.4%; <2weeks 16/74, 21.6%; $P < 0.001$). Features such as blood in stool, fever and weight loss were also positively associated with having significant findings.
Laboratory parameters: WBC, Hemoglobin, ESR, Albumin and CRP were not correlated with IBD. Mean Hemoglobin (10.5 ± 2.1 vs 12.8 ± 1.9; $P = 0.001$) and Albumin (27.5 ± 6.7 vs 35.4 ± 10.8; $P = 0.008$) were significantly lower in the malignancy group. Calprotectin was done in 36/109 patients. Mean Calprotectin was significantly higher with IBD and TB (199.5 ± 299.8 vs 809.8 ± 540.8; $P < 0.001$).
Four radiologically reported parameters – fat stranding, lymphadenopathy, vascular engorgement and pelvic free fluid-were analyzed from CT reports. Of these only fat stranding was associated with IBD or TB (20/46, 44% vs 10/52, 19%; $P = 0.009$).
Conclusion: One-third of study patients had significant pathology (IBD/TB/Malignancy). Two third of patients have a negative endoscopy or acute inflammatory findings on endoscopy. Prospective data may guide patient selection for endoscopic evaluation in patients with Bowel Wall Thickening on CT scans.

	Normal or Acute pathology	Crohns Disease (CD)	Ulcerative Colitis (UC)	Tuberculosis (TB)	Malignancy	Total

Introduction: It is difficult to detect and diagnose early carcinoma of the esophagogastric junction by conventional endoscopy or image-enhanced endoscopy. Recently, several fluorescent probes which are activated by cell surface-associated enzymes overexpressed in cancers have been developed. We have demonstrated that Glutamate-proline-hydroxymethyl rhodamine green (EP-HMRG), which can be enzymatically activated and becomes fluorescent after cleavage of a dipeptidylpeptidase (DPP)-IV-specific sequence, is useful for the detection of head and neck squamous cell carcinoma (Mizushima et al., *Head & Neck*, in press).
Aims and Methods: We investigated whether early adenocarcinoma of esophagogastric junction (EGJ) can be detected by applying EP-HMRG, using samples resected by endoscopic submucosal dissection (ESD).
Consecutive 12 patients underwent ESD for early adenocarcinoma of EGJ at 4 hospitals between May 2016 and July 2017 were recruited.
After ESD, fluorescence imaging was performed immediately after spraying EP-HMRG, and fluorescence intensity of tumor and normal mucosa regions of interest (ROI) was prospectively measured. Immunohistochemistry was also performed to investigate the expression of DPP-IV.
Results: The major histological type in the cases was differentiated type (10 differentiated type/2 undifferentiated predominant type). The lesions were located at E (4 cases), EG (2 cases), E = G (2 cases), GE (2 cases) and G (2 cases). Background mucosae around lesions were LSBE (1 case), SSBE (6 cases), normal squamous epithelium without Barrett mucosa (1 case) and gastric mucosa with atrophy and intestinal metaplasia (4 cases). In 11 out of 12 cases, tumor lesions became fluorescent within a few minutes after application of EP-HMRG. In cases with subsquamous tumor extension, point-like fluorescent lesions were observed at which cancerous glands were exposed over the squamous epithelium. Fluorescence intensity in the tumor lesions was significantly higher than that in the normal mucosa 7 min after spraying of EP-HMRG. Immunohistochemical examination demonstrated that the cancerous area, but not normal epithelium, strongly expressed DPP-IV. However, in a case with a history of previous radiotherapy, cancer legion did not become fluorescent, and did not express DPP-IV.
Conclusion: Fluorescence imaging with EP-HMRG would be useful for detection of early carcinoma of EGJ.

Introduction: Computed tomography colonography (CTC) is the gold standard radiological investigation for colorectal cancer screening. The Post-Imaging Colorectal Cancer (PICRC) rate (i.e. colorectal cancers that develop after a negative CTC) is a key quality indicator of CTC; however, PICRC rates have not been previously reported in a national screening programme.
The Word Endoscopy Organisation (WEO) has, through a consensus process, agreed a standard methodology for calculating PICRC rates to enable international benchmarking of rates (1). This rate (which the WEO terms PICRC-3y) is calculated by dividing the PICRCs detected 6 months to 3 years after a negative CTC (false negatives) by the sum of the true positives (defined by CTCs with a cancer diagnosis within 6 months) and false negatives (PICRCs). This study aimed to determine the rate of PICRC-3y in the English National Health Service (NHS) Bowel Cancer Screening Programme (BCSP).
Aims and Methods: Data from each BCSP CTC is entered into a national database, the Bowel Cancer Screening System. All colorectal adenocarcinomas, within and outside the BCSP, are validated and registered by the National Cancer Registration and Analysis Service. This retrospective observational study interrogated these databases to identify BCSP true positive and false negative CTCs. CTCs were included regardless of whether they were preceded or followed by a colonoscopy within a screening episode.

	True Positive CTC	False Negative CTC	To year end	PICRC-3y Rate
2006–2008	18	1	2009–2011	5.26% (95% CI 0.1–26)
2009	45	2	2012	4.26% (95% CI 0.5–14.5)
2010	55	5	2013	8.33% (95% CI 3.6–18.1)
Total	118	8		6.35% (95% CI 2.8–12.1)

[Results]

Results: Of the 8 PICRCs, 3 were detected at subsequent BCSP procedures, one at 1 year surveillance, and 2 following re-invitation for screening at 2 years. Five were detected outside the BCSP.
Conclusion: 1. The PICRC-3y in the BCSP is 6.35%, higher than the rate in the published literature (4.4%)(2) and the corresponding rate for Post Colonoscopy Colorectal Cancer (PCCRC) over the same period (2.5%).
2. CTC is commonly reserved for patients who are either deemed unsuitable for colonoscopy, or in whom colonoscopy has failed, meaning that there are likely to be substantial differences between the populations undergoing each examination.
3. Because CTC and colonoscopy are performed in different populations, those having CTC more likely to be frailer with greater co-morbidity, the higher rate of PICRC when compared to colonoscopy may relate to the difficulty of investigating such patients, who may not be fit enough for, or refuse an intervention even if a lesion is found.

P1491 IN VIVO DIAGNOSIS OF FOOD ALLERGY WITH CONFOCAL ENDOMICROSCOPY

T. Rath, R. Atreya, J. Siebler, M.F. Neurath, Y. Zopf
University Hospital Erlangen, Ludwig Demling Endoscopy Center of Excellence, Erlangen, Germany

Contact E-Mail Address: timo.rath@uk-erlangen.de
Introduction: The immune-mediated adverse reaction to food is defined as food allergy, which can be divided into IgE mediated or non-IgE mediated food allergy. In the majority of cases, white light endoscopy is unremarkable in patients with food allergy and hence, obtaining several biopsies within the upper and lower GI tract is an integral part in the work-up of suspected food allergy. Within this study, we aimed to assess the potential of probe-based confocal laser endomicroscopy (pCLE) as an advanced endoscopic imaging technique allowing for in vivo microscopic imaging of the intestinal mucosa for the diagnosis of food allergy.
Aims and Methods: 29 Patients with suspected food allergy manifesting with dietary-induced abdominal pain and diarrhea were included. From all patients detailed clinical information were obtained including parameters of food allergy or intolerance and diagnostic criteria of irritable bowel syndrome. In all patients ileocolonoscopy was performed using high-definition endoscopes with digital chromoendoscopy. Intestinal lavage with quantification of a large panel of markers of food allergy or intestinal inflammation including TNF, food specific IgE and eosinophilic cationic protein was performed in the terminal ileum, the caecum and the rectosigmoid junction in all patients. At these sites real-time microscopic imaging with pCLE was performed after intravenous contrast with 10% fluorescein.
Results: Of 29 patients (mean age 53 years) with suspected food allergy manifesting with dietary induced abdominal pain and diarrhea, diagnosis of food allergy was established in 19 patients (65.5%). In both, patients with and without proven food allergy, high-definition endoscopy revealed macroscopically normal mucosa. However, in patients with food allergy and macroscopically normal mucosa, pCLE showed increased cellular infiltrates within the lamina propria with crypt distension as well as vascular alterations with dilated and tortuous vessels and increased vascular branching compared to those without proven food allergy. Further, patients with food allergy exhibited signs of barrier dysfunction with increased epithelial cell shedding, epithelial gaps and erosions with fluorescein leakage into the lumen compared to patients without food allergy.
Conclusion: Patients with food allergy exhibit signs of microscopic inflammation and structural barrier dysfunction in macroscopically intact mucosa during pCLE. Thus, pCLE holds the potential to facilitate in vivo real-time diagnosis of suspected food allergy.

Introduction: Gastric cancer is one of the most common malignancies worldwide. The accurate diagnosis of tumor invasion depth is critical for therapeutic strategy and prognosis. Without fluorescent label, multiphoton imaging (MPM) could directly reveal tissue architecture based on two-photon excited fluorescence (TPEF) and second harmonic generation (SHG). In this study, we aimed to explore the feasibility of MPM to assess the gastric tumor morphology and infiltration.
Aims and Methods: Unstained slides of 18 fresh gastric tissues with different T staging were examined by multiphoton microscopy. Morphological and quantitative analysis were studied. Nuclear area was defined as the area of nuclear boundary. Collagen content was the ratio of the SHG pixels over whole pixels.
Results: Gastric normal and tumor tissues under different T stages were visually presented with cellular and subcellular features on fluorescent imaging. Nuclear area of normal and cancerous cells were $32.01 \pm 2.89\mu m^2$ and $58.41 \pm 6.06\mu m^2$ ($P < 0.001$). Collagen contents were quantified by 0.087 ± 0.012 in normal mucosa but 0.020 ± 0.007 in cancerous mucosa ($P < 0.001$). All results were correlated well with the paired H&E stained slides.
Conclusion: Our findings suggested the convincing potential of MPM for judging T staging of gastric cancer. Without staining intervention, TPEF and SHG on MPM could objectively and quantitatively indicate the subcellular and molecular changes during carcinogenesis. With the advancement of deep penetration, self-focus imaging and 3D visualization, label-free multiphoton imaging compacted with endoscopy could be further introduced to realize a real-time in vivo assessment of tumor invasion clinically.

P1493 DO WE UNDERESTIMATE THE ROLE OF HYPOTHALAMIC-PITUITARY-ADRENAL AXIS ACTIVATION BY GLP-1/GLP-1 RECEPTOR AGONIST TREATMENT? FIRST DATA FROM GLP-1 RECEPTOR POSITRON EMISSION TOMOGRAPHY OF THE HUMAN PITUITARY

M. Gotthardt[1], **M. Boss**[1], L. Deden[1], J. Booij[1], M. Brom[1]
[1]*Radboud University Medical Center, Department of Radiology and Nuclear Medicine, Nijmegen, Netherlands*

Contact E-Mail Address: marti.boss@radboudumc.nl
Introduction: We have developed a technology for in vivo imaging of the GLP-1 receptor (GLP-1R) using Ga-68-NODAGA-exendin for PET/CT (positron emission computed tomography / computed tomography), This technology enables non-invasive in vivo quantification of radiotracer uptake into tissues, representing a measure for GLP-1R density. During clinical studies measuring beta cell mass with this technology in patients with diabetes, we have observed a high uptake into the dorsal pituitary. Here, we analyse the first in human imaging data of the pituitary and formulate a hypothesis concerning the role of pituitary GLP-1R signalling.
Aims and Methods: Pituitary uptake in Ga-68-NODAGA-exendin for PET/CT scans obtained in prospective clinical studies in patients before and after bariatric surgery was quantified. Patients with type 2 diabetes (T2D) and morbid obesity (body mass index (BMI) >40 or BMI >35 with co-morbidity) prior to or 1 year after bariatric surgery were included. PET/CT from pelvis to skull was performed one hour after injection of 100 MBq of Ga-68-NODAGA-exendin. The maximum standardized uptake value (SUVmax) was measured in a volume of interest (VOI) placed in the sella turcica.
Results: To date, we have collected data from 4 patients after bariatric surgery (the last patients from a finalized cross sectional analysis pre/post bariatric surgery) and 9 patients before bariatric surgery (from an ongoing longitudinal study). Analysis of these data revealed a marked inter-individual difference in the pituitary uptake but also a clearly higher uptake in patients prior to bariatric surgery. The uptake ranged from 0.83 to 2.8 (average 1.81 ± 0.99) in the post bariatric surgery group and from 1.9 to 9 (average 4.5 ± 2.46) in the pre bariatric surgery group, with only a slight overlap between groups. No uptake in other areas of the central nervous system has been observed in any of the patients.
Conclusion: Although the number of patients analysed so far is limited and we have switched to whole-body scanning only during a running a cross-sectional study in order to assess the tissue distribution of GLP-1R in humans, the high radiotracer uptake indicates towards a highly relevant physiological action of GLP-1 in the pituitary. We hypothesise that the pituitary is an important target for GLP-1R signalling to the central nervous system and that in morbidly obese individuals or individuals with poorly controlled diabetes, the hypothalamic-pituitary-adrenal (HPA) axis is highly sensitive to GLP-1-mediated activation (Sharma et al 2014; Chiodinin et al 2006). The pituitary uptake may be directly related to increased cortisol levels in obese T2D patients and may predict failure or even contradictory effects of GLP-1 receptor agonist (GLP-1RA) treatment (Mikulaskov et al 2016, Diz-Chavez et al 2016). Furthermore, GLP-1R expression levels seem to decrease after bariatric surgery, which may indicate towards reduced HPA axis activity, potentially explaining in part weight loss and improved glycaemic control. Due to the close anatomical proximity and the limited spatial resolution of PET/CT, binding of Ga-68-NODAGA-exendin to the infundibular nucleus of the hypothalamus (IFN) is an alternative to neuropituitary binding. Further studies are warranted to exactly determine the role of GLP-1R signalling in the pituitary/IFN, including the correlation of pituitary/IFN uptake of Ga-68-NODAGA-exendin with cortisol production, glycaemic control, body weight (loss) and other important parameters.
Disclosure: Martin Gotthardt is patent holder for exendin analogs for imaging

Introduction: MRI is increasingly used to assess gastrointestinal motility and post-processing methods add value through objectively assessing the presence or absence of contractile activity. Such metrics often do not offer insights into the nature of contractile action, rather their presence or absence. Greater insight may be needed to determine how changes in contractile frequency, amplitude or contraction length may be associated with gastrointestinal symptoms. The objective of this study was to provide preliminary validation of an MRI based method to generate a spatio-temporal map of contractile activity in the stomach and colon.
Aims and Methods: Two cohorts of subjects were selected displaying 1) gastric ($n=24$) and 2) colonic motility ($n=20$). Subject preparation and disease status was heterogeneous to provide a spectrum of motility on which to test the spatio-temporal motility assessment technique. The technique involved delineating the bowel lumen along with inner and outer bowel wall along a chosen section of the gastrointestinal tract. A series of diameter measurements were made automatically at a 2mm interval orthogonal to the central axis of the lumen. These measurements were automatically propagated through the time series using a previously validated image registration algorithm. Contractions were quantitatively summarised with two methods measuring 1) Normalised Contraction Plot (NCP) and 2) Combined Velocity Distance (CVD). Both metrics were correlated against a three-point subjective but consensus scoring system for the gastric data and a previously validated numerical, semi-quantitative scoring system for the colonic data.
Results: Good correlation was seen between reader scores and both motility metrics (NCP, $R=0.85$, $P<0.001$, CVD, $R=0.93$, $R<0.001$) in the gastric data. Good correlation was also seen between the reader scores and the two metrics in the colonic data (NCP, $R=0.82$, $P<0.001$, CVD, $R=0.78$, $R<0.001$).
Conclusion: Spatio-temporal mapping of the stomach and colon correlates well with reader scores in a range of datasets and provides both a quantitative and qualitative means of assessing contractile activity in the gastrointestinal tract.

P1495 SHORT- TERM AND LONG-TERM OUTCOMES OF SELF-EXPANDABLE METALLIC STENT PLACEMENT AS A BRIDGE TO SURGERY FOR MALIGNANT COLONIC OBSTRUCTION

Y. Miyasako[1], Y. Sumida[1], T. Takasago[1], T. Kuwai[1], H. Konishi[1], K. Tao[1], R. Miura[1], K. Kuroki[1], Y. Tamaru[1], A. Yamaguchi[1], H. Kouno[1], H. Kohno[1]
[1]*Kure Medical Center And Chugoku Cancer Center, Gastroenterology, Kure, Japan*

Contact E-Mail Address: yuki.mm1231@gmail.com
Introduction: In Japan, self-expandable metallic stent (SEMS) placement for malignant colorectal obstruction has been performed from 2012. However, SEMS placement as a bridge to surgery (BTS) is not recommended in the European Society of Gastrointestinal Endoscopy Clinical Guideline. Additionally, malignant effects of SEMS placement as BTS on long-term outcomes have not been broadly recognized. Therefore, we retrospectively reviewed the records of patients to clarify the safety and efficacy of SEMS placement and short-term and long-term outcomes of BTS.
Aims and Methods: Three-hundred-ninety-two patients who underwent surgery for colorectal cancer (pStages II, III, and IV) in our hospital from May 2012 to August 2017 were reviewed. Of the 392 patients, 54 patients with malignant colorectal obstruction underwent BTS (group A), and 338 patients without malignant colorectal obstruction underwent surgery (group B). First, we evaluated short-term outcomes of the BTS group. Second, we compared long-term outcomes between the two groups as the 3-year overall survival (3yOS) and 3-year disease-free survival (3yDFS) rates for each stage.
Results: Patients' mean ages were 70 years (group A) and 73 years (group B), and the male-to-female ratios were 25:29 (group A) and 182:156 (group B). Tumor sites (cecum/ascending/transverse/descending/sigmoid/rectum) were 2/6/5/8/32/1 (group A) and 37/58/35/16/135/57 (group B). The pStages (II/III/IV) were 21/19/14 (group A) and 153/120/65 (group B), with no significant differences between the groups. Regarding SEMS placement in group A, technical and clinical success rates were 98% (54/54) and 92% (53/54), respectively. Colonoscopy for preoperative evaluation of the proximal colon was performed in 45 patients (83.3%), and synchronous multiple cancers in the proximal colon were found in 8 patients (14.8%). The only severe complication of SEMS placement was one case of perforation due to obstructive colitis. Regarding long-term outcomes, 3yOS/3yDFS rates were 95%/83.1% (group A) and 88.0%/81.9% (group B) in pStage II, and 66.2%/57.3% (group A) and 87.2%/66.2% (group B) in pStage III. The 3yOS rates were 42.0% (group A) and 35.1% (group B) in pStageIV. No significant differences were observed between the groups in long-term outcomes (median follow-up periods were 763 days in group A and 738 days in group B), using the Kaplan-Meier method and long-rank test.
Conclusion: SEMS placement can be effectively and safely performed, and contribute to preoperative evaluation of the proximal colon. According to long-term outcomes, the BTS group was not inferior to the normal surgery group despite the higher malignant potential due to malignant colorectal obstruction. These findings suggest that the malignant effects of SEMS placement as BTS on long-term outcomes may be small in cases in which the perforation rates were low.

P1496 THE BOUGIECAP: A NEW METHOD FOR TREATMENT OF OESOPHAGEAL STRICTURES

B. Walter[1], S. Schmidbaur[1], I. Rahman[2], A. Hann[1], P. Duarte[2], A. Meining[1]
[1]*Ulm University, Department of Internal Medicine I, Ulm, Germany*
[2]*University Hospital Southhampton, Gastroenterology, Southhampton, United Kingdom*

Contact E-Mail Address: benjamin.walter@uniklinik-ulm.de
Introduction: Non-malignant strictures in the upper GI tract are often treated endoscopically by using polyvinyl Savary-Gilliard dilators. However, the drawbacks to this technique are the lack of direct optical feedback of the bougienage and the need for fluoroscopic guidance during the procedure. A novel device, BougieCap (Ovesco, Tuebingen, Germany), allows direct optical control of bougienage.
Aims and Methods: Patients with a benign stenosis of the oesophagus and with clinical symptoms of dysphagia were recruited from two endoscopy centres for planned dilatation with the BougieCap. The device, which is a single-use transparent conical cap, is fixed to the tip of the endoscope. Different sizes for standard gastroscopes and pediatric scopes are available. For the bougienage procedure the endoscope is inserted and positioned in front of the stenosis. Under direct vision, pushing forward with the endoscope enables the conical cap to dilate the mucosa in the area of the stenosis by the conversion of longitudinal force vectors into radial force vectors. Endoscopic procedure could be repeated sequentially with a larger sized cap if necessary. Primary endpoint of the study was success of endoscopic dilatation. Secondary endpoint was improvement of symptoms of dysphagia as assessed by Dysphagia Handicap Index (DHI) before and 14 days after bougienage (dysphagia score 0: No dysphagia: able to eat normal diet; 1: Moderate passage: able to eat some solid food; 2: Poor passage: able to eat semi-solid foods; 3: Very poor passage: able to swallow liquids only; 4: No passage: unable to swallow anything).
Results: 23 patients (m/f, 11/12) underwent the procedure, mean age was 69.9 years (±18.7). Etiology of strictures was peptic (n = 9), radiation (n = 8), anastomosis (n = 3), caustic ingestion (n = 2) or unknown (n = 1). Median diameter of strictures was 9 mm (±2.3). Successful dilatation with BougieCaps was possible in 91% (n = 21). Symptoms of dysphagia decreased from a mean dysphagia score of 3.0 (±0.6) before endoscopic treatment to 1.7 (±0.7) 14 days after treatment (Mann-Whitney, $p<0.0001$). A stiff guide-wire was used in 4 cases to aid with bougienage, exclusively using a pediatric scope. In two cases with a narrow stricture and no usage of guide wire treatment failed as a result of high resistance at the site of stricture causing buckling of the endoscope in the pharynx. On average 2.3 (±0.2) BougieCaps of subsequent sizes were used per patient. No severe complications were reported. Adverse events were loss of 2 BougieCaps in the stomach causing no symptoms.
Conclusion: Endoscopic treatment of benign stenoses using the BougieCap enables direct visual control of the bougienage procedure and therefore of mucosal damage within the area of strictures. This might help to adapt endoscopic treatment even more precisely to the stricture. Symptoms of dysphagia are improved in short-term follow-up. Additional wire guidance is reasonable for selected cases (narrow lumen, pediatric scope).
Disclosure: Nothing to disclose

P1497 SHORT AND LONG-TERM RESULTS OF SELF-EXPANDABLE METAL STENTS FOR ACUTE MALIGNANT COLORECTAL OBSTRUCTION

R. Morais[1], C. Coelho[2], E. Rodrigues-Pinto[1], F. Vilas Boas[1], P. Moutinho Ribeiro[1], S. Lopes[1], P.R. Pereira[1], G. Macedo[1]

Contact E-Mail Address: ruimorais20@gmail.com
Introduction: Self-expandable metal stents (SEMS) are widely used as an alternative to surgery for palliation purposes or as bridge-to-surgery (BTS) in acute malignant colorectal obstruction (MCRO), despite concerns about the effect of stenting on adverse events (AEs) and long-term survival.
Aims and Methods: Our aim was to evaluate SEMS clinical success, AEs and impact on short and long-term outcomes.
We performed a retrospective study from 92 consecutive patients with acute MCRO that placed SEMS in a tertiary center between January 2010 and December 2017.
Results: Forty-nine patients placed SEMS as BTS and 43 for palliative purposes. The median age of the patient population was 69 years (IQR 61–79), and 55.4% of the patients were male. Most of the obstructions (96.7%) were on the left colon. At the time of the procedure, based on additional imaging studies after colonic stenting and perioperative findings, 72.8% of patients (n = 67) had lymph node invasion and 58.7% (n = 54) had metastatic disease. Long-term clinical

success was achieved in 84.8% of the patients, with no significant differences between palliation and BTS groups (81.4% vs. 87.8%; p = 0.562). Clinical success was higher when tumor location other than sigmoid (94.3% vs. 78.9%; p = 0.047) and when shorter SEMS (< 110 mm) were placed (100% vs. 64%; p = 0.002). Immediate and post-procedure AEs occurred in 6.5% and 17.3% of the patients, respectively, with no significant differences between the palliative and BTS group. The main post-procedure AEs were perforation (n = 6) and stent re-obstruction (n = 6). Nineteen percent of the palliative cohort were considered clinical failures, with 87.5% of them requiring further surgery; 11.6% of the palliative group were left with a permanent stoma; surgery-related AEs did not occur in patients with previous SEMS AEs; the occurrence of SEMS AEs did not influence overall survival. Twelve percent of the patients in the BTS group were considered clinical failures. Surgery was performed after a median time of 10 days (IQR 7–17) and was urgent in 12.2% of the patients; 16.3% of the BTS group were left with a permanent stoma. SEMS immediate (p = 0.542) and post-procedure AEs (p = 0.360) were not associated with tumor recurrence. Patients with post-procedure SEMS AEs had an inferior overall survival (median: 161 vs. 1592 days; p = 0.047). In the multivariate analysis, only SEMS-related AEs were independently associated with overall survival estimation (HR 4.06, 95% CI 1.2–13.7; p = 0.024).

Conclusion: SEMS allow relief of acute MCRO; yet, AEs are seen in almost 20% of patients. Main contributors for surgery after stent failure are perforation and stent re-obstruction. SEMS should be the first line option for palliation even in patients with longer life expectancy. In the BTS setting, SEMS-related AEs decrease survival.

Disclosure: Nothing to disclose

P1498 TWO DECADES AFTER THE FIRST, WHAT ARE THE OUTCOMES OF DUODENAL STENTING: EXPERIENCE OF A FRENCH TERTIARY CENTER ABOUT 220 CASES

J.-P. Ratone[1], **F. Caillol**[1], C. Zemmour[2], E. Bories[1], C. Pesenti[1], V. Lestelle[1], S. Hoibian[1], S. Godat[1], A. Proux[3], G. Capodano[3], M. Giovannini[1]

Introduction: Malignant gastric outlet obstruction (MGOO) often complicates the natural history of pancreatic adenocarcinoma but not only. However, the use of gastroduodenal self-expandable metal stents (GD-SEMS) has improved life's quality of these patients. In current practice, the effectiveness of these GD-SEMS seemed imperfect and we wanted to report our results including all neoplastic diseases.

The main aim was to evaluate patients' diets using the level of oral intake score (LOIS, 0: no oral intake, 1:liquids only, 2:soft solid, 3:full diet). The secondary endpoints were the evaluation of the complication rate, the median survival, the endoscopic duodenal reintervention rate, the endoscopic biliary reintervention rate, as well as the attempt to identify groups where the efficiency would be better or worse.

Aims and Methods: We retrospectively included all patients who underwent one or more GD-SEMS between January 2011 and December 2016 in our center (Paoli-Calmettes Institute Marseille, France). All datas was calculated using the computerized record of each patient including dietary assessments and medical observations.

Results: We included 220 patients (women = 56%, mean age = 67 [29–94]). Median time of hospitalization was 7 days [1–52]. 50% of patients had pancreatic adenocarcinoma and 50% had another malignant disease. WHO score was inferior at 3 in 122/220 cases (56%). The two most frequent locations of MGOO are second duodenum (91/220 = 41%) and genu superius (46/220 = 21%). 66% of the patients (145/220) had already undergone oncological treatment before the first stent placement and 34% (75/220) had received no treatment. Median LOIS before GS-SEMS was 0[0–2]and median LOIS after was 2[0–3]. Median increase of LOIS was 2 ($p < 0.001$). This increase of LOIS patients was more important for patients with general state preserved (WHO score < 3): 1.90 vs 1.40; $p < 0.001$. The complication rate was 2%(4/220) with 3 perforations. The median survival was 4 months. At 1 month, the duodenal reintervention rate and the biliary reintervention rate were respectively 27% and 19%. During follow-up, 150/220 (68%) patients needed only one duodenal procedure and 70/220 (32%) needed multiple duodenal procedures. The median permeability of GD-SEMS was 2.3 months and GD-SEMS was significantly more longer effective in the WHO score < 3 group versus WHO score > 2 group (3.81 vs 1.51; $p < 0.001$). Median permeability was also better significantly in the subgroup oncologic treatment post GD-SEMS than subgroup no oncologic treatment post GD-SEMS (4.76 vs 1.25; $p < 0,01$). No significantly difference was observed between subgroups pancreatic cancer and other malignant diseases (2.37 vs 2.17; p = 0.733).

Conclusion: Our study is in agreement with the data of the literature. GD-SEMS are, thought imperfect, effective on dysphagia with a low risk of complications (2%). Unlike the clinical impression we had, multiple endoscopic procedures are not systematic since they concern only 32% of patients. The duration of hospitalization is relatively long probably because it is about fragile patients whose duodenal stricture is not the only health problem. Given the very low median survival (4 months), this endoscopic treatment seems to always be adequate or even sufficient in most cases. However, the subgroup analysis makes it possible to identify a subgroup for which the efficiency is better and more durable (WHO score < 3, palliative chemotherapy post GD-SEMS). This subgroup could represent in the future the good candidates for endoscopic bypass.

Introduction: Sleeve leak is the most feared complication after laparoscopic sleeve gastrectomy (LSG), causing significant morbidity and mortality. Endoscopic treatment with fully covered self-expandable metal stents (FC-SEMS) may offer a useful non-invasive approach in this setting. BETA^{TM} esophageal stents (Taewoong Medical Co., Gyeonggi-do, South Korea) are FC-SEMS specifically designed for post-bariatric leaks to reduce risk of migration. Moreover, endoscopic suturing with APOLLO OverStitch^{TM} has been described as a therapeutic approach for large gastrointestinal leaks.

Aims and Methods: In this study, we aimed to report our experience in managing post- LSG leaks with BETA^{TM} esophageal stents with or without previous endoscopic suturing. We retrospectively reviewed all cases of endoscopic management of post-LSG leaks with BETA^{TM} esophageal stents and APOLLO OverStitch^{TM} suturing system referred at our institution from June 2014 to July 2017. Type of endoscopic treatment, number of procedures, outcome and complications were analyzed.

Results: Thirteen patients treated using BETA^{TM} esophageal stents for post-LSG were included in this retrospective analysis. Eight patients (61.5%) received previous unsuccessful endoscopic treatments (pig-tail plastic stent, clips, conventional FC-SEMS). Eight patients (61.5%) who presented with larger leaks underwent a combined endoscopic approach with both endoscopic suturing and BETA^{TM} stent, while 5 patients (38.5%) with smaller leak were treated using only BETA^{TM} stent. The overall success rate was 92.3% (12/13). One patient finally underwent gastrectomy after failure of multiple endoscopic procedures. A total of 16 BETA^{TM} stent were placed, which were left in place for a median of 27 days (range 16–53). No stent migration or serious adverse events were observed during a mean follow-up of 3.6 months (range 0–11).

Conclusion: In our experience, endoscopic management of post-LSG leaks with BETA^{TM} is safe and effective, with high rate of clinical success and no significant adverse events. The combined approach with APOLLO OverStich^{TM} endoscopic suturing system seems safe and effective in case of larger leaks. Further multicentric randomized controlled trial are needed to confirm these data.

[2]*Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh, India*

Contact E-Mail Address: sarthakmalik87@gmail.com

Introduction: Peptic ulcer disease (PUD) related gastric outlet obstruction (GOO) is known to respond favourably to endoscopic balloon dilation (EBD). However, data on efficacy of EBD for other etiologies of benign GOO is sparse.

Aims and Methods: We aimed to compare response of EBD among different etiologies of GOO.

Records of all patients with benign GOO who underwent EBD at our tertiary care centre between January 1998 to December 2017 were analysed. Dilation was done using through-the-scope balloons. Procedural and clinical success of EBD was compared amongst different etiologies.

Results: A total of 306 patients were evaluated, of whom, 264 (mean age – 37.89 ± 17.49; males – 183, females – 81) underwent dilation. Etiologically caustic ingestion was the commonest cause of GOO (53.8%) followed by drug abuse (21.6%) and PUD (12.87%). Overall procedural and clinical success was achieved in 200 (75.7%) and 243 (92.04%) patients respectively requiring a mean (SD) of 2.55 (2.81) and 5.37 (3.98) sessions respectively. Caustic related GOO responded less favourably, requiring a higher number of dilation sessions and having more refractory strictures than other etiologies. Drug induced GOO performed worse than PUD related GOO. Of the 264 patients, 9 (3.4%) had perforation during EBD, 3 of them had contained leak and were managed conservatively, while 6 patients underwent successful surgery.

Conclusion: EBD is successful in a majority of patients with benign GOO, with caustic-GOO and drug-induced GOO being more different than PUD-related GOO

Introduction: Benign oesophageal stricture is a rare condition which can result from various causes such as peptic or caustic oesophagitis, radiation, or anastomosis. Endoscopic dilation is an effective treatment nowadays and can be performed in different manners. The aim of our work is to report the experience of our gastroenterology unit in a Moroccan university hospital concerning dilation of benign oesophageal stricture and to compare hydrostatic dilation with Savary Gillard bougie dilation.

Aims and Methods: The prospective study was led between January 2009 and January 2018 and included 130 patients with benign oesophageal strictures. We compared the outcome of two groups of patients following the method used (Group 1: bougie dilators, Group 2: balloon dilation). We studied the correlation between the number of sessions, the long-term outcome and each method. We used the chi-squared test and Fisher test for the study with a p-value <0.05. Propofol sedation was used for all the patients.

Results: Within 130 patients, 39% were male, and 61% were female. The average age was 42 years. Oesophageal strictures were from peptic origin in most of the cases (34.6%), followed by Plummer-Vincent syndrome in 31.5%, anastomotic strictures in 13%, post radiation strictures in 8.4%, and caustic strictures in 12%. One case of mycotic stenosis was reported in a HIV-positive patient. Group 1 (bougie dilators) included 111 patients (86%) and Group 2 (balloon dilation) included 19 patients (14%). 270 sessions of dilation were realized with an average of 2.2 sessions per patient (from 1 to 10). No complication was noted, and the success rate was 95% and 5% underwent surgery.

Comparing the two groups for the number of dilation sessions needed did not yield a significant correlation ($p=0.359$). The correlation between the two groups for the long term outcome was also not significant. A significant correlation was found between the type of stricture and the number of dilation sessions needed ($p=0.02$). Strictures caused by the Plummer-Vincent syndrome and peptic ones needed the least number of dilation sessions (more than 50% of patients did not need more than 2 dilation sessions) and had all a satisfying result (100%). Multivariate analysis between the type of stricture and the long term outcome yielded a significant correlation ($p < 0.05$).

Conclusion: Endoscopic dilation of benign oesophageal strictures is an efficient technique, especially in the case of Plummer-Vincent Syndrome and peptic strictures. Complications are rare if the procedure is followed properly. In our study, results confirmed that endoscopic dilation is a safe and efficient treatment for dysphagia. Bougie dilators remain also the most used technique in our experience.

[2]*Jiangsu Province Hospital, Gastroenterology Department, Nanjing, China*

Contact E-Mail Address: lixuan20091225@163.com

Introduction: Lymph node metastasis (LNM) is the most important risk factor for endoscopic surgery in early gastric cancer (EGC) patients. We aimed to investigate the rate of LNM, analyze the endoscopic and clinicopathological features related to LNM, and investigate risk factors of EGC with LMN.

Aims and Methods: A total of 10039 patients and underwent gastrectomy with lymphadenectomy were reviewed between January 2010 and December 2015 at Jiangsu Province Hospital in China. Among them, we identified 1004 (10%) EGCs. First, endoscopic and clinicopathological features related to LNM were analyzed, then risk factors for LNM were identified using univariate and multivariate analysis. Finally, a nomogram for predicting LNM was established and validated.

Results: LNM occurred in 123 (12.3%) EGC. Most of EGCs were male ($n=720$,71.7%) and mean age was 59.65 ± 11.09 years. The rate of *H.pylori* infection was 78.0%(783/1004). LNM was significantly associated with age, sex, location, lesion size, macroscopic type, depth of invasion, differentiation type, histological morphology, lymphovascular invasion (LVI) and TMN stage. By multivariate analysis, significant independent risk factors for LNM in EGC were identified as following, male sex (OR 2.365, 95% CI 1.064–5.257, $P=0.035$), depressed type (OR 2.721, 95% CI 1.232–6.008, $P=0.013$), submucosa invasion (OR 2.987, 95% CI 1.100–8.111, $P=0.032$), LVI (OR 5.186, 95% CI 1.751–15.366, $P=0.003$), tumor located in corpora (OR 8.904, 95% CI 1.029–77.07, $P=0.047$), tumor located in angle (OR 12.998, 95% CI 1.400–120.677, $P=0.024$). Moreover, a predictive nomogram with these independent factors for LNM in EGC patients was constructed. After external validation, the AUROC curve for predicting LNM was 0.863, respectively.

Conclusion: EGC were investigated in 10.0% of gastric cancer, which LNM occurred in 12.3% of EGC. Independent risk factors of LNM included male sex, macroscopic type, the depth of invasion, LVI and tumor located in corpora or angle. A nomogram was successfully established, which may help to predict LNM in patient with EGC and evaluate endoscopic submucosal dissection feasibility in EGCs.

Introduction: Radical gastrectomy is the cornerstone of the treatment of locally advanced gastric cancer. An irradical resection, i.e. gastrectomy with a tumor-positive resection margin, is seen in approximately 1.8–8.4% of patients.[1]

Aims and Methods: This study aimed to evaluate factors associated with a tumor-positive resection margin after gastrectomy and to evaluate the influence of hospital volume.

In this national cohort study, patients with junctional or gastric cancer that underwent curative gastrectomy between 2011–2017 were included. The primary outcome was irradicality of the operation defined as the microscopic presence of tumor cells at the resection margin. The association of patient- and disease characteristics with irradicality was tested with multivariable regression analysis. The association of annual hospital volume with irradical resections was tested and adjusted for the patient- and disease characteristics.

Results: In total, 2799 patients were included. An irradical resection was seen in 265 (9.5%) patients. Factors associated with irradicality were: tumor located in the entire stomach (OR[95%CI]: 3.38[1.91–5.96] reference: gastro-esophageal junction), cT3, cT4, cTx (1.75[1.20–2.56], 2.63[1.47–4.70], 1.60[1.03–2.48], reference: cT0-2), pN+ (2.73[1.96–3.80], reference: pN-), and diffuse and unknown histological subtype (3.15[2.14–4.46] and 2.05[1.34–3.13], reference: intestinal). Unknown differentiation grade was associated with a decrease risk for an irradical resection (0.50[0.30–0.83], reference: poor differentiated/undifferentiated). Compared to a hospital volume of <20 resections/year, 20–29 and >39 resections was associated with lower probability for irradicality (OR 0.56[0.42–0.76] and 0.34[0.18–0.64]).

Conclusion: Tumor location, cT, pN, histological subtype and tumor differentiation are associated with irradicality. The association of irradicality with an annual hospital volume of <20 resections may underline the need for further centralization of gastric cancer care in the Netherlands.

Introduction: To standardize outcome reporting in esophageal surgery, the Esophageal Complications Consensus Group (ECCG) developed a standardized platform. Recently, this group published outcomes of 2704 patients that underwent an esophagectomyin 24 high-volume hospitals in the period 2015–2016.

Aims and Methods: The aim of this study was to report postoperative morbidity and mortality in the Netherlands using the definitions of the ECCG. All patients who underwent esophagectomy for cancer of the esophagus or esophagogastric junction in the Netherlands in 2016 were selected from the Dutch Upper gastrointestinal Cancer Audit (DUCA). Patient outcomes including postoperative complications, 30-day/in-hospital mortality and readmission rate were reported according to the definitions of the ECCG platform.[1] Outcomes of the DUCA were compared with the recently published outcomes of the ECCG[2] with Chi-square analysis.

Results: Some 797 patients were included from 22 hospitals. In 1 patient, the postoperative outcome was unkown. In 17 patients readmission status was unknown. Some 168 (21%) patients had an ASA score of $\geq$III and 250 (31%) patients a Charlson comorbidity score of $\geq$2. In total, 498 patients (63%) had at least one postoperative complication (versus ECCG: 57%, $p=0.07$). The most common complications were pneumonia (21% DUCA versus 15% ECCG, $p < 0.01$), anastomotic/staple-line failure or localized conduit necrosis (18% versus 11%, $p < 0.01$) and atrial dysrhythmia requiring treatment (13% versus 15%, $p=0.28$). Readmissions occurred in 105 of 780 patients (13%(ECCG 11%, $p=0.13$). The 30-day/in-hospital mortality was 2.5% for the DUCA group and 2.4% for the ECCG group ($p=0.88$).

Conclusion: The registration of complications according to the ECCG platform in the national audit promotes the use of uniform definitions and allows international comparison of outcomes. The overall complication rate, readmission

rate and mortality in the Netherlands were comparable with the outcomes of the ECGG. However, anastomotic leakage and pneumonia were more frequently reported in the Netherlands.

Introduction: Radical gastrectomy is the cornerstone of the treatment of gastric cancer. For tumours invading the pancreas, an en-bloc partial pancreatectomy may be needed to obtain a radical resection.
Aims and Methods: The aim of this study was to evaluate the outcome of gastrectomies combined with partial pancreatectomy for gastric cancer. Patients who underwent gastrectomy with or without a partial pancreatectomy for gastric cancer or gastro-oesophageal junction cancer between 2011–2015 for gastric were selected from the Dutch Upper GI Cancer Audit (DUCA). Outcome parameters were the pathological resection margin (pR0) and Clavien Dindo grade ^{3}III postoperative complications. The association between partial pancreatectomy and severe postoperative complications was analysed with multivariable logistic regression. Overall survival was estimated using the Kaplan Meier method and subgroups were compared using log-rank test.
Results: Of 1966 patients that underwent a gastrectomy, 55 patients (2.8 per cent) also underwent an en-bloc partial pancreatectomy. A pR0-resection was achieved in 45 of 55 patients (82 versus 85 per cent in the group with no additional resection, $p = 0.82$). Clavien Dindo grade ^{3}III complications occurred in 21 of 55 patients (38 versus 17 per cent). Pancreatectomy increased the odds of having a Clavien Dindo grade ^{3}III complication (OR: 3.13, 95 per cent c.i. 1.76–5.59). Median overall survival [95 per cent c.i.] of patients with partial pancreatectomy was 15[6.8–23.2] months, for patients with and without perioperative systemic therapy, it was 20[12.3–27.7] and 10[5.7–14.3] months, and for patients with R0 and R1/R2 resection it was 20[11.8–28.3] and 4[0.0–10.9] months.
Conclusion: Gastrectomy with partial pancreatectomy is associated with an pR0-resection rate of 82 per cent but an 3-fold increased risk for postoperative morbidity.

Introduction: In the Netherlands and Rotterdam region, postoperative mortality after surgery for gastric cancer was considerably higher than for any other type of cancer surgery.
Aims and Methods: To determine modes of failure and to develop proposals for preventive measures to decrease mortality, confidential review meetings were organised and supervised by a committee of experts.
Gastric cancer patients operated between 1999 and 2008 were selected from the regional cancer registry for 16 hospitals in the south-western part of the Netherlands. Per hospital, a maximum number of 9 cases with postoperative death or prolonged hospital stay were selected for review. Chart review was performed within the regional hospitals using an incident analysis tool the so-called Prevention and Recovery Information System for Monitoring and Analysis (PRISMA methodology). The primary goal of PRISMA is to systematically identify and classify causes of errors. Causes of error were classified into technical, organisational, human, patient-related or not specified using the Eindhoven Classification Model.
Results: The review comprised 106 patients with a median age of 74 years. There was considerable heterogeneity in protocols concerning diagnostic work up, surgery, postoperative care and treatment of complications between hospitals and surgeons. The most frequent technical complication was anastomotic leakage ($n = 27$) or duodenal stump dehiscence ($n = 11$). Some 56% of the operations were classified as high-risk procedures because of patient frailty or the extent of surgery. Human error was considered contributory in 65% of the cases, mainly for not adapting the treatment plan or related to insufficient preoperative examination. Organisational failure was less important, with 'culture of overconfidence' listed as the main factor.
Conclusion: A qualitative approach is able to highlight modes of failure for gastric cancer surgery. This study shows that serious adverse events for gastric cancer surgery often tend to occur when three or more contributing causes coalesce, *i.e.* patient-, surgeon- and organisational factors. Outcome after gastrectomy for cancer could possibly be improved by regional audits that will reveal areas for improvement and stimulate standardization of (surgical) protocols.
Disclosure: Nothing to disclose

P1508 THE IMPACT OF BODY POSITION ON GASTRIC EMPTYING AFTER PANCREATICODUODENECTOMY

Introduction: Abnormal gastric emptying velocity is a common complication after surgery of the upper intestine. Particularly after pancreaticoduodenectomy (PD), gastric emptying can be impaired (pylorus preserving procedure) or accelerated (classic Whipple procedure – pylorus resection). In this trial we aimed to study the impact of body position in gastric emptying in patients after PD and its impact on postprandial glucagon-like peptide-1 (GLP-1), insulin and glucose plasma concentrations.
Aims and Methods: 38 patients after PD, 19 subjects in sitting and 19 in supine position, were studied 2–118 (median: 19) months after the operation. Median age was 63 years, the male/female ratio 1.1, and body mass index 22.6 kg/m^2. 21 of the patients had undergone a pylorus preserving PD and 17 a classical Whipple procedure. All subjects ingested a mixed liquid test meal containing 1 g acetaminophen to measure gastric emptying. Before the meal and 10, 20, 30 and 60 minutes thereafter venous blood was drawn for the measurement of GLP-1, acetaminophen, glucose, and insulin.
Results: Fasting glucose, fasting insulin, the early integrated concentrations of acetaminophen and GLP-1 (0–30 min.) as well as integrated concentrations over 0–60 minutes of glucose and insulin are presented in Table 1. Gastric emptying speed revealed to be different between sitting and supine body position (Figure 1, Table 1). Postprandial GLP-1, insulin and glucose plasma concentrations showed no differences between the groups. Velocity of gastric emptying did not influence integrated insulin and glucose concentrations (0–60 min.). Body position had no impact on postprandial early integrated GLP-1 plasma concentrations.
Conclusion: Body position – sitting vs. supine – showed to have a significant effect on gastric emptying speed in patients after PD, sitting subjects emptied their stomachs faster. Be that as it may, no further impact of body position on postprandial glucose, insulin and GLP-1 plasma levels could be shown.

	Sitting body position	Supine body position	*p-value**
Acetaminophen

Introduction: Sepsis is a common and devastating disease that contributes a significant burden to global health care. After pulmonary sepsis, abdominal sepsis is the second most common form of sepsis and requires an intensive care unit to treat affected patients. Pathogenesis of sepsis and its complications involve numerous cytokines and endothelial factors that have pro- and anti-inflammatory effects. Interferon-gamma (IFN-γ) is an important regulator of infection and inflammation. Interferon-gamma (IFN-γ) is the only member of the type IFN II family. INF-γ inhibits viral replication directly and is produced predominantly by natural killer (NK) and natural killer T (NKT) cells as part of the innate immune response. It is also produced by effector T cells. IFN-γ is regulated by cytokines secreted by antigen-presenting cells, most notably interleukin (IL)-12 and IL-18. The IFN-γ gene is located on chromosome 12q14; several single nucleotide polymorphisms (SNPs) in this gene are associated with immune and infectious diseases. Further, some polymorphisms are associated with septic processes induced by trauma and respiratory infections

Aims and Methods: The aim of the present study was to evaluate IFN-γ gene polymorphisms in Mexican-Mestizo patients with abdominal sepsis (AS) and to determine their association with disease severity and mortality.

We recruited 120 patients with AS and 120 healthy controls and identified 2 IFN-γ gene polymorphisms, one at +874 A/T (rs2430561) and another at -1616 T/C (rs2069705), by automated DNA sequencing. Disease severity of patients with AS was evaluated according to the Acute Physiology and Chronic Health Evaluation (APACHE II) scale, Mannheim index, Controlling Nutritional Status (CONUT) score, and survival.

Results: The +874T allele (Mannheim index: Odds ratio (OR) = 1.92, 95% confidence interval (CI): 1.06–3.49, P = 0.031 and CONUT score: OR = 2.10, 95% CI: 1.16–3.83, P = 0.013), **the +874AT genotype** (CONUT score: OR = 2.74, 95% CI: 1.07–7.02, P = 0.031), **the dominant model AT+TT** (CONUT score: OR = 2.81, 95% CI: 1.19–6.68, P = 0.016), **the AC haplotype** (APACHE II scale: OR = 1.22, 95% CI: 1.03–1.46, P = 0.020), **the TC haplotype** (APACHE II scale: OR = 1.41, 95% CI: 1.15–1.74, P = 0.0007; Mannheim index: OR = 1.60, 95% CI: 1.38–2.05, P = <0.0001; CONUT score: OR = 2.08, 95% CI: 1.70–2.56, P = <0.0001), **and the TT haplotype** (Mannheim index: OR = 1.74, 95% CI: 1.29–2.35, P = 0.0002; CONUT score: OR = 1.39, 95% CI: 1.03–1.89, P = 0.020) **were significant risk factors for progression to severe AS. Whereas, the AT haplotype** (APACHE II scale: OR = 0.58, 95% CI: 0.47–0.72, P = <0.001; Mannheim index: OR = 0.53, 95% CI: 0.44–0.67, P = <0.0001; CONUT score: OR = 0.40, 95% CI: 0.32–0.50, P = <0.0001) **was significantly associated with protection against severe AS. The AC haplotype** (OR = 1.80, 95% CI: 1.55–2.21, P = <0.0001), **and the TC haplotype** (OR = 1.53, 95% CI: 1.25–1.87, P = <0.0001) **were associated with increased mortality. In contrast, the -1616T allele, the dominant model CT+TT, and the AT haplotype** (OR = 0.21, 95% CI: 0.06–0.74, P = 0.007; OR = 0.20, 95% CI: 0.05–0.81, P = 0.014; OR = 0.15, 95% CI: 0.11–0.21, P = <0.0001, respectively) **were significantly protective against death.**

Conclusion: Our study suggests an important role for IFN-γ polymorphisms in the incidence, development, and outcome of abdominal sepsis in the Mexican-Mestizo population.

P1510 LONGSTANDING POSTOPERATIVE FLUID COLLECTION INFLUENCES RECURRENCE OF PANCREATOBILIARY MALIGNANCY

Y. Kim[1]
[1]*Konkuk University Medical Center Digestive Disease Center, Internal Medicine, Seoul, Korea (Republic of)*

Contact E-Mail Address: yjgim82@gmail.com

Introduction: Postoperative abdominal fluid collection (PAFC) is frequently observed after surgery for pancreatobiliary malignancy. The duration of PAFC differs among patients, and little is known about the effects of the presence and duration of PAFC. The aim of this study was to evaluate the effects of PAFC on the outcomes of surgery for pancreatobiliary adenocarcinoma.

Aims and Methods: Data from 187 consecutive patients with pancreatobiliary adenocarcinoma who underwent curative surgery between August 2005 and February 2017 were analyzed retrospectively. The presence of PAFC was evaluated by computed tomography at < 1 week postoperatively; longstanding PAFC was defined as that lasting > 4 weeks.

Results: Of the 187 patients, 143 (76.5%) had PAFC and 71 (49.7%) had longstanding PAFC. The recurrence rates of pancreatobiliary adenocarcinoma in the presence and absence of PAFC were 55.9% and 43.2%, respectively. The presence of PAFC was not associated significantly with the recurrence of pancreatobiliary adenocarcinoma (p = 0.618), but longstanding PAFC was (p = 0.046). In a subgroup analysis, longstanding PAFC was related to the recurrence of only pancreatic cancer (p = 0.021). In patients with pancreatobiliary adenocarcinoma, recurrence and cancer-specific survival (CSS) were associated with high pathologic T stages (T3-4), lymph node involvement, perineural invasion (all p < 0.001), and non-receipt of adjuvant chemotherapy (p = 0.005 and p = 0.002, respectively).

Conclusion: The incidence of PAFC in patients with pancreatobiliary adenocarcinoma after surgery was 76.5%, and 49.7% had longstanding PAFC. The presence of PAFC was not associated significantly with recurrence or CSS in patients with pancreatobiliary adenocarcinoma. However, longstanding PAFC was associated with the recurrence of pancreatobiliary adenocarcinoma.

Introduction: Fistulas are the main complication of sleeve gastrectomy (SG). Several types of fistulas are distinguished according to their communication with an abscess and/or an over-diaphragmatic involvement (Type I to III). Management with an endoscopic internal drainage (EID) using a double-pigtail stent has shown encouraging results. To our knowledge, the results of this approach according to the type of fistula have not been evaluated. Thus, the originality of this study rests on the evaluation of the effectiveness of the EID according to the type of fistula.

Aims and Methods: This is a retrospective analysis of a prospective unicentric cohort of patients who developed a fistula after SG. The type of fistula was always classified initially by a CT scan with oral opacification: fistula without a communicating abscess (Type I), fistula with a communicating abscess (Type II), fistula with an abscessed intra-abdominal communicating collection and susdiaphragmatic (Type III).

Our treatment algorithm consisted solely of the insertion of a naso-jejunal feeding tube (NJFT) for Type I fistulas and the placement of a NJFT with EID with or without surgical drainage depending on the septic status for type II and III fistulas.

Results: Forty-nine patients were included (13 males / 36 females), with a mean age of 41 years (18–56) and an average initial Body Mass Index (BMI) of 46 kg/m2 (38–70). 16 patients had a type I fistula (33%), 25 a type II (51%) and 8 a type III (16%).

The clinical success rate of the procedure with fistula healing was 100% (16/16) in the group I, 96% (24/25) in the group II and 12% (1/8) for group III with a statistical difference between group I, II versus III p = 0.001

Mean time for diagnosis of the fistula was significantly higher in type III, 5 (2–32) days for type I, 5.8 (2–67) days for type II and 20.7 (5–122) days for type III p = 0.04 (I, II versus III).

The mean estimated size of the defect was significantly higher in type II and III versus type I, 2.8 mm (1–4) for type I, 11.2mm (5–20) for type II and 10 mm (5–15) for type III.
The average scheduled endoscopic session required was significantly higher in type III ($p = 0.001$ I, II versus III), 2 (1–3), 2.7 (2–5) and 5.2 (2–10) for Type I and II, and III respectively. Number of unscheduled reinterventions were significantly higher in type III ($p = 0.03$). The NJFT was left in place significantly higher in type III ($p = 0.001$).
Conclusion: Our study shows that it is essential to characterize the type of fistula before the endoscopic treatment of post-sleeve fistulas to better guide the proper management. Our treatment algorithm is available for Type I and II with high clinical success rate. In addition, postoperative monitoring of patients is essential in order to detect a fistula as early as possible and avoid type III fistula requiring a complex endoscopic treatment with low success rate.
Disclosure: Nothing to disclose

P1512 EFFICACY OF ENDOSCOPIC VACUUM-ASSISTED CLOSURE COMPARE WITH SELF-EXPANDABLE METALLIC STENT FOR POSTOPERATIVE ANASTOMOTIC LEAK OF GASTRIC CANCER

S.I. Choi, J.C. Park, J.E. Lee, E.H. Kim, S.K. Shin, S.K. Lee, Y.C. Lee
Institute of Gastroenterology, Yonsei University College of Medicine, Internal Medicine, Seoul, Korea (Republic of)

Contact E-Mail Address: bestcsi@yuhs.ac
Introduction: Post-operative anastomotic leak is a life-threatening complication with a high mortality rate at gastrointestinal surgery. Endoscopic vacuum assisted closure (EVAC) has been attempted as a new non-surgical treatment option for anastomotic leakage replacing previous self-expanding metal stents (SEMS). There were many reports of EVAC treatment for post-esophagectomy anastomotic leakage, but not for post-gastrectomy.
Aims and Methods: Between Jan 2007 and Feb 2018, total 39 cases of anastomotic leak occurred in patients who underwent gastrectomy for treatment of gastric cancer. Among them, 28 patients were treated with SEMS only, 7 patients were treated with EVAC following after SEMS failure, and 4 patient was initially treated with EVAC only. We compared clinical characteristics and therapeutic outcomes between patients treatment with EVAC or EVAC after SEMS ($N = 11$) and patients treatment with only SEMS ($N = 28$). Our aims are to compare the clinical outcomes of SEMS with EVAC as treatment for anastomotic leak after gastrectomy and to discuss the efficacy of EVAC.
Results: Median follow up duration was median 17 months (range 0–48). All cases with EVAC treatment were healing successfully (11/11, 100%). Two cases of treatment failure occurred in patients who treated with SEMS (2/28, 7.1%). Median duration of EVAC treatment was shorter than SEMS treatment (15 days [range 6–47] in EVAC and 36 days [range 7–108] in SEMS). Relatively larger size leakage was treated successfully with EVAC treatment (median 2.1cm in EVAC and 1.0cm in SEMS). The anastomotic stenosis occurred in one patient of EVAC treatment (1/11, 9.1%) and in six patients with SEMS treatment (6/28, 21.4%) within 1 year.
Conclusion: As well as SEMS, EVAC can be the effective endoscopic treatment option for anastomotic leakage after gastrectomy. Considering of the size of anastomotic leakage may be important in determining treatment options. Further large number randomized controlled trials are needed to define efficacy and benefit of EVAC.

Characteristic	Total (n = 39)	EVAC (n = 11)	SEMS (n = 28)	P-value
Age	66.0(39–82)	68.0(55–81)	63.5(39–82)	0.450
ASA 1 or 2, n (%)	24(61.5)	6(54.5)	18(64.3)	0.718

Contact E-Mail Address: boschdianne@outlook.com
Introduction: In January 2014, the Dutch bowel screening program was introduced to reduce the mortality rate of colorectal cancer. Because of this programme a rise in endoscopically found colorectal polyps is expected, which in turn will increase the number of surgical resections.
Aims and Methods: The aim of this study was to evaluate complications of surgically resected colorectal polyps and compare the amount of surgical resections and encountered malignancies before and after implementation of the Dutch bowel screening program.
This retrospective cohort study included patients who underwent surgical removal of colorectal polyps between January 2012 and December 2017. Patients with preoperatively established malignancy and polyposis were excluded.
Results: 143 patients were included. The surgical procedure was a segmental colectomy in 115 patients (80.4%). The procedures were performed laparoscopically in 79.7% ($n = 114$). Major complications (Clavien-Dindo $\geq$ 3b) occurred in 7 patients (4.9%), without mortality. The anastomotic leakage rate was 3.5% ($n = 4$).
In 2012, 3.2‰ of all conducted colonoscopies resulted in surgery ($n = 18$), compared to 5.8‰ in 2016 ($n = 30$). The overall malignancy rate before the implementation of the screening program was 28.9%, compared to 22.4% after the implementation ($p = .406$). High-grade dysplasia was seen in 77.4% of encountered adenomas before the implementation compared to 42.5% after implementation ($p = .001$).
Conclusion: After the implementation of the screening program the amount of surgically resected colorectal polyps almost doubled. Nevertheless the malignancy and high-grade dysplasia rate decreased.

Introduction: Recent prevalence of three-dimensional (3D) printer has enabled to produce 3D model of internal organs easily. Although the usefulness of 3D model has been demonstrated in regard to parenchyma organ such as liver[1] and kidney[2], there are few reports as to the intestine.
Total mesenteric excision (TME) with lateral lymph node dissection (LLND) is the standard treatment for locally advanced lower rectal cancer in Japan[3]. The branching patterns of iliac arteries and veins vary among individuals. Therefore, it is important to understand individual variations in advance of LLND. The anatomy of pelvic vessels is being evaluated using reconstructed 3D image of iliac arteries and its branches in selected patients in our institution[4].
Here, we aimed to address the usefulness of pelvic 3D model as a navigation modality in LLND.
Aims and Methods: We selected patients who underwent resection of the rectum with LLND from June 2017 to March 2018. First, we made 3D images from enhanced computer tomography (CT). Arteries and bones were reconstructed using volume rendering technique. Vessels, nerves, ureters, muscle, and metastasized lymph nodes were reconstructed by defining as region of interest. Then, a pelvic 3D model was produced using the reconstructed 3D image.

The usefulness of the pelvic 3D model was evaluated by questionnaire (1 = disagree strongly; 2 = disagree; 3 = not decided; 4 = agree; 5 = agree strongly) for surgeons.
Results: 3D models were created in a total of nine patients; seven underwent laparoscopic surgery and two open surgery. LLND of the left side was performed in two patients, LLND of the right side in five, and bilateral LLND in two. According to the Adachi-classification[5], types of arterial variation were determined as follows; Type Ia in seven sides, Type Ib in one, Type III in two, Type IVa in one.
A total of eleven sides of hemipelvic models were produced in nine patients. Superior gluteal artery, inferior gluteal artery, internal pudendal artery and obturator artery were all depicted. Furthermore, we were also able to reproduce obturator and sciatic nerves and levator ani, piriformis, coccygeus and internal obturator muscle. The mean time and cost for producing a hemipelvic model were about 26 hours (18.5–60) and 150 euros (130–200).
The average score of the questionnaire was 4.8. There were some favorable comments as follows: 1) the pelvic 3D model is superior to a reconstructed 3D image presented on screen in understanding of pelvic anatomy. 2) it may be useful in educating residents and students who are unfamiliar with lateral lymph nodes and their surrounding structure.
Conclusion: A pelvic 3D model appeared useful to understand pelvic anatomy. Although it needs a long time and expensive cost to produce the current pelvic 3D model, the tool may be useful as navigation in LLND and teaching residents and students pelvic anatomy.

Introduction: Transanal total mesorectal excision (taTME) seems to be a novel down-to-up approach for benign and malignant rectal disease. In addition, laparoscopic and taTME simultaneously (2-team taTME) against lower rectal cancer might be more promising approach. The aim of this study was to evaluate the short-term outcomes of 2-team taTME for lower rectal cancer.
Aims and Methods: A retrospective review was conducted on initial ten patients who underwent 2-team taTME from November 2017 to April 2018 in our single institution. All information was carefully reviewed and collected, including patient demographics, operative details, and surgical outcome. The primary endpoint was the quality of TME, and the secondary endpoint was short-term adverse event in the patient treated with 2-team taTME against lower rectal cancer.
Results: Mean ages were 68 years, and 7 patients in male. The average of BMI was 23.3 ± 2.8 kg/m^2. The average tumor distance from anal verge was 4.0 ± 2.0 cm. The median operative time was 226 minutes (156–263). There were no intraoperative complications including organ injury and conversion to open surgery. The median number of harvested lymph nodes was 9 (8–22). Overall positive CRM ($\leqq$0.5 mm) and DRM ($\leqq$1 mm) were 10% (n = 1) and 0%. Although postoperative complication was occurred in 8 patients (80%), there were no severe complications (Clavien-Dindo classification$\geqq$Grade3). The median length of hospital stay was 14 days.
Conclusion: Our results suggest that 2-team taTME for lower rectal cancer appears to be an oncologically safe and feasible with acceptable short-term outcomes. Further studies with more patients and longer follow-up are needed.

Introduction: Fibrosis and fistula development constitute the main complications associated to Crohn's disease. The Wnt signalling pathway induces fibroblast activation and epithelial mesenchymal transition (EMT) which are involved in these complications. Recent results in our laboratory have showed that Crohn's disease patients presenting a stricturing (B2) or a penetrating (B3) behavior undergoing surgical resection differ in the pattern of Wnt signaling (Ortiz-Masià, D *et al.,* ECCO Congress, 2018).
Aims and Methods: We aim to analyse the potential role of the Wnt pathway in favouring fistula development over fibrosis. CD patients were categorized according to Montreal classification (B2 orB3) and unaffected mucosa of patients with colorectal cancer was used as a control. mRNA was isolated from epithelial cells, fibroblasts or intestinal tissue and the expression of EMT markers, Wnt ligands, Wnt targets and Fzd receptors was analyzed by RT-PCR (Relative (Gene/b-actin) mRNA expression; fold induction vs control group). Isolated epithelial crypts or fibroblasts from controls were treated with WNT2b for 10 hours and the mRNA expression of EMT markers was analyzed. Fzd4 was Immunoprecipitated from surgical resections from B2 and B3 CD patients and the binding of WNT2B and FZD4 was analyzed by Western blot. Statistical analysis was performed by ANOVA + Kewman-Keuls test. Correlations between data were analysed using Pearson's correlation coefficient (* $p < 0.05$).
Results: CD patients presented an increased expression of Wnt target genes and Wnt inhibitor, DKK1 as well as a generalized overexpression of Wnt ligands (WNT2, WNT3, WNT6, WNT10A and WNT10B), with the exception of WNT2B which was up-regulated in the fistulizing group and down-regulated in the stenotic group compared with control. The expression of WNT2b significantly correlated with, VIMENTIN ($r = 0.6315$, $P = 0.0087$*), and STAT3 ($r = 0.4919$, $P < 0.0001$*), only[L1] in intestinal tissue from the fistulizing CD group. WNT2b exogenous administration increased mRNA expression of vimentin, snail1 and snail2 while decreased E-cadherin expression in isolated crypts, but no in fibroblasts. Epithelial cells and fibroblasts showed a different pattern expression of FZD receptors and higher levels of Fzd4 mRNA expression were observed in epithelial cells from B3 than B2 CD patients. Immunoprecipitation of FZD4 and Wnt2b was detected in human intestine and the signal was higher in samples from B3 than B2 CD patients.
Conclusion: Wnt2b may induce EMT and play a role in fistula development in CD patients through Fzd4 interaction.

Introduction: DSS-induced colitis has been shown to affect rodent gut microbiota[1]. STW5 (Iberogast®), a standardized multicomponent hydro-alcoholic herbal preparation, was shown to be effective in functional dyspepsia and irritable bowel syndrome and was shown experimentally to be effective against DSS-induced colitis[2] through anti-inflammatory and antioxidant properties. Present study was designed to show whether the beneficial treatment of DSS-induced colitis with STW5 also involves its effect on gut microbiota.
Aims and Methods: The experimental model of colitis was induced in Wistar rats by administering 5% DSS in drinking water for 7 days. Treatment with STW5 was started at the same time as DSS administration by giving it orally in doses of 2 and 5 ml/kg. Rats were sacrificed 24 hours later and fecal samples from cecum were collected to study the taxonomic diversity of gut microbiota. Selected main microbial phyla and genera were quantified using quantitative Real Time-PCR.
Results: The abundance of Proteobacteria in the DSS-induced colitis group was increased more than 25 fold but this rise was largely prevented after co-administration of STW5. In addition, DSS colitis induced an increase in the relative abundance of the Bacteroidetes, Prevotella and Bacteroides. Within the Firmicutes phylum, DSS increased the abundance of Enterococcus, an effect that was almost completely prevented by co-administration of STW5. Furthermore, Blautia within the Firmicutes phylum was decreased in the DSS-induced colitis group, and the abundance was almost restored by STW5. The relative abundance of Euryarchaeota represented by Methanobrevibacter was markedly decreased in the DSS colitis group but slightly increased by STW5.
Conclusion: Many changes in gut microbiota induced by DSS have been prevented or reduced by STW5. This adds to our understanding of the mechanisms underlying the beneficial use of the herbal preparation in colitis induced by DSS.

Introduction: Inflammatory bowel diseases (IBD), ulcerative colitis (UC) and Crohn's disease (CD) show an increased risk of thrombosis, complication where decreased levels of circulating PROS1 may play a role. PROS1 is a well-established anticoagulant, that works as cofactor for activated protein C. Additionally, PROS1 (expressed in T lymphocytes), due to an agonist function of anti-inflammatory tyrosine kinase TAM receptors TYRO3, AXL and MERTK, exhibiting an inhibitory role in the innate immunity, has been reported regulating inflammation or susceptibility in experimental colitis models (Rothlin et al. 2015, Carrera Silva et al, 2013). We hypothesized that PROS1 in IBD may result in decreased plasma levels, increasing not only the thrombosis risk, but also the inflammatory process of IBD. Of the total plasma PROS1, 40% circulate as an active free form, and the rest is linked to complement C4b-binding protein (C4BP) as an inactive complex. Thus, if so, a decrease of circulating "free" protein S, could be secondary to increased C4BP, which for excessive binding, reduce its availability.
Aims and Methods: 1) to compare PROS1 levels between CD, UC, activity status (Indexes: CDAI, Mayo), patterns (Montreal) and healthy controls, 2) to determinate C4BP levels due to its possible influence on PROS1 levels. Free PROS1 and C4BP were determined by immunoturbidimetry, Liatest, Stago, France, in 103 IBD patients (45 M, 58 F, UC: n 66, CD n 37) and 30 healthy controls (18 M, 12 F), mean ages: 37.5 ± 15.6, 41.4 ± 14.6, 38.2 ± 12.2, respectively.
Results: Mean PROS1 levels in CD ($89.9. \pm 28.0$) were significantly lower compared with controls (109.6 ± 23.9, $p = 0.0019$) and UC (104.4 ± 27.0, $p = 0.0076$). Within the CD group, a statistical difference versus controls was observed in patients with active disease (n 25, levels 84.9 ± 24.1, $p = 0.0004$), but not in patients in remission (n12: 100.2 ± 33.5). Moreover, the moderate-severe subset (n21), presented the lowest levels (84.0 ± 25.9) versus controls $p = 0.0006$. In UC, PROS1 levels did not show differences between subsets (42 active, 24 remission: 101.1 ± 26.3 and 110.0 ± 27 respectively) or with controls. CD patterns (behavior, location) and UC extent (12 proctitis, 54 more extensive) exhaustively analyzed did not show significant differences. Mean levels of C4BP in the controls were 109.9 ± 8.8. Values of C4BP in CD, unlike augmented (which could be associated with potential free PROS1 decline for excesive binding in the inactive complex), were massively decreased in all subsets (in the global sample 98.7 ± 14.4, in active patients 98.8 ± 12.0, in moderate-severe subset 98.4 ± 12.6, in remission 98.3 ± 19.1) versus controls ($p = 0.0004$, $p = 0.0008$, $p = 0.0014$, $p = 0.0222$ respectively). C4BP showed to be diminished versus controls in the overall results of the UC sample ($p = 0.0010$), especially in the severe-moderate subgroup (100.1 ± 9.8, $p = 0.0001$) which also reached significance compared with remission (105.2 ± 10.1, $p = 0.0322$).
Conclusion: 1) Free PROS1 levels were significantly lower in active CD versus controls (especially in the severe-moderate activity subsets), but in the case of UC the levels were indistinguishable from controls, 2) On contrary, C4BP levels were reduced in both diseases, 3) Decrease of Free PROS1 in CD, was not secondary to a potential increased binding of free PROS1 due to C4BP increase. These results stimulates to follow this research, in order to investigate the potential role of reduced levels of PROS1 in circulation, not only in the traditionally considered aspect related with the risk of thrombosis, but also as a possibly factor that enhances the inflammatory process in CD

Introduction: Microscopic colitis (MC) is an important cause of chronic diarrhoea in adults. Histopathology is the gold standard for diagnosis and but colonic biopsy has a variable yield. Endoscopically the mucosa appears normal, often leading to delayed diagnosis. It is not clear whether the described changes are strictly restricted to colon or extends to other parts of GIT also. This may have a bearing on treatment decisions.
Aims and Methods: The aim of the current study was to evaluate the terminal ileum using the narrow band imaging (NBI) and high-definition white-light endoscopy (HDWLE) in patients with MC. We also aimed to document and describe the histopathological findings in the ileum of patients with MC.
Materials and methods: We prospectively recruited patients aged more than 18 years with suspected MC (July 2016 to December 2017). Patients with malignancy, coeliac disease, small intestinal bacterial overgrowth, inflammatory bowel disease, gastrointestinal tuberculosis and severe comorbidities were excluded. Patients underwent blood investigations, imaging including CECT abdomen (if indicated), stool analysis, hydrogen breath tests using glucose, lactose and lactulose. All patients underwent colonoscopy with ileal intubation if possible. Patients underwent both HDWLE and NBI during the same setting by same observer. NBI finding were recorded in a predefined format. Four pieces of biopsies were taken from caecum/ascending colon and four from pieces from descending colon/sigmoid colon. Additional four pieces of biopsies were taken from terminal ileum. Each set of biopsies was collected in separate containers and labelled for further histopathological processing and examination by an expert gastrointestinal histopathologist. The diagnosis of MC was made using statements of the European Microscopic Colitis Group 2012.
Results: Of 53 patients enrolled in the study, and a final diagnosis of MC was established in 43 [mean age – 45.83($\pm$15.92), males – 27]. 25(58.1%) patients had collagenous colitis (CC), 14 (32.5%) had Lymphocytic colitis (LC) and 4(9.4%) had mixed picture fulfilling criteria for both. The HDWLE findings of ileum revealed normal mucosa in all patients. On NBI, intravillous capillary network was regular unbranched with semi-circular pattern in 41(95.4%) in cases and in all controls. Sparse and irregular pattern was seen in 2(4.7%) cases. Dilated and meandering vessels were seen in none ($p = 1.00$). Peyer's patches domes were indistinct in 5(9.4%) cases, normal in 38(88.4%) cases and all of the controls ($p = 0.570$). Peyer's patch vessels were regular and unbranched in 38(88.4%) cases and all of the controls. They were sparse and irregular in 5 cases (11.6%) ($p = 0.570$). Histopathological findings of terminal ileum revealed normal villi in 39 (90.6%) cases of MC, with 4 patients having partial villous atrophy. The crypt villous ratio was grouped as 1:1.5, 1:3, 1:4 and 1:5 in 2 (4.6), 26 (60.4),11 (25.5%) and 4 (9.3) patients respectively. Lymphoplasmacytic infiltrate was grouped as mild, moderate and severe, and was present in 10 (23.2), 2 (4.6%) and 1 (2.3%) patients respectively. The mean ($\pm$standard deviation) number of intraepithelial lymphocytes (IEL) per high power field were 16.33 ± 24.54.
Conclusion: This prospective study, for the first time, describes the NBI findings of ileum in patients with MC. Traditionally, ileum is considered to be spared in patients with MC. However, we found histological involvement of ileum in form of increased lymphoplasmacytic infiltrate and IEL in ileal mucosa along with presence of partial villous atrophy in some patients.

Introduction: Microscopic colitis (MC) is an important cause of chronic diarrhoea in elderly. Histopathology forms gold standard for diagnosis and has a variable yield. Hydrogen (H2) breath tests are used frequently to analyse the pathophysiology of functional gastrointestinal disorders, small intestinal bacterial overgrowth (SIBO), carbohydrate malabsorption and oro-cecal transit time.
Aims and Methods: Data regarding prevalence of SIBO, lactose tolerance, and oro-cecal transit time (OCTT) in patients of MC is sparse. Hence, we aimed to evaluate these in patients of MC.
Materials and methods: We prospectively recruited patients diagnosed with MC aged more than 18 years during the period July 2016 to December 2017. Glucose hydrogen breath test was done to evaluate for SIBO. A rise $\geq$12 ppm over the

fasting value in h2 concentration within 2hours of ingestion of glucose were measured by gas chromatography using Model-12 Microlyzer, (Quintron, USA) in 2 consecutive readings was taken as suggestive of SIBO. Lactulose hydrogen breath test was done to calculate OCTT. Patients were instructed to avoid taking antibiotics or probiotics 4 weeks prior to the test. They were given 15 ml lactulose syrup containing 10 gm lactulose to drink and end expiratory breath samples were taken after every 15 minutes for upto 3–4 hours. Time taken for rise in breath hydrogen by ≥12ppm over the baseline value in two consecutive readings was considered to be OCTT. Lactose breath test was done for lactose intolerance. Patients were given lactose at a dose of 25g in 250ml of water and breath samples were taken every 15 minutes up to 4 hours. A rise ≥20 ppm over the fasting value in H_2 concentration in two consecutive readings was considered suggestive of lactose intolerance.

Results: 43 patients of MC [mean age – 45.83(±15.92), males – 27] and 10 controls were recruited. Out of 43 cases with MC, 25(58.1%) patients had collagenous colitis (CC), 14 (32.5%) had Lymphocytic colitis (LC) and 4(9.4%) had mixed picture fulfilling criteria for both. In the MC group, 9(28.1%) were found to be lactose intolerant while in controls 3(42.9%) were lactose intolerant ($p = 0.654$). Glucose hydrogen breath test did not find any patient with SIBO in the MC group, however, SIBO was present in 4(9.5%) controls ($p = 0.001$). The mean (+ standard deviation) OCTT measured in MC group was 130.38 ± 47.95 mins and 97.14 ± 48.55mins ($p = 0.109$) in controls. OCTT was prolonged in 73% of patients with MC and 43% of controls.

Conclusion: Lactose intolerance was common in patients with MC, which might add to the severity of diarrhoea. OCTT was found to be prolonged in msot patients with MC. No patient with MC was found to have SIBO.

Introduction: Inflammatory bowel disease (IBD) is characterized by inflammation and immune disorders of the gut, gut-associated lymphoid tissue (GALT, including Peyer's patch, lamina propria, mesenteric lymphatic node, et al) plays as the first line of defense in intestinal mucosa. Increasing evidences suggest worse prognosis of IBD patients with obesity, while the mechanism is not yet to be elucidated. Here we try to explore the effects of obesity on IBD through GALT perspective.

Aims and Methods: Twelve weeks of 45% high-fat diet (HFD) was used to induce obesity. After 6 weeks of HFD feeding, mice were fed with three cycles of dextran sodium sulfate (DSS) to induce chronic colitis, and each cycle was composed of 7-day 2% DSS and 14-day normal water. Animals were divided into 4 groups, namely normal diet (ND), HFD, DSS and HFD+DSS groups.

Results: The body weight decreased in DSS mice than ND mice, as well as in HFD+DSS mice than HFD mice. Compared with ND group, number of inflammatory infiltration focus in colon were higher in HFD, DSS and HFD+DSS groups, and the highest number appeared in the last group. Consistent with these, the highest serous 4KD FITC-Dextran level, an intestinal permeability marker, was observed in HFD+DSS group, followed by DSS group and HFD group. These evidenced that both HFD and DSS promoted intestinal inflammation and permeability, and HFD+DSS caused the most serious gut damage. In the meantime, the immune responses of GALT in HFD, DSS and HFD+DSS mice were disordered, especially in HFD+DSS group. In Peyer's patches, compared with those of ND mice, $CD19^+$B lymphocytes decreased in HFD, DSS and HFD+DSS mice; the accumulation of $CD3^+$T lymphocytes arranged from lowest to highest in ND, HFD, DSS and HFD+DSS mice, as well as $CD4^+$ T/$CD8^+$T ration. In lamina propria of colon, $F4/80^+CD11b^+$ macrophages, $F4/80^-Ly6G^+CD11b^+$neutrophils, $F4/80^-CD11C^+MHCII^+$dendritic cells, $CD3^+$T lymphocytes, $CD4^+$T/$CD8^+$T cells ratio and $CD19^+$B lymphocytes were higher in HFD and DSS mice than ND mice, and all of these cells were further increased in HFD+DSS mice. In mesenteric lymphatic nodes, lower $CD3^+$T lymphocytes and higher $CD19^+$B lymphocytes were observed in HFD, DSS and HFD+DSS groups than ND group.

Conclusion: DSS induces more severe colitis in obesity mice than normal mice. Immune responses of GALT are activated both in HFD and DSS mice, and HFD deteriorates this immune disorder induced by DSS. These results suggest that obesity may aggravate colitis through regulating immunoreaction of GALT.

Contact E-Mail Address: jerry1989@hsc.pku.edu.cn

Introduction: Fungal dysbiosis plays important role in the pathogenesis of ulcerative colitis (UC). Type 3 innate lymphoid cells (ILC3) were also reported as a pivotal player in defending fungal invasions and inducing intestinal inflammation. However, the effect of fungal dysbiosis on bio-function of ILC3 in UC pathogenesis is not very clear.

Aims and Methods: To investigate the mucosal fungal composition, 10 untreated UC patients were recruited, and both non-inflamed and inflamed mucosae were collected for an ITS 1–2 *rRNA* sequencing. Flow cytometric analysis were performed to detect circulatory and mucosal ILCs composition and cytokines expression. *In vitro* co-culture of *Candida albicans*, bone marrow-derived dendritic cells (BMDC) and sorted Nkp46$^-$ ILC3 cells were performed to investigate the mechanism of fungal dysbiosis involved in UC pathogenesis.

Results: Compared to non-inflamed mucosa, Ascomycota decreased ($p < 0.05$) and Zygomycota increased ($p < 0.01$) at phylum level in inflamed mucosa of UC patients. *Wickerhamomyces* decreased ($p < 0.05$) and *Candida, Aspergillus, Cladosporium, Lentinula,* and *Paecilomyces* increased at genus level. Flow cytometric analysis showed an increase of pro-inflammatory Nkp46$^-$ ILC3 ($p < 0.05$) in both circulation and inflamed mucosa of UC patients. Furthermore, IFN-γ^+ Nkp46$^-$ ILC3 ($p < 0.01$) and IL-17A$^+$ Nkp46$^-$ ILC3 subset ($p < 0.05$) were increased in mucosal Nkp46$^-$ ILC3 cells in inflamed mucosa. In addition, BMDC, co-cultured with heat-killed *Candida albicans*, expressed more IL-23 ($p < 0.05$), and promoted Nkp46$^-$ ILC3 to produce IL-17A ($p < 0.05$).

Conclusion: We have demonstrated the increase of invasive fungi and pro-inflammatory Nkp46$^-$ ILC3 in inflamed mucosa of UC patients. *In vitro* analysis has shown that BMDC have been stimulated by *C. albicans* to express IL-23 and subsequently facilitates Nkp46$^-$ ILC3 to express IL-17A. These data prove that fungal dysbiosis facilitates Nkp46$^-$ ILC3 in inflamed mucosa of UC patients, which is mediated by DCs produced IL-23.

Introduction: Fibrosis is a common complication of Crohn's disease and it is related to dysregulated tissular repair following inflammation. Macrophages play a central role in both mucosal repair and fibrosis and these cells constitute an important source of pro-fibrotic factors [1]. $CD16^+$ macrophages are increased in fibrotic tissue of Crohn's disease patients [2] and we aim to analyse the relevance of CD16 positive macrophages as a source of fibrotic mediators in murine intestinal fibrosis.

Aims and Methods: Colon resections from donor mice were transplanted subcutaneously into the neck of recipient mice. After 7 days, intestinal grafts were obtained. An adjacent segment of the colon from each donor mouse was kept to be used as autologous control tissue. [3] The expression of macrophage markers, pro-fibrotic markers and Wnt ligands and receptors was analyzed by qPCR.

Results: Fibrotic tissue compared with control tissue revealed: a) increased profibrotic markers Vim (4.6 ± 1.1 vs 1.0 ± 0.1), α-Sma (13.0 ± 1.7 vs 1.1 ± 0.2) and Col1a1 (69.4 ± 17.3 vs 1.7 ± 0.7); b) increased macrophage markers F4/80 (7.9 ± 2.2 vs 1.1 ± 0.1), CD16 (23.8 ± 3.5 vs 1.3 ± 0.3), CD206 (10.2 ± 4.6 vs 1.3 ± 0.4) and CD86 (15.8 ± 2.9 vs 1.1 ± 0.2); c) increased expression of Tgf-β (2.1 ± 0.2 vs 1.0 ± 0.0). Moreover, fibrotic tissue showed: a) a positive and significant correlation between CD16 and Wnt6 and between CD16 and Tgf-β and b) a positive correlation between Wnt6 and Fzd10.

Conclusion: CD16 positive macrophages are increased in murine intestinal fibrosis and these cells may act as a source of fibrotic factors such as Tgf-β and Wnt6.

P1526 PRESENCE OF ADHERENT-INVASIVE *ESCHERICHIA COLI* IN INFLAMMATORY BOWEL DISEASE IMPACTS THE EFFICACY OF FECAL MICROBIOTA TRANSPLANTATION

Z. Xu[1], C. Chevarin[2], T. Zuo[1], J. Zhang[1], S. Wong[1], F.K.-L. Chan[1], J.J.Y. Sung[1], J. Yu[1], N. Barnich[2], **S.C. Ng**[1,3]

Introduction: Adherent invasive *Escherichia Coli* (AIEC) can invade the gut epithelium and colonise the mucosa of patients with inflammatory bowel disease (IBD). Despite the increasing use of fecal microbiota transplantation (FMT) to treat IBD, the mechanisms and factors affecting treatment outcome is unclear.

Aims and Methods: This study aimed to determine the prevalence and define the genetic and functional characteristic of AIEC in patients with Crohn's Disease (CD). Secondly, we assessed if the presence of AIEC compromise the efficacy of FMT in a murine model of colitis. We isolated *E Coli* from ileum tissues of Chinese Crohn's disease patients (n = 56) and healthy subjects (N = 16) and classified them as AIEC pathotype using gentamicin protection assay with Int-407 intestinal cells. Bacterial whole genome sequencing was performed on all AIEC strains isolated. We compared the virulence properties and antibiotic resistance of these isolates with AIEC strains isolated from western countries and other publicly available *E. coli* pathotypes deposited in NCBI database. Amongst 21 AIEC strains isolated, we selected AIEC62d strain which has the strongest invasion property and *E. coli* K12 (a non-pathogenic strain) to infect C57BL/6 wild type mice (n = 26). After 7 days of 2% DSS treatment, we gavaged these mice with fecal solution from healthy human subject and assessed the Disease Activity Index (DAI), colon length and histology score of the colon 7 days after fecal transplant.
Results: AIEC was present in 37.5 and 12.5 percent of mucosa of CD and healthy subjects, respectively. Most AIEC strains belonged to B2 phylogroup. Over 65 percent isolates from CD were multi-antibiotic resistant and they harboured stronger pathogenicity than the non-resistant strains ($p < 0.05$). The genome of AIEC62d resembled that of LF82 (the AIEC reference strain) and possessed nearly all virulence genes (pduC, ibeA, lpfA, etc.). Its invasion ability was greater than that of LF82 (4.25% versus 3.5% in Intestine-407 cells). Mice treated with FMT showed a significant reduction in the number of AIEC in the colon. After FMT, mice colonised with AIEC62d strain showed significant shortening of colon and had more severe histology activity than mice colonised with *E. coli* K12 non-pathogenic strain.
Conclusion: AIEC that possess antibiotic resistant properties is common in CD subjects. The presence of AIEC compromised the efficacy of FMT in mice, leading to incomplete recovery of inflammation. Future FMT practice should consider patient stratification based on AIEC presence and virulence factors and their effects on FMT outcomes. This study was supported by ANR/RGC Joint Research Scheme (RGC Project No. A-CUHK402/17).

Introduction: Perianal abscesses are caused by an infection of obstructed anal crypt glands resulting in a collection of pus. Previous cohort studies[1] suggested that a third of patients with Crohn's Disease who had surgery for perianal abscess underwent these procedures prior to their diagnosis of Crohn's disease. The incidence of inflammatory bowel disease after a diagnosis of perianal abscess and potential predictors of a future diagnosis of inflammatory bowel disease in this cohort is unknown.
Aims and Methods: The Health Improvement Network (THIN) represents a group of General Practices (primary care) covering 6.2% of the UK population, which is representative of the UK population structure. Incident cases of perianal abscess were identified between 1995 and 2017. Subjects with perianal abscess were matched to controls of the same age (+/− 1 year), gender, smoking and weight (within 120 days of the diagnosis of perianal abscess) within the same general practice. Primary outcome was designated as a diagnosis of Crohn's Disease or ulcerative colitis. Subjects who developed a diagnosis of inflammatory bowel disease within 6 months following the index date were excluded. A cox regression model was also used to assess potential predictors of a diagnosis of Crohn's disease or ulcerative colitis following a diagnosis of perianal abscess.
Results: The risk of Crohn's disease was higher in the perianal abscess cohort compared to the control population; adjusted HR 7.54 (95% CI 4.88–11.66), $p < 0.0001$. The risk of ulcerative colitis was higher in the perianal abscess cohort compared to the control population; adjusted HR 2.02 (95% CI 1.36–2.97), $p < 0.0001$. Anaemia in men (HR 4.11 (95% CI 2.02–8.34), $p < 0.0001$), and use of antidiarrheal medications (HR 2.49 (95% CI 1.55–3.99), $p < 0.0001$) within 180 days of index date were found to indicate an increased likelihood of a diagnosis of Crohn's disease in the future. Anaemia in men (HR 2.55 (95% CI 1.02–6.37), $p = 0.046$), diarrhoea (HR 2.24 (95% CI 1.26–3.99), $p = 0.006$) and use of anti-diarrhoeal medication (HR 2.17 (95% CI 1.13–4.18), $p = 0.030$) within 180 days of index date, were found to indicate an increased risk of future diagnosis of ulcerative colitis.
Conclusion: The results suggest that patients with a diagnosis of perianal abscess are at an increased risk of having a subsequent diagnosis of Crohn's disease and ulcerative colitis. Physicians should have a low threshold for focussed history, examination and investigation to screen for inflammatory bowel disease in the perianal abscess cohort, particularly males with anaemia and those with a co-prescription for antidiarrheals.

Introduction: Inflammatory bowel disease (IBD) is accompanied by a complex interplay of intestinal microbiota, host immune genetics and environmental factors (1). During the process, chemicals released upon the immune response from neutrophils such as reactive oxygen and nitrogen species, are known to induce mutagenesis within the affected tissue. The evolving tissue morphology is underlined by focal molecular changes within the affected gastrointestinal mucosa (2). It is expected that the resulting somatic DNA mutations of specific oncogenes and tumor suppressor genes are the main drivers of malignant conversion towards IBD-associated colorectal cancer. The molecular mechanisms of this transition exhibit distinguishing features that are not observed in other pathways of colorectal carcinoma development (3).
Aims and Methods: The aim of the project was to map the occurrence of somatic DNA mutations in inflammatory tissue of IBD patients to determine their frequency and relationship to the course of neoplastic transformation, the severity of inflammation and other clinical and laboratory parameters. The mutational spectra were then compared to profiles obtained from advanced colorectal adenomas and carcinomas resulting from traditional and serrated pathways.
Tissue samples were processed from a cohort of 20 patients with various types of ulcerative colitis and Crohn's disease. In addition tissues were processed from 2 patients with sporadic adenomas (advanced tubular and advances serrated). DNA was extracted using standard protocols from tissue resections (native or FFPE). Targeted NGS sequencing of 60 genes was performed on Illumina MiSeq sequencer using SureSeq^{TM} Solid tumor hybridization-based enrichment panel (Oxford Gene Technology, Oxfordshire, UK). NGS data was processed by NextGENe sequence analysis suite (Softgenetics, State College, PA).
Results: The diverse mutation spectra obtained were remotely reflecting the "reverse" Vogelstein model of molecular progression of IBD. Unlike in advanced adenomas, the frequency of prominent genes from traditional and serrated pathways was significantly lower in IBD samples.
Conclusion: Mutations in cancer driver genes indicate initiation of malignant conversion and are useful in assessment of the risk of IBD-related colorectal cancer. At the same time, presence of specific mutations in inflammatory tissue may be relevant for prediction of IBD therapy response, however, such assumption would need further confirmation. This work was funded by project no. MO1012

Introduction: Chronic inflammation in inflammatory bowel disease (IBD) causes tissue damage including extracellular matrix degradation. The inflammatory cascade holds both catabolic and repair signals. Tofacitinib, a small-molecule Janus kinase (JAK) 1/3 inhibitor, is studied in the treatment of IBD. Interleukin (IL)-6, -11 and -22 are IBD relevant cytokines that signals through JAK-pathway. IL-6 is a pleiotropic cytokine that acts as both a pro-inflammatory signalling molecule and as a repair molecule of the intestinal epithelium in response to injury. IL-11,

a family member of IL-6, is suggested to have same effects as IL-6, and IL-22 is important for intestinal homeostasis and repair. Type III collagen is a main constituent of the extracellular matrix (ECM) of the intestinal interstitial matrix. Consequently matrix metalloproteinase (MMP) degraded type III collagen measured by the biomarker C3M, may serve as a surrogate of intestinal ECM remodelling *ex vivo*.

Aims and Methods: We investigated the impact of Tofacitinib, IL-6, IL-11 and IL-22 on ECM remodelling in an intestinal *ex vivo* model as a potential drug-screening tool. Biopsy punches from porcine colonic tissue were incubated in William E culture media for 72 hours. The explants were stimulated at baseline, 24 and 48 hours with Tofacitinib (1uM, 0.1uM, 0.01uM), IL-6 (50 ng/mL, 5 ng/mL, 0.5 ng/mL) and IL-11 and IL-22 (100 ng/mL) or without stimuli (w/o). A competitive ELISA setup was used to estimate MMP degraded type III collagen (C3M) at 48 and 72 hours in explant supernatant. Viability was assessed by Alamar blue.

Results: The Jak 1/3 inhibitor, Tofacitinib, significantly decreased C3M release at 48 and 72 hours in a dose dependent manner, with the lowest concentration (0.01uM) being most potent. IL-6 significantly decreased the release of C3M at 72 hours in a dose-dependent manner, with the highest concentration being most potent. IL-11 and IL-22 stimulation significantly decreased C3M release at 48 and 72 hours. Stimuli did not affect viability.

Conclusion: IL-6, IL-11 and IL-22 attenuated degradation of type III collagen, thus supporting a protective role of these cytokines. There was a bell-shaped dose response curve of Tofacitinib on C3M release and ECM remodelling, in which low concentrations was protective. The dose effect of IL-6 and Tofacitinib on C3M and ECM remodelling suggests applications of this model to profiling treatments candidates, and provide an easier to use system to investigate the effect of drugs in the complicated intestinal biology.

Introduction: Ulcerative colitis (UC) is associated with an increased risk of developing colitis-associated cancer (CAC). An inhibitor for SMAD7 (GED-0301), a molecule involved in the TGFβ1 and BMP pathways and highly expressed in UC affected colonic mucosa, is being investigated to determine its efficacy in reducing inflammation in UC patients. While inhibiting SMAD7 may ameliorate intestinal inflammation, no evidence is currently available to determine the effect on CAC risk, as both TGFβ1 and BMP are known to enhance late stages of colorectal carcinogenesis, and may possible have a role in CAC as well. As the inhibition of TGFβ1 and BMP pathways are exerted through the SMAD7-induced inhibition of phosphorylation of both SMAD3 and SMAD 1/5/8, respectively, we aimed to evaluate the expression of SMAD proteins in non-neoplastic, dysplastic and malignant colonic epithelium. This could give us an insight into the potential effect of SMAD7 inhibition during neoplastic progression in UC patients.

Aims and Methods: To evaluate the activity of the TGFβ1 and BMP pathways, cytoplasmic expression of SMAD7 and nuclear expression of p-SMAD3 and p-SMAD 1/5/8 was assessed by immunohistochemistry in a cohort of 25 archival colon tissue samples (8 CACs, 8 dysplastic lesions and 9 non-neoplastic mucosal samples) from patients who have undergone colectomy for UC. Protein expression was evaluated by both digital quantification and validated by blinded semi-quantitative scoring by a pathologist. In the same samples, expression of *SMAD7* mRNA in the colonic epithelium was evaluated with *in situ* hybridisation with specific target probes for the mRNA and evaluated by digital quantification. Significant differences were tested with one-way ANOVA.

Results: Cytoplasmic SMAD7 shows a significant increase of expression with the progression of the neoplastic process from inflamed to malignant epithelium ($p < 0.0001$). This is linked with an increase of BMP activity, evaluated by P-SMAD1/5/8 nuclear expression ($p < 0.0001$), but not of TGFβ1 activity evaluated by p-SMAD3 expression ($p = 0.53$). The differential SMAD7 expression amongst the stages of neoplastic progression is not correlated with changes in the mRNA level, a discrepancy that could be due to still unknown post-transcriptional or post-translational regulation of the protein. Interestingly, within the cancers, higher SMAD7 expression was detected in approximately 88% of CAC samples (7/8 samples), with the exception of one cancer treated with neo-adjuvant radiotherapy before collection due to the radiation damage.

Conclusion: Within our CAC sample cohort, TGFβ1 and BMP pathways do not show suppression in the presence of increased SMAD7. The increase in SMAD7 expression during neoplastic transformation may be a protective response to negate the carcinogenic effect of TGFβ1 and BMP on cancer. Although inhibiting SMAD7 as a therapy for UC may remit inflammation, it could potentially drive neoplastic generation and progression due to further enhancement in TGFβ1 and BMP pathways. We envisage further mechanistic studies *in vitro* and *in vivo*, in particular in organoids and mice model of CAC, could help in understanding the TGFβ superfamily pathway in colitis-associated cancer.

Introduction: Compared to healthy controls Crohn's Disease [CD] patients show a decrease in diversity and abundance of various microbial species. To this day it remains unclear whether these findings represent etiologic factors or simple consequences of protracted inflammation. In a colonoscopy-based screening study we have shown that ≥40% of asymptomatic first degree relatives [FDR] of CD patients have subclinical intestinal inflammation (IBD 2014;20:1049) – a finding consistent with previous fecal calprotectin-based studies (*Gastroenterology* 2003;124:1728). Of those with inflammation 10% had CD at biologic onset (very early disease with typical histological features) while the remaining had minimal inflammation – a nonevolving phenotype in between that of healthy FDR and FDR with CD. Hence – because of the very initial stage of the inflammatory process – FDR represent the ideal population to test the hypothesis that dysbiosis predates *clinical* CD and might be one of its causative factors.

Aims and Methods: For microbiome analysis we used next-generation sequencing 16S (bacterial) using DNA extracted from ileo-cecal biopsies of normal healthy controls ($n = 10$), CD patients ($n = 23$) and asymptomatic FDR ($n = 25$). Endoscopy and histology had categorised FDR into healthy ([FDR_1] $n = 9$), intermediate ([FDR_2] $n = 12$) and CD phenotypes ([FDR_3] $n = 4$). Data were analysed using Illumina CASAVA pipeline version 1.8.2 (Australian Genome Research Facility). Fifteen taxa were clustered into a phylogenetic tree using hierarchical clustering. Principal coordinates analysis (PCoA) was run on weighted UniFrac distances between Operational Taxonomic Units (OTUs) counts. Univariate negative binomial regressions with log-link functions were applied to assess the association between grouping and OTUs counts for each taxon (5 of the 15 taxa were excluded due to excess of zero OTUs counts), with controls as reference group. Statistical significance was set at 10%.

Results: As previously reported *Faecalibacterium prausnitzii, Ruminococcus, Akkermansia muciniphila* were decreased while *Bacteroides fragilis and* Enterobacteriaceae were significantly increased in CD patients compared to controls with an overall decrease of microbial diversity in CD patients. In the PcoA ellipse centroids of FDR were positioned in opposite quadrants as compared to CD patients, but close to the centroid for controls. In contrast, no clear separation between the 3 FDR groups was observed. Hence the microbial profile of FDR as a whole was very similar to that of controls and dissimilar to that of CD patients. Estimates of coefficients contrasting FDR_3 and controls showed larger p-values than those for estimates of coefficients contrasting CD patients and controls in 9 out of 10 taxa. Taxa for which CD and controls had significantly ($p < 0.10$) different OTUs, but FDR_3 and controls did not ($P > 0.1$), were: unknown, Actinobacteria, Firmicutes, Synergistetes, and TM7.

Conclusion: Intestinal microbial profiling reveals significant differences between healthy controls and CD patients. However, FDR bear a microbial profile remarkably similar to healthy controls in terms of species abundance and presence of specific bacterial species. In particular the microbiome of FDR_3 – that is, patients with CD at its biologic onset – is to a large extent superimposable to that of healthy controls. This observation raises the possibility that the dysbiosis associated with *clinical* CD might only be a consequence over time of the changed intestinal micro-environment due to the disease process.

Introduction: Gut microbial dysbiosis and decreased diversity of the gut microbial ecosystem are now considered an essential factor in driving mucosal inflammation in inflammatory bowel disease (IBD). Small intestinal bacterial overgrowth (SIBO), defined as the presence of excessive and/or abnormal type of bacteria in the small bowel, plays an uncertain role in the pathogenesis of IBD.

Aims and Methods: We aimed to establish the prevalence of small intestinal bacterial overgrowth (SIBO) in patients with IBD, both ulcerative colitis (UC) and Crohn's disease (CD) compared with controls. Using the search terms 'small intestinal bacterial overgrowth (SIBO)' and 'Inflammatory Bowel Disease (IBD)' or 'small intestinal bacterial overgrowth (SIBO)' and 'Ulcerative Colitis (UC) or Crohn's Disease (CD)', 8 case-control studies that met inclusion criteria were identified when searching relevant databases. Prevalence rates for SIBO and relevant demographic and geographic data as well as information on the diagnostic modalities were extracted and prevalence rates and 95% confidence intervals (CI) of SIBO in IBD, UC and CD and controls calculated. In addition, the influence of the diagnostic modality (breath tests, aspirate or biopsy and culture or both) was determined.

Results: The final dataset combined 8 independent studies that recruited 553 adult patients with IBD and 1930 controls. Eight studies employed breath tests (five utilized glucose breath test (GBT), one each utilized lactulose and xylose breath test) and only one study used small bowel aspirate and culture for diagnosis of SIBO. Across all testing methods, the prevalence of SIBO in patients with IBD compared with controls was increased with an OR = 6.4 (95% CI 2.73–14.76), $p < 0.000$. In patients with IBD prevalence of SIBO was 28.9% (95% CI 25.10–32.65) as compared to 9.7% (95% CI 8.33–11.03) in controls. When the method of detection was limited to breath tests, the prevalence of SIBO in IBD was 30.8% (95% CI 27.72–35.85) compared to 10.0% (95% CI 8.43–11.69) in controls. In contrast, based upon culture techniques, the prevalence of SIBO in IBD was 15.5% (95% CI 6.2–28.84) vs 7.3% (95% CI 5.24–9.34). Only studies utilizing breath tests reported separately the prevalence of SIBO in UC and CD. In patients with CD the prevalence of SIBO is 32.8% (95% CI 25.04–40.48) as compared to 15.7% (95% CI 11.39–19.91) in patients with UC. There was no evidence that the association between SIBO and IBD was influenced by publication bias.

Conclusion: Regardless of the diagnostic modalities, prevalence of SIBO is significantly increased in patients with IBD when compared to controls. The prevalence of SIBO in patients with CD is double compared to those with UC. Compared to culture-based methods, the accepted gold-standard for the diagnosis of SIBO, breath tests overestimate the prevalence of SIBO and may have insufficient diagnostic specificity. While better diagnostic tests are required, it is critical to determine if SIBO in IBD is the cause for symptoms or a consequence of other abnormalities of gut function.

P1533 THE EFFECTS OF ENTERIC GLIAL CELLS ON DENDRITIC CELL AND ITS POTENTIAL IMMUNOMODULATORY ROLES IN DEXTRAN SULPHATE SODIUM-INDUCED COLITIS

Y. Huan[1]
[1]Sichuan University & Westchina Hospital, Gastroenterology, Chengdu, China

Contact E-Mail Address: yuhuan86@126.com

Introduction: It is demonstrated in our previous study that the Enteric glial cells (EGC) closely connect with immune cells and play a vital role in maintaining gut immune homeostasis. Here, we reported that EGCs has direct effect on DCs, and could induce tolerogenic DCs by releasing nerve growth factor (NGF), which also could restore immune tolerance in vivo, and ameliorate DSS-induced mouse colitis.

Aims and Methods: DCs were generated from mouse bone marrow (BMDC), and co-cultured with EGC (ratio 1:1) which stimulated by Lipopolysaccharides (LPS) previously ($DC_{EDC\text{-}LPS}$) or not. Then the co-culture system was treated with anti-NGF. The expression of CD40, CD80, CD86 and major histocompatibility complex II (MHC-II) on the surface of DCs was determined by flow cytometry. The NGF and IL-10 secretion in culture supernatants was measured by ELISA. C57BL/6 mice were fed with 2.5% Dextran Sulphate Sodium (DSS) for 7 days to induce experimental colitis, the therapeutic action of $DC_{EGC\text{-}LPS}$ such as: disease activity index (DAI), histopathology score and Myeloperoxidase (MPO) were evaluated, the inflammatory cytokines and chemokines (IL-10,TNF-α,IL-1β) in colon tissue were measured by ELISA. The propotion T cell subsets of Th1,Th2,Th17 and the generation of IL-10-secreting Treg (Treg1) cell in mesenteric lymph nodes (MLN) was measured by intracellular staining and flow cytometry analysis

Results: DCs co-cultured with EGC (ratio 1:1) which stimulated by LPS previously did not up-regulate MHC-II, CD40, CD80, CD86, and secreted significant levels of the anti-inflammatory cytokine IL-10 and TGF-β, compared with $DC_{Control}$ and DCs co-cultured with EGC which did not stimulated by LPS, but the anti-NGF treatment partly abrogated these effect.

$DC_{EDC\text{-}LPS}$ injection significantly ameliorated DSS colitis in mice, as DAI, histopathology score and MPO score were decreased. $DC_{EDC\text{-}LPS}$ injection strikingly reduced the production of over-expressed pro-inflammatory cytokines such as TNF-α, IL-1β, and IL-17, in colon tissue, increased the proportion of IL-10-positive Treg cell in mice MLN, and restored the decreased IL-10 level and the imbalance of Th cell subsets.

Conclusions: EGCs could induce tolerogenic DCs by releasing NGF, and $DC_{EDC\text{-}LPS}$ could alleviate the severity of DSS induced colitis in mice. This beneficial effect might be linked that $DC_{EDC\text{-}LPS}$ could restore the imbalance of Th cell subsets, prompt the differentiation of Treg, and ultimately reduced the over-expressed pro-inflammatory cytokines and increase IL-10 level.

Introduction: Few studies have investigated the blood proteome of inflammatory bowel disease (IBD). We characterized the serum abundance of proteins encoded at 163 known IBD risk loci, and tested these proteins for their biomarker discovery potential.

Aims and Methods: Based on the Human Protein Atlas (HPA) antibody availability, 218 proteins from genes mapping at 163 IBD risk loci were selected. Targeted serum protein profiles from 49 Crohn's disease patients (CD), 51 ulcerative colitis patients (UC) and 50 sex and age-matched healthy individuals were obtained using multiplexed antibody suspension bead array assays. Differences in relative serum abundance levels between disease groups and controls were examined. Replication was attempted for CD-UC comparisons (including disease subtypes), by including 64 additional patients (33 CD and 31 UC). Antibodies targeting a potentially novel risk protein were validated by paired antibodies, Western blot, immuno-capture mass spectrometry and epitope mapping.

Results: By univariate analysis, thirteen proteins mostly related to neutrophil, T- and B-cell activation and function were differentially expressed in IBD *vs.* healthy controls, three in CD *vs.* healthy controls and two in UC *vs.* healthy controls (Table; $q < 0.01$). Multivariate analyses further differentiated disease groups from healthy and CD subtypes from UC ($p < 0.05$). Extended characterization of an antibody targeting a novel, most discriminative serum marker, the laccase (multi-copper oxidoreductase) domain containing 1 (LACC1) protein, provided evidence for antibody on-target specificity.

Conclusion: Using affinity proteomics, we identified a set of IBD-associated serum proteins encoded at IBD risk loci. These candidate proteins hold potential to be exploited as diagnostic biomarkers of IBD.

Introduction: It is well known that smoking is a risk factor for developing and clinical course of Crohn's disease (CD), but at the other side smoking is protective factor of ulcerative colitis (UC). Molecular pathways that are influenced by smoking in CD and UC are poorly understood.

Aims and Methods: The aim of our study was analyze influence of smoking on the mRNA expression of cytokines in mucosa of patients with CD as well as UC. We performed cross-sectional study. The cohort consists of 87 IBD patients (47CD patients and 40 UC patients) followed at IBD center of University Hospital Bratislava- Ružinov. We recorded demographic and clinical data of each patient including smoking. We performed colonoscopy in each patient and took biopsy from inflamed and non-inflamed sigma (CD,UC) and terminal ileum (CD). mRNA was extracted from mucosal biopsy samples for each cytokines (IL-6, IL-8, IL-12, IL-17, IL-23, TNFα, CCR1, CCR2, CCR5, CCR9, CCL5, TLR2, TLR4, TLR5, CD207, CD206) and transcription factor FoxP3 and was normalised to house-keeping gene (GAPDH). Finaly, we compared mRNA expression of target cytokines in mucosa of smokers and non-smokers of IBD patients.

Results: Smokers with Crohn′s disease had significant higher mRNA expression of proinflammatory cytokine TNF α ($p = 0.003$) in inflamed mucosa in sigma in compared with non-smokers. In smokers with ulcerative colitis we observed significant higher mRNA expression of anti-inflammatory cytokine IL 10 ($p = 0.022$) in non-inflamed mucosa of sigma. Similarly, smokers with UC have significant higher mRNA expression of cytokines TLR 2 ($p = 0.024$) and CCR1 ($p = 0.049$) in non-inflamed mucosa of sigma.

Conclusion: According to our, smoking stimulates mRNA expression of anti-inflammatory cytokine IL-10 in smokers with UC, but on the other side smokers with CD had significant higher mRNA expression of pro-inflammatory cytokine TNF in mucosa of sigma.

Introduction: The management of low-grade dysplasia (LGD) in ulcerative colitis (UC) is uncertain due to the variable risk of progression to colorectal cancer (CRC). Chromosomal copy number alterations (CNAs) are known to occur in colonic epithelial cells of UC patients who have developed CRC. The burden of CNAs in precursor LGD relative to high-grade dysplasia (HGD) and CRC has not been defined, and the correlation between LGD CNA burden and future CRC risk is unknown.

Shallow whole genome sequencing[1] is a novel, high-throughput, cost-effective technique for high-resolution CNA assessment in formalin-fixed, paraffin-embedded tissue. We have successfully utilised this technique using as little as 500 picograms of relatively degraded DNA that has been extracted from archival tissue as much as 20 years old, at a cost of approximately €75 per tissue sample.

Aims and Methods: To define the genomic changes that differentiate LGD from both HGD and CRC, we identified 19 UC proctocolectomy specimens with HGD and/or CRC, and analysed 77 neoplastic regions of interest (36 LGD, 34 HGD and 7 CRC).

To determine the utility of shallow whole genome sequencing in predicting future CRC, we then analysed dysplastic tissue from 35 patients: 13 'progressor' patients with 27 LGD lesions who subsequently developed HGD and/or CRC a median 427 days later (IQR 213–777 days), and 22 'non-progressor' patients with 26 LGD lesions who remained free of HGD and CRC at least 5 years later. The two patient groups are matched for age, gender, disease duration and LGD location.

Histological diagnosis was confirmed by two blinded pathologists. Shallow whole-genome sequencing (0.1x) was performed using a standardised pipeline for epithelial cell enrichment, DNA extraction, library preparation, next generation sequencing and bioinformatic analysis.

Results: A median 12% of the genome of LGD tissue from proctocolectomy specimens showed CNAs (IQR 4–32%), compared to 23% in HGD/CRC (IQR 19–42%, $p = 0.003$). Similarly, the number of CNA events was greater in HGD and CRC compared to LGD ($p < 0.001$). Multiple CNAs involving key driver genes were more frequent in HGD/CRC compared to LGD (adjusted p values < 0.05), including 8q gain (*MYC* loss, OR 17.2), 4q loss (OR 4.59) and 18q loss (*DCC*/*SMAD4* loss, OR 4.15).

Both the maximal total CNA burden and number of CNA events are greater in the LGD lesions of progressor patients compared to the LGD lesions of non-progressor patients ($p < 0.01$).

A Kaplan-Meier survival analysis of the 35 grouped 'progressor' and 'non-progressor' patients demonstrates that patients in this cohort bearing LGD with the 25% greatest number of copy number alteration events are significantly more likely to develop future CRC/HGD than the remaining 75% of patients (HR 7.1, $p < 0.001$).

Conclusion: LGD lesions demonstrate a surprising genomic diversity in copy number alteration burden, with some LGD lesions bearing CNA profiles indistinguishable from HGD and CRC. Shallow whole genome sequencing has potential translational utility, by stratifying patients with LGD according to their future risk of progression to HGD and/or CRC.

Introduction: Inflammatory bowel diseases (IBDs) are a heterogeneous group of disorders exhibited by two major phenotypic forms: Crohn's disease and ulcerative colitis. Although the etiology of IBD is unknown, several factors released from the white adipose tissue (WAT) and skeletal muscles including adipokines and myokines, as well as changes in intestinal microbiome were proposed. Recently, we have reported that the voluntary wheel running reduced colonic inflammation in rodent models of colitis but the effect of forced treadmill exercise has not been extensively studied.

Aims and Methods: The role of protective myokines such as irisin and adipokines including adiponectin affecting the course of IBD in experimental animals forced to exercise has not been fully elucidated. We determined the effect of moderate forced treadmill running for 6 weeks with the speed 12 cm/sec in mice fed a high-fat diet (HFD) compared to those on a standard chow diet (SD) with intrarectal administration of 2,4,6-trinitrobenzenesulfonic acid (TNBS) colitis. To minimize distress, mice did not run during or after TNBS colitis. The disease activity index (DAI), colonic blood flow (CBF), the colonic tissue content of IL-17, IFNγ, TNF-α, IL-1β, IL-6 and IL-10 using Luminex Multiplex Assays, the stress oxidative markers MDA, reduced glutathione, SOD and plasma myokine irisin, adipokines leptin and adiponectin levels and real-time PCR and protein expression of proinflammatory factors in colonic mucosa and mesenteric fat were assessed.

Results: Macroscopic and microscopic colitis in sedentary SD mice was accompanied by a significant fall in CBF and moderate increase in colonic tissue weight and a significant increase in the plasma levels of TNF-α, IL-6 and IL-1β ($p < 0.05$). In sedentary HFD mice, colonic lesions were aggravated, colonic tissue weight increased and the IL-1β, TNF-α, IL-6, IL-17, and IFNγ and leptin levels significantly increased. Simultaneously, a significant decrease in the plasma irisin and adiponectin levels was observed in HDF fed mice compared with SD mice ($p < 0.05$). Treadmill exercise significantly increased the macroscopic and microscopic colitis, substantially decreased CBF and raised the plasma TNF-α, IL-6, IL-1β, and leptin levels while decreasing both, the plasma irisin and the plasma and WAT concentrations of adiponectin in HFD mice ($p < 0.05$). The protein expression of heme oxygenase (HO-1) and hypoxia inducible factor1α (HIF-1α) were significantly increased in colonic mucosa of treadmill exercising HFD mice with colitis.

Conclusion: We conclude that: 1. experimental colitis is exacerbated in HFD mice, possibly due to a fall in colonic microcirculation and an increase in the plasma and mesenteric fat content of proinflammatory biomarkers, and 2. forced treadmill running exacerbates the severity of colonic damage in mice fed a HFD through the rise in oxidative stress, the increase in expression and activity of proinflammatory factors including leptin released from WAT and the attenuation of protective mediators irisin and adiponectin.

Introduction: The pathogenesis of perianal fistulas is poorly understood. The reasons why fistulas originate have been explained in idiopathic cases, with the cryptoglandular theory being widely accepted. However, in Crohn's disease, it is thought to involve interplay between microbiological, immunological and genetic factors. It remains unclear why the fistula persists.

Aims and Methods: We undertook a pilot study with the aim of defining how metabolic profile varies in idiopathic (cryptoglandular) cases of perianal fistula and Crohn's perianal fistula. Fistula tissue biopsy was obtained from the fistula tract of 31 patients with idiopathic perianal fistula and 20 patients with Crohn's anal fistula. Ultraperformance liquid chromatography-mass spectrometry (UPLC-MS) profiling in positive mode was implemented to detect metabolites present in fistula samples. Samples were analysed using hydrophilic liquid chromatography (HILIC). The validated hydrophilic liquid (HILIC) chromatographic method developed at the MRC-NIHR National Phenome Centre, IRDB Building, London, UK(1).

Multivariate data analysis was performed using the SIMCA software (v.14.0.2, Umetrics, Umeå, Sweden). Principle component analysis (PCA) and orthogonal partial least squares discriminant analysis (OPLS-DA) models were built to find metabolites that can predict IBD fistula.

Metabolite putative identification was conducted by matching accurate *m/z*measurements of detected chromatographic features to theoretical value from in-house databases and on-line databases such as the human metabolite database (HMDB, http://www.hmdb.ca/) KEGG (http://www.genome.jp/kegg/ligand.html), METLIN (http://metlin.scripps.edu/) and previous publications.

Results: Significant OPLS-DA model (p.value CV-ANOVA 0.0117) separated well between idiopathic and IBD fistula patients. Robust statistical parameters were obtained with R2X 0.212 R2Y 0.658, Q2Y 0.260).

Eighty features were selected from the OPLS-DA model as potential predictors of the group separation. From these, 26 putatively assigned including validation of the arginine with standard. 18 of these 26 features were increased and 8 decreased in CD perianal fistula.

Conclusion: This study highlights the potential for metabolite profiling to differentiate Crohn's and idiopathic perianal fistula groups. Further work is required to understand the pathways to which the significant amino acids described may be related to, as these may offer clues as to the underlying pathogenesis.

Introduction: Crohn's CD disease is a pathology characterized by a chronic inflammation of the intestinal tract engendered by an excessive activation of lymphocytes T, which would be responsible for a change of the immune answer. The gene CTLA-4 (Cytotoxic-T-Lymphocyte Antigen 4) and the gene CD28 (Cluster of differentiation), represent two good candidates genes to explain the physiopathology of CD. While the molecule CTLA-4 plays a leading role in the negative control of Lymphocytes T activated, the protein CD28 assures an opposing role, by guaranteeing their activation, their survival and their expansion. Besides, several studies analyzed the possible association of these two genes with certain autoimmune diseases as type 1 diabetes, celiac disease and rheumatoid arthritis.

Aims and Methods: Searching a correlation between polymorphisms of -318 C/T, 49 A/G CTL-4 gene and SNP IVS 3 17 T/C CD28 gene studied by PCR-SSP and CD and compare the results to control group.

Results: The study concerned 50 CD's patients and 108 controls. The frequency of the allele C of the SNP-318 C/T was more important in CD patients (94%) than in controls (91.2%). The frequency of the allele A of the SNP 49 was more frequent in patients (75%) than in controls (70.8%), The frequency of the allele T of the SNP IVS 3 17 T/C was also superior in patients (83%) than in healthy (80.1%) and a frequency of the more considerable haplotype TCA was more frequent in CD patients (61.8%) than in controls (52.3%). However, these differences were not significant (p = 0.3917; p = 0.4422; p = 0.54; p = 0.1133).

Conclusion: We concluded to the absence of an association between allelic and haplotypic polymorphisms Crohn's disease studied population. Our results are in agreement with most of the studies. To our knowledge, for the gene CD28, our study is the first one that searched an association between the disease of Crohn's disease and the polymorphism. Other studies with more large scales with various ethnic groups and stratification according to the risk factors are necessary to explore the exact role of the polymorphisms of the gene CTLA-4 and CD28 in the physiopathology of Crohn's disease.

P1540 CROHN'S DISEASE PHENOTYPE DIFFERS BY BODY MASS INDEX AT PRESENTATION

J. Cooney, **A. Bancil**, S. Rafiq, A. Woods, D. Braim, I. Stanton, M. Mendall
Croydon University Hospital, Gastroenterology, London, United Kingdom

Contact E-Mail Address: asbancil@gmail.com

Introduction: There is increasing appreciation that patients with Crohn's disease (CD) are likely to have either a low or high body mass index (BMI) at presentation, compared to subjects with ulcerative colitis (UC) and healthy controls. It is possible that the pathogenesis of CD may be different between patients with low and high BMI at presentation. The relationship between BMI at presentation and CD phenotype has not been previously evaluated.

Aims and Methods: 182 subjects diagnosed with CD between 1976 and 2017 had their BMI recorded at the time of diagnosis (n = 97) or by validated recall (n = 85), together with their disease location and disease behaviour at the time of diagnosis. Association between BMI at diagnosis, phenotype and risk factors were analysed by logistic regression, adjusting for year of diagnosis, age at diagnosis and sex.

Results: The table shows the distribution of CD location, CD behaviour, risk factors and patient characteristics, across the different BMI categories.

Variables	Low BMI (n = 13)	Normal BMI (n = 85) (reference)	Overweight BMI (n = 49)	Obese (n = 35)
Age at Dx: Mean (SD)	32.4 (15)	33.3 (16)	35.1 (14)	38.1 (14) (p = 0.02)
Sex (Male)	6 (46%)	45(53%)	19(44%)	21(60%)
Year of Dx: Mean (SD)	2005 (16%)	2008 (11%)	2007 (13%)	2010 (11%)
Location L1	4 (31%)	12 (12%)	9 (22%)	13 (37%) (p < 0.04)
Location L2	3 (23%)	14 (15%)	15 (35%)	7 (20%)
Location L3	6 (46%)	57 (67%)	19(44%)	14 (40%) (p < 0.01)
Behaviour B1	3 (23%)	16 (19%)	14(32%)	11(31%)
Behaviour B2	6 (46%)	38 (45%)	10(23%)	16 (46%)
Behaviour B3	4 (31%)	25 (29%)	14 (32%)	7 (20%)
Behaviour Perianal	3(23%)	13(16%)	6(14%)	5(14%)
Surgery	6 (46%)	39 (46%)	15 (35%)	7 (20%) (p < 0.05)
Extraintestinal manifestations	3 (23%)	2 (2%)	3 (6%)	6 (17%)

[Results Table]

Dx: diagnosis, SD: standard deviation, Disease location L1: ileal, L2: colonic, L3: ileocolonic, Disease behaviour B1: non stricturing non penetrating, B2: stricturing, B3: penetrating.

There was evidence that CD phenotype differed according to BMI. Extremes of BMI were associated with an ileal location. Obesity at the time of diagnosis was associated with an older age at diagnosis, and a reduced need for surgery. Ileocolonic disease was associated with a normal BMI at diagnosis. There was a trend for smoking to be associated with low BMI at diagnosis.

Conclusion: Evidence is presented for an association between BMI at presentation and differences in CD phenotype. Further study is recommended to evaluate these relationships further.

Introduction: Depression and anxiety are significant predictors of worse health-related qualify of life in inflammatory bowel disease (IBD) patients. Nevertheless, the role of anxiety and depression in IBD patients under anti-TNFα treatment has been poorly investigated.
Aims and Methods: The aim of the study was to evaluate both the frequency of anxiety and depression symptoms in IBD patients under anti-TNFα therapy, and the potential factors influencing the development of these symptoms.
A prospective observational cohort study was designed. All IBD patients older than or with 18 years under treatment with anti-TNFα were consecutively included. Prevalence of anxiety and depression was assessed in IBD outpatients using the Hospital Anxiety and Depression scale (HAD). When using this scale we considered scores of 8 or higher to be abnormal. Relapse was defined in Crohn's disease (CD) as a Harvey and Bradshaw index higher than 4, and in ulcerative colitis (UC) as a Partial Mayo index higher than 2. Patient demographics and disease characteristics were also collected: age, sex, marital status, smoking habit, type of IBD, phenotype included in Montreal classification, extra-intestinal manifestations, clinical activity, prior surgery, perianal disease and steroid or immunosuppresant use. Results are shown as OR and 95% CI, and analysed by logistic regression.
Results: Eighty patients were consecutively included (37 male, mean age 40 years, range from 20–67). Sixty patients (75%) had CD and twenty ulcerative colitis (25%); sixty-one (76%) of them were under maintenance treatment with infliximab and nineteen (24%) with adalimumab. Anxiety and depression symptoms were presented in 49.4% and 25.3%, respectively. Females were more likely to have anxiety (OR = 4.73; 95% CI: 1.82–12.26; p = 0.001) and depression (OR = 3.56; 95% CI: 1.14–11.06; p = 0.028). Patients with active disease were no more likely to have anxiety (OR = 1.001; 95% CI: 0.973–1.029; p = 0.972) or depression (OR = 1.013; 95% CI: 0.984–1.042; p = 0.389). None of the other socio-demographic and clinical parameters were significantly associated with the development of anxiety or depression.
Conclusion: An important number of IBD patients under anti-TNFα present anxiety or depressive symptoms. Female gender is associated with more anxiety and depression in this group of patients. However disease activity was not associated with an increase in either anxiety or depression.
Disclosure: Nothing to disclose

P1542 PREVALENCE OF ANAEMIA IN INFLAMMATORY BOWEL DISEASE: PRELIMINARY RESULTS OF THE OBSERVATIONAL ITALIAN MULTICENTRE IG-IBD STUDY RIDART 1

Introduction: Anaemia is the most common extra-intestinal manifestation in inflammatory bowel disease (IBD).
Aims and Methods: The RIDART 1 is an independent, observational, multicentre study, promoted by the Italian Group for the study of Inflammatory Bowel Disease (IG-IBD) with the primary aim to define the prevalence of anaemia in an unselected population of Italian patients with IBD. 3220 unselected Italian patients with IBD were included. The follow-up of anaemic patients was extended up to six months after recruitment in order to evaluate how anaemic patients were treated and if the ECCO guidelines for the treatment of iron deficiency anaemia in IBD were correctly applied. Here we showed preliminary results describing the main features of IBD patients with anaemia in terms of demography, disease activity, anaemia pathogenesis and severity 20 months after starting the study.
Results: Of the 3220 IBD patients included, 392 (12.2%) had anaemia. No difference between anaemic and non-anaemic subjects were observed as far as patient age, gender and disease duration. Body mass index was significantly (p = 0.0051) lower in the anaemic group (22 ± 2.5 kg/m^2) compared with the non-anaemic one (24 ± 2 kg/m^2). In most cases (86%) anaemia was mild (Hb≥9.5 g/dL), and only 2% of patients had severe anaemia (Hb < 8.0 g/dL). Hb was lower in patients with active disease and correlated significantly with CDAI in Crohn's disease (p = 0.0182) and CAI in ulcerative colitis (p = 0.0021). An isolated iron deficiency was responsible for 61.7% of anaemic cases, while the remaining cases had anaemia of chronic disease (12.8%), vitamin deficiencies (2.8%), and various combinations of iron and/or vitamin deficiencies and inflammation (22.7%).
Conclusion: The lower prevalence of anaemia in RIDART1 (12.2%) in comparison to that reported in previous European studies may be due to the fact that, in recent years, more attention is paid to the impact of anaemia in IBD patients, and both anaemia and IBD are more efficiently treated than in the past. Caution, however, must be used in the interpretation of the present data since the RIDART 1 study is still under way.

Introduction: Periodontitis is a disease manifested by the loss of clinical attachment, deepening of the gingiva pockets, loss of bone supporting the teeth roots and their mobility leading consequently to the need for teeth extraction. Periodontal disease is the second cause (just after the dental caries) of premature loss of natural teeth. The course and severity of periodontitis are significantly influenced by the virulence of the plaque bacteria, as well as the immune defenses of the organism.
Aims and Methods: The aim of the study was to determine the state of periodontium based on CPITN index in correlation to smoking habits and type of treatment in patients suffering from Crohn's disease (CD).
The 110 subjects (80 with Crohn's disease and 30 healthy control) aged 18–65 (mean 34.9) were included to the study. Disease phenotype at diagnosis was classified according to the Montreal classification. Studies included only these patients who had conducted a complete diagnostic workup of the entire gastrointestinal tract. The complete assessment of the periodontium was based on the CPITN index which is a simple and quick screening tool.
Results: In the studied population, a statistically significant difference was found between the groups in the range of CPITN (p = 0.018). In the CD group, symptoms of inflammation (codes 1–4) were noted in 87.5% of subjects, while in the healthy group they concerned 76.9%. In CD patients group codes 3 and 4 (evidence of occurrence shallow or deep periodontal pockets) in total were found in 18.8% while in the control group it was 6.7% and only related to code 3. Code 4 has not been recorded in anyone in the control group.
A statistically significant relationship was found between CPITN and the age of patients in the entire studied population (p = 0.0004). There was no significant correlation between periodontium and gender or type of treatment in CD.
Statistical analysis showed no significant differences between the groups in the field of cigarette smoking despite the fact that in the group with CD current and past smokers were up to 47.5%, while in the control group they constituted 26.7%, respectively. In the studied population there was no significant correlation between cigarette smoking and the value of CPITN.
Conclusion: The results of the study indicate higher CPITN values in people with CD compared to the control group regardless of gender, type of treatment and smoking. This may indicate the association of the Crohn's disease with periodontal health.

Introduction: Ulcerative colitis (UC) is a chronic inflammatory bowel disease of unknown aetiology. UC typically affects the rectum and may extend towards the proximal colon over time. This disease behaviour is clinically relevant and impacts on long-term outcomes. It is known that proximal disease extent is associated to higher burden of systemic inflammation and greater severity. Extensive colitis is also related to a higher colorectal cancer risk. The natural course of UC is unpredictable and the risk factors associated to proximal progression have not been clarified. It is important to identify patients at high risk of proximal disease extent in order to optimize treatment and follow-up.
Aims and Methods: The aim of this study was to investigate the rate of proximal disease progression and to identify risk factors associated with extent of disease in rectal and left-side UC in the biologic era. This is an observational, retrospective study, that included all cases diagnosed with rectal and left-side UC confirmed from January 2005 to December 2016. Proximal disease extent was assessed according to Montreal Classification criteria: proctitis (E1) when the involvement is limited to rectum, left-side colitis (E2) if extent is distal to splenic flexure, and extensive colitis (E3) if colonic involvement extends proximal to splenic flexure. Proximal disease extent was defined as progression from E1 or E2 to E3, confirmed by endoscopy. Demographic, clinical, endoscopic, laboratory and drugs received data were collected on all patients. Mann-Whitney test were performed for continuous variables and chi-square test for categorical variables to compare the baseline characteristics between the non-extent group and the extent group. The Cox logistic regression model was used to identify risk factors associated with proximal disease extent.
Results: We included 71 patients with distal UC: 36 E1 and 35 E2; 46.5% were male. Median follow-up of 7 (IQR 4–9) years. A total of 14 (19.7%) progressed to extensive colitis; median time to progression was 5 (IQR 1–8) years. 3 patients underwent colectomy during follow-up (2 in non-extent group). At diagnosis, 3 patients received anti-TNF therapy and only 2 patients had extent and 1 no progressed. Baseline patient characteristics including age, gender, smoking habit, hypertension, obesity, diabetes mellitus, history of appendectomy, family history of inflammatory bowel disease and initial laboratory data were not significantly different in the extent group compared with patients whose ulcerative colitis did not extend. However, extent group were more likely to suffer from primary sclerosing cholangitis (14.3% versus 0%, $p = 0.016$). Furthermore, there was no significant difference in Mayo score at diagnosis between the two groups. In the multivariate analysis, risk factors associated with proximal disease extent were female sex (HR 6.7, 95% CI 1.4–32.5) and arthropathy at diagnosis (HR:3.7, 95% CI 1.1–12.8), whereas the use of oral 5-aminosalicylic acid since the diagnosis was a protective factor of proximal disease extent (HR: 0.19, 95% CI 0.04–0.82).
Conclusion: The disease proximal progression was observed in 19.7% of patients with limited UC over time. This study suggests that female sex and arthropathy represent risk factors to proximal disease extent, whereas the use of 5-aminosalicylic acid oral at diagnosis is associated as a protective factor of disease extent in patients with limited UC. No conclusion can be drawn from the possible influence of biologic treatment on the proximal disease extent.

P1545 THE ROLE OF SLEEP DISORDERS IN INFLAMMATORY BOWEL DISEASES (IBD) CLINICAL COURSE

M. Sochal, A. Gabryelska, M. Krzywdzinska, R. Talar-Wojnarowska, E. Malecka Panas
Medical University of Lodz, Department of Digestive Tract Diseases, Łódź, Poland

Contact E-Mail Address: sochalmar@gmail.com
Introduction: Etiology of Crohn's disease (CD) and ulcerative colitis (UC) has not been clearly defined and is multifactorial. Sleep may modulate the activity of the immunologic system. Mouse colitis model showed that sleep continuity disturbances exacerbated clinical and histopathological signs of the disease. The role of the sleep disturbances in inflammatory bowel diseases (IBD) clinical course is poorly understood.
Aims and Methods: The aim of the study was to evaluate compare the sleep patterns in patients with of IBD depending on the disease activity.
25 individuals with IBD in exacerbation (age: 45 ± 13.5; 45% of men) and 25 in remission (age: 43 ± 14.5; 68% of men) were included in the study and completed questionnaires assessing sleep quality: Pittsburgh Sleep Quality Index (PSQI), Athens insomnia scale (AIS). The mood level (using Beck Depression Inventory (BDI)) and the level of pain (using Visual Analogue Scale (VAS) and Laitinen Pain Scale (LPS)) were measured. The active disease will be defined as the Harvey-Bradshaw index score >6 on the CD and the partial Mayo scale >3 in the UC. Information about the progress of the disease, methods of treatment and socio-demographic variables were also collected.
Results: Differences between quality of sleep and the type of IBD were not significant (CD: $n = 24$ 5 ± 1.5 and UC: $n = 26$ 5 ± 2 $p = 0.977$ for PSQI; CD: 6 ± 2.25 and UC: 4 ± 4 $p = 0.691$ for AIS). Patients in exacerbation presented decreased quality of sleep in both PSQI (6 ± 2 $p = 0.035$) and AIS (8 ± 3.5 $p = 0.001$) compared to remission group (4 ± 1.5 for PSQI and 4 ± 2 for AIS). Additionally, exacerbation group score was higher in VAS (5 ± 2.5 $p = 0.006$), LPS (5 ± 3 $p = 0.004$) and BDI (9 ± 5 $p = 0.003$) scale than in remission group (2 ± 1.5 for VAS, 2 ± 1.5 for LPS; 5 ± 3.5 for BDI). Subsequent ANCOVA analysis has shown that sleep disorders in exacerbation were more severe than in remission and were independent of covariates such as VAS, LPS and BDI regarding both sleep questionnaires PSQI ($p = 0.010$) and AIS ($p < 0.001$).
Conclusion: Patients with UC have similar sleep problems compared to those with CD. Decreased sleep quality may not depend on pain and depression, which are generally recognized as factors influencing sleep quality. The problem of sleep disturbances in IBD exacerbation should be considered in the disease treatment.
Disclosure: Nothing to disclose

P1546 SELECTED CYTOKINES IN PERIODONTITIS IN PATIENTS WITH CROHN'S DISEASE – PRELIMINARY RESULTS FROM POLIBD STUDY

Introduction: Il-1β is a universal factor that stimulates the inflammatory reaction and can induce the secretion of other cytokines. Interleukin-6 (Il-6) is secreted to stimulate immune response in the inflammatory and auto-immune processes. Pro inflamatory cytokines mediate inflammation in both Crohn's disease (CD) and periodontitis conditions. However, the influence of periodontitis ovelaping CD on cytokine levels has not been elucidated up to the date. From clinical point of view, characteristic patern of inflammatory cytokines may be usefull durning the differentiation between common periodontitis and early stage of oral manifestation of CD.
Aims and Methods: The aim was to determine the serum levels of selected cytokines for CD patients depending on the condition of the periodontium as well as the habit of smoking, the type of treatment, the time elapsed from the diagnosis and disease phenotype according to the Montreal classification.
40 patients aged 18–65 years (mean 33.8) with Crohn's disease were involved to the studies. Patients completed survey and dental examination with CPITN index calculating according to WHO recommendations was performed. Following, the data on the Il-1β and Il-6 levels were assessed by MagPix 13-plex bone panel.
Results: Overall cytokine levels were low. Il-1β levels were 0.20–1.68 pg/mL (mean 0,59 pg/mL) and Il-6 levels were 2.03–100.50 pg/mL (mean 11,73 pg/mL). Levels of both interleukins were significantly statistycally positively correlated ($R = 0.32$, $p = 0.039$).
Suprisingly, Il-1β was negatively correlated with state of periodontium related to CPITN ($R = -0.31$, $p = 0.047$).
We didn't find any relationship between interlekin levels and smoking. The disease phenotype, type of tretment and time elapsed from diagnosis weren't significantly correlated with Il-1β nor Il-6 levels.
Conclusion: Since cytokine levels, including Il-1β and Il-6, are expected to be increased in the course of Crohn's disease, our results differ from results obtained by other authors. We noticed differences in Il-1β serum level of CD patients related to the state of periodontium. Some other findings reported changes (an increase) in periodontitis only in salivary or gingival fluid levels of Il-1β and Il-6 but not in serum.
Disclosure: Nothing to disclose

P1547 PREDICTIVE FACTORS OF BONE LOSS IN INFLAMMATORY BOWEL DISEASE

F. Errabie[1], A. El-Mekkaoui[2], W. Khannoussi[3], Z. Ismaili[4], G. Kharrasse[5]

[5]*Faculty of Medicine Oujda, Avicenne, Oujda, Morocco*

Contact E-Mail Address: fadoua.errabie@gmail.com
Introduction: Patients with inflammatory bowel disease (IBD) have an increasing risk of developing bone and mineral metabolism disorders. Osteopenia and osteoporosis are a frequent but often underestimated complications in these patients. Several factors could contribute to osteopenia, while pathogenetic mechanisms are still ambiguous.
Aims and Methods: The aim of this study is to assess the prevalence and the risk factors associated with bone loss in IBD patients.
We conducted a prospective and descriptive study including 104 patients with IBD supervised within our department. Only patients who had bone densitometry and a phosphocalcic biology analysis were included. Bone mineral density (BMD) was measured with diphotonic x-ray absorptiometry of the lumbar spine and the neck of the left femur. Results were expressed with T score (osteopenia: -2.5 standard deviation (SD) $< T <$ -1 SD, osteoporosis: $T < -2.5$ SD) according to the World Health Organization (WHO) specifications.
Results: 104 patients with IBD were included (55 women, 49 men), 55 had Crohn's disease (CD) (52.88%), 40 had ulcerative colitis (UC) (38.46%), and 9 had indeterminate colitis (8.65%). The average age at diagnosis was 37.86 years [15–73]. BMD was normal in 47 patients (45.2%) and reduced in 57 patients (54.8%). In 22 cases osteopenia was diagnosed (21.15%) and 35 patients had osteoporosis (33.65%). In patients with Crohn's disease, 56% of cases (31/55) had a reduced BMD (osteopenia in 13 cases and osteoporosis in 18 cases). 60% of patients with UC (24/40) had reduced BMD (osteopenia in 8 cases and osteoporosis in 16 patients) and 22% of patients with indeterminate colitis (2/9) had a reduced BMD (osteopenia in 1 case and osteoporosis in 1 patient), rheumatologic manifestations were found in 19 patients with a reduced BMD, 27% of which had ankylosing spondyloarthritis. 29 patients received a full

corticosteroid therapy dose for at least 4 weeks. The univariate analysis showed a statistically significant relationship between osteoporosis and age over 38 years (0.04), active tobacco consumption (0.049), diabetes ($p = 0.04$), and low body mass index, particularly below 20 kg/m^2 ($p = 0.022$).
Conclusion: Bone Loss and osteoporosis are commonly reported in patients with IBD. Bone Mineral Density screening must be conducted systematically for patients with IBD. The predictive factors of osteoporosis found in our series are age over 38, smoking, diabetes and low body mass index, particularly below 20 kg/m^2.
Disclosure: Nothing to disclose

P1548 THE EPIDEMIOLOGICAL PROFILE OF INFLAMMATORY BOWEL DISEASE IN EASTERN REGION OF MOROCCO

F. Errabie[1], A. El-Mekkaoui[2], W. Khannoussi[3], Z. Ismaili[4], G. Kharrasse[5]
[1]*Mohammed VI University Hospital, Gastroenterology, Oujda, Morocco*
[2]*CHU Mohammed Vi Oujda, Dept. of Gastroenterology, Oujda, Morocco*
[3]*Mohammed VI University Hospital, Hepato Gastroenterology, Oujda, Morocco*
[4]*Medical School, Hepato Gastroentetology, Oujda, Morocco*
[5]*Faculty of Medicine Oujda, Avicenne, Oujda, Morocco*

Contact E-Mail Address: fadoua.errabie@gmail.com
Introduction: Initially described in Northern Europe and the USA, inflammatory bowel disease (IBD) is now present worldwide. Africa is considered a continent of low incidence. However, the frequency of infectious colitis and the inadequacy of health systems in these countries explain the difficulty of assessing the actual incidence of these diseases.
Aims and Methods: The objective of our study was to describe the epidemiological and sociodemographic profile of IBD in the eastern region of Morocco.
Descriptive and analytical retro-prospective study including 240 patients who were diagnosed with IBD at the Hepato-gastroenterology department of Mohamed VI University Hospital of Oujda over a course of 6 years and 3 months from January 2011 to April. 2017. The data was collected using an exploitation sheet and the statistical analysis was done using Excel version 2010 and SPSS version 21.0.
Results: Among all eastern oriental inhabitants, the overall IBD prevalence was estimated at 10.3 / 100,000. The incidence of IBD progressively increased, especially for Crohn's disease (CD), during the studied period. The average age was 38.2 ± 13 (14–80 years) with a slight female predominance (sex ratio to 1.1). The majority of our patients came from an urban setting (93.3%). In this study 240 patients with established IBD diagnosis were included. among them, 132 patients were diagnosed with CD (55% of the total), 79 patients with ulcerative colitis (32.9% of the total), and 29 cases (12.1%) of indeterminate colitis (IC). In the CD group, patients were younger than those in ulcerative colitis, with average ages of 35.84 ± 12.8 and 41.56 ± 14.6 years, respectively. In our study, active smoking was noted in 3.8% of ulcerative colitis (UC) patients, and 7.5% of CD patients ($p = 0.2$). There was a personal history of appendectomy in 2 patients with UC (2.5%) compared with 19 patients (14.4%) in the CD group ($p = 0.003$). The presence of anoperineal lesions was significantly associated with the male sex ($p = 0.03$). Ten (10) patients with CD (7.6%) and 12 patients with UC (15.2%) had a family history of IBD ($p = 0.06$).
Conclusion: Our study allows a better knowledge of the epidemiological profile of IBD in the eastern region of Morocco. These patients appear to be young with a female predominance and predominantly of urban origin. The creation of a national registry of IBD is necessary and will not only allow the knowledge of the epidemiological and socio-demographic data but also an improvement of the subsequent care presented to these patients.
Disclosure: Nothing to disclose

P1549 PRESENCE OF GRANULOMAS IN INTESTINAL BIOPSIES FROM PATIENTS WITH CROHN'S DISEASE CORRELATES WITH DISTINCT DISEASE CHARACTERISTICS

N. Perlepe[1], S. Siakavellas[2], E. Koureta[2], I. Delladetsima[3], G. Papatheodoridis[2], G. Bamias[1]

Contact E-Mail Address: nikoletaperl@hotmail.com
Introduction: Detection of granulomas in intestinal biopsies is highly suggestive of a diagnosis of Crohn's Disease (CD). The clinical significance of granulomas for the phenotype and natural history of CD has not been established yet, as previous studies produced conflicting results.
Aims and Methods: We aimed to evaluate if granuloma detection correlated with specific characteristics and/or a particular disease course in a defined cohort of patients with CD.
We retrieved all histological reports from an 8-yr period (2010–2017) that corresponded to the cohort of patients with CD with a regular and complete follow-up at our tertiary, reference IBD centers. Patients were classified according to the presence (or absence) of granulomas. The two groups were compared for various epidemiological, laboratory and clinical characteristics, as well as the clinical course and response to treatment.
Results: We identified biopsies from 220 patients with CD [male = 95, age 40.5 ± 14.8 yrs, 17–76 (mean ± SD, range)] during the study period. Seventy-one patients (32.3%) were found to have epithelioid granulomas in at least one biopsy. The presence of granulomas was significantly associated with younger age at symptom initiation (37.2 ± 13.1 vs. 42.2 ± 15.3 years, $P = 0.015$), active smoking status ($P = 0.032$), weight loss and bloody stools at presentation ($P = 0.001$ and $P = 0.012$ respectively). Patients with granulomatous disease showed a trend towards colonic localization of the disease (non-L1 Montreal phenotype) ($P = 0.097$), and increased number of flares during follow-up (3.4 ± 2.4 vs. 2.6 ± 1.8 flares, $P = 0.079$). The latter trend persisted even when duration of follow was taken into account (0.6 ± 0.5 vs 0.5 ± 0.4 flares per year of follow-up, $P = 0.071$).
Conclusion: The presence of granulomas in biopsies from patients with CD was associated with specific disease characteristics and more frequent disease flares. Thus, granulomas may serve as a surrogate marker for a distinct subgroup of CD patients who may demonstrate more aggressive disease behavior.

Introduction: Risk of colorectal cancer is increased among patients with ulcerative colitis.
Aims and Methods: Study design: Retrospective data analysis using the National Health Insurance Fund social security databases including inpatient-, outpatient care, medications as well as the special drug reimbursement database of patients with the diagnosis of ulcerative colitis (UC) from 2007 to 2016. This is an observational / non-interventional, retrospective, epidemiological study.
Study population: All of the adult – over 18 years of age – UC patients between the examined period.
Eligibility criteria: Patients who have at least two events in all of relevant health care services or at least 1 inpatient event only with UC diagnosis (ICD codes: K51) K50 (Crohn's disease-CD) and K51 (UC) occurrence together: 80:20 distribution ratio. A patient having colorectal cancer (CRC) is defined using ICD codes (C1500 – C2690) with the requirement of having at least two appearances in the in- or outpatient care (with the corresponding codes).
Primary endpoint: Analyze patient characteristics, epidemiology, CRC incidence and treatment patterns of UC patients in Hungary.
Results: The number of all UC patients between 2007–2016 was 27,850; 0.24% of total Hungarian population suffered from UC in 2016. The annual incidence of UC varies from 15.1 to 29.5 with a declining tendency. The female/male ratio is 55/45%. The median age of the patients with UC is 51 (male 49, female 53) in the examined period. Two thousand four hundred and fifty-two patients were diagnosed with CRC (8.8% of the total UC population). Ratio of mortality was 14.2% in the total group, 3941 of 27850 patients died. 24.8% of the total death was observed among patients with UC and CRC. Median survival of CRC was 64.7 months (95% CI 58.4–77.7). No significant difference can be observed between the different age groups, the confidence intervals are very wide due to the small sample size in the younger age groups. One thousand and ninety-five patients (2.89%) were treated with biological therapy between 2007–2016, while 2.1% of total UC population was treated with anti-TNF alpha therapy in 2016 that is more than 490 patients. The prevalence was 1.2% for ADA and 1.1% for IFX in the total UC population. The onset of biological therapy is between 20 and 39 years in the majority of the patients, average age is 37 years. This is 16 years less compared to the average age of total UC population.
Conclusion: Both the prevalence and incidence of UC are high in Hungary. While the ratio of co-existing CRC was 8.8%, 24.8% of these patients died during the examined decade. 2.89% of the UC population was treated with biological therapy in the examined period. Patients receiving biological therapy are typically from the younger part of the total UC population

Introduction: MicroRNAs (miRNAs) are short non-coding RNAs that regulate gene expression. Growing number of studies have shown that miRNAs are highly involved in different inflammatory diseases including ulcerative colitis (UC). To date, miRNA deregulation profiles in active UC have not been fully explored.
Aims and Methods: The aim of this study was to evaluate and compare miRNA profiles in tissues of active UC, UC in remission (inactive UC) and healthy controls. In the initial stage, miRNAs were sequenced in tissue samples of 32 healthy controls, 23 active UC and 21 sample of UC in remission using next generation sequencing platform. Most deregulated miRNAs were further validated in a second cohort of individuals with 38 healthy controls, 38 aactive UC and 36 inactive UC patients using RT-PCR based arrays. A multidimensional scaling analysis using Spearman's correlation distance was performed to identify the similarities in miRNA expression profiles.
Results: Next-generation sequencing results of tissue samples from patients with active UC and healthy controls revealed 108 differentially expressed miRNAs, while 74 miRNAs were deregulated comparing active UC and UC in remission. Interestingly, only 31 deregulated miRNAs were found comparing healthy control and inactive UC tissues. In the validation phase, eight miRNAs (hsa-miR-223-3p, hsa-miR-155-5p, hsa-miR-146a-5p, hsa-miR-431-5p, hsa-miR-146b-3p, hsa-miR-493-3p, hsa-miR-1180-3p and hsa-miR-424-3p) have been confirmed as consistently deregulated when comparing active UC and healthy controls. In parallel, only three miRNAs (hsa-miR-223-3p, hsa-miR-431-5p and hsa-miR-1180-3p) were confirmed as deregulated between healthy controls and inactive UC tissues.
Conclusion: Ulcerative colitis has unique miRNA signatures in colon tissues comparing active disease stage and disease in remission, which also differ from healthy controls. Furthermore, individuals with UC in remission have a more comparable miRNA expression profile with healthy controls than with active UC.

Introduction: Identification of patients at high risk of disabling disease course would be invaluable to guide initial therapy in Crohn's disease (CD). Clinical parameters at diagnosis are insufficient to predict a disabling course of CD (1). The objective of this study was to evaluate a combination of clinical, serological and genetic factors to predict complicated disease course in paediatric-onset CD.
Aims and Methods: Paediatric-onset CD patients, diagnosed before 17 years between 1988 and 2004 and followed more than 5 years were extracted from the French population-based Epimad registry. Complicated disease course was defined by the progression from an inflammatory (B1) to a complicated behavior (stricturing B2, or penetrating B3) or an intestinal resection within five years after diagnosis. Available data included clinical data at diagnosis, serological markers at inclusion (ASCA, ANCA, anti-OmpC, anti-Cbir1, anti-Fla2, anti-Flax) and 370 candidate Single Nucleotide Polymorphisms (SNP) associated with CD or other immune-mediated diseases or having a role in inflammation pathways, interaction with micro-organisms, or modulation of innate immunity. A lasso logistic regression model with stability selection was used to select variants associated with severe disease. After this selection step, a final lasso logistic model was performed including clinical, serological and selected variants.
Results: Two-hundred and nineteen patients were included, with a median age at CD diagnosis of 14.3 years (IQR [11.9–16.0]). Among the 156 patients with inflammatory disease (B1) at diagnosis, 35% (n = 54) progressed to a severe disease defined by a complicated behaviour or an intestinal resection during the five years following diagnosis. Final model included location at diagnosis (L1 or L3 at higher risk), ANCA (protective) and ASCA-IgG (higher risk) and 15 SNPs. Half of SNPs were known as susceptibility loci of IBD or CD including NOD2. This model showed good predictive measures with an AUC of 0.85, a sensitivity of 77%, a specificity of 80%, a positive predictive value of 68% and a negative predictive value of 87%.
Conclusion: In this population-based paediatric-onset CD cohort, a combination of clinical, serotypic and genotypic variables is able to predict disease progression with a high accuracy. After validation in an independent cohort, this prediction score will be helpful to identify patients needing early biological therapy.

Introduction: Crohn's disease (CD) and ulcerative colitis (UC) are the two major diseases that make up the inflammatory bowel disease (IBD). The major clinical manifestations occur in the gastrointestinal tract, especially in the small intestine and colon. The etiology is multifactorial, with an interaction between individual genetic characteristics, predisposition and environment. These factors must be involved in the modification of the immune response with consequent formation of altered inflammatory response. Studies indicate that several genes, in addition to those involved in the modulation of the immune response, are differentially expressed in patients with CD. vs UC. The discovery of microRNAs (miRNAs) as important regulators of gene expression and their role in human diseases, including inflammatory and chronic degenerative diseases, have indicated miRNAs as ideal candidates for diagnostic biomarkers, prognostics and potential therapeutic targets. An important feature of miRNAs is their stability and easy detection in body fluids.
We aimed to identify deregulated miRNAs in DII and to apply bioinformatic analysis strategies to identify target mRNAs and molecular pathways modulated by miRNAs through meta-analysis of literature data.
Aims and Methods: A meta-analysis was performed for the identification of miRNA expression data in IBD. Inclusion and exclusion criteria were applied and 10 studies were selected, from which relevant miRNAs with increased or decreased and statistically significant expression were collected compared to controls, type and number of analyzed samples (serum, plasma or tissue) with CD and / Or UC, platforms used for analysis of global miRNAs expression and validation of data, author name and date of publication. Significantly deregulated miRNAs in DIIvs. Controls were used in bioinformatic analysis to predict the target mRNAs regulated by these miRNAs. Prediction analyzes of miRNA target transcripts and enrichment of biological functions of the target genes were performed.
Results: The results showed 6 CD miRNAs with increased expression and 51 UC. On the other hand, miRNAs with decreased expression were found 51 CD and 26 UC.
The miRNAs that showed the greatest number of interactions with DII deregulated genes were let-7a-5p, let-7b-5p and miR-199a-5p, miR-150-5p, miR-362-3p and miR-224- 5p. In the RCU were -155-5p and miR-24-5p, miR-335-5p and miR-16-5p. Suggesting that they may play an important role in the molecular mechanisms of disease. In addition, the results were used to identify gene interactions and biologic processes with: inflammatory process and response to the immune system. We show that miRNAs and target genes may be useful biomarkers for the development of new therapeutic strategies for patients with IBD.
Conclusion: Several interrelated genes and miRNAs were identified as potential regulators of gene expression. Such miRNAs and genes may play important roles in the development and progression of inflammatory bowel disease. The miRNAs regulate several target genes and important molecular pathways, knowledge of these altered molecular pathways may be useful for the future development of more accurate treatment strategies for patients with DII.

Introduction: Patients with inflammatory bowel disease (IBD) should undergo multiple colonoscopies during their clinical history. Adequate bowel preparation is essential to high-quality colonoscopy but in our tertiary referral center for IBD it is not uncommon to find suboptimal bowel cleansing in these patients. In literature only few studies on bowel preparation in IBD patients can be found.
Aims and Methods: To assess bowel preparation in IBD patient, identify possible causes for suboptimal bowel cleansing and identify strategies for its optimization. Consecutive outpatients with IBD (ulcerative colitis [CU] and Crohn's disease [CD] were prospectively enrolled before (ileo) colonoscopy at Gastroenterology and Endoscopy Unit of ASST Fatebenefratelli Sacco in Milan. Patients answered to a questionnaire with different items (type of bowel preparation, completeness of preparation, adherence to instructions given for preparation, palatability, side effects, Bristol Scale of stools in the previous weeks). Informations about IBD type, duration of disease and treatment were also collected. Bowel preparation was evaluated by Boston Bowel Preparation Scale (BBPS); BBPS $\geq$ 6, at least 2 in every segment was considered adequate preparation. In a second part of the study, bowel preparation instructions were modified according to the last guidelines and patients received a telephone call to stress the importance of adherence to the suggested bowel preparation; the same questionnaire of the first part was administered to patients.
Results: In the first part we enrolled 120 patients (58 UC, 60 CD, 2 undetermined colitis) who had taken low volume PEG (lvP) in 57%, high-volume PEG (hvP) in 20%, stimulant laxatives (SL) in 16%, other (i.e. mix between PEG and stimulant laxatives) in 7% of cases. 53% of patients assumed correctly (i.e. respect of the timetable, completeness, correct diet) the preparation. 6% of patients assumed the preparation with a split modality. Median time between preparation and colonoscopy was 15 (5–25) hours. 28% of patients fasted on the lunch before preparation. Adequate bowel preparation was observed in 67% of patients, without differences with the type of IBD. In the second part of the study we enrolled 161 patients (80 UC, 80 CD, 1 undetermined colitis). LvP was assumed in 60%, hvP in 8%, SL in 24%, other in 8%. 70% of patients assumed correctly (i.e. respect of the timetable, completeness, correct diet) the preparation. 14% of patients assumed the preparation with a split modality. 6% of patients fasted on the lunch before preparation. Median time between preparation and colonoscopy was 14 (3–22) hours. Adequate bowel preparation was observed in 75% of patients, without differences with the type of IBD. In this second group of patients, independent predictors of adequate bowel preparation were age (OR 0.97, 95%CI 0.95–1), constipation (OR 0.08,95%CI 0.02–0.46) and time between preparation and colonoscopy (= R 0.82, 95%CI 0.72–0.94).
Conclusion: Few studies are available on bowel preparation in IBD patients. The results of our study suggest that motivation of the patient to follow instructions for the preparation (including split preparation) may be beneficial. Special attention to older patients and bowel habits when prescribing colonoscopy are needed to assure adequate preparation. The role of the referring gastroenterologist may be of pivotal importance in stressing the importance of accurate execution of bowel preparation.

P1555 UTILITY OF THIOPURINE METABOLITE TESTING IN INFLAMMATORY BOWEL DISEASE

A.Y. Carbajo, J. Barrio, F.J. García Alonso, J.A. Garrote, M. Cimavilla, R. Torres Yuste, R. Sánchez-Ocaña, M.A. Marinero, R. Atienza
Hospital Universitario Río Hortega, Valladolid, Spain

Contact E-Mail Address: anaycarbajo@gmail.com
Introduction: Thiopurine use in inflammatory bowel disease is limited by drug toxicity and lack of therapeutic efficacy. 6-Thioguanine (TGN) levels between 235 and 450 pmol/8 $\times$ 10^8 erythrocytes (RBC) have been found to correlate with therapeutic response while 6-methyl mercaptopurine (6-MMP) levels greater than 5700 pmol/8 $\times$ 10^8 RBC correlate with hepatotoxicity. Traditionally, thiopurine dosing has been weight based, but recent studies suggest basing doses on thiopurine metabolite testing might improve outcomes.
Aims and Methods: Single-center observational study including all consecutive patients undergoing thiopurine metabolite testing between July 2016 and September 2017. Demographics, dose, test indication, clinical status, action taken, and outcome were obtained. We assessed the utility of thiopurine metabolite testing and the relationship between disease activity, dose, and metabolite levels in a real-world setting.
Results: A total of 122 patients (65.6% Crohn's disease, 32% ulcerative colitis and 2.5% IBD-unclassified) were included. Median age was 44.5 years (IQR: 34–53) and 59.8% were male.
A total of 114 (93.4%) patients were on azathioprine (median dose 2.1 (IQR 1.7–2.4) mg/kg/day) and 8 (6.6%) on mercaptopurine (median dose 1.0 (IQR 0.8–1.3) mg/kg/day).
Test indication was: active disease (8.2%), adverse effects (12.3%), to check compliance (9.8%), to adjust dose in patients with combined treatment with biologics (therapy de-escalation) (25.4%), to check thiopurine levels after dose adjustment for toxicity (18.1%) and others (26.2%). Twelve (9.8%) patients presented a shunt toward 6-MMP in their thiopurines metabolism.
TGN levels were sub-therapeutic in 30 (25%), therapeutic in 43 (36%), and supratherapeutic in 46 (39%). The results for patients receiving either azathioprine or mercaptopurine were combined and analyzed by weight-based dosing. An association between dosing and categorized distribution of TGN levels could not be found (p = 0.09)
Therapy was changed as a result of testing in 72 (59%) patients. Table 1 outlines rates of change in therapy by test indication.
Conclusion: Metabolite testing resulted in a change in management in most patients not responding to thiopurines or experiencing adverse events. Weight-based dosing did not associate a higher proportion of subjects presenting therapeutic levels.
Disclosure: Nothing to disclose

P1556 THE EVALUATION OF IL-33/ST2 LEVELS CAN PREDICT MUCOSAL RESPONSE TO ANTI-TNF THERAPY IN ULCERATIVE COLITIS

Introduction: Tumor necrosis factor (TNF) inhibitors (anti-TNF) are considered to be effective in inducing mucosal healing in patients with moderate-to-severe Ulcerative Colitis (UC). The role of IL-33 and its receptor, ST2, in intestinal inflammation is incompletely understood, with both pro-inflammatory and regulatory properties described. Recent evidence has shown that anti-TNF is able to modulate the IL-33/ST2 axis in inflammatory conditions.
Aims and Methods: The aim of our study was to explore the potential role of the IL-33/ST2 axis in the mucosal healing process mediated by anti-TNF therapy in UC.
Endoscopic MAYO score was calculated before the first anti-TNF infusion (T0) and after 6 weeks (T2). 26 UC patients (MAYO score at T0 $\geq$ 2), grouped into 14 responders with mucosal healing (MAYO score $\leq$ 1) and 12 non-responders to anti-TNF at T2 (MAYO score $\geq$ 2) were enrolled. 10 healthy controls undergoing routine colonoscopy for tumor screening were also enrolled. At each time point, serum samples were collected. ELISA and western blot were performed to assess IL-33/ST2 protein levels and to evaluate protein isoforms, respectively. Intestinal biopsies were also taken from the rectum and IHC was done to evaluate mucosal IL-33/ST2 expression and localization.
Results: IL-33 protein levels were significantly increased in responders *vs.* non-responders, both at T0 and T2. Among responders, IL-33 protein was slightly reduced at T2 vs. T0, while unchanged in non-responders. Interestingly, significantly higher levels of ST2 were found in responders *vs.* non-responders at T0, while no differences between groups were found at T2. Among responders, ST2 levels were dramatically reduced at T2 *vs.* T0. No significant differences were

Abstract No: P1555
Table 1: Change in therapy by test indication

	Active disease n = 10	Adverse effect n = 14	Check compliance n = 12	De escalation n = 31	After adjustment n = 22	Other n = 32	Shunters n = 12
Change in management, n (%)	9 (90)	14 (92.9)	10 (83.3)	19 (61.2)	8 (36.4)	12 (38.7)	11 (91.7)
Change drug, n (%)	5 (50)	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)
Cease drug, n (%)	0 (0)	1 (7.1)	4 (33)	9 (29)	2 (9.1)	0 (0)	1 (8.3)
Change dose, n (%)	2 (20)	10 (71.4)	3 (25)	10 (32.2)	5 (22.7)	11 (35.5)	4 (33.3)
Encourage compliance, n (%)	0 (0)	0 (0)	3 (25)	0 (0)	0 (0)	0 (0)	0 (0)

found in non-responders at both time points. Healthy controls showed significantly lower levels of both IL-33 and ST2 compared with other groups. Full-length, bioactive IL33 (31 kDa), ST2L (76 kDa) and sST2 (52 kDa) were expressed in all experimental groups; the cleaved, less active form of IL33 (24 kDa) was increased in only non-responders vs. responders and healthy controls. IHC confirmed these observations. In particular, IL-33 and ST2 staining was more intense within the inflamed and ulcerated mucosa of responders compared to non-responders at T0. After 6 weeks, ST2 staining was even more evident in responders, notably localized to the healed mucosa and in close proximity to areas of re-epithelialization. Little to no staining for both IL-33 and ST2 was present in healthy controls.
Conclusion: Our results suggest a possible role for IL-33/ST2 in predicting gut mucosal wound healing in patients with moderate-to-severe UC treated with anti-TNF. IL-33/ST2 axis could thus represent a useful diagnostic tool to evaluate therapeutical options in IBD patients. Further studies are underway to determine mechanisms of action that support these findings.

P1557 CLINICAL AND COST EFFECTIVENESS OF THERAPEUTIC DRUG MONITORING (TDM) OF INFLIXIMAB IN ADULT INFLAMMATORY BOWEL DISEASE (IBD) PATIENTS

S. Ganesananthan[1], A.B. Hawthorne[2], D. Durai[2]
[1]*Cardiff University, School Of Medicine, Cardiff, United Kingdom*
[2]*University Hospital of Wales, Gastroenterology, Cardiff, United Kingdom*

Contact E-Mail Address: ganesananthans@cardiff.ac.uk
Introduction: Infliximab (IFX) is very effective in active IBD but up to 60% of patients will lose response or experience attenuated response to IFX due to fluctuating drug levels or formation of antibodies to IFX (ATI). There is growing evidence of efficacy of TDM. The National Institute of Health and Care Excellence (NICE) do not recommend routine TDM in the NHS.
Aims and Methods: Our primary objective was to assess clinical and cost effectiveness of IFX TDM in IBD. We retrospectively analysed 122 IFX drug levels and 89 ATI levels from 85 patients [54 male (64%), 32 females (36%); mean age: 39.13 years (±14.25); Crohn's Disease (CD) n = 62, Ulcerative Colitis (UC) n = 23; 46 patients (54%) were on combination immunosuppressive therapy]. Patients were allocated to 3 groups based on the intent of TDM: Maintenance group (MG)- proactive TDM on patients with quiescent IBD, secondary loss of response group (SG)- reactive TDM on active patients with established primary response to IFX and post-induction group (PG)-TDM at week 14 post induction. In each sub-group, patient baseline characteristics (CRP, haemoglobin, calprotectin, colonoscopy, MRI, CT) were assessed to construct a global assessment of patient state (active, remission or responding to drug) prior and after TDM led patient management for efficacy of IFX. Cost of IFX (INFLECTRA) was £123.50 (+VAT) per 100mg while cost of TDM (IDKMONITOR ELISA KIT) was £45 per drug level assay and £45 per ATI assay. Calculations were done comparing TDM to empirical IFX dose escalation and switching of drug. Patients were compared to empirical dose escalation; once, before class drug change in PG and twice in SG. Patients on MG were assumed to be left on stable dose for one year with levels being monitored twice a year.
Results: In MG (n = 51), 10 (20%) patients were de-escalated or stopped IFX and maintained in remission and 41 (80%) IFX was continued. The mean IFX level was 1.89mg/l vs 4.34, (p = 0.06) and mean ATI 85.10 vs 9.22, (p = 0.0007) respectively in the two subgroups. The 20% (n = 10) of patients were maintained in remission till date for a mean of 12.2 months (Range 3–30 months) and were previously on IFX for a mean of 61.7 months (Range 20–132months). In the 80% of patients (n = 41), 2 became active after de-escalation, 2 became active despite having therapeutic IFX, 36 remained in remission and 1 patient's status was unknown after stopping IFX (not included in cost savings calculation). Potential cost savings in MG was £669 per person per year (17% savings). In SG(n = 63), 21 (33%) patients switched drug or had surgery post TDM and in 42 (67%) IFX dose was escalated or maintained. The mean IFX levels was 2.24mg/L vs 3.48mg/L (p = 0.19), mean ATI 74.90IU vs 10.29IU (p = 0.0005) respectively in the two subgroups. 16 of 21 patients improved with change of drug, (remission = 8, 2 active, 3 unknowns) showing a 76–90% efficacy post TDM. 28 of 42 from IFX dose escalated SG subgroup improved (12 in remission), 12 patients were still active and 2 unknowns. Cost savings for SG group was £318.61 per person (13% savings). In PG, 2 of 8 achieved remission and 6 of 8 remained active and their mean IFX level were 2.2 vs 0.8 mg/L (p = 0.09) and mean ATI 0 IU vs 16.7 IU (p = 0.22) respectively. Cost saving of £607 per person in the PG group.
Conclusion: IFX TDM in IBD is clinically useful and has saved cost in all three patient groups with proactive TDM in post-induction and maintenance group benefitting the most
Disclosure: Nothing to disclose

P1558 CLINICAL OUTCOMES OF CONCOMITANT PRIMARY SCLEROSING CHOLANGITIS AND INFLAMMATORY BOWEL DISEASE: A SYSTEMATIC REVIEW

K. Wu, **N. Ding**, A. Thompson
St Vincent's Hospital, Department of Gastroenterology, Melbourne, Australia

Contact E-Mail Address: dingnik@gmail.com
Introduction: Primary sclerosing cholangitis (PSC) is a chronic immune-mediated liver disease commonly associated with inflammatory bowel disease (IBD) with the majority being diagnosed with ulcerative colitis (UC). The impact of PSC on clinical outcomes of IBD is unclear. Appropriate management for this patient group is also not well adapted.
Aims and Methods: Our aim was to perform a systematic review of all studies to further characterise the distinct risk of CRN in patients with concomitant PSC-IBD, risk of colectomy as well as response to biologic therapy. A systematic review of studies assessing risk of primary outcomes was conducted. Searches for relevant English language studies from 2000-March 2018, assessing primary outcomes comparing patient cohorts of PSC-IBD and IBD alone, were performed in MEDLINE, EMBASE and Cochrane Library according to PRISMA guidelines. All studies were appraised using the Newcastle-Ottawa Scale.
Results: Twelve studies were identified exploring risk of CRN in PSC-IBD, with 5 studies also reporting colectomy risk. Increased risk of CRN was shown in 11 out of 12 studies which included all 5 PSC-UC studies (RR: 2.58–10.0), 1 study with associated Crohn's disease (CD) (OR = 6.78; 95%CI: 1.65–27.9; P = .016) and 5 studies with unspecified IBD (HR: 2.01 [95%CI: 1.09–3.71] – 21.4 [95%CI: 9.6–47.6]) as shown in table. PSC-CD patients were isolated in 2 other studies; 1 study finding that the risk of CRN in patients with concomitant PSC-CD appeared to be similar to the risk in patients with CD alone (2.9% vs 2.6%) and the other study also concluding that PSC did not increase the risk of CRN in patients with CD (HR = 0.45; 95% CI 0.18–1.13; P = 0.09). Overall, a decreased risk of colectomy was found in 3 of the 5 studies (RR: 0.46–0.67).
The data for response to biologic therapy in PSC-IBD patients is limited by cohort studies with significant heterogeneity. Regarding anti-TNF therapy, a cohort study demonstrated safety and efficacy in all 5 treated patients with PSC-IBD. Conversely, a remission rate of 26% was found in a larger cohort of 19 PSC-IBD patients on anti-TNF therapy. The evidence is similarly limited for the use of vedolizumab in PSC-UC patients; 2 studies were included with clinical remission rates of 21% and 57% at 30 and 29 weeks respectively. The evidence for biologic therapy outcomes are largely found in case reports and series.
Conclusion: The risk of developing CRN in PSC-UC patients is higher while possibly being lower in PSC-CD patients. The risk of colectomy is not paralleled, perhaps due to vigilant colonic surveillance and endoscopic intervention. Further characterisation is needed to better understand and manage these patients. This review also demonstrates the paucity of data regarding the utility of biologic

Introduction: Crohn's disease (CD) is a chronic inflammatory condition of the intestinal tract resulting in ongoing tissue damage and impaired wound healing. The reduced ability of CD patients to heal damaged tissue is reflected by the tendency of CD patients to develop fistula and fibrosis. ADATMS13-processing of von Willebrand factor (VWF) reflects activated VWF, which is essential for initiation of primary hemostasis. Activated VWF is one of the rate-limiting factors in platelet activation and tethering to the damaged endothelium, and consequently is considered a surrogate biomarker for platelet activation. Any dysregulation in VWF processing could contribute to the development and progression of CD due to impaired and dysregulated wound healing, leading to a failure in the secondary hemostasis response.
Aims and Methods: The aim of the study was to investigate the processing of VWF, a marker of endothelial dysfunction, in patients with CD to assess primary hemostasis and platelet activation.
We developed two biomarkers specifically targeting the ADAMTS13-processed form of VWF (VWF-A), and formation/endothelial release of VWF by quantification of the pro-peptide (VWF-N). Serum samples from 13 irritable bowel syndrome (IBS) patients with high-grade inflammation and 51 CD patients and were included in the study together with 10 age-matched healthy subjects.
Results: Levels of VWF-N ($p < 0.05$; $p < 0.0001$) and VWF-A ($p < 0.05$; $p < 0.01$) and were significantly increased in CD and IBS patients compared to healthy subjects, respectively. VWF-N level ($p < 0.001$) discriminated CD and IBS patients from healthy subjects with an area under the curve (AUC) of 0.94. No significant differences were observed in the ratio of VWF-N/VWF-A between CD, IBS and healthy subjects.
Conclusion: CD and IBS patients showed an increased formation, but notably also an increase in activated VWF, indicating a sustained elevated primary wound healing response as compared to healthy subjects. Biomarkers of the dynamics of wound healing activation could serve as supplementary markers of intestinal healing in patients with inflammatory bowel diseases.

Introduction: Currently, there are no serologic biomarkers useful in clinical practice for predicting the risk of developing strictures in Crohn's disease (CD) and for identifying early stages of intestinal fibrosis with the aim of optimising the therapeutic management. Current biomarkers in CD are only predictors of a disabling disease course. Serum sialic-acid-binding immunoglobulin-like lectin (Siglec)-7 is an inhibitory natural killer receptor, whose serum levels are associated with advanced liver fibrosis in hepatitis C virus infection. This study aimed at assessing serum Siglec-7 in CD patients with fibrostenosing phenotype.
Aims and Methods: Blood samples were collected from 30 CD patients (nine with fibrostenosing phenotype, eight with penetrating phenotype and 13 with inflammatory phenotype), 15 patients with ulcerative colitis (UC) and 26 control subjects. Serum concentrations of soluble Siglec-7 were measured by a commercially available quantitative ELISA kit.
Results: Among CD subgroups, serum Siglec-7 was significantly ($p < 0.05$) increased in CD patients with fibrostenosing phenotype (median 2071 pg/ml, range 1367–3292) in comparison to those with penetrating (median 1331 pg/ml, range 995–2132) or inflammatory (median 1356 pg/ml, range 846–1909) behaviour. No difference was found between penetrating and inflammatory phenotypes. In addition, serum Siglec-7 was significantly ($p < 0.05$) up-regulated in patients with stricturing CD in comparison to both UC patients (median 1519 pg/ml, range 846–2909) and control subjects (median 1114 pg/ml, range 750–1506). Serum Siglec-7 was significantly ($p < 0.001$) higher in all the 30 CD patients (median 1411 pg/ml, range 846–3292) in comparison to control subjects.
Conclusion: Our study showed an increase of serum levels of Siglec-7 in CD patients with fibrostenosing behaviour in comparison to those with penetrating or inflammatory CD. These preliminary results support a role for serum Siglec-7 as a fibrogenic biomarker in CD.

Introduction: Patients with inflammatory bowel disease (IBD) have varying disease courses with phases of inactive disease and flares of active disease with impairment of the intestinal epithelial barrier leading to tissue damage. Due to the large surface area, basement membrane is abundant in the intestinal tissue and its constituents, such as laminins, play an important role in the intestinal epithelial homeostasis. The laminin gamma 1 chain is highly abundant along the entire crypt-villus axis in the basement membrane.
Aims and Methods: We investigated if a serum biomarker of the basement membrane (LG1M) could serve as surrogate biomarkers for disease activity in a rat *in vivo* colitis model and in IBD patients. Serum from male Sprague Dawley rats that received 5–6% dextran sulfate sodium (DSS) ($n = 21$) or regular drinking water ($n = 9$) for 5 days was included and scored for disease activity index (DAI). In addition, serum from 44 Crohn's disease (CD) patients with inactive ($n = 20$) or active ($n = 24$) disease and healthy subjects ($n = 20$) was included in this study. A competitive ELISA for matrix metalloproteinase (MMP) 9 mediated degradation of the laminin gamma 1 chain (LG1M) was used to estimate the level of laminin degradation in serum. Sections of the distal colon from the rats were assessed histologically for structural changes.
Results: LG1M were significantly elevated in CD patients serum compared to healthy subjects ($P < 0.001$; $P < 0.001$), but with lower levels in active CD compared inactive CD. The findings of LG1M were confirmed in the *in vivo* colitis model, in which the levels of LG1M in DSS rat serum with high DAI were significantly lower ($P = 0.004$) compared to controls. LG1M correlated negatively to DAI ($r^2 = 0.2153$; $P < 0.01$). The structure of the distal colonic tissue in DSS rats was disrupted compared to controls with loss of crypt architecture and total surface area.
Conclusion: Our data indicate that the basement membrane biomarker, LG1M, may be applied as non-invasive surrogate biomarker of disease activity in CD patients and thus aid in monitoring patients. We report lower serum levels of LG1M in active disease compared to inactive disease in both the *in vivo* model and patient samples. The decreased amount of LG1M during active disease corresponds to the apparent loss of surface area in the intestine, which results in a reduction of the total amount of laminins for MMP mediated degradation.

Contact E-Mail Address: kunovic_ana@yahoo.com
Introduction: Inflammatory bowel disease (IBD) is commonly associated with alteration in fat and lean mass. The conventional indices for assessment of nutritional status such as body mass index (BMI) have been suboptimal and therefore require better modalities which can be assessed by bioimpedance analysis. In addition, correlation of body composition with disease activity has not been well studied. The aim of this study was to evaluate the association of body composition and muscle strength with disease activity in adult patients with Crohn's disease (CD) and ulcerative colitis (UC).
Aims and Methods: All patients underwent the analysis of body composition measured by bioelectrical impedance analysis (TANITA body composition analyser, BC-420MA). Lean mass (LM), fat-free mass index (FFMI) and skeletal muscle index (SMI) were calculated using standard formulae. Muscle strength was obtained from handgrip strength values (HS) measured with Jamar Hydraulic Hand Dynamometer. Medical history data were obtained from clinical and electronic medical records. In order to evaluate disease activity, we used

clinical indices: Crohn's Disease Activity Index (CDAI) for CD patients and Partial Mayo Score for UC patients.
Results: In this study we have enrolled 75 patients (CD = 58, UC = 17; 50.7% male, 49.3% female). Clinically active disease (defined as CDAI > 150 or Partial Mayo Score≥3) was present in 25 patients (16.9% CD and 42.9% UC). There were no statistically significant differences among patients with active and inactive disease in FFMI [kg/m^2] 17.7 (14.9–20.1) vs. 18.2 (15.3–26.2), SMI [kg/m^2] 8.9 (7.1–10.7) vs. 9.3 (7.8–10.8), LM [kg] 50.4 (43–72.4) vs. 55 (43.3–90.5), and fat mass [%] 19.7 (14.9–45) vs. 23 (17.5–45), $p > 0.05$. Muscle strength was significantly lower in patients with active disease (26.6 ± 10.9 kg) comparing to inactive group (32 ± 11.5 kg), $p = 0.048$. Underweight patients, defined as BMI < 18.5 kg/m^2, were significantly more prevalent in active group comparing to inactive (27.8% vs 8.8%, $p = 0.04$, $\chi^2 = 4.219$).
Conclusion: Results of our study haven't shown consistent association between body composition and disease activity. However, muscle strength was lower in group of patients with clinically active disease**.** Body composition analysis by BIA could be useful tool in evaluation of patients with inflammatory bowel diseases; however, there is a need to define age, gender and disease specific, percentile-based thresholds which can simplify the screening procedures in clinical practice.
Disclosure: Nothing to disclose

P1563 ASSOCIATION BETWEEN PROPOSED DEFINITIONS OF CLINICAL REMISSION/RESPONSE AND WELL-BEING IN PATIENTS WITH CROHN'S DISEASE

Introduction: Recently, definitions of remission/response based on stool frequency (SF) and abdominal pain (AP) have evolved; however, data to support the validity of this approach are lacking. This analysis examined the association between the Inflammatory Bowel Disease Questionnaire (IBDQ) item 10 (**Table**), which can be considered a measurement of wellbeing, and clinical remission/response defined by SF and AP scores derived from the Crohn's Disease Activity Index (CDAI).
Aims and Methods: Analyses included patients (pts) from 2 adalimumab (ADA) phase 3 and 1 upadacitinib (UPA) phase 2 Crohn's disease trials with SF ≥4 and/or AP score ≥2 at baseline. IBDQ item 10 responses (scores ranging from 1–7) were categorized into 1/2 (feeling unwell all/most of the time), 3/4/5 (feeling unwell a bit/some/little of the time) and 6/7 (feeling unwell hardly any/none of the time) and analysed vs change from baseline to week 12/16 in SF and AP scores and clinical remission at week 12/16 defined as SF ≤2.8, AP score ≤1.0 and neither worse than baseline. Item 10 response change categories were also grouped (≤−2 to ≥+2-point-change from baseline) and analysed vs percentage change from baseline to week 12/16 in SF and AP with clinical response defined as ≥30% decrease in average daily SF and/or AP score; both not worse than baseline. Statistical differences were based on Mood's two sample median test or chi-square test (2-sided alpha = 0.05).
Results: Overall, 695 pts (40% with prior anti-tumour necrosis factor [TNF] exposure) from the ADA and 163 from the UPA (96% with prior anti-TNF exposure) trials were included. In the ADA trials, the median percentage changes from baseline to week 12 in SF (−62%; n = 194) and AP scores (−83%; n = 193) were greater (both $P < 0.001$) in pts with IBDQ item 10 response scores 6/7 vs 1/2 (−13% [n = 127] and −3% [n = 128], respectively). In the UPA trial, changes in SF and AP (−76% and −73%, respectively [both n = 38]) were greater (both $P < 0.001$) in pts who responded 6/7 vs 1/2 (−14% and 0% [both n = 38]) at week 16. A significantly greater number of pts who responded 6/7 to item 10 in the ADA (62%) and the UPA (61%) trials met the definition of clinical remission compared with pts who responded 1–5 (both $P < 0.001$; **Table**). Pts in the ADA trials with ≥+2-point change in the IBDQ item 10 had greater median percentage reduction in SF (−50% [n = 339]) and AP scores (−64% [n = 338]) vs pts with +1-point (−32% and −31%, respectively [both n = 137]), 0-point (−17% [n = 139] and −14% [n = 138]), or −1-point change (−19% [n = 58] and 0% [n = 57]) from baseline. In the UPA trial, pts with ≥+2-point change (n = 71) had greater change in SF (−68%) and AP scores (−55%) vs pts with +1-point (−35% and −25% [n = 33]), 0-point (−8% and −3% [n = 46]), or −1-point change (−22% and 0% [n = 13]).
Conclusion: The strong association demonstrated between SF and AP defined remission/response and overall wellbeing support the validity of these measures in clinical trials.

Studies	IBDQ Item 10 "How often during the last 2 weeks have you felt generally unwell?" Response Category	n	Clinical Remission* Individual Category (%)	Clinical Remission* Grouped Categories (%)
Adalimumab	1. All of the time; 2. Most of the time	37; 91	0; 4	3
	3. A good bit of the time; 4. Some of the time; 5. A little of the time	110; 119; 144	11; 13; 31	20
	6. Hardly any of the time; 7. None of the time	134; 60	58; 70	62

Introduction: Bowel wall fibrosis is a relevant complication of Crohn's disease (CD), as its emergence is associated with stenosing and penetrating complications, reduced response to medical therapy and increased need for surgical interventions. To evaluate the relative proportion of fibrotic vs. inflammatory tissue in CD affected segments may be helpful to guide therapeutic decisions. In the last few years, ultrasound elastography (UE) and magnetic resonance imaging (MRI) have demonstrated good accuracy in quantifying CD-related ileal fibrosis as compared with histological examination.
Aims and Methods: The present study was aimed to compare the diagnostic performances of MRI and UE in the quantification of CD-related ileal fibrosis. Consecutive patients with ileal or ileocolonic CD underwent UE and MRI 5 days apart. Bowel wall stiffness at UE was quantified by calculating the strain ratio (SR) between the mesenteric tissue and the bowel wall. Strain ratio ≥2 was used to identify severe ileal fibrosis. Parameters evaluated at MRI included wall thickening, edema, pattern andprogression of contrast enhancement 70 seconds (70s) and 7 minutes (7m) following gadolinium injection.
Results: 28 CD patients (20M, mean age 28 yrs.) were prospectively included in the study. 21 patients (75%) had ileal and 7 ileocolonic (25%) localization. A significantly higher percentage of lesions with stratified contrast pattern at 70s was found in patients with severe fibrosis at UE with respect to patients with mild/moderate fibrosis (50% vs. 8%, $p < 0.05$). A highly significant correlation was observed between SR at UE and progression of contrast enhancement at 7m at MRI ($r = 0.65$, $p = 0.002$). Additionally, patients with severe fibrosis at UE (SR≥2) were characterized by significantly higher values of contrast

enhancement progression at 7m with respect to patients with low/moderate fibrosis (14.5% vs -0.7%, p = 0.001). By using UE as a gold standard, ROC curve analysis identified a cut-off value of 8.85% for MRI contrast enhancement progression at 7 min which was able to identify severe ileal fibrosis with a sensitivity of 87.5 and a specificity of 100%.
Conclusion: Results of this study demonstrate a good agreement between UE and MRI in identifying ileal fibrosis in patients with CD.

Contact E-Mail Address: julien.kirchgesner@gmx.com
Introduction: Definition criteria of acute severe ulcerative colitis (ASUC) are well established, as well as the treatment strategy after hospital admission. In contrast, there are few data regarding predictors of colectomy at hospital admission. The aim of this study was to build a predictive score of colectomy based on clinical, biological and endoscopical parameters in patients with ASUC.
Aims and Methods: All consecutive patients with ASUC treated with intravenous corticosteroids, ciclosporin or tumor necrosis factor antagonists (anti-TNFs), and hospitalized in two French academic hospitals between January 2002 and January 2017 were included. Clinical, biological and endoscopical parameters at hospital admission were retrospectively collected. Treatment exposure was recorded and patients were followed until occurrence of colectomy or loss of follow-up. Predictors of colectomy within one year after admission were assessed by Cox survival analysis. The risk factors identified by multivariate analysis were used to build a predictive score of colectomy within one year after admission for ASUC.
Results: A total of 270 patients with ASUC were included with a median follow-up of 2.0 years (interquartile range [IQR] 0.5–4.8). Median age at occurrence of ASUC was 32 years (IQR 24–47), 30% (81) and 12.6% (34) had a past or current exposure to thiopurines and anti-TNFs at admission, respectively. Median C-reactive protein (CRP) and albumin level at hospital admission were 53mg/L (IQR 18.6–110) and 30.7g/L (IQR 26.3–35.2), respectively. *Clostridium difficile* infection was diagnosed at hospital admission in 4.3% of patients (10) and 93.7% (253) were treated with intravenous corticosteroids as first line treatment. One year after occurrence of ASUC, 54.8% (148) were exposed to thiopurines, anti-TNFs or vedolizumab. The cumulative risk of colectomy was 12.7% (95%CI, 8.8–17.3) and 21.5% (95%CI, 15.7–27.9) at one and five years after the episode of ASUC, respectively. By multivariate analysis, previous treatment by anti-TNFs or thiopurines (Hazard ratio (HR), 3.93; CI 95% 1.85–8.34), presence of *Clostridium difficile* infection (HR, 3.65; CI95% 1.09–12.28), CRP level above 30mg/l (HR, 3.08; CI95% 1.12–8.52), and albumin level below 30 g/l (HR, 2.66; CI95% 1.20–5.90) were associated with an increased risk of colectomy within one year after admission. We developed a score based on these four predictors (1 point for each item, from 0 to 4). The cumulative risk of colectomy within one year extended from 0 to 100% in patients with a score of 0 and 4, respectively (Table 1).

Score	N patients	Cumulative risk of colectomy at 3 months (%)	Cumulative risk of colectomy at 1 year (%)
0	41	0,0	0,0
1	91	7,1	9,6
2	113	6,5	10,7
3	24	24,1	53,0
4	1	100	100

[Table 1]
Conclusion: In this exploratory cohort of consecutive patients with ASUC, we identified previous treatment by anti-TNFs or thiopurines, presence of *Clostridium difficile* infection, CRP level above 30mg/L, and albumin level below 30 g/L as independent predictors of colectomy within one year. A score combining these predictors is highly predictive of the occurrence and risk magnitude of colectomy within one year after admission. These results need to be validated in a replicative cohort.
Disclosure: Nothing to disclose

Introduction: Several studies have shown the protective function of trefoil factors in the gastrointestinal tract and their up-regulated expression at the site of mucosal damage. However, the role of serum trefoil factor 3 (TFF3) in inflammatory bowel disease (IBD) still needs to be clarified.
Aims and Methods: The aim of the current study was to evaluate the role of TFF3 as a biomarker of intestinal inflammation in patients with IBD and to compare TFF3 values with those of fecal calprotectin (FCP) in IBD patients. This prospective study enrolled 128 patients with IBD and 16 healthy controls. The patients were divided into four groups: with active ulcerative colitis (UC) (n = 32), with UC in remission (n = 32), with active Crohn's disease (CD) (n = 32), and with CD in remission (n = 32). Serum levels of TFF3 were measured by ELISA, FCP levels were evaluated with quantitative immunochromatographic point-of-care test (Quantum Blue).
Results: The patients with active UC had the highest TFF3 levels. They were significantly higher than those of the controls ($p < 0.001$), active CD patients ($p < 0.001$), UC patients in remission ($p < 0.001$) and CD patients in remission ($p < 0.001$). UC patients in remission had really close mean values of TFF3 to those of the control group, with no significant difference ($p = 0.720$). There was a moderate correlation between TFF3 and FCP values in patients with active UC ($r = 0.516$, $p = 0.041$) and in UC patents in remission ($r = 0.593$, $p = 0.015$). In healthy controls and in CD patients correlation was not found.
Conclusion: Serum human TFF3 correlated well with FCP levels and was able to identify patients with active UC. It has potential for being used as a marker for mucosal healing in UC patients. Further validation is needed to better establish the utility of TFF3 in IBD patients
Disclosure: Nothing to disclose

P1567 DETERMINATION OF ANORECTAL FUNCTION WITH HIGH RESOLUTION ANORECTAL MANOMETRY IN ULCERATIVE COLITIS DURING DISEASE ACTIVITY AND AFTER REMISSION

Introduction: Ulcerative colitis (UC) can impair anorectal function, resulting in distressing and disabling symptoms such as incontinence and increases in the stool frequency, urgency and tenesmus. Previous studies have linked rectal disorders during UC to an overactive rectum with an increased anorectal sensitivity and decreased rectal compliance. However, these results were based on conventional anorectal manometry, with the well-known limit provided by the use of less sensors, usually water perfused. Actually, there are no data reported on the rectal function in UC investigated with High-resolution anorectal manometry (HRAM).
Aims and Methods: The aim of this prospective study was to assess the anorectal function with HRAM in patients with mild-to-moderate UC at the first presentation. Secondary aims were to verify modifications after remission and to compare these data with those obtained in healthy volunteers (HVs).
Patients with UC satisfying the following inclusion criteria were included: an established diagnosis of UC, mild-to-moderate left- side colitis or proctitis according to the endoscopic Baron index. The exclusion criteria for patients with UC were a first disease flare, severe UC, previous anorectal surgery, strictures, or any other anal pathology.
The subjects' gender, age at diagnosis, anorectal symptoms (pain, number of liquid stools per day, urgency, sensation of incomplete evacuation, tenesmus, leakage, fecal incontinence), endoscopic disease activity and treatments (including steroids, 5-ASA, immunosuppressants) were recorded.

Abstract No: P1567

Table 1: HRAM features before and after remission in UC vs HV (* $p < 0.05$)

	Anal resting pressure (mmHg)	Maximum anal squeeze pressure (mmHg)	Anal length (cm)	First sensation threshold (air ml)	desire to defecate threshold (air ml)	urgency to defecate threshold (air ml)	maximum discomfort threshold (air ml)	Rectal compliance (ml/mmHg)
UC before treatment	70.8 ± 18.1	170.7 ± 49.2	3.4 ± 0.6	27.4 ± 13	55.5 ± 12.2*	101.1 ± 8.5*	115.5 ± 26.6*	8 ± 4*
UC after remission	71.8 ± 19.8	165.1 ± 42	3.4 ± 0.6	33.4 ± 13.3	70.5 ± 28.1	118.8 ± 28.5	141.5 ± 29.1	14 ± 7
HVs	74.3 ± 13.3	160.7 ± 35.8	3.6 ± 0.3	32.4 ± 10	75.4 ± 18.2	125.8 ± 22.5	175.5 ± 33.1	16 ± 5

All UC patients underwent HRAM before starting treatment and after remission. HRAM was performed with Sandhill InSight equipment, with a 7 cm long recording sites catheter. All recording sites were constituted by 4 recording pressure sensors arranged radially (28 pressure sensors). Two additional pressure sensors were located at the distal tip of the catheter in order to record intrarectal pressure and intra-balloon pressure. A disposable inflatable balloon was located at the tip of the catheter. The procedure was performed in left lateral (Sims) position after water enema irrigation. After accommodation time, the following parameters were assessed: anal resting pressure (ARP), length of anal canal, pushing endorectal pressure (PEP), recto-anal gradient pressure (RAGP, defined as the pressure difference between rectal pressure and lowest anal canal pressure during straining), rectal sensation and rectal compliance.

Results: Ten patients with UC (8 females) and 10 healthy volunteers (HV, 5 females) were prospectively enrolled. Before therapy, UC patients showed similar values for anal sphincter function to HVs, whereas rectal threshold volume for first sensation, desire to defecate, urgency to defecate and maximum discomfort were significantly lower than HVs values ($p < 0.05$). Rectal compliance was significantly impaired in UC than HVs ($p < 0.001$). After remission, rectal threshold volumes, as well as rectal compliance significantly increased (Table 1). An inverse linear correlation was found between regression of urgency and stool frequency and rectal compliance ($r = 0.811$).

Conclusion: HRAM can provide useful information about anorectal function in UC patients complaining urgency symptoms, in particular assessing the compliance of rectal wall that seems to be the responsible of the genesis of these symptoms.

Introduction: Sleep quality decreases in inflammatory bowel disease (IBD) but there is no study analyzing their dream characteristics. In this study we aimed to measure depression, anxiety, sleep quality, sleepiness level and dream anxiety level quantitatively.

Aims and Methods: Patients who were following up in our IBD-specific outpatient clinic were enrolled prospectively into the study. Control group enrolled from the healthy relatives of other diagnosed patients from other outpatient clinics. Socio-demographic data collected from all participants. The Van Dream Anxiety Scale (VDAS), The Pittsburg Sleep Quality Index (PSQI), Epworth Sleepiness Scale (ESS) Beck Depression Index (BDI) and State Trait Anxiety Inventories (STAI) were used to assess the depression, anxiety levels, sleep quality and dream anxiety of all participants. Crohn's Disease Activity Index (CDAI) and Mayo Score were calculated to measure the disease activity.

Results: Demographic data were summarized in Table 1. Depression, state anxiety, trait anxiety and dream anxiety were higher in healthy controls (HCs) when compared to IBD patients and it was statistically significant ($p = 0.004$, $p = 0.0001$, $p = 0.004$, $p = 0.0001$ respectively). There was no statistically significant difference in sleep quality but sleepiness in daytime seen more common in HCs when compared to IBD patients ($p = 0.99$ and $p = 0.0001$ respectively). There was not any statistically significant difference seen in depression, state anxiety, trait anxiety, dream anxiety, sleep quality and sleepiness in daytime between CD and UC patients. There was not any correlation between disease activity indices and psychological parameters.

Conclusion: In our study anxiety and depression levels were lower in IBD patients as compared to controls on the contrary to results of previous studies; moreover dream anxiety score were higher in HCs. This may be due to traditional social support to sick people in our society, which alleviates burden of all daily living costs and care. Alexithymia seen common in IBD and it may affect the awareness and expressing IBD patients' mood status. Lastly most of our patients were in remission, it may affect psychological parameters positively. Comparative studies investigating coping strategies of IBD patients who had different sociocultural background are needed.

	IBD Patients (n = 136)	Healthy Controls (n = 168)	p
Age (years)	39.28 ± 12.75	36.54 ± 14.14	0.077
Gender (n)	Female:58 (42.6%) Male:78 (57.4%)	Female:89 (52.7%) Male:80 (47.3%)	0.073
Marital Status (n)	Married:95 (69.9%) Divorced: 2 (1.5%) Partner lost: 2 (1.5%) Never married: 37 (27.2%)	Married:75 (44.6%) Married but living separate:3 (1.8%) Divorced:18 (10.7%) Partner lost:1 (0.6%) Never married: 71 (42.3%)	0.0001*

Introduction: Inflammatory bowel diseases (IBDs) are chronic inflammatory diseases characterized by a relapsing-remitting course that may result in appreciable morbidity. Little is known about the characteristics of patients with IBD admitted to intensive care units (ICU).

Aims and Methods: Retrospective cohort study including consecutive patients with IBD admitted to a gastroenterology ICU between June 2003 and February 2018. We aimed to characterize the outcomes of these patients.

Results: 55 patients were included, 27 with ulcerative colitis (UC) and 28 with Crohn's disease (CD). Mean age was 47 (15–81) years and 60% were female (n = 30). Cirrhosis was present in 7 patients (12.7%), the etiology being primary sclerosing cholangitis in 3, nonalcoholic steatohepatitis in 3, and chronic hepatitis B in one. At ICU admission, 19 patients (34.6%) were treated with corticosteroids, 16 (29.1%) with immunomodulators (14 with azathioprine; 2 with 6-mercaptopurine), and 10 (18.2%) with biological therapy (7 with infliximab, 1 with adalimumab and 2 with vedolizumab). During hospitalization, 28 patients (50.9%) started corticosteroids, 5 azathioprine (9.1%), 3 ciclosporine (5.5%), 2 6-marcaptoprine (3.6%), and 1 Infliximab (1.8%). Nine patients (16.3%) received total parenteral nutrition.

The most common causes of admission were: 36.4% IBD flares/complications, 25.5% infectious complications, and 18.2% toxic megacolon. Regarding patients admitted for IBD flares/complications, in 25% it was the inaugural manifestation of IBD.

During hospitalization, 37 patients (67.3%) developed infectious complications, being the most common infection pneumonia (24.3%), Cytomegalovirus colitis (24.3%), urinary tract infection (21.6%), secondary peritonitis (8.1%), and pelvic abscess (5.4%).

Fifteen patients (27.3%) were submitted to a surgery for IBD complications, 10 with UC (18.2%) and 4 with CD (7.2%). Surgery indications were: toxic megacolon (33.3%), refractory UC (26.7%), iatrogenic pneumopetitoneum after colonoscopy (13.3%), hemorrhagic shock (13.3%), abscess (6.7%), and intestinal occlusion (6.7%).

Eight patients (14.5%) died, of whom, 3 patients (37.5%) were under immunomodulatory (n = 2) and biological therapy (n = 1), and 4 patients (50.0%) had cirrhosis. Causes of death were: multiorgan failure in the context of septic shock in 7 cases and hemorrhagic shock in 1 case.

Conclusion: Infections are a major cause of ICU admissionin IBD patients and constitute an important complication during hospitalization, contributing to morbidity and mortality in these patients. Early identification of infectious signs, especially in patients under immunosuppression is essential for the optimal management of these patients.

Introduction: Crohn's disease is an inflammatory bowel disorder with several well-known extraintestinal manifestations, such as erythema nodosum, uveitis, and arthritis. Less commonly observed are cutaneous, so-called metastatic lesions of the vulva, which represent a diagnostic and therapeutic dilemma and require a multidisciplinary approach.
Aims and Methods: The objective of this study was to report a case series of patients with vulvar Crohn's disease (VCD), describe its clinical features, histopathologic characteristics and therapeutic management.
In this retrospective study, we reviewed all cases of VCD seen in our department between 2008 and 2016. Data concerning age at diagnosis of VCD, vulval symptoms at presentation, histologic findings, and different treatment modalities were recorded. Only patients with both clinical features of VCD [knife-cut fissures, edema, ulceration] and histologic confirmation were included. A total of 3 cases were identified among 106 female patients with CD.
Results: Case 1: A 58-year-old patient, presented with a 4-year history of vulvar pain and itching. She had no bowel complaints. Clinical examination revealed hypertrophic exophytic lesions associated with linear ulcearations involving the vulva. A biopsy from the lesional skin showed non caseating gigantocellular granuloma. In view of the clinical and histopathological features, a diagnosis of Crohn's disease of the vulva was made. Anti TNF treatment with adalimumab was started, resulting in a significant regression of the lesions.
Case 2: A 47-year-old patient presented to our department with complaints of painful, persisting vulvar ulcers, and resulting dysperunia for 2 years. On clinical examination she had unilateral vulvar oedema with multiple ''knife-cut'' linear ulcers. A skin biopsy was done which revealed dense inflammatory lymphocytic infiltrate with non caseating granulomas. Treatment with adalimumab was initiated. An improvement of symptoms was noted.
Case 3: A 16-year-old patient with no remarkable medical history, presented with a 2-year- history of persistent cheilitis and vulvar pain. Clinical examination of the external genitalia revealed 'knife-cut' vulvar fissures with important bilateral labial swelling and multiple papules on the surrounding skin. Histological analysis showed chronic inflammatory infiltrate with noncaseating tuberculoid granulomas. Anti-TNF treatment with infliximab was started with partial regression of lesions.
Conclusion: Our findings highlight the importance of keeping VCD on the differential diagnosis when faced with a range of vulvar symptoms. Anti-TNF agents seem to be an efficient treatment strategy for this particular localization.

[2]*University Hospital Centre Zagreb, Center for Clinical Nutrition, Zagreb, Croatia*

Contact E-Mail Address: viktor.domislovic@gmail.com
Introduction: Vitamin D is a hormone with immunomodulatory properties that could potentially influence inflammatory bowel disease (IBD) pathogenesis and activity. Epidemiological data have shown an increased risk of IBD, hospital admission, surgery, and loss of response to biologic therapy in patients with vitamin D deficiency. On the other hand, Crohn's disease (CD) and ulcerative colitis (UC) can also lead to vitamin D deficiency. This two-way relationship between vitamin D and IBD suggests the need for monitoring and regular supplementation of vitamin D. Our goal was to investigate prevalence of untreated and undertreated vitamin D deficiency among IBD patients.
Aims and Methods: In this cross-sectional study levels of vitamin D were measured in a random sample of Caucasian patients with IBD during winter in Croatia. Levels of vitamin D lower than 50 nmol/L were considered deficiency, and between 50 and 75 nmol/L as insufficiency. Patients receiving treatment were defined as those taking vitamin D supplementation of 800–1600 IU daily. Untreated patients were defined as those with vitamin D deficiency and not receiving vitamin D supplementation, while undertreated group was defined as those receiving vitamin D supplementation and with vitamin D deficiency. Medical history data were recorded from clinical and electronic medical records. Disease activity was defined as Crohn's Disease Activity Index (CDAI) <150 or Partial Mayo Score ≥ 3 for CD and UC, respectively.
Results: Levels of vitamin D were measured among 83 patients with IBD (64 CD, 19 UC). There was statistically significant difference in distribution of patients on vitamin D supplementation therapy and those with vitamin D deficiency ($p=0.01$, $\chi^2=6.45$). Prevalence of vitamin D deficiency was 71.1% (N = 59), while prevalence of patients receiving vitamin D supplementation therapy was 16,9% (N = 14). Among analysed patients we noticed relatively high proportion of untreated (63.9%, N = 53) and undertreated (7.2%, N = 6) patients. Median concentrations of vitamin D levels in patients receiving supplementation were 53.5 (36–111) nmol/L which belonged into the group of vitamin D insufficiency, and were significantly different comparing to 36 (26–49) nmol/L in untreated group (p = 0,015). Prevalence of vitamin D insufficiency was 20.4% (N = 17). Multivariate analysis showed that vitamin D deficiency was associated with resection of terminal ileum (OR = 4,04, 95% CI (1,1–14,6), p = 0,03), and was not associated with, gender, phenotype, disease activity, disease duration, small bowel involvement, or smoking status ($p > 0.05$).
Conclusion: Not only vitamin D deficiency is common among IBD patients, but the proportion of untreated and undertreated patients is considerably high. Lower concentrations of vitamin D could be partially explained with lower sun exposure during winter. Resection of terminal ileum is the largest risk factor for vitamin D deficiency. We suggest regular monitoring of vitamin D levels in IBD patients regardless of vitamin D supplementation therapy.
Disclosure: Nothing to disclose

P1572 PREVALENCE AND FACTORS ASSOCIATED WITH SEXUAL DYSFUNCTION AND QUALITY OF LIFE IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

V. Domislović[1], A. Barišić[2], M. Brinar[1], Ž. Krznarić[1,2]
[1]*University Hospital Center Zagreb, Department of Gastroenterology and Hepatology, Zagreb, Croatia*
[2]*University Hospital Centre Zagreb, Center for Clinical Nutrition, Zagreb, Croatia*

Contact E-Mail Address: viktor.domislovic@gmail.com
Introduction: Inflammatory Bowel Disease (IBD) has a negative impact on quality of life (QOL) and sexuality is one of its major determinants. The impact of disease characteristics on sexuality and intimacy is one of the main concerns of IBD patients. Despite the obvious relevance of this problem, knowledge of the extent and the determinants of sexual dysfunction in persons with IBD is limited. The main goal of the study was to determine the prevalence of sexual dysfunction (SD), erectile dysfunction (ED) and association with quality of life (QOL) in patients with IBD, and to search for factors associated with SD and ED.
Aims and Methods: In this cross-sectional study a random sample of patients treated in outpatient clinic fulfilled anonymous validated questionnaire on their sexual function and QOL. In International Index of Erectile Function (IIEF) for males, five domains were evaluated through questions on erectile function, orgasmic function, sexual desire, intercourse satisfaction and overall satisfaction. In women were six domains assessed, desire, arousal, lubrication, orgasmic function, satisfaction and pain. For both scores, higher scores indicated a better function. Patients also fulfilled IBDQ-32, a validated questionnaire for assessing quality of life in IBD patients. IBDQ-32 score is ranging from 32 to 224 with higher scores representing better quality of life. Disease activity was defined as Crohn's Disease Activity Index (CDAI) >150 or Partial Mayo Score ≥ 3 for CD and UC, respectively.
Results: We have enrolled in the study 95 patients who fulfilled the questionnaire (64 CD, 31 UC). Among them were 51 man and 44 women. Average age of included patients was 38 (95% CI: 36.9–44). In women, SD rates were 38.6% (N = 17), and were significantly higher than 9.8% (N = 5) in men ($p=0.001$, $\chi^2=10.19$). QOL was significantly lower in patients with SD, in which IBDQ-32 score amounted 163 (141–192) vs. 192 (163–203). An ED was reported by 22% (N = 11) of male IBD patients, and was significantly higher in patients with active comparing to inactive disease (57.1% vs. 16.7%, p = 0.03). Patients with erectile dysfunction had lower IBDQ-32 score (178 (138.5–188.75) vs. 196 (181–205), p = 0.03). Multivariate analysis showed that the significant predictors for SD were female gender (OR = 6.3, 95% CI 1.84–21.73) and perianal disease (OR = 7.2, 95% CI 1.7–29.7). Disease duration, disease activity, history of lower abdominal surgery, presence of stoma and current biological treatment were not significant predictors of sexual dysfunction.
Conclusion: The results show that SD is highly prevalent in IBD patients, with women to man ratio of almost 4 to 1. Erectile dysfunction is present in approximately every fifth male patient. Patients with both SD and ED have lower QOL. Significant and strong predictors for SD are perianal disease and female gender. Improvement of QUL is one of the main goals in treating IBD patients. Because of its strong connection with sexual function and satisfaction, it is important to identify those problems and to provide proper psychological support, medical treatment and educational information.
Disclosure: Nothing to disclose

P1573 SEROLOGICAL ASSESSMENT OF TYPE XVI COLLAGEN REFLECTS INTESTINAL STRICTURES IN CROHN'S DISEASE PATIENTS

J.H. Mortensen[1], M. Lindholm[1], A. Di Sabatino[2], P. Giuffrida[2], G. Mazza[3], M. Pinzani[3], M.A. Karsdal[1], T. Manon-Jensen[1]

Contact E-Mail Address: jhm@nordicbio.com
Introduction: Stricturing disease remains one of the biggest complications leading to intestinal resection in Crohn's disease (CD), and affecting 30–50% of patients with CD. Intestinal strictures are caused by fibrosis development, as a result of increased collagen deposition. Intestinal fibroblasts and myofibroblasts are the main effector cells for intestinal fibrosis development and intestinal subepithelial myofibroblasts have shown to produce significantly elevated levels of type XVI collagen in CD patients.
Aims and Methods: We investigated a novel serum biomarker, quantifying type XVI collagen (C16-C), as a biomarker for intestinal fibrosis in CD patients.

Serum from CD patients (n = 44) and healthy subjects (n = 50) was included. The Montreal classification for CD disease behaviour (B1, non-stricturing/non-penetrating: n = 20; B2: stricturing, n = 11; B3: penetrating n = 13) and disease location (L1, ileum: n = 14; L2, colon: n = 5; L3, ileum + colon: n = 25) was applied. The patients were classified as having inactive disease (n = 20) or active disease (n = 24) based on the Crohn's Disease Activity Index (CDAI) score. Competitive ELISA was applied for the quantification of C16-C in serum from CD patients (total serum samples: n = 94).
Results: The biomarker C16-C was significantly elevated in patients with CD compared to healthy donors ($P < 0.001$, AUC: 0.81). CD patients with strictures (B2) demonstrated significantly elevated serum levels of C16-C compared to CD patient without strictures (B1 and B3), and healthy donors. Furthermore, the diagnostic accuracy to separate CD patients with strictures (B2) from CD patient without strictures (B1 and B3) was 76% ($P < 0.01$, AUC: 0.76) and healthy donors 96% ($P < 0.001$, AUC 0.82). In addition, C16-C was also elevated in CD patients with ileum or ileum+colon disease involvement compared to only colon involvement and healthy donors ($P < 0.05$). There was no significant difference between patients with active or inactive disease.
Conclusion: Our data demonstrates that type XVI collagen can be quantified in serum from CD patients. The biomarker C16-C was significantly associated with stricturing disease phenotype, indicating that this biomarker might be a biomarker for intestinal fibrosis in CD, and may predict intestinal fibrosis development in CD.

Introduction: Patients with ulcerative colitis may develop short-term or long-term complications such as malabsorption, arthropathies, erythema nodosum or primary sclerosing cholangitis, but the most serious complication is severe acute colitis.
Aims and Methods: The aim of this study was to assess the prevalence of complications in UC and to determine the risk factors related to the occurrence of these complications.
Our study included 76 patients with UC supervised within our department, we studied the following parameters in all these patients: age at the time of diagnosis, sex, smoking habits, extent of the disease, delayed diagnosis or therapy instaurment, therapeutic means and the occurrence of complications. The data was collected with an exploitation sheet.
Results: There was 48 women and 28 men. The average age at diagnosis was 39, 94 (17–74) years. The average duration of disease progression was 38.7 months. No patient had a history of appendectomy. UC was classified as E3 in 50% of cases, E2 in 41% of cases and E1 in 9% of cases. The treatment was based on 5 AZA (5-aminosalicylic acid) in 45 patients (59, 21%), Thiopurines in 23 patients (30, 26%), methotrexate in 4 patients (5.2%) and anti -TNF in 4 patients. All patients in our series had the following complications: malabsorption in 71 patients (93, 4%), acute severe ulcerative colitis in 29 patients (38,15%) of which 12 (15,7%) had a subtotal colectomy, peripheral joint involvement in 24 patients (31.5%), ankylosing spondyloarthropathy in 10 patients (13.5%), thromboembolic complications in 4 patients (5.26%) and a single case of anterior uveitis (1.31%). In a univariate analysis, anemia and the use of corticosteroid therapy in the course of UC were statistically correlated to a delay of 5-AZA therapy establishment of more than 2 months of symptoms onset (p: 0.029, p: 0.05). The delayed diagnosis is statistically related to malabsorption occurrence (p: 0.016), the E3 profile increases the risk of acute severe ulcerative colitis occurrence (p: 0.02) and therefore the resort to colectomy (p: 0.016).
Conclusion: The occurrence of complications in ulcerative colitis is frequent particularly malabsorption. In our study: delayed diagnosis and 5-AZA treatment establishment of more than 2 months and the E3 profile are risk factors for occurrence of complications during UC.
Disclosure: Nothing to disclose

P1575 SERUM BIOMARKERS REFLECTING TISSUE-REMODELLING CORRELATES WITH THE SIMPLE ENDOSCOPIC SCORE FOR CROHN'S DISEASE

J.H. Mortensen[1], M. Lindholm[1], T. Manon-Jensen[1], M.A. Karsdal[1], J.S. Agnholt[2], H. Grønbæk[2], A. Kirch Dige[2]

Introduction: Endoscopy is a mainstay in Crohn's Disease (CD) monitoring. However, endoscopic evaluation of the intestinal mucosa is time-consuming and inconvenient for the patients. Therefore biomarkers that can substitute the need for endoscopic examinations are warranted. Currently, the best validated biomarker for endoscopic disease activity in CD is faecal calprotectin (fCalp).
Aims and Methods: We investigated, whether circulating levels of the tissue-remodeling biomarkers VICM, basement membrane turnover (P4NP, C4M) and Pro-C3, reflects endoscopic disease activity in CD.
We investigated blood samples from 9 CD patients before and after 4 weeks of adalimumab treatment (n = 18) along with serum from male Sprague Dawley rats treated with 1–3% DSS for 7 days (n = 42) and the disease activity index (DAI: faecal consistency, visible blood in faeces and weight loss) was applied. CD patients underwent colonoscopy before and after adalimumab treatment. Endoscopic disease activity was scored by the Simple Endoscopic Activity Score in CD (SES-CD). We measured levels of the biomarkers VICM, P4NP, C4M and Pro-C3 by ELISA. The serum levels of the biomarkers were combined in a backwards multivariate regression model. This model was correlated with the SES-CD score compared with fCalp and C-reactive protein (CRP) levels.
Results: In the samples from CD patients (n = 18) the only biomarkers that contributed significantly to the multivariate analysis model were VICM, P4NP/C4M and Pro-C3. fCalp and CRP did not contribute and was therefore excluded. This model (VICM; $P = 0.003$, P4NP/C4M; $P = 0.025$, and Pro-C3; $P = 0.022$) correlated significantly with the SES-CD score (overall model; $r^2 = 0.53$, $P < 0.001$). fCalp had a moderate correlation with the SES-CD score alone ($r^2 = 0.30$, $P = 0.016$), and CRP did not correlate with SES-CD ($r^2 = 0.03$, $P = 0.40$). Lastly, only the combination of the tissue remodeling biomarkers (VICM, P4NP/C4M, Pro-C3) could separate patients with mild (SES-CD < 7) from patients with moderate to severe endoscopic disease activity (SES-CD > 6) ($P < 0.01$, AUC: 0.89 [CI:0.75–1.0]), fCalp did not demonstrate significant discriminative power ($P = 0.12$, AUC:0.76 [CI:0.43–1.0]). At day 7 the DSS rats with DAI > 7 had significantly elevated serum levels of C4M and P4NP compared to controls ($P < 0.05$). C4M ($r^2$0.29, $P < 0.001$) and P4NP ($r^2$0.21, $P = 0.005$) correlated with DAI score in DSS-treated rats.
Conclusion: The combined tissue-remodeling biomarkers correlated significantly with the endoscopic disease activity in CD. The data was supported by findings from the DSS model. These biomarkers performed better than the established biomarkers fCalp and CRP, and may be used as surrogate markers for endoscopic disease activity assessment.

Introduction: The consequences of malnutrition in ulcerative colitis (UC) are multiple and include significant reductions in bone mineral density, prolongation of disease activity time, and shortening of the duration of clinical remission. The Controlling Nutritional Status Score (CONUT) is based on the determination of albumin, total cholesterol and absolute lymphocytes to offer high sensitivity and specificity in the detection of malnutrition. This score has been used as a predictor of severity and mortality in various malignant and inflammatory pathologies, however, there have been no reports associated with UC.
Aims and Methods: The aim of the present study was to determine the utility of the CONUT score as a nutritional screening method and predictor of severity in UC patients.
A prospective study was conducted, which included 60 UC patients (period November 2016 to October 2017). All patients were adults, of both genders, Mexican mestizos, with diagnosis of UC confirmed by histology. Clinical records were reviewed to obtain the demographic, clinical and biochemical characteristics of the disease. The severity of the disease was measured using the Truelove and Witts score (TW). The risk of malnutrition was assessed using the CONUT score (low risk, 0–4 points, moderate, 5–8 points, and high, 9–12 points).
Results: The proportion was equal between gender. The mean age of presentation was 40.6 ± 13.3 years. The extent of the disease at the time of diagnosis was proctitis in 61.7% of patients, pancolitis (30%) and left colitis (8.3%). Patients presented an intermittent course of the disease (45%) or active and then inactive (36.7%), only 18.3% presented continuous activity. Regarding the activity of the disease by TW, 8.3% behaved as inactive, 18.3% mild activity, 60% moderate activity and 13.3% severe activity. 19 patients (31.8%) presented extraintestinal manifestations Thirty-three patients (55%) had as sole treatment 5-aminosalicylates. Fourteen patients (23.3%) required surgical treatment. When measuring the CONUT score, 93.3% of the patients presented a risk of malnutrition (mild 15 patients, moderate 26 patients and severe 15 patients). The patients with the highest CONUT score showed moderate to severe activity on the TW score, while those with a lower CONUT score had mild activity or inactivity (6.84 ± 2.86 vs 4.1 ± 3.02, $p = 0.009$). A higher score of CONUT was associated with C-reactive protein (CRP) values ≥ 45 (7.37 ± 2.45 vs. 4.97 ± 3.19, $p = 0.002$) and erythrocyte sedimentation rate (ESR) ≥ 30 (6.78 ± 2.78 vs. 4.60 ± 3.26, $p = 0.009$). A cut point of 6-points CONUT score (AUC:0.75, $p = 0.001$) was obtained by means of a ROC curve to discriminate between patients with inactive

or mild UC compared with those with moderate to severe activity, with a sensitivity of 64% and specificity of 88%; the positive predictive value (PPV) and negative predictive value (NPV) was 93 and 47% respectively. A CONUT score ≥6 points confers risk of moderate to severe activity by the TW score (OR:12.25 (2.46–60.91) p = 0.001). This same cut-off point (≥6 points) confers risk to present elevated biochemical markers: ESR > 30 (OR: 5.0 (1.51–16.56) p = 0.005), with a sensitivity of 63% and specificity of 75, PPV 83% and NPV 50%; and CRP > 45 (OR: 3.5 (1.2–10.19) p = 0.02), with a sensitivity of 67% and specificity of 64%, PPV 60% and NPV 70%.
Conclusion: CONUT score could be a predictor of clinical/biochemical severity in UC patients, as it is related to the severity measured by the TW score and with values of CRP≥45 and ESR≥30, the latter being independent predictors of colectomy and severity in UC patients.

Introduction: Ulcerative colitis (UC) is a chronic condition with a heavy economic burden for the health system and the society. The need of lifelong treatments, hospitalizations and surgery causes significant direct costs and indirect costs due to sick leave, reduced employment opportunities and early retirements. Previous cost of illness analyses are available, but very few data have been published in Italy, especially in the south.
Aims and Methods: Our aim was to evaluate prospectively, in a one-year period, the costs of UC in a consecutive cohort of Sicilian patients (pts), and assess their correlation with diseases activity (evaluated by Mayo Score), location, WPAI scoring and quality of life. Pts giving informed consent were asked to fill questionnaires on Quality of life (Eq5D), Work Productivity (WPAI-RCU), Cost of Illness (COI) and use of health resources (HRU). We collected data on hospitalizations, type of hospital stay, surgery, number of visits to the treating physician and in the emergency room, laboratory tests, radiological or endoscopic examinations, histology and drugs. This report concerns data at 6 months.
Results: We recruited 77 consecutive pts with UC coming to our IBD clinic between May and November 2017. 2 of the 77 patients enrolled abandoned the study. Mean age was 46.81 ± 13.64 years, 40 were males (54%). Disease location was pancolitis in 31 pts (40.3%), UC was limited to the left colon in 46 (59.7%). At baseline, 24 (31.2%) were in clinical remission, 24 (31.2%) had mild UC, and 19 (24.7%) had moderate UC. At 6 months, 3 patients underwent endoscopic evaluation because of active disease. Mean cost/patient was 5738.77 € in the 6 months observation period, being higher in pts with extensive disease (7.243.38€) than in limited disease (4.472.2€). The main component of direct costs is due to drugs. There was a statistical difference in costs among pts on biologics (11.140.56 €), as compared to thiopurines (354.47 €), and other treatments (766.86 €). (p < 0.001). Regarding HRU, 11 pts had at least one diagnostic procedure, 3 submitted to endoscopy; 70 had at least one lab test, 4 were hospitalized, 4 had a visit to the emergency room. As far as concerns work productivity, 38 pts were unemployed, and 37 had a job. There was no significant relationship between disease activity and work impairment, assessed by the WPAI score. Disease activity was significantly related to quality of life assessed by the EQ5D Index (p < 0.012). Mean work missing hours (absenteeism) were 19.6 hours.
Conclusion: Our preliminary results confirm that in Southern Italy, UC has high direct costs mainly related to biological therapy. Mean cost/patient was 5738.77 € in 6 months. Disease activity does not significantly impact on work productivity, but significantly impacts on quality of life. We expect data of this ongoing study will provide useful information to all stakeholders, from health authorities to drive resource allocation, patients' association and physicians to improve disease management.

Introduction: Mucosal healing (MH) is to date the most validated target in Crohn's disease (CD). However, its use is limited by the low acceptability of repeated endoscopies. In this context, faecal calprotectin (Fcal) is a more convenient tool to monitor MH. Recently, transmural healing assessed using MRI was associated with sustained clinical remission and lower risk of surgery. We aimed to assess the performances of Fcal to assess transmural healing in CD.
Aims and Methods: We included consecutively and prospectively all CD patients requiring MRI. MRI was performed with injected and diffusion-weighted sequences with no bowel cleansing and no rectal enema. The bowel was divided into five segments to be analysed (ileum, right colon, transverse colon, left/sigmoid colon and rectum). MRI quantitative parameters such as apparent diffusion coefficient (ADC) or relative contrast enhancement (RCE) were assessed. Clermont score [2] and Magnetic Resonance Index of activity (MaRIA) [1] were also calculated. Transmural healing was defined as previously published (no segmental Clermont score > 8.4 [2,3] or MaRIA > 7 [4] with no stricture and no fistula).
Results: Overall, 118 patients were prospectively included (mean age = 25.9 ± 12.7 years, 53.4% of female, 34.6% of current smokers, 33.9% with perianal lesions and 22.9% with prior intestinal resection. Montreal classification was: L1 = 41.0%, L2 = 10.3%, L3 = 48.7%, B1 = 32.5%, B2 = 40.1%, B3 = 27.4%. The patients were treated with anti-TNF (90.0%), thiopurines (39.0%), methotrexate (8.5%) and/or steroids (17.8%). The median values of CDAI, CRP and Fcal were 170 [82–246], 5.9 mg/L [2.3–20.4] et 598 µg/g [139–1800]. The correlation was moderate between Fcal and total MaRIA or total Clermont score ($\rho = 0.40$ for both). The correlation between Fcal and MaRIA or Clermont score, respectively, were $\rho = 0.39$ (p = 0.006) and $\rho = 0.38$ (p = 0.007) for patients with isolated ileal location and $\rho = 0.42$ (p = 0.001) and $\rho = 0.45$ (p < 0.001) for patients with ileocolonic location. The correlation was almost perfect between MaRIA and Clermont score ($\rho = 0.96$; p < 0.0001). Overall, 25 patients (21.2%) achieved transmural healing. The median value of Fcal was significantly lower in patients with transmural healing (284 µg/g [100–931] vs 620 µg/g [191–1800], p = 0.023). Using a ROC curve, Fcal < 400 µg/g was the best cut-off value to detect transmural healing (AUC = 0.64; Se = 0.68; Spe = 0.63; PPV = 0.33; NPV = 0.88; accuracy = 0.64).
Conclusion: Fcal was moderately correlated with transmural healing in patients with CD. These two tools could be complementary to monitor patients with CD.

P1579 FEATURES OF SMALL INTESTINE PERMEABILITY IN AUTOIMMUNE DISEASES OF THE DIGESTIVE SYSTEM: INFLAMMATORY BOWEL DISEASES AND AUTOIMMUNE LIVER DISEASES

D. Akberova[1], D. Abdulganieva[1], D. Mukhametova[1], **A. Odintsova**[2]

Introduction: There is a close relationship between the intestine and the liver, due to the anatomical structure and its unique vascular structure. The liver receives about 75% of its blood supply from the intestine. The protective mechanism of maintaining immune homeostasis in the liver largely depends on the intestinal barrier function and detoxification ability of the liver in a healthy stage. Therefore, the evaluation of intestinal barrier function in inflammatory bowel diseases (IBD) and autoimmune liver diseases (AILD) is a great interest.
Aims and Methods: We aimed to assess the comparative condition of small intestine permeability in patients with IBD and AILD.
125 people were included in to the study. Of these, 60 patients with IBD (31 (52%) women, 29 (48%) men) and 45 patients with AILD (39 (87%) women and 6 (13%) men), 20 – a group of healthy individuals. The average age at IBD – 35.02 ± 1.1 years, AILD – 50.6 ± 7.4 years, in the control group – 30.13 ± 1.5 years.
Determination of small intestine permeability was conducted by a double "sugar test" (the ratio of lactulose/mannitol) using the method of high – performance liquid chromatography – mass spectrometry.
Results: Increased permeability of the small intestine was found in IBD and AILD. Thus, the average ratio of lactulose/mannitol at IBD was 0.024 [0.014;

0.05] ($p < 0.001$) and AILD – 0.101 [0.065; 0.257] ($p < 0.001$), which is higher than in the control group – 0.011 [0.009; 0.017]. In patients with IBD and AILD the differences in the degree of barrier dysfunction – the ratio of lactulose/mannitol was in patients with AILD was higher – 0.101 [0.065; of 0.257] than in patients with IBD – 0.024 [0.014; 0.05] ($p < 0.001$).
Conclusion: Patients with IBD and AILD has increased small intestine permeability by comparison to the control group. The degree of barrier function impairment was higher in patients with AILD than in patients with IBD.
Disclosure: Nothing to disclose

P1580 PATIENT-NEAR ADALIMUMAB TROUGH-LEVEL TESTING BY A NOVEL QUANTITATIVE RAPID TEST; THE QUANTUM BLUE ADALIMUMAB ASSAY

A. Røseth[1], **I. Lindsjô**[1]
[1]*Lovisenberg Diaconal Hospital, Medicine, Oslo, Norway*

Contact E-Mail Address: idakdahlen@hotmail.com
Introduction: Therapeutic drug monitoring (TDM) has become standard clinical practice and overwhelming clinical evidence indicates that dose-optimization improve clinical outcome by decreasing the risk for anti-drug-antibodies and improves the efficacy of the drug itself. Watanabe et al recently demonstrated that increasing trough levels were closely associated with endoscopic response and mucosal healing (*Clin Gastroenterol Hepatol* in press) However, this has been hampered by the high cost of and the absence of a near patient testing.
Aims and Methods: This was to co correlate a CE -marked Point of Care (POC) rapid test for Adalimumab (ADA) trough level, with an established laboratory test used by Norwegian physicians. This POC facilitates the Quantum Blue reader developed by the BüHLMANN Laboratories, AG, Basel, Switzerland. We also wanted to investigate whether a nurse without ordinary lab training could successfully perform this assay.
The study comprised 49 pts with IBD receiving ADA treatment; At the day of infusion, blood for ADA-trough level was collected in addition to 3 ml serum for QB-ADA rapid test.
Part A: All the practical work was performed by the nurse (IL). After vortexing for 3 seconds, the serum was diluted 10uL in 190 uL assay buffer and vortexed for 5 sec. 80uL was applied to the rapid test cassette and read after 15 min using the QB reader.
Results: There was a good correlation between the QB-ADA rapid test and the laboratory based test, Spearmann rank $r = 0.88$, $p < 0.001$. The average within/between assay CV was 23.0/16.9 respectively. More importantly, the ADA-POC correctly identified all the 8 trough values < 5, and the 19 > therapeutic range of 12ug/ml. 22 values was between 5 and 12, the POC correctly identified 21 of these.
Conclusion: In this investigation, we document a close correlation between a 15 min. rapid test for ADA trough level with that of a standard lab-test. We have also shown the robustness of this test since a nurse can accurately perform it. This means that TDM now can be performed in a near-patient facility like an IBD nurse in an out patient clinic without any significant delay.
Disclosure: Dr Arne Røseth is a medical consultant for Bûhlmann labs, the manufactures of the ADA-trough kits.

Introduction: Serum albumin concentrations may be reduced in Crohn's disease due to malnutrition and because albumin is an acute phase protein. The aim of this study was to investigate if serum albumin concentrations are associated with disease activity.
Aims and Methods: Seventy patients aged 16 years and above with newly diagnosed, untreated Crohn's disease were consecutively included in a cross-sectional study between April 1, 2012 and December 1, 2016. Descriptive data, including age, gender and disease distribution were registered, as well as serum albumin concentrations. Disease activity was evaluated using the Simple Endoscopic Score for Crohn's Disease (SES-CD), fecal (f)-calprotectin, CRP and the Harvey Bradshaw Index (HBI). Correlations were calculated by Spearman rank order test, and associations between albumin and disease activity markers were explored by linear regression analysis and measurements of albumin quartile concentrations vs. SES-CD scores.
A receiver operating characteristics (ROC) analysis was performed to determine a cut-off for s-albumin for severe vs. non-severe disease activity. SES-CD scores were categorized in non-severe (0–15) and severe disease activity (16 or above).
Results: Study participants had a median (range) age of 32 (16–78) years, and 44% were males. Small intestinal (49.3%) and ileocecal (37.3%) disease distribution were most frequent. Median SES-CD was 7.5 (1–37), and albumin 37.4 g/L (18.3–51.0). The SES-CD correlated best with CRP ($r = 0.66$) and albumin ($r = -0.66$), $p < 0.001$ for both, followed by f-calprotectin ($r = 0.51$, $p < 0.001$) and HBI ($r = 0.34$, $p = 0.004$).
A linear regression model using log-transformed SES-CD as dependent variable showed significant association with albumin ($r^2 = 0.45$, $B = -0.67$, $p < 0.001$). SES-CD increased significantly with decreased s-albumin concentrations for the three lowest quartiles (Fig.1).
A ROC analysis using SES-CD ≥ 16 as indicator for severe disease gave an area under the curve of 0.873 (std. error 0.063, $p < 0.001$, 95% CI 0.750–0.997). The optimal cut-off of s-albumin was 35.0 g/L, with a sensitivity of 81.3% and a specificity of 90.7%
Conclusion: Serum albumin concentrations were significantly associated with SES-CD, and decreasing albumin quartile concentrations corresponded with increased SES-CD scores in patients with newly diagnosed Crohn's disease. An albumin concentration of 35.0 g/L was identified as the optimal cut-off for severe disease as defined by SES-CD. CRP, f-calprotectin and HBI scores were also significantly correlated with SES-CD. Albumin may be an indicator of disease activity in newly diagnosed Crohn's disease.

Introduction: Therapeutic Drug Monitoring is widely used in the adjustment of Infliximab (IFX) therapy and is expected to be used in the adjustment of biosimilars. SB2, a biosimilar of the originator IFX, has been recently approved by the European Medicines Agency (EMA) for the treatment of Inflammatory Bowel Disease (IBD).
Aims and Methods: The aim of this study was to evaluate the accuracy of three different methods for the quantification of biosimilar SB2. Moreover, the existence of IFX, CT-P13 and SB2 cross-immunogenicity was also evaluated. Three different IFX quantification assays were evaluated: an in-house built method, a commercially-available ELISA assay and a point-of-care device (POC-IFX). Spiking with known concentration of originator IFX, CT-P13 and SB2 were performed in donors' samples and the percentage of recovery of each assay was evaluated. Reactivity of SB2 to patients-extracted anti-IFX and anti-CT-P13 antibodies was quantified using the in-house built method.
Results: The results show that all tested IFX-optimized assays are equally accurate in measuring SB2 levels: the intraclass correlation coefficient (ICC) between theoretical and measured concentrations varied from 0.945 to 0.983. Quantitative comparison showed an excellent ICC between the three assays when evaluating SB2, originator IFX and CT-P13. Regarding SB2, ICC was 0.986, 0.979 and 0.974 for POC IFX/in-house ELISA/in-house and ELISA/POC IFX, respectively. Finally, the anti-IFX and anti-CT-P13 sera reacted almost to the same extent to SB2, originator IFX and CT-P13, with ICCs ranging from 0.986 to 0.993
Conclusion: Our results suggest that either ELISA commercial assay, POC IFX or the in-house method can be used to measure IFX biosimilar SB2 in an accurate fashion. Moreover, these drugs were shown to have a high cross-immunogenicity: this means that switching between them in a patient that has measurable levels of anti-drug antibodies will likely yield no clinical benefit.
Disclosure: FM served as speaker and received honoraria from Merck Sharp & Dohme, Abbvie, Vifor, Falk, Laboratorios Vitoria, Ferring, Hospira and Biogen.

P1583 QUANTIFIED TERMINAL ILEAL MOTILITY DURING MR ENTEROGRAPHY AS A BIOMARKER OF CROHN'S DISEASE ACTIVITY: A PROSPECTIVE STUDY

Introduction: Previously, quantified MRI small bowel motility has been demonstrated as a non-invasive, objective biomarker of Crohn's Disease (CD) inflammatory activity in retrospective investigations (1,2). In this study we prospectively evaluate the accuracy of quantified small bowel motility for CD activity against endoscopic and histopathological standards of reference. We also include the MaRIA score (validated MRI index of CD severity) to provide context (3).
Aims and Methods: 82 subjects (42 male, median age 32.5 years) recruited from two centres, underwent colonoscopy and MR enterography separated by median 5 days (range 0 to 14). The Crohn's Disease Endoscopic Activity Index (CDEIS) was scored in the terminal ileum (TI), and a histopathological activity score (eAIS) derived. TI motility was quantified using a validated motility algorithm based on image registration and the magnetic resonance index of severity (MaRIA) score calculated. Sensitivity and specificity of Motility (> 0.3 AU) and MaRIA (≥ 11) for disease activity (CDEIS ≥ 4 or eAIS ≥ 1) was compared using McNemar's test, and Receiver Operating Characteristic (ROC) area under the curves constructed. Motility was correlated with reference standards using Spearman's rank.
Results: Against CDEIS, motility had sensitivity and specificity of 92.7% and 66.7%, which was significantly higher & lower respectively than MaRIA (78.1% $P = 0.03$ and 80.5% $P = 0.05$). Against eAIS, motility had sensitivity and specificity of 91.7% and 73.5% for inflammatory activity. Sensitivity, but not specificity, was significantly higher than MaRIA (75.0% $P = 0.03$ and 73.5% $P = 1.0$ respectively). Motility had moderate negative correlations with eAIS $R = -0.61$, $p < 0.001$) and CDEIS ($R = -0.59$, $p < 0.001$) and had a ROC AUC of 0.86 (CDEIS), 0.87 (eAIS) respectively.
Conclusion: In this dual-site prospective study, quantified motility appears a valid biomarker for endoscopic and histopathological activity in Crohn's disease.
Disclosure: Alex Menys is the CEO of Motilent Ltd.

Introduction: A tight control of inflammation based on symptoms and faecal biomarkers is now recommended in patients with Crohn's disease (CD) [1]. However, questionnaires from large cohort demonstrated that venipuncture is more acceptable than stools collection for CD patients [3]. While faecal chitinase 3-like 1 (CHI3L1) is highly accurate to assess endoscopic activity in CD [3], the performances of serum CHI3L1 to evaluate mucosal healing in patients with CD remains unknown.
Aims and Methods: We aimed to assess the performances of serum CHI3L1 to assess mucosal healing and to monitor the risk of clinical relapse in patients with CD.
We enrolled in this prospective multicenter study (8 centers), all the patients with CD requiring ileo-colonoscopy. Blood samples were taken just before performing the endoscopy (cross-sectional study) and every three months during one year (longitudinal study) to measure the level of serum CHI3L1 (ELISA assay). Clinical relapse was defined as CDAI > 150. Non-parametric tests (Mann-Whitney) were used to compare the level of CHI3L1 in patients with or without mucosal healing. ROC curves were performed to define the best threshold to detect mucosal healing according to clinical relevance. For the longitudinal study, ANOVA for repeated measures was used.
Results: Overall, 103 patients with CD were included (42.7% male, 35.0% active smokers, 43.7% with prior bowel resection). Among them, 29.1% had isolated ileal CD, 11.6% had isolated colonic CD and 59.3% presented with ileocolonic CD. Complicated CD was observed in 45.7% of the patients (stricturing CD (B2) = 28.2% and fistulizing CD (B3) = 17.5%). The median CDAI was 101 [51–214] and the median calprotectin was 100 µg/g [74–295].
The median level of serum CHI3L1 was significantly lower in patients with mucosal healing defined as no ulcer (52.3 vs 81.9; $p = 0.004$), CDEIS = 0 (52.5 vs 77.1; $p = 0.0228$), CDEIS ≤ 3 (60.0 vs 91.5; $p = 0.0294$), SES-CD = 0 (51.1 vs 90.8; $p = 0.0006$) and SES-CD < 2 (60.1 vs 91.6; $p = 0.0366$). Using ROC curves, we determined the most relevant thresholds to detect endoscopic activity defined as no ulcer (cut-off value = 75.0; AUC = 0.65, Se = 54.9%, Spe = 75.0%, PPV = 71.8%, NPV = 58.9%), CDEIS = 0 (cut-off value = 75.0; AUC = 0.69, Se = 55.9%, Spe = 81.5%, PPV = 88.4%, NPV = 42.3%), CDEIS > 3 (cut-off value = 77.0; AUC = 0.64, Se = 60.0%, Spe = 67.0%, PPV = 46.2%, NPV = 78.6%), SES-CD = 0 (cut-off value = 75.0; AUC = 0.68, Se = 57.7%, Spe = 79.1%, PPV = 76.9%, NPV = 60.7%) and SES-CD ≤ 2 (cut-off value = 87.0; AUC = 0.62, Se = 60.0%, Spe = 64.0%, PPV = 30.8%, NPV = 85.7%).
Overall, 25 patients were monitored with serum CHI3L1 testing every 3 months (83 measurements). Serum CHI3L1 was significantly increased in the patients with clinical relapse within 3 months ($p < 0.0001$). Using a ROC curve, we identified CHI3L1 > 64.0 as the best threshold to predict clinical relapse in patients with CD (AUC = 0.70, Se = 82.4%, Spe = 56.1%, PPV = 32.6%, and NPV = 92.5%.
Conclusion: Serum CHI3L1 is a promising surrogate marker of mucosal healing and may be a highly acceptable tool to predict the risk of relapse (high NPV).
Disclosure: This study was granted by Lesaffre company.

Introduction: In recent years a proactive attitude is getting more common in treating inflammatory bowel disease (IBD) patients. We now look beyond symptoms and imaging, biomarkers and drug monitoring help guide the treatment changes.
This strategy that is based on regular assessment of disease activity by using objective clinical, imagistic and biological outcome markers and the subsequent adjustment of treatment is called ''treat to target approach''.
Aims and Methods: Capsule endoscopy has a well-defined role in Crohn's disease patients' diagnosis and monitoring. We present our experience of capsule endoscopy use in Crohn's disease patients monitored in a treat to target manner.
We prospectively evaluated 17 Crohn's disease patients followed in proactive manner using fecal calprotectin in a single center.
Rapid reader 8 software and Pillcam colon 2 capsule were used in the study. A panendoscopy examination was realized setting the capsule to record before swallowing it.
Results: Seventeen patients with known Crohn's disease had a pan-enteric endoscopy. All patients had high levels of fecal calprotectin, but only 13 of them had symptoms. We had an incomplete examination due to capsule retention in the ileum for 9 hours. Active lesions were found in 15 patients: two of them had ileocolic ulcerations, one had gastro-duodenal and ileal lesions, one had a peri-anastomotic fistula and 11 patients had ileal disease. Two patients had no lesions. Pan-enteric endoscopy examination identified lesions in 88% of patients with raised fecal calprotectin (even in asymptomatic patients).
Conclusion: In selected Crohn's disease patients (inflammatory pattern) without known/suspected stenosis the pan-enteric endoscopy using colon capsule might

be used in conjunction with biomarkers to actively monitor the patients in a treat to target approach. This helps to stratify disease activity (due to well known limitations of clinical assessment) and can be paramount to guide therapeutic modifications.
The addition of FICE 1 and blue mode can detect even subtle lesions and therefore the risk of recurrence in this patients.

Introduction: Value-based care is a promising strategy to improve quality of care and control costs, but warrants systematic measurement of patient-reported outcomes. Telemedicine is a powerful tool to enable continuous monitoring of outcomes in chronic diseases. For inflammatory bowel diseases (IBD), implementation of telemedicine previously showed to reduce outpatient visits and hospital admissions (1). However, cost-utility analyses are lacking. We therefore evaluated the incremental cost-utility of telemedicine versus standard care for IBD patients.
Aims and Methods: We used data from the 12-month myIBDcoach trial in which 909 IBD patients were randomized to telemedicine (n = 465) or standard care (n = 444). Direct healthcare costs were estimated based on resource use multiplied by the appropriate unit prices, indirect or productivity costs were calculated using the friction-cost method, a license fee of €40 was calculated for patients using telemedicine, and utilities were assessed using EQ5D (Dutch tariff). Cost-utility and uncertainty were estimated using the non-parametric bootstrapping method.
Results: Telemedicine resulted in a mean yearly cost saving of -€554 per patient (95%CI, [€-987, €2,094]; mean costs of €9495 for standard care and €8941 for telemedicine) and was associated with a small mean gain in quality adjusted life years (QALY) of 0.002 (95%CI, [-0.022, 0.018]). As myIBDcoach results on average in lower costs and somewhat better health, overall this innovative intervention dominates usual care. Telemedicine was cost-reducing in 76% of the replications. However, there is still uncertainty, as dominance occurs only in 57% of the replications (figure 1).
Conclusion: Telemedicine with myIBDcoach is on average cost-reducing compared to standard care with maintained quality of life. However, there is large uncertainty and it might be of interest to detect whether a subgroup can be identified in which use of myIBDcoach results in higher QALY without higher costs. Trials with longer follow-up are required to determine whether telemedicine can improve quality of life and disease outcomes on the long term.
Disclosure: Nothing to disclose.

P1587 WHAT DO IBD PATIENTS KNOW ABOUT DIET AND PREVENTIVE PRACTICES IN IBD?

J.M. Costa[1], T. Leal[1], B. Arroja[1], B. Gonçalves[1], R. Gonçalves[1], J.B. Soares[1]
[1]*Hospital de Braga, Gastroenterology, Braga, Portugal*

Contact E-Mail Address: julianamcosta87@gmail.com
Introduction: The IBD patients' understanding of their disease is of extreme importance for its long-term management.
Aims and Methods: We aim to evaluate the knowledge of IBD patients have about the role of diet, sun exposure, vaccination and smoking habits on their disease.
A cross-sectional observational study was performed through the application of a questionnaire (by e-mail using *google forms* platform) to patients of our IBD outpatient clinic and members of the national association of IBD patients.
Results: We received 412 valid questionnaires (66.3% females, mean age ± SD of 37 ± 13years, 63.6% patients with Crohn's Disease and 57.8% patients under immunosuppression/biologic therapy).
The majority of participants acknowledged diet as an exacerbation factor for IBD (76.7%) and have modified their diet after the diagnosis of their disease (83%). The majority have never received advice on sun exposure (68%), thus being unaware of the risk of skin cancer associated with IBD and/or IBD therapy (66.5%). Most patients have never done skin cancer screening (88.9%), nor have they adjusted their lifestyles with reference to sun exposure (65.3%). The majority of patients (54.6%) discussed the vaccination plan with their gastroenterologist, presenting an updated vaccination plan (92.7%). Only 46.8% of the participants take influenza vaccine yearly. The anti-pneumococcal vaccine had been prescribed in 43.4% of patients. The majority never smoked (56.8%), nor did they discuss the topic of smoking with their gastroenterologist (62.9%). Only 15% of patients have changed their smoking habits after diagnosis: 54 out of 60 quit smoking and 8 out of 234 began smoking.
Conclusion: The participants in this study revealed limited knowledge about the role of diet, sun exposure, vaccination and smoking in IBD. It is absolutely necessary to invest in IBD patients' education about these issues in order to provide them with an active role in the treatment of their disease and prevention of its complications.

Introduction: To assess descriptively, whether Crohn's disease (CD) patients with fCal testing one year after biological treatment initiation have different characteristics and outcomes compared to patients without such testing in real-life treatment setting.
Aims and Methods: A non-interventional, retrospective patient chart review study was carried out in 4 Finnish gastro clinics (EUPAS17190 registration). The study included patients with confirmed CD diagnosis, who had initiated a biological therapy for CD at any time between January 2010 – June 2016 (N = 186). The collected data included patient characteristics, CD characteristics, drug treatments, laboratory test results, health care resource use and outcomes. fCal had been assessed one year (±2months) after biological treatment initiation in 46.8% of the patients who formed the fCal-group (n = 87) whereas the remaining patients formed the non-fCal- group (n = 99). For the purposes of the analysis, only patients with follow-up period of at least 14 months were considered (fCal-group, n = 80; non-fCAL, n = 70).
Results: The study cohort consisted of patients aged on average 44.2 years, 58.0% male, CD duration of 10.0 years (sd 9.7) and follow-up period of 1249.5 days (range 429–2369) with no significant differences between fCal and non-fCal groups. The patients with and without fCal testing at 1 year had relatively similar disease location: ileal (20.0% vs 18.6%; p = 0.83), ileocolonic (58.8% vs 51.4%; p = 0.37) and colon (21.3% vs 30.0%; p = 0.22). There were no differences in prior biological exposure (33.8% vs 35.7%, p = 0.80) or number of previous biological treatments (0.38 vs 0.49; p = 0.29) in the compared groups. During the study period 44 (55.0%) and 37 (52.9%) composite events (surgical procedure, corticosteroid initiation, treatment failure or dose increase) occurred in fCal and non-fCal groups, respectively (p = 0.79) with no statistically significant differences in mean time to composite event from the biologic initiation (414.2 vs 368.8 days; p = 0.64) between groups. Nine surgical procedures were performed in each group during the follow-up. There were no statistically significant differences in mean time to surgery from biological initiation in patients with and without fCal-testing (526.1 vs 531.3 days). Patients with fCal testing at 1 year had overall more fCal-testing during the follow-up period (5.8 vs 3.7, $p < 0.001$). The difference remained significant also when the fCal test at 1 year was excluded for the fCal-group ($p < 0.05$). However, there were no differences in the proportion of patients with imaging (colonoscopy, ileal or perianal MRI, abdominal CT, esofagogastroduodenoscopy) 12 ± 2 months after biologic initiation (25.0%

and 34.3% of patients in fCal and non-fCal groups, p = 0.213). Treatment-site specific differences were observed for the use of imaging. In three study sites, proportionally more patients in non-fCal group underwent imaging at 1 year (39.6% vs 26.2%; p = 0.14; n = 109) even though the difference did not reach statistical significance, whereas the opposite was true for one site (22.7% vs 21.1%; p = 0.90; n = 41). Non-fCal patients had significantly lower leukocyte levels at baseline (6.89 vs 8.47, p = 0.004) and at 1 year (5.88 vs 6.78, p = 0.030) and higher haemoglobin values at 1 year (141.16 vs 135.13, p = 0.04).
Conclusion: This study showed only minor differences in long-term outcomes of CD patients with and without fCal measurement 12 ± 2 months after biological initiation in Finland. However, measuring fCal potentially decreases the use of imagining for assessing response to biological treatment in real-life setting.

Introduction: Vedolizumab (VDZ), an $\alpha_4\beta_7$ integrin antagonist, was approved in Germany in 2014 for the treatment of moderately to severely active Crohn's disease (CD). This study descriptively assessed the real-world effectiveness and safety of VDZ and anti-tumour necrosis factor-alpha (anti-TNFα) after VDZ was introduced in Germany.
Aims and Methods: A retrospective chart review (15 sites) investigated patients (pts) with CD who were biologic- (bio-) treatment naïve or had received one prior anti-TNFα at initiation of index treatment with VDZ or anti-TNFα between 15 July 2014 and 20 October 2015. Time to first chart-documented clinical remission (Harvey Bradshaw Index [HBI] < 5), abdominal pain (AP) resolution (score of 0 or 1), and liquid stools (LS) resolution (≤1.5 per day) were assessed using time-to-event Kaplan-Meier analyses over 26 weeks.
Results: The study investigated 69 VDZ (14% bio-naïve; 67% female) and 105 anti-TNFα (40 adalimumab, 65 infliximab; 62% bio-naïve; 55% female) pts. At baseline, pts' median age was 40 years (VDZ) vs 34 years (anti-TNFα); their median disease duration was 10 years (VDZ) vs 6 years (anti-TNFα); and 28% (VDZ) vs 26% (anti-TNFα) received a corticosteroid. The outcomes of interest were available in the medical chart for a subset of pts: HBI score in 57 VDZ (8 bio-naïve) and 70 anti-TNFα (41 bio-naïve) pts; AP in 57 VDZ (10 bio-naïve) and 70 anti-TNFα (41 bio-naïve) pts; and LS in 46 VDZ (7 bio-naïve) and 67 anti-TNFα (40 bio-naïve) pts. By Week 26, more VDZ vs anti-TNFα pts had AP resolution (63% vs 56%) whilst clinical remission (14% vs 33%) and LS resolution (30% vs 50%) were lower in VDZ pts (**Table**); however, differences were not statistically significant (log-rank test: clinical remission = 0.060; AP = 0.552; LS = 0.060). Proportionally, more bio-naïve vs one prior anti-TNFα pts who received VDZ achieved clinical remission (25% vs 13%) and AP resolution (69% vs 61%) by Week 26, although there was only a small bio-naïve VDZ sample (**Table**). A similar percentage of bio-naïve and one prior anti-TNFα pts who received anti-TNFα achieved clinical remission by Week 26 (34% vs 33%); symptom resolution was more likely in the bio-naïve cohort (AP: 58% vs 53%; LS: 53% vs 46%) (**Table**). Differences between cohorts by prior treatment history were also not statistically significant (log-rank test: clinical remission = 0.279; AP = 0.748; LS = 0.287). Adverse events occurred in 32% of VDZ vs 43% of anti-TNF pts.
Conclusion: This study included pts with CD who received VDZ shortly after launch and were mostly anti-TNFα failure pts of long disease duration, whereas pts treated with anti-TNFα were mostly bio-naïve and had shorter disease duration. The difference in pts' baseline status is a limitation of this study. Results revealed outcomes were similar between VDZ and anti-TNFα cohorts. Biologic treatments appear to be more effective in bio-naïve CD pts.

Introduction: The use of biologic agents in the elderly raises questions concerning their efficacy and safety in this particularly vulnerable population. Data regarding the gut selective drug vedolizumab (VDZ) in the elderly are scarce.
Aims and Methods: We aimed to evaluate the efficacy and safety of VDZ in elderly patients with inflammatory bowel disease (IBD). IBD patients over the age of 60 years completing a 14-week induction with VDZ were included. Patients were followed at the Tel Aviv Medical Center between 2015–2018. Clinical response and remission rates at weeks 14 and 52 were defined as a drop in Harvey-Bradshaw Index (HBI) of ≥3 or a score of ≤3, respectively, for Crohn's disease (CD), and as a drop in partial Mayo score of ≥2 or a score of 0, respectively, in ulcerative colitis (UC). Endoscopic assessment was performed using the Simple Endoscopic Score for CD (SES-CD) and the Mayo score for UC in those for whom the data was available. Clinical details, including response rates and side effects, were documented at each infusion and were retrieved from patients' files.
Results: A total of 31 patients (61% females) at an average age of 70 ± 7.8 [range 60–89] years and disease duration of 15 ± 11.2 [range 2–41] years, were included. Patients were followed up for 42 ± 16.3 (range 14 -52) weeks. Currently 20 patients reached the 52-week end-point.
HBI score at baseline (n = 16) was 8.25 ± 2.8 and the partial Mayo score (n = 15) was 4.5 ± 1.77. At week 14, remission and response in CD patients were 60% (n = 10) and 19% (n = 3), respectively. In the UC cohort, 47% (n = 7) achieved clinical response, however no UC patient achieved clinical remission. At week 52, remission and response in CD patients were 55% (n = 6) and 22% (n = 2), respectively, and 50% (n = 3) and 17% (n = 1) had endoscopic response and remission, respectively. In the UC cohort, 67% (n = 6) and 11% (n = 1) had clinical response and remission, respectively, and 30% (n = 2) had endoscopic response. Noticeably, the majority of patients (65%, n = 20) previously failed at least one anti-TNF, and 30% (n = 10) previously failed two anti-TNF agents. In the CD cohort at week 14, patients naïve to biologic therapy (n = 6) had higher response rates than those previously exposed to anti-TNF agents (n = 10), 80% vs 50% (P = 0.31) and significantly greater clinical remission rates, 60% vs 0% (P = 0.02). A similar trend towards greater week 14 response rates in anti-TNF naïve patients was observed in UC: 40% vs 60% (P = 0.3). However, at week 52, there were no differences in response or remission rates. Combined VDZ-immunomodulators at induction (16%, n = 5) was not associated with differences in response or side effects. Five patients (2 CD and 3 UC) stopped treatment: 4 due

Abstract No: P1589
Table 1: Kaplan-Meier Estimates of Responders Over 26 Weeks,% (standard error)

Follow-up Week	Outcome	Bio-naïve: Anti-TNFα	Bio-naïve: VDZ	Prior anti-TNFα: Anti-TNFα	Prior anti-TNFα: VDZ	Total: Anti-TNFα	Total: VDZ
Week 6	**Clinical remission**	2.8 (2.7)	0 (0)	3.6 (3.5)	2.9 (2.9)	3.2 (2.2)	2.5 (2.5)
Week 6	**AP resolution**	7.4 (4.1)	30.0 (14.5)	14.3 (6.6)	21.5 (6.0)	10.3 (3.7)	22.9 (5.6)
Week 6	**LS resolution**	5.1 (3.5)	0 (0)	11.9 (6.5)	3.1 (3.1)	7.8 (3.3)	2.6 (2.6)
Week 14	**Clinical remission**	20.4 (6.9)	25.0 (21.7)	28.2 (9.1)	7.6 (5.3)	24.0 (5.6)	9.9 (5.5)
Week 14	**AP resolution**	37.5 (7.7)	53.3 (16.6)	29.9 (8.9)	31.7 (7.1)	34.6 (5.9)	35.7 (6.7)
Week 14	**LS resolution**	27.8 (7.5)	25.0 (21.7)	28.7 (9.2)	10.5 (5.8)	28.2 (5.8)	12.4 (5.9)
Week 26	**Clinical remission**	33.7 (10.3)	25.0 (21.7)	33.0 (9.7)	13.0 (7.3)	32.8 (6.9)	14.4 (6.9)
Week 26	**AP resolution**	58.3 (7.9)	68.9 (16.8)	52.6 (10.3)	61.4 (8.6)	56.0 (6.3)	62.5 (7.7)
Week 26	**LS resolution**	53.3 (8.7)	25.0 (21.7)	45.8 (11.1)	29.7 (9.7)	50.3 (6.9)	29.9 (9.2)

to lack of response and 1 due to arthralgia. Additional side effects included a temporal flu-like illness after infusion (n = 2) and allergic reaction upon infusion (n = 2). Three patients were lost to follow-up.
Conclusion: Clinical response rates to VDZ in elderly IBD patients are similar to previous reports in younger patients. Anti-TNF naïve IBD patients may have greater response rates. VDZ has a favorable safety profile and is a valid and attractive option for this age group.

Introduction: Ustekinumab (UST), a monoclonal antibody targeting interleukin-12/23, has been shown in randomised clinical trials (RCTs) to be effective in inducing and maintaining clinical remission in Crohn's disease (CD).[1] However, as drug efficacy in a clinical setting may substantially differ from its effectiveness in the setting of a controlled RCT, real-world studies are necessary to assess clinical benefit. We retrospectively analysed patient records from 3 German IBD centres to evaluate the effectiveness and safety of UST in moderate to severe CD.
Aims and Methods: Patient records from one academic centre, one community hospital and one specialised outpatient unit in Germany from Dec 2016-Apr 2018 were retrospectively reviewed. Patients had moderate-severe CD and had previously shown intolerance, lack of response, or lost response to conventional immunosuppressive therapies or TNFα antagonists. UST was applied according to the German label; induction as infusion (6 mg/kg bw) at week 0, followed by s.c. injection (90mg) at week 8 and every 8 weeks thereafter. Effectiveness of UST was analysed by comparing CRP values prior to therapy and following the 3rd UST application, after ca. 17–22 wks. Patients were stratified in 2 groups according to inflammation prior to UST (CRP $\geq$5mg/L = active disease; CRP < 5mg/L = remission) and evaluated after therapy for remission (CRP < 5mg/L) or partial response (CRP decrease of $\geq$50% compared to baseline). Hypersensitivity reactions and drug-related adverse events (AEs) were assessed.
Results: Treatment data of 80 patients [59% female (F); mean age 40.02 ± 14.02yrs] were collected. Data sets of 52 patients [54% F; 39.50 ± 13.62yrs] were evaluable with respect to efficacy. 63.5% [33/52; 49% F; 40.4 ± 11.80 yrs] had active disease (CRP $\geq$5mg/L) prior to UST. In the active disease group, 36.4% (12/33) responded and 36.4% (12/33) showed partial response. Of those 36.5% [19/52; 63% F; 39.1 ± 15.01 yrs] in remission at baseline, 57.9% (11/19) maintained remission. In the active disease group, prior anti-TNF-treatment (in 15/33; 45.5%) had a significant positive effect on response (p = 0.029). Median baseline CRP values did not significantly differ between anti-TNF-naïv vs. -experienced patients. In contrast, prior anti-TNF therapy (10/19; 52.6%) had no significant effect on response (p = 0.260) in the remission group. Overall, UST was well tolerated, with no cases of anaphylaxis or acute hypersensitivity reactions. However, drug-related AEs occurred in 7/80 (8.75%), including dizziness, headaches, joint pain, vomiting, pruritis and psoriasis-like skin reactions (n = 3). Ustekinumab was discontinued in 10/80 (12.5%), primarily due to lack of response (n = 7). 3 patients received additional ''booster'' infusions due to unsatisfactory therapy response.
Conclusion: This study suggests that UST is generally well tolerated and has enduring long-term effectiveness in anti-TNF-experienced patients with active CD in a real-world setting. Our data suggest that in patients who do not respond to Ustekinumab within 24 weeks, additional treatment options should be evaluated and therapy optimised to increase the likelihood of long-term remission.
Disclosure: Jürgen Stein and Irina Blumenstein have received consultancy fees from Janssen-Cilag. All other authors have no conflicts of interest.

Introduction: The anti-tumor necrosis factor (TNF) antibody SB2 is a biosimilar infliximab and has recently been approved in the European and US market for treatment of inflammatory bowel disease (IBD) patients. These are the first prospective data investigating clinical effectiveness, immunogenicity, safety and economic aspects over the course of 6 months following a switch from reference infliximab to SB2 in IBD patients.
Aims and Methods: This is a single-center, prospective, observational cohort study. We assessed clinical effectiveness, immunogenicity, safety and economic aspects regarding the switch from reference infliximab to the biosimilar SB2 in IBD. All patients receiving reference infliximab in the outpatient clinic for IBD at the University Hospital of Erlangen, Germany were switched to the biosimilar SB2 between February and April 2017 and prospectively assessed for 6 months. Harvey-Bradshaw Index (HBI) was used to determine clinical disease activity in Crohn's Disease (CD) and Partial Mayo Score (PMS) in Ulcerative Colitis (UC) patients. Trough-level (TL) and anti-drug antibodies (ADA) were measured at every SB2 application throughout the study period, using the Promonitor® test. The occurrence of adverse events was registered. Drug costs for SB2 were compared to the pricing of originator infliximab.
Results: In this analysis we report 114 IBD patients (72 CD, 42 UC) receiving reference infliximab who were enrolled and switched to SB2. The median age was 39.5 years (19–78) and the median duration of previous infliximab treatment before the switch was 131 weeks (range 2.9–478.3). Median disease activity for CD was a HBI of 3 (range 0–11) at baseline, 2 (0–13) at week 8, 2 (0–12) at week 16 and 2 (range 0–10) at week 24. Median disease activity in UC was a PMS of 0 (range 0–6) at baseline, 1 (range 0–6) at week 8, 1 (range 0–6) at week 16 and 1 (range 0–2) at week 24. TL for all IBD patients was a median of 6.3ug/ml (range $\leq$0.2–33.7) at baseline, 4.8ug/ml (range $\leq$0.2–31.1, comparison to baseline p = 0.07) at week 8, 5.3ug/ml (range $\leq$0.2–34.5, p = 0.11) at week 16 and 4.7ug/ml (range $\leq$0.2–33.4, p = 0.16) at week 24. Pre-existing ADA persisted in 7 patients over the follow-up period; 4 patients developed new ADA and 2 lost ADA positivity. Of all patients, 12 discontinued SB2 treatment (3 anaphylaxis, 1 recurrent infections, 6 secondary loss of response, 2 serious adverse events), 1 paused while nursing and 4 were lost to follow-up (1 change of physician, 3 unknown). Regarding serious adverse events, there was one malignancy (mamma carcinoma) diagnosed after the second and one ileocecal resection performed after the third SB2 application. Over 6 months the switching to SB2 led to a cumulative costs-saving of 354,137.88€ compared to the pricing of reference infliximab.
Conclusion: Our data demonstrate that in IBD patients switched from reference infliximab to the biosimilar SB2 no loss of effectiveness or increased immunogenicity was observed. SB2 was well tolerated and the switch resulted in substantial cost-saving in a real-life setting.

Introduction: It is reported that the single nucleotide polymorphism (SNP) c.415C>T in exon 3 of *NUDT15* affects thiopurine-induced leukopenia in Asian patients with Crohn's disease (CD). Previously, we have reported that SNP c.52G>A and c.36_37insGGAGTC in exon1 also affect the thiopurine-induced leukopenia in patients with ulcerative colitis (UC) and CD (Kojima Y *et al. World J Gastroenterol* 2018; 24: 511–518).
Aims and Methods: In this study, we studied additional SNPs both exon1 and 3 in 123 patients, namely the newly reported SNPs in patients with acute lymphoblastic leukemia (Moriyama T *et al. Blood* 2017; 130: 1209–1212) including, c.37_42delGGAGTC, c.101G>C, c.103A>G in exon 1 and c.416G>A in exon 3.

One-hundred and twenty-three Japanese patients with UC and CD treated with thiopurines were enrolled. Genotyping for total seven SNPs of the *NUDT15* genes was performed using Custom TaqMan SNP genotyping assays or Sanger sequencing. The changes in WBC count, mean corpuscular volume (MCV), platelet count, hemoglobin, CRP, amylase, albumin, AST, ALT, and ESR were evaluated.

NUDT15	No. of Patients (%)	5/123 (4.1%)	3/123 (2.4%)	26/123 (21.1%)	89/123 (72.4%)
Exon 1	c.36_37insGGAGTC	+	–	–	–
Exon 1	**c.37_42delGGAGTC**	–	–	–	–
Exon 1	c.52G>A	–	+	–	–
Exon 1	c.101G>C	–	–	–	–
Exon 1	**c.103A>G**	–	–	–	–
Exon 3	c.415C>T	+	–	+	–
Exon 3	**c.416G>A**	–	–	–	–

[Number of Patients of Each Genotype of NUDT15]

Results: The results of SNP analysis of *NUDT15* were shown in Table (newly found SNPs were indicated in bold).

C.52G>A and c.36_37insGGAGTC in exon 1 were found in 3 (2.4%) and 5 (4.1%) of 123 patients, respectively. All five patients with c.36_37insGGAGTC in exon 1 were heterozygotes of c.415C>T in exon 3. Twenty-six patients (21.1%) had c.415C>T in exon 3 alone. Two were homozygote (T/T) and 24 were heterozygote (C/T). There were no cases with c.37_42delGGAGTC, c.101G>C, c.103A>G exon 1 and c.416G>A in exon 3. The WBC count gradually decreased after initiation of thiopurine treatment in the mutated cases (n=34) and was significantly lower at 8, 10, and 16 weeks (p=0.0036, 0.0048, and 0.017, respectively). Mean corpuscular volume (MCV) of RBC also increased after treatment of thiopurines started and was significantly higher in mutated cases at 10 weeks (p=0.0083). Three cases showed severe hair loss and two of three were homozygote of c.415C>T (T/T) and one of three was heterozygote of c.415C>T (C/T). Platelet count, hemoglobin, CRP, amylase, albumin, AST, ALT, and ESR did not differ significantly between the wild-type and mutated cases.

Conclusion: SNPs in exon 1 of *NUDT15* also affect thiopurine-induced leukopenia in patients with inflammatory bowel disease (IBD). Severe hair loss was observed in c.415C>T in exon 3. There were no cases with newly found SNPs c.37_42delGGAGTC, c.101G>C, c.103A>G in exon 1 and c.416G>A in exon 3 in Japanese patients with IBD.

Disclosure: Nothing to disclose

P1594 THE PREOPERATIVE USE OF ANTI-TNF α-ANTIBODIES IN IBD PATIENTS UNDERGOING RESECTIVE ABDOMINAL SURGERY HAS NO INFLUENCE ON PERI- AND POSTOPERATIVE COMPLICATIONS

I. Braun[1,2], W. Heitland[3], F. Bader[3], F. Huber[3], S. Janelidze[2], F. Schnitzler[1,4], T. Ochsenkühn[1,2,5]

Introduction: There is still controversy whether the use of anti-TNF-α-antibody therapy (TNF-inhibitors) has an influence on the rate of postoperative complications and sometimes surgeries are delayed to wait for the reduction of antibody levels. Therefore, our aim was to assess the effect of preoperative TNF-inhibitors on the postoperative course in our IBD patients who received resective surgery.

Aims and Methods: A total of 176 patients with Crohn's disease (CD) or ulcerative colitis (UC) who underwent IBD related resective abdominal surgery at the hospital of the IBD-center-Munich between 2012 and 2016 were retrospectively analyzed. We recorded type, dosage and timing of application and identified patients who received TNF-inhibitors or not.

Patients were divided into 3 groups: Group 1 included patients who received TNF-inhibitors within one month before surgery, group 2 included patients treated with TNF-inhibitors more than 1 and less than 4 months and group 3 patients who have never received TNF-inhibitors. Postoperatively, we assessed the rate, type and time point of major and minor complications, reoperations and length of hospital stay. We defined early complications by appearance within 10 days and late complications within 11 to 90 days after surgery. We used Chi2-, Student's T- and Levene-test for statistical analysis.

Results: In 40 UC patients, proctocolectomy and ileo-pouch-anal anastomosis were performed in 92.5% (n=37), 7.5% (n=3) received other resections. 136 CD patients had ileocecal resections in 47.8% (n=65), anastomotic resections in 23.5% (n=32) and a combined resection of the small and large bowel in 28.7% (n=39). In CD 44.9% of patients received open laparotomy (in UC 20%), 47.7% were operated laparoscopically (in UC 77.5%) and in 7.3%, surgeons converted to open laparotomy (in UC 2.5%).

83 patients were assigned to group 1 (CD: 83%), 39 to group 2 (CD: 80%) and 54 to group 3 (CD: 76%). In groups 1 and 2, most patients received either infliximab (G1: 50.6%, G2: 89.7%) or adalimumab (G2: 43.3%, G2: 2.5%), only 6.0% and 7.6% of patients in both groups received golimumab or certolizumab.

The rates of proctocolectomies, ileocecal resections, and open laparotomies were comparable in all 3 groups, as well as disease duration and severity, age and sex distribution, the CD/UC ratio, median days of hospital stay, and reoperation rates.

	Group 1*	Group 2*	Group 3*
All complications*	**20.4%**	**30.7%**	**31.5%**
Major complications*	6%	10.2%	5.6%
Minor complications*	10.8%	12.8%	20.3%
Major plus minor complications *	3.6%	7.7%	5.6%

*[Rates of postoperative complications * differences statistically not significant]*

Late complications occurred more frequent in group 3 as compared to group 1 (14.9 vs. 3.5%, p < 0.01), early complications occurred similarly in all groups. Postoperative complications in CD correlated with the open laparotomy technique (p=0.003) and the prolonged duration of disease (p=0.004), independently from TNF-exposure.

Conclusion: Independently from the preoperative time interval, the use of TNF-inhibitors before surgery did not increase the risk of postoperative complications, reoperations or prolonged hospital stays as compared to patients without such preoperative therapy. Long disease duration was a risk factor for a complicated postoperative course.

Based on these data, the preoperative use of TNF-inhibitors might even exert a protective function. The introduction of infliximab and adalimumab biosimilars provides a chance to perform large prospective trials on strategies how we could best use TNF-inhibitors before surgery.

Introduction: Vedolizumab is a humanized immunoglobulin G1 monoclonal antibody (mAb) directed towards the integrin α4β7. Clinical trials have demostrated the efficacy and safety of vedolizumab (VDZ) in the induction and maintenance of Crohn's disease (CD) and ulcerative colitis (UC). We describe real-world treatment outcomes with VDZ in five tertiary Spanish hospitals.

Aims and Methods: EC treated with VDZ until october 2017 in five Spanish hospitals.

- Clinical response and remission were defined by Partial Mayo Score (UC) or Harvey Bradshaw Index (HBI) and were assessed after induction, at 6 and 12 months. We evaluated treatment persistence as well.
- We studied predictive factors of clinical benefit (response or remission) after induction in UC and CD patients.
- We evaluated if clinical benefit was different in UC and CD patients after exposure to one or more antiTNF agents.

Results: One hundred and three patients were included (52 female (50.5%), UC 40(38.8%), CD63(61.2%), median age 42.9±15.01 y, median disease duration 11.5±8.15 years). Median HBI was 7±3 and PMS was 6±2 at baseline. Majority of patients were refractory to antiTNF treatment: 22 patients (21.6%) had failed to 1 antiTNF and 71 (69.6%) to 2 or more antiTNF agents. Almost 60% of patients were using steroids during induction and 25 (24.5%) received concomitant immunomodulators. Median duration of VDZ treatment was 8.5±6.3 months. Clinical response after loading VDZ was achieved by 79 patients (77.5%). Clinical response and remission at 6 and 12 months were: 42.5%(25/59),33.9%(20/59),41.4%(12/29) and 41.4%(12/29), respectively. In October 2017, 72 patients (70,6%) were persistent on VDZ therapy. Clinical benefit (response or remission) was not associated to the number of antiTNF agents used previously or disease type (UC or CD). No factor (age, sex, disease duration, concomitant immunomodulators or steroids, smoking habit, disease type or severity of illness,) was associated to induction response in UC patients. Disease duration (67%<5 years vs 85.3% > 5 years, p=0.04) and baseline HBI (<7:96.3% vs >7:67.6%, p=0.05) were associated to induction response in CD patients. Thirty-five patients (34.3%) needed dose scalation.

Conclusion: VDZ is effective in IBD patients with long-term persistence of treatment in almost 70% of them. Severity of illness actvity and shorter time duration disease were associated to worse induction response in CD patients.

Introduction: There are limited data on infliximab therapy de-escalation for inflammatory bowel diseases (IBD). The aim of the study was to assess the rate of relapse following infliximab de-escalation in IBD patient in remission as well as predictors of the relapse including infliximab through level prior to de-escalation.

Aims and Methods: We performed a single-center study on 96 patients with IBD in clinical (Harvey Bradshaw Index <4 or Mayo Score <2) and biological (CRP $<$ 5mg/l) remission for whom the dose of infliximab was decreased or the infusion interval increased. The data were retrieved from a prospective IBD database (CNIL No. 1412467) between June 2012 and September 2017. The primary criterion was the relapse during the follow-up defined by the onset of clinical relapse associated with the need for infliximab optimization or biologic switch. Actuarial analysis was performed.

Results: A total of 146 de-escalations were performed in the 96 patients. There were 57 (53%) males with a median age of 36 at infliximab de-escalation. Regarding the 65 (68%) patients with Crohn's disease, 43(72%) were B1 according to the Montreal classification, 27 (28%) previously underwent surgery and 22 (14%) had perianal Crohn's disease. Seventeen of the 31 patients with UC had pancolitis. Among the 146 de-escalations, 54 (37%) were based on the clinical and biological remission only and 92 (63%) were based on a clinical remission associated with an infliximab through level above 7 mg/L. The type of de-escalation was mainly a dose reduction from 10 to 5 mg/kg (30(20%) de-escalations) and a prolonged interval between infusions of 2 weeks (90(62%) de-escalations). The cumulative probabilities of relapse following anti-TNF de-escalation were 16% and 47% at 1 and 2 years respectively. By multivariate analysis, smoking (HR $=2.2$, IC95[1,07–4,58], p $=0.03$), diagnosis of ulcerative colitis (HR $=2.9$, IC95[1,45–5.98], p $=0.0028$), absence of combination therapy at infliximab initiation (HR $=2.65$, IC95[1,34–5.1] increased the risk of relapse. Of note a strategy based on therapeutic drug monitoring decreased the risk of relapse (HR $=0.48$, IC95[0.24–0.96], p $=0.03$). Infliximab trough level above 3 mg/L following infliximab de-escalation was associated with less relapse. Pre- and post- infliximab trough level were well correlated (spearman correlation $\rho = 0{,}67$, p $< 0{,}0001$).

Conclusion: Infliximab dose de-escalation increase the risk of IBD relapse. The use of infliximab trough level to assess the feasibility of dose de-escalation seems a prerequisite to decrease the risk of relapse. Infliximab trough level post de-escalation may be predictable.

Introduction: Vedolizumab (VDZ) is the first gut-specific monoclonal antibody alternative to anti-tumor necrosis factor alpha (anti-TNF-alpha) therapy in patients with moderate-to-severe inflammatory bowel disease (IBD). It has been registered since 2016 in Hungary, but currently the high treatment costs are considerably limiting the availability of VDZ. All newly initiated VDZ therapy was individualized, it should be approved by the steering committee of five Hungarian IBD-specialist. The aim of our non-interventional retrospective study was to assess the efficacy of induction VDZ therapy on clinical and endoscopic activity in moderate or severe active IBD with previous anti-TNF failure or intolerance in real-life setting.

Aims and Methods: Anti-TNF-alpha therapy intolerant IBD patients who received VDZ therapy were enrolled between July 2016 and January 2017 in Hungary. The therapeutic response was assessed based on the changes of clinical (Crohn's Disease Activity Index [CDAI], Mayo score) and endoscopic (Simple Endoscopic Score for Crohn Disease [SES-CD], endoscopic Mayo score) scores. Clinical response was defined as >3 points decrease in the total Mayo score or >100 decrease in CDAI score from baseline. Remission was defined as Mayo score ≤ 2, with no individual subscores >1, or as CDAI score ≤ 150. Mucosal healing was defined as Mayo endoscopic subscore ≤ 1 or as SES CD score ≤ 4.

Results: 49 Crohn's disease (CD) and 73 ulcerative colitis (UC) patients received VDZ induction therapy after anti-TNF failure or intolerance. The mean age was 40.6 years (range 18–85; median 39) and the average disease duration was 10.3 years (range 1–36; median 9). Extraintestinal manifestations occurred in 32 patients (26.2%), and in 10 cases (8.2%) IBD was associated with primary sclerosing cholangitis (PSC). At the baseline the mean CDAI and SES-CD were 303 (range 40–430; median: 312) and 19.5 (range 6–37; median 18) in the CD group and mean Mayo and eMayo score were 9.59 (range 5–12; median 10) and 2.72 (range 2–3; median 3) in the UC group, respectively. Clinical response during the VDZ induction therapy was seen in 30 (61.2%) CD and 61 (83.6%) UC patients. The proportion of clinical remission and steroid-free remission was higher in the UC group compared with CD group (47.9% and 30.1% vs. 48.9% and 38.8%, respectively). In 51 cases the first-year VDZ treatment could have been completed during the study period, however in 20 cases (39.2%) primary non-response for induction therapy was observed. 31 patients received maintenance VDZ therapy. The rate of response, clinical remission and steroid-free remission were substantially higher in UC (55.0%, 41.4% and 41.4%) compared with CD (27.3%, 18.2% and 18.2%) by the end of first-year therapy. Significant difference was observed between UC and CD subgroups in terms of mucosal healing both by the end of induction and by the end of first-year therapy (48.3% and 51.7% vs. 9.1% and 13.6%).

Conclusion: Our results suggest that both induction and the one-year long maintenance VDZ therapy is effective and it is a safe therapeutic option in anti-TNF-alpha failure or intolerant IBD patients with moderate or severe disease activity, however significant difference was observed between the UC and CD subgroups. Mucosal healing was achievable in every second UC and in only every fifth CD patients both by the end of the induction and by the end of first-year treatment in this difficult-to-treat population.

Introduction: The occurrence of signs of Crohn's disease (CD) such as fistula and stricture in ulcerative colitis (UC) patients after total proctocolectomy ileal pouch anal anastomosis (TPCIPAA) is called Crohn-like disease (CLD), or Crohn's disease of the pouch. The aim of this study is to investigate long-term prognosis and risk factors of CLD.

Aims and Methods: The records of patients who underwent TPIPAA operation between 2000–2017 were investigated. The criterion for inclusion in the study was the histopathological diagnosis of UC in the operation material. CLD was defined as ulcer morphology similar to CD detected in the pouch or afferent loop, or fistula or stricture developed during postoperative period. Two groups of patients were included as control groups. The first group who had pouchitis and / or cuffitis after TPCIPAA without signs of CD is named "diseased control group". The second control group consists of UC patients without complaints after TPCIPAA operation. Data about age at the diagnosis, age at the operation, smoking habits, family history of CD, preoperative colonoscopy and CT findings were recorded. The demographic, clinical and laboratory data of all three groups were compared using the Pearson Chi-Square test, the Fisher Exact test and the Kruskal Wallis test for the comparison of parameters between groups.

Results: A total of 1166 records of UC patients were examined, we found 57 patients who underwent TPCIPAA operation, 9 patients were excluded. From remaining 48 patients, 16 were grouped as CLD, 15 were in the diseased control group, and 17 were in the control group. The rate of inadequate examination of the terminal ileum before the operation in CLD, diseased control and control group were 31.2%, 26% and 11.8% respectively. The difference between three groups was not statistically significant. There were 6 patients (37.5%) In CLD group with fistula, including 5 with perianal fistula and 1 with pouch – vaginal fistula. The mean time of the appearance of the fistula after operation was 44 ± 13.5 months. All patients with fistula had also cuffitis. Three of these patients had permanent ileostomy. In one patient, fistula flow stopped after ileostomy, but in the remaining 5 patients, fistulas were still active. Obstructive complications were present in 6 patients (37.5%). The stenosis was in the cuff and the afferent loop in 3 patients for each. Two of these patients underwent endoscopic balloon dilation. The remaining 6 patients without fistula or stricture had pouchitis and/or ileitis, and none were in remission despite medical treatment. During the follow up period with the mean of 69 ± 45.8 months, none of 16 patients with CLD were in remission except one patient who had permanent ileostomy. Comparisons of the three groups revealed that the age at the time of operation in CLD group was less than that of other two groups and that

18.7% (3/16) of patients with CLD had ulcer morphology suggesting CD in the preoperative colonoscopy. Any of patients in the diseased control and the control group had endoscopic findings suggesting CD.
Conclusion: CLD is more common in patients who had an inadequate preoperative investigation of terminal ileum. To detect ulcers on colonoscopy before surgery with morphological aspects suggesting CD is a risk factor for CLD, even if the ileum is normal. In CLD mucosal remission could not be achieved in any patient despite combined immunosuppressive therapy. Fistula rate was about 40% in CLD patients, and 3 of 6 patients with fistula in our series required permanent ileostomy.

Introduction: Gastrointestinal injury caused by dextran sodium sulfate (DSS) is a suitable and reliable porcine experimental model of inflammatory bowel disease (IBD).
Aims and Methods: The purpose of this study was to evaluate effect of probiotic *Lactobacillus casei* DN 114001 (LC) on DSS-induced experimental IBD. Eighteen experimental mature female pigs (*Sus scrofa* f. domestica; weight: 33–36 kg, mean 34.3 ± 1.0; age: 4–5 months), were enrolled into the study: controls with no treatment (n = 6); DSS (n = 6) and DSS+LC (n = 6). LC was administrated to fasting animals in a dietary bolus in the morning on day 1–7 (4.5*10^10 live bacteria/day), DSS (Sigma-Aldrich) simultaneously on day 3–7 (0.25 g/kg/day). All animals were fed twice a day (standard assorted A1 food of equal amounts). On day 8, the pigs were sacrificed (after 24 hours of fasting) by means of pharmacological euthanasia (i.v. embutramide, mebezonium iodide and tetracaine hydrochloride; Intervet International BV) and exsanguinated. Immediate autopsy was performed and specimens for structural and morphometric analysis were taken. Specimens of the stomach, small and large intestine were routinely processed, formalin-fixed, and tissue sections 5 μm thick were cut (Microtome model SM2000 R, Leica). Sections were stained with haematoxylin-eosin (Merck) and evaluated using a BX-51 microscope (Olympus) equipped with image analysis software ImagePro plus 7 (Media Cybernetics). Histopathology score (from 0 to 11) was measured (according to Ref. 1): by summing scores of loss of mucosal architecture (0, 1, 2 or 3), cellular infiltration (0, 1, 2 or 3), muscle thickening (0, 1, 2 or 3), crypt abscess formation (0 or 1), and goblet cells depletion (0 or 1). The length of crypts (all segments) and length and width of villi (small intestine only) were assessed. The grade of mitosis, conveyed as mitotic index [mitotic index (%) = number of mitotic figures * 100 / number of all evaluated cells] and the grade of apoptosis, conveyed as apoptotic index [apoptotic index (%) = number of apoptotic cells * 100 / number of all assessed cells] were evaluated. Apoptotic activity was also assessed immunohistochemically by detection of activated caspase-3 (Cell Signaling Technology) and standard peroxidase technique. Kruskal-Wallis test was used for statistical analysis (software IBM SPSS Statistics, version 22, IBM).
Results: Histopathology score was increased significantly only in the large intestine, from 0 (controls) to 3.80 ± 1.47 (DSS; $p = 0.007$) and 3.60 ± 1.36 (DSS+LC; $p = 0.015$). The length of jejunal villi and crypts were significantly different in controls (293.1 ± 93.1; 312.1 ± 60.5 μm), DSS group (307.7 ± 84.9; 439.8 ± 87.9; $p = 0.023$; $p < 0.001$) and DSS+LC group (282.0 ± 108.7; 385.2 ± 101.2; $p > 0.05$; $p < 0.001$). The length of ileal crypts was 281.8 ± 62.3 (controls), 347.0 ± 78.4 (DSS; $p < 0.001$) and 323.3 ± 73.3 (DSS+LC; $p < 0.001$), respectively. The length of villi in the ileum increased from 251.3 ± 85.3 (controls) to 291.5 ± 127.9 (DSS; $p = 0.047$) and 244.8 ± 93.7 (DSS+LC; $p = 0.015$). The length of colonic crypts increased from 421.0 ± 65.8 (controls) to 660.0 ± 124.9 (DSS; $p < 0.001$) and 659.3 ± 119.7 μm (DSS+LC; $p < 0.001$). Mitotic index of the colonic mucosa was 1.19 ± 0.33% (controls), 3.10 ± 1.82 (DSS; $p = 0.009$) and 2.40 ± 1.17% (DSS+LC; $p = 0.049$), respectively. Other changes, including apoptotic activity at any investigated segment of the gastrointestinal tract, did not reach any statistical significance.
Conclusion: Treatment with probiotic strain LC reduced morphological changes in DSS-induced experimental IBD.
Acknowledgements: the Study was supported by Research Project PROGRES Q40–15.

Introduction: The need for newer therapies remains an important challenge to properly manage patients with Ulcerative Colitis (UC). Colectomy still remains the last resort faced by patients that are non-responsive to current medical therapies. The increasing incidence of UC and the advent of biological drugs ultimately generated a new economic burden associated with UC that remains to be explored. To date there is little evidence about direct and indirect medical and societal costs across Europe. Although Health-related quality of life (HRQoL) outcomes are crucial to assess UC treatment benefits, it is still poorly reported in the literature.
HCD Economics in conjunction with the University of Chester (UoC) UK, are undertaking a pan-European burden of illness study (LUCID) across 10 countries (Denmark, France, Germany, Italy, Norway, Poland, Romania, Spain, Turkey and the UK) including 377 physicians and 3,582 patients.. LUCID is governed by an expert review group consisting of charity, academic, medical and health economist representatives.
Aims and Methods: The primary objective is to quantify UC-related costs from a societal perspective. The secondary objective is to determine the impact on patient's HRQoL.
The study population includes adult patients diagnosed with UC at least 24 months prior to the index date (date of clinical consultation). The study cohort comprises two arms: Arm 1: patients with moderate or severely active UC at initiation of documentation period, Arm 2: patients with prior moderate or severely active UC who had achieved mild UC or remission.
Data are to be collected by means of two questionnaires: physician on-line clinical record form (CRF), and written public and patient involvement engagement form (PPIE). The CRFs collect information on direct medical resource utilisation over the 12 month documentation period. The PPIE form covers out-of-pocket expenses and work loss (direct non-medical and indirect costs), as well as quality of life, disability and work-related activity (EQ-5D-5L, IBD-DI and Work Productivity and Activity Impairment Questionnaire, WPAI).
Full ethical approval is being sought from the UoC Faculty of Health and Social Care Research Ethics Committee.
Results: This study will enable the generation of a granular database comprehensively detailing the wide variety of costs that accompany living with UC. Per-patient costs are calculated by multiplying the quantities of the resource use collected in the study with the national unit price of each resource. Costs associated with temporary and long-term work absence (including early retirement) are valued using the traditional human capital approach.
Conclusion: The LUCID burden of illness study aims to comprehensively contribute to the evidence base for socioeconomic burden of UC. This study adds value to all stakeholders including: academics, patients, carers, government/payers and the pharmaceutical industry. The intent is to publish the findings in peer review publications to inform the international community.

Introduction: Anti-TNF and thiopurines are the only drugs that demonstrated efficacy in preventing postoperative recurrence (POR) in Crohn's disease (CD). There are only two large RCTs in this setting assessing the efficacy of infliximab (IFX) or adalimumab (ADM). Moreover, real-life experience has been scarcely reported.

Aims and Methods: All CD patients in whom anti-TNF agents were prescribed for primary prevention of POR within the first 3 months after ileocecal or ileocolonic resection with anastomosis were identified from the ENEIDA registry (a large, prospectively maintained database of the Spanish Working Group in IBD - GETECCU-). Only those patients who had at least one endoscopic assessment within 18 months after surgery were included. Clinical and endoscopic features were collected before and within 18 months after surgery. Endoscopic POR was defined by a Rutgeerts score >i1 and advanced endoscopic POR by >i2. Clinical POR relied on the criteria of the treating physician. Surgical POR was defined by the need of the new intestinal resection during follow-up.

Results: A total of 152 patients were included, 55 treated with IFX and 97 with ADM. Concomitant use of immunosuppressants was prescribed in 39%, of which 83% thiopurines and 17% methotrexate. 44% received an additional 3-month course of metronidazole after surgery. Anti-TNF was started after a median time of 32 days (IIQ13–44) from surgery. Regarding risk factors for POR: 23% were active smokers, 44% had prior resections, 44% had penetrating CD behaviour, and 28% had a history of perianal disease. In total, 27 (18%) had none, 59 (39%) had only 1, and 66 (43%) had >1 risk factor for POR. 82% had been exposed to anti-TNF prior to the index surgery (73% within the last 6 months). Median time of follow-up on anti-TNF was 29 months (IIQ 13–48). 121 patients (80%) had one endoscopic assessment within 18 months of follow-up and 31 patients (20%) had more than one endoscopic assessment in this period time. Overall, 34% had endoscopic POR and 14% advanced endoscopic POR. Additionally, 30% presented clinical POR as considered by the treating physician and 3% developed surgical POR, with no differences between IFX and ADM. Treatment was dose-escalated in 24% of patients, being similar for IFX and ADM. Endoscopic or clinical POR were the main reason to dose-escalate anti-TNF. In the univariate logistic regression analysis perianal disease, prior exposure to anti-TNF, concomitant immunosuppressant therapy and penetrating behaviour were associated to endoscopic POR. In the multivariate analysis only the perianal disease was associated with endoscopic POR (OR 3.11, 95% CI 1.46–6.61).

Conclusion: Use of anti-TNF agents for the prevention of POR in real practice is markedly different from RCTs: they are more frequently used in combination with immunosuppressants and/or a 3-month course of metronidazole, a great proportion is anti-TNF experienced, and meet high-risk criteria for POR. In this setting, although anti-TNFs prevent POR in a large proportion of patients (particularly advanced endoscopic lesions), still one-third of patients develop early endoscopic lesions.

Introduction: Poor treatment adherence is a common problem among chronic diseases such as inflammatory bowel disease (IBD). Since treatment adherence may be closely related to the risk of symptomatic relapse in IBD patients, identifying potential features associated with the lack of adherence may be useful for relapse prevention.

Aims and Methods: We aimed to determine lack of adherence to oral and parenteral treatments among IBD patients from Argentina and to identify factors associated with non-adherence.

A multicenter cross-sectional study involving seven referral centers from three cities of Argentina was undertaken. Patients with a diagnosis of ulcerative colitis or Crohn's disease were invited to answer an anonymous online survey which included the 8-item Morisky Medication Adherence Scale, a 5-point Likert Scale to evaluate adherence to biologic therapy, and a questionnaire that contemplated the following variables: age, gender, years from diagnosis, education level, type of medical insurance, smoking, history of surgery and/or hospitalizations due to IBD, number of annual visits to a gastroenterologist, perception of easy communication with the gastroenterologist, use of e-mail for consultation, overall satisfaction with medical attention, use of other chronic medications. Univariate analyses were performed for aminosalicylate adherence, thiopurine adherence and biologic adherence. Multivariate analyses looking for independent variables associated with lack of adherence were furtherly performed in each case.

Results: Overall, 447 ulcerative colitis and 135 Crohn's disease patients were enrolled. Median age was 37 years (range 21–72), 39.86% were male; median time from diagnosis was 6 years (0.5–35). When analyzing treatment adherence, 91.41% were under treatment with at least one oral medication. According to the Morisky Scale results, 50.37% of these patients reported a low adherence to their oral medications. Ulcerative colitis patients had a lower risk of low adherence when compared to Crohn's disease subjects [OR 0.57 (0.37–0.87)]. Low adherence was more prevalent when considering aminosalicylate consumption (52.21% had a score compatible with low adherence). Independent variables significantly associated with low aminosalicylate adherence were use of other chronic medication [OR 1.49 (1.01–2.25)] and the lack of perception of easy communication with the gastroenterologist [OR 1.67 (1.1–2.95)]. Low adherence to thiopurines was reported in 40.25% of patients who were under that treatment; lack of perception of easy communication with the gastroenterologist [OR 1.2 (1–5.8)] and smoking [OR 3.75 (1.53–9.17)] were significantly associated with thiopurine low adherence. When considering biologic treatment, 21.8% reported low adherence; subcutaneous administration instead of intravenous was significantly associated with low adherence to biologics [OR 4.8 (1.57–14.66)].

Conclusion: Low treatment adherence is common among IBD patients, especially among aminosalicylate consumers. Clinical features were found to be associated with an increased odds of poor adherence to medications that are potentially modifiable and thus efforts should be directed towards that aim.

P1603 INFLIXIMAB DOSE-REDUCTION IN INFLAMMATORY BOWEL DISEASE (IBD) PATIENTS IN PROLONGED DEEP REMISSION: POTENTIAL IMPLICATIONS ON DE-ESCALATION STRATEGIES IN A REAL-LIFE CLINICAL SETTING WITHOUT A THERAPEUTIC DRUG MONITORING (TDM) APPROACH

Introduction: An increasing number of IBD patients are treated with Infliximab (IFX). Potential costs and safety concerns encourage de-escalation strategies particularly in patients with low risk of relapse. Few studies have investigated the impact of increasing dose intervals on maintenance of remission whereas a dose-reduction strategy has been reported in IBD patients only in conjunction with a TDM approach.

Aims and Methods: The aim of this study was to evaluate the effect of Infliximab dose-reduction on clinical remission in IBD patients in deep remission.

In this retrospective single-centre study, patients treated with IFX monotherapy every 8 weeks and in composite deep remission for at least 1 year had a dose reduction of their infusion from 5 mg/kg to 3 mg/kg. Patients were followed up every 3 months and relapse was defined by composite markers of clinical, biological and endoscopic recurrence. IFX was increased at 5 mg/kg in patients with relapse and infusion reaction or intolerance to IFX was recorded. Statistical analysis was perfomed by SPSS package.

Results: Fifty-seven patients (17F, 40M) were included (33 Crohn's disease [CD] and 24 ulcerative colitis [UC]) with a mean follow-up after dose reduction of 12.7 ± 8.5 months. Mean duration of IFX before dose reduction was 45.8 ± 28.4 months. Overall, 14 (24.5%, 6 UC and 8 CD) patients relapsed during the follow-up. Cumulative probability of relapse free survival was $74.9\% \pm 0.06\%$ at 1 year and $69.2\% \pm 0.08\%$ at 2 years. Patients with relapse had an IFX re-escalation to 5 mg/kg dose with clinical response in 11/14 (78.5%). None of the patients

reported adverse events during maintenance with dose reduction whereas one patient (1/14, 7.1%) reported an infusion reaction after re-escalation to 5 mg/kg. No difference in the mean duration of IFX before dose reduction was observed in patients with relapse compared to patients maintaining remission (45.2 ± 28.6% months vs. 44.8 ± 28.2% months, p = 0.1). In CD patients there was a trend of association between duration of IFX before dose reduction < 36 months and the risk of relapse, although not statistically significant (OR = 2.07; CI 95% 0.3–12.4, p = 0.4).

Conclusion: In a real-life clinical setting, IFX dose reduction is feasible and safe in IBD patients with composite deep remission with a relatively low risk of relapse at 2 years. More than three-quarters of patients who relapsed regain remission after IFX re-escalation. In CD patients an IFX use > 36 months seems to be associated with a lower risk of relapse after dose reduction.

Introduction: Thiopurines are the treatment of choice for the prevention of post-operative recurrence (POR) in Crohn's disease (CD) in high-risk patients, whereas those at low risk should be monitored and treated only in case POR occurs. Endoscopic assessment of POR is recommended within the first year following surgery in all patients. With this strategy, up to 50% of patients will develop POR within 6–12 months after surgery. In patients with established POR, anti-TNF agents may be of benefit, but scarce data on this are available.

Aims and Methods: Our aim was to evaluate the rate of endoscopic remission and improvement of mucosal lesions under rescue therapy with anti-TNF for established POR. Retrospective, multicentre, nationwide study in CD patients who received therapy with anti-TNF agents because of established POR as defined by a Rutgeerts' endoscopic score >i1. Epidemiological, clinical, biological and endoscopic features were collected before and after starting anti-TNF. Endoscopic improvement and remission were defined by a reduction in the baseline Rutgeerts' score and by a score <i2, respectively. Clinical POR was defined by the presence of 2 out of the following 3 criteria: weight loss, increase in stool frequency, and new onset of abdominal pain, in the setting of POR at endoscopy or MRI enterography.

Results: 287 CD patients treated with infliximab (n = 126) or adalimumab (n = 161), 70% in combination with immunosuppressants, because of established POR were included. Table 1 summarizes the baseline characteristics of the patients. Endoscopic assessment was available in 190 patients (66%) after a median time of anti-TNF treatment of 16 months (IQR 11–31). Among these patients, 114/190 (60%) had endoscopic improvement and 82/190 (43%) achieved endoscopic remission (Rutgeerts i0-i1). Of the 82 patients with clinical POR at anti-TNF start, 60 patients (73%) achieved clinical remission. Median time of follow-up on anti-TNF treatment was 45 months (IQR 20–75). During this time, 44 patients (15%) developed clinical POR and 17 patients (7%) developed surgical POR. Univariable and multivariable logistic regression model showed that combination therapy with thiopurines and treatment with infliximab were the only factors associated with a higher rate of both endoscopic improvement (OR 2.97; 95%CI 1.6–5.7, and OR 2.23; 95%CI 1.2–4.2, respectively), and endoscopic remission (OR 2.28; 95%CI 1.2–4.3, and OR 2.65; 95%CI 1.5–4.8, respectively).

Conclusion: Rescue therapy with anti-TNF is efficient for the treatment of established POR, even in patients in whom endoscopic POR occurs while on azath.

	Overall (n = 287)	Infliximab (n = 126)	Adalimumab (n = 161)	p value

Introduction: 5-aminosalicylates (5-ASA) are commonly used in the treatment of ulcerative colitis (UC). The benefit of continuing 5-ASA in UC patients who initiate anti-tumor necrosis factor alpha (anti-TNF) biologics is unknown.

Aims and Methods: We aimed to compare clinical outcomes in UC patients already on 5-ASA who started anti-TNF and then either continued or stopped 5-ASA. Our primary outcome was any adverse clinical event defined as a composite of new corticosteroid use, hospital admission, or colectomy. We utilized two national databases: the United States (U.S.) Truven MarketScan health claims database and the Danish National Patient Register linked with the Danish National Prescription Register. Patients with UC who started anti-TNF after having been on oral 5-ASA for at least 90 days were included. Patients were classified as stopping 5-ASA if therapy was discontinued within 90 days of starting anti-TNF. Analyses were performed using multivariable Cox regression models controlling for age, sex, disease duration, 5-ASA treatment duration, and baseline healthcare utilization. Hazard ratios (HR) with 95% confidence intervals (95% CI) are reported comparing stopping 5-ASA with continuing 5-ASA (reference group).

Results: Of 4,363 U.S. anti-TNF-treated UC patients, 1,667 (38.2%) stopped 5-ASA and 2,696 (61.8%) continued 5-ASA. Among 699 anti-TNF-treated Danish UC patients, 225 (32.2%) stopped 5-ASA and 474 (67.8%) continued 5-ASA. In both cohorts, the incidence rates of adverse outcomes were similar in those who continued or stopped 5-ASA and there were no significant differences in the risk of adverse outcomes in adjusted analyses (Table 1).
Conclusion: In two separate national databases, stopping 5-ASA in UC patients starting anti-TNF therapy did not increase the risk of adverse clinical events including corticosteroid use, hospitalizations, and colectomy. These results should be validated in a prospective clinical trial.

Introduction: The new biological vedolizumab (anti-a4b7) blocks the migration of leukocytes from the vasculature into the gut. It leads to sustained steroid-free remission in about 30% of Crohn's disease (CD) and ulcerative colitis (UC) patients. In UC, this remission is reached much faster (47% after 6 weeks) than in CD (15% after 6 weeks), rendering treatment with vedolizumab much more cost-efficient in UC than in CD[1]. Deeper insight into the immunological effects of vedolizumab is necessary to explain differences between the mechanistic impact of vedolizumab therapy in CD and UC.
Aims and Methods: The aim of this study was to determine the binding capacity of vedolizumab to both immune cells in blood and to isolated mucosal cells from the inflamed ileal and colonic mucosa. We collected peripheral blood and intestinal biopsies from patients with CD and UC prior to vedolizumab treatment, and peripheral blood from healthy controls. Intestinal biopsies were dissociated into cell suspensions from the epithelial layer and lamina propria separately. We engineered fluorescent-labeled vedolizumab and assessed the percentage of vedolizumab-bound cells as well as the level of vedolizumab binding per cell type, using flow cytometry.
Results: Vedolizumab binds a large variety peripheral blood immune cells (*i.e.* $CD4^+$T cells, $CD8^+$ T cells, B cells, eosinophils, NK cells and monocytes). Vedolizumab binds nearly all eosinophils (median 91% [IQR 83–94]) and gut mucosa directed $CD4^+CD38^+CD62L^{neg}$ T cells[2] (median 82% [IQR 68–91]), at high levels. Vedolizumab also binds the majority of B cells (median 84% [IQR 75–92]), $CD8^+$ T cells (median 70% [IQR 60–80]) and $CD4^+$ T cells (median 55% [IQR 48–61]), at intermediate levels. Vedolizumab binds to 37% (IQR 21–50) of NK cells and to only 5% (IQR 2%-10%) of monocytes, at intermediate levels. The highest level of binding was observed on the gut directed $CD4^+CD38^+CD62L^{neg}$ T cells, which was significantly higher than on $CD4^+$ T cells, $CD8^+$ T cells and B cells ($P < 0.0001$). Before vedolizumab treatment, no significant differences in percentage of vedolizumab-bound cells or levels of vedolizumab binding were observed between patients with CD, UC, and similar to healthy controls.
Within the intestinal mucosa, vedolizumab preferably binds lamina propria cells, at moderate levels, and in particular $CD8^+$ T cells from the terminal ileum (median 64% [IQR 28–94]). These lamina propria $CD8^+$ T cells from the terminal ileum also showed the highest levels of vedolizumab binding.
Conclusion: Vedolizumab binds to a large variety of immune cells in both peripheral blood and intestinal mucosa. Indeed, the highest level of binding was observed on a specific subset of gut directed $CD4^+$ T cells. Pretreatment percentages of vedolizumab-bound cells or levels of vedolizumab binding do not explain differences between mechanistic impact of vedolizumab therapy in CD and UC. These results provide baseline data for correlating vedolizumab binding capacities to clinical response in IBD patients.

Introduction: Acute severe ulcerative colitis (ASUC) remains a life-threatening condition. Short and long-term clinical outcomes are still highly variable despite the widespread use of Oxford protocol and the current availability of infliximab (IFX) or cyclosporine (CyA) as rescue therapies. We aimed to report our single-center experience on clinical outcomes of patients with ASUC and the factors affecting its course.
Aims and Methods: We retrospectively collected data from 202 consecutive hospital admissions (106 patients) for ASUC from January 2006 to July 2017. The response to intravenous steroids and rescue therapy, and the occurrence of toxic megacolon (TM) were assessed as short-term outcomes, whereas long-term outcomes included remission after one year from the episode of ASUC and colectomy free-survival along the entire follow-up.
Results: The overall response rates to intravenous steroids and rescue therapy were 47.5% and 91.8% (IFX: 74/79, 93.7%; CyA: 16/19, 78.9%), respectively, while TM occurred in 24 cases (11.9%). After one year from the episode of ASUC, only 25.4% of patients were in continuous clinical remission. After a median follow-up of 37 months (IQR 9.25–98 months), 28 patients (26.4%) underwent colectomy. Colectomy-free survival rates at 3 months and 1 year were, respectively, 82.1% and 77.4%. At multiple mixed-effect regression analysis, systemic CMV infection (defined by blood positivity for CMV-DNA or pp65 antigenemia) was an independent predictor of nonresponse to IFX rescue therapy (OR 0.12, CI 0.02–0.78, $p = 0.031$), occurrence of TM (OR 4.21, CI 1.35–13.12, $p = 0.013$), and colectomy (OR 4.56, CI 1.41–14.55, $p = 0.010$), together with TM (OR 4.77, CI 1.70–13.35, $p = 0.003$). Semi-parametric survival Cox analysis confirmed systemic CMV infection (HR 3.54, CI 1.47–8.51, $p = 0.005$) and TM (HR 3.00, CI 1.35–6.65, $p = 0.007$) as independent risk factors for colectomy.
Conclusion: Detection of CMV in blood – but not on rectal biopsies – is an independent risk factor affecting the main clinical outcomes of patients with ASUC.

Contact E-Mail Address: mgiulia.demarzo@gmail.com
Introduction: In Inflammatory Bowel Disease (IBD) patients treated with anti-tumour necrosis factor (TNF) drugs there is approximately 40% per year likelihood of experiencing secondary loss of response (LOR). In these patients, an increase of the dose of the drug is often carried out in order to restore disease response, and as a fact, higher drug trough levels (TL) are associated with a better disease outcome and a lower likelihood of LOR. However, there are no data concerning drug TL and adverse events (AEs).
Aims and Methods: To evaluate the possible association between drug TL and AEs in IBD patients treated with adalimumab (ADA) and infliximab (IFX).
We included in this analysis 113 patients (65 males, 86 Crohn's Disease, 27 Ulcerative Colitis) treated with IFX (50, 44%) or ADA (63 56%). Twenty-seven patients (24%) were in combo therapy with an immunomodulatory drug. We considered the TL only if it was concomitant (*plus/minus* 1 week) to the occurrence of the AE. TL were measured using a homogeneous mobility shift assay (Prometheus Laboratories, San Diego, United States).
Results: During a median follow up of 16 months (range, 1–144) we observed 103 AEs, mainly infections (n = 81, 79%), followed by dermatologic reactions

(n = 13, 13%). TL were available during 88 AEs (85%): 61 samples from patients in monotherapy and 27 from those in combo-. There was no statistical difference in median TL at the time of AEs occurrence in patients in combo- *vs.* monotherapy (6.9 mcg/mL [range 0.0–20.3 mcg/mL] *vs.* 6.2 mcg/mL [range 0.0–36.2 mcg/mL, $P = 0.42$). Moreover, considering a cut off of 7 mcg/mL for IFX TL ($P = 0.57$) and 5 mcg/mL for ADA TL ($P = 0.75$), we observed no statistical difference in terms of AE occurrence. Moreover, even considering a higher cut off of 15 mcg/mL for IFX TL and 10 mcg/mL for ADA TL, we still did not observe any statistically significant difference in terms of occurrence of AEs experience.

Conclusion: IBD patients with higher anti-TNF TL do not seem have a greater risk of occurrence of AEs as compared to patients with lower TL, independently of mono or combo therapy. Physicians' decision to increase anti-TNF dosage should be based on clinical evaluation and should not be influenced by concerns regarding the potential for AEs occurrence.

Introduction: The most commonly drug regimen for ustekinumab in Crohn's disease (CD) is 90 mg every 8 weeks. Some patients will partially respond to ustekinumab or will experience a secondary loss of response. These patients might benefit from shortening the interval between injections. The efficacy and safety of ustekinumab 90 mg every 4 weeks (90mg q4W) is unknown.

Aims and Methods: All patients with active CD, as defined by CDAI > 150 and one objective sign of inflammation (CRP > 5 mg/L and/or fecal calprotectin > 250 ug/g and/or radiologic and/or endoscopic evidence of disease activity) who required ustekinumab dose escalation to 90mg q4W for loss of response or inadequate response to ustekinumab 90mg q8W were included in this retrospective multicentre cohort study.

Results: Sixty-nine patients, with a median age of 33 years (interquartile range (IQR), 27–42) and median disease duration of 11 years (IQR, 7–16) were included. Optimization was performed after a median of 5.4 months (IQR, 3.2–7.8) of ustekinumab treatment initiation. Ustekinumab was associated with corticosteroids and immunosuppressants in respectively 36% (n = 25/69) and 33% (n = 23/69) of cases. Clinical response was observed in 68% (n = 41/69) after a median of 2.1 months (IQR, 1.0–3.0). Among the 23 patients with colonoscopy during follow-up, 9 had mucosal healing. At the end of follow-up (median 6.8 months (IQR, 3.7–10.8), 45% (n = 31) were still treated with ustekinumab, 22% (n = 15) were hospitalized, and 15% (n = 10) underwent surgery. Adverse events were reported in 10% (n = 7) of patients, including two serious adverse events (pneumonitis, infectious colitis). In multivariate analysis, colonic location (L2) (Hazard Ratio (HR), 4.6 (95%CI, 1.8–8.4); p = 0.047), inflammatory behavior (B1) (HR, 9.1 (95CI%, 1.2–16.5); p = 0.015) and duration of ustekinumab therapy before optimization (HR, 3.2 (95%CI, 1.2–5.4); p = 0.043) were associated with clinical response at 2 months.

Conclusion: This is the first study that evaluates the efficacy and safety of ustekinumab optimization 90mg q4W in CD. Two-thirds of patients recaptured response following treatment optimization. Colonic location, inflammatory behavior and duration of ustekinumab therapy before optimization were associated with clinical response at 2 months

Introduction: Management of perianal fistulising Crohn's Disease (pfCD) remains a significant challenge. While the advent of biological agents has led to improvement in clinical outcomes, their effect on MRI endpoints is less well-established. This is despite MRI being a more accurate measure of treatment success, given the possibility of persistence of fistula tracts despite clinical improvement (1).

Aims and Methods: We performed a systematic review to assess rates of fistula improvement on MRI pelvis, following biological therapy. Online databases MEDLINE, EMBASE and Cochrane were searched until February 2018, for randomised controlled trials, cohort and case control studies that reported on MRI outcomes following biological therapy in the adult population (2). 8 papers met this criterion, all of which administered an anti-TNFa (Infliximab or Adalimumab) as the biologic. All 8 papers examined clinical outcomes, with heterogeneity in endpoints. 7 defined remission as closure of all baseline draining fistulas and "response" as ≥50% reduction; 2 of these studies required this at a single time point and 6 across two consecutive visits. One study defined clinician-reported decrease in fistula drainage as "response". Radiologically, "healing" was defined as disappearance of tracts on T2-weighted sequences. Degree of radiological improvement was assessed in 4 papers, defined as decrease in T2-hyperintensity (2 papers), decrease in number of tracts/collections (1 paper), or decrease in number or volume (≥10%) of tracts/collections (1 paper). Endpoints ≤12 weeks post treatment commencement were considered short-term, and those >12 weeks long-term.

Results: Of 208 unique papers identified in the search, 8 met the inclusion criteria, with a total sample size of 233. 67 patients received a post-treatment MRI ≤12 weeks of induction therapy. 6/67 (9%) achieved radiological healing of the underlying fistula tract, 11/22 (50%) had improvement and 9/22 (41%) had no improvement. 146 patients underwent MRI >12 weeks post induction. 33/146 (23%) achieved healing, 20/45 (44%) had improvement and 15/45 (33%) had no improvement. The odds ratios of MRI healing compared to clinical was 0.14 (95% CI, 0.03–0.54) in the short-term and 0.34 (95% CI, 0.21- 0.58) in the long-term, demonstrating the relative infrequency of radiological healing.

Van Assche score findings varied, with some reporting significant differences between clinical responders and non-responders (3–5), and pre- and post-treatment (6), while others reported no significant difference (7).

Conclusion: There are discrepancies between clinical and MRI outcomes in pfCD, following biological treatment. Lack of consensus on the definition of MRI improvement, or a universally accepted grading system, has led to variability of endpoints assessed and heterogeneity in reported rates of improvement. Further studies assessing recurrence rates in patients who do achieve healing, and variables which prognosticate for radiological healing, will aid management of pfCD.

Disclosure: Nothing to disclose

Abstract No: P1610

Introduction: No prospective data evaluating work productivity and activity in real world practice are available in patients with moderate to severe ulcerative colitis (UC) treated with Golimumab (GLM) for more than 3 months. The aim of this study is to assess the change of work productivity, activity and quality of life (QoL) in UC patients treated with GLM for 1 year in an observational real-world setting in Germany.

Aims and Methods: The validated WPAI-questionnaire (**W**ork **P**roductivity **A**ctivity **I**mpairment Questionnaire) was used for the primary analysis. The change of work productivity and ability for daily activities at 3 months and 12 months versus baseline visit was evaluated.

The 4 subscores of WPAI were assessed: disease-related absence from work (absenteeism), working while sick (presenteeism), total work productivity impairment (TWPI) and activity impairment. TWPI was the primary endpoint. To assess disease-specific quality of life the IBDQ (**I**nflammatory **B**owel **D**isease **Q**uestionnaire) was used. Analysis population included all treated pts (N = 287) and patients who completed the WPAI and were employed at baseline (N = 203).

Results: 287 UC patients were included in the study. At baseline, 61% had moderate UC, 18% had severe UC by global physician's assessment. Slightly less than half of the population were male (48%). 75% of the subjects were either employed full-time or part-time. 269 patients completed the WPAI and 203 were analyzed for the primary efficacy endpoint, as these were employed at baseline.

12 months after start of treatment all WPAI subscores showed significant improvements compared to baseline. Similarly significant improvements were detected in the IBDQ.

	Change from BL Mo 3(%)	Change from BL Mo 12 (%)
WPAI		
TWPI [mean ± SD]	−16.6 ± 32.1 (N = 99)*	−20.2 ± 29.2 (N = 53)*
Absenteeism [mean ± SD]	−−14.9 ± 38.6 (N = 132)*	−20.1 ± 41.4 (N = 77)*
Presenteeism [mean ± SD]	−14.1 ± 28.6 (N = 100)*	−19.3 ± 28.2 (N = 56)*
Activity impairment [mean ± SD]	−13.5 ± 28.2 (N = 149)*	−25.9 ± 29.5 (N = 92)*
	Change from BL Mo 3	Change from BL Mo 12
IBDQ	26.0 ± 35.7 (N = 191)*	41.2 ± 38.7 (N = 121)*

*[*comparison vs baseline: $p < 0.001$]*

Conclusion: GLM treatment results in significant improvement of work productivity and daily activities in patients with UC up to 12 months after start of treatment. Patients also experience a significant improvement in their QoL in terms of IBDQ.

Introduction: Drug-induced toxicity by commonly used therapeutics, aminosalicylates (ASA) and azathioprine (AZA), in patients with inflammatory bowel disease (IBD) have been described in a literature, with AZA-induced pancreatitis occurring more frequently in IBD patients than in other AZA-treated patients. IBD are also often accompanied by extraintestinal immune-inflammatory diseases, frequently involving hepato-pancreato-biliary system.

Aims and Methods: To investigate frequency and clinical presentation of drug-induced toxicity and its association with extraintestinal diseases in IBD patients treated with common therapeutic protocols.

Patients with verified IBD (endoscopy and histopathology) were included in the retrospective study. For each subject we collected general and anamnestic data, laboratory and other diagnostic findings, data regarding application of therapeutic protocols, clinical response to applied therapy and the presence of extraintestinal immune-mediated diseases, drug-induced toxicity and disease complications. Drug-induced toxicity was confirmed empirically (symptom withdrawal after drug cancellation).

Results: Out of 258 IBD patients (male 55%, female 45%, mean age 40.8 yrs), 51.6% had ulcerative colitis and 48.4% had Crohn's disease. Extraintestinal and/or concomitant autoimmune disease was present in 21.3% of IBD patients. Drug-induced toxicity occurred in 16.3% IBD patients, AZA-induced more frequently than ASA-induced (69% and 31%). The incidence of AZA-induced toxicity was 18%, while ASA-induced toxicity was 5%. Drug-induced toxicity manifested as hepato-pancreato-biliary disorders in 21/42 patients (50%), including: toxic pancreatitis (43%), more frequently AZA-induced than ASA-induced (66.7% vs. 33.3%, $p < 0.05$) and toxic hepatitis (7%) presented only in ASA treated patients. The incidence of toxic pancreatitis was 7.3% among AZA treated IBD patients. The second most frequent drug-induced toxicity were hematologic disorders (11/42, 26%), which were all AZA-induced, with the incidence of 6.7% in IBD patients. Patients with extraintestinal disease and/or concomitant autoimmune disease more often developed drug-induced toxicity ($p < 0.05$).

Conclusion: Suspicion of drug-induced toxicity in IBD patients requires multidisciplinary diagnostic approach in order to differentiate drug-induced toxicity from immune-inflammatory extraintestinal manifestations, especially when they are presented as hepato-pancreato-biliary disorders.

Disclosure: Nothing to disclose

P1613 EFFICACY AND SAFETY OF BIOSYMILAR INFLIXIMAB CT-P13 IN PATIENTS WITH CROHN'S DISEASE WHO WERE NAïVE TO ANTI-TNF THERAPY: PRELIMINARY RESULTS FROM POLIBD STUDY

A. Pekala[1], S. Jarmakiewicz[2], B. Witas[1], **R. Filip**[1]

[1]*Faculty of Medicine, University of Rzeszów, Poland, Department of Gastroenterology with IBD Unit, Rzeszow, Poland, Rzeszów, Poland*

Contact E-Mail Address: r.s.filip@wp.pl

Introduction: CT-P13 biosimilar monoclonal antibody to infliximab (IFX) approved for the same indications as its IFX counterpart in Poland.

Aims and Methods: The purpose of the study was to evaluate the efficacy and safety of biosimilar infliximab in Crohn's disease (CD) in patients from Subcarpathian Region (South- Eastern Poland). 93 patients with CD naïve to anti-TNF therapy were enrolled (30 females/63 males); aged from 18 to 69 years, treated with CT-P13 in the Department of Gastroenterology between years 2010 and 2017. 7 (7.5%), 43 (46.2%) and another 43 (46.2%) of patients had ileal, ileo-colonic and colonic CD respectively. All patients received standard immunosuppression with no additional steroid nor antibiotic therapy.

Results: In 56% of the patients clinical remission was achieved (CDAI score < 150). Response to treatment (CDAI score reduction of ≥70 points) was noticed in 31% patients, and 13% patients worsen. Secondary loss of treatment in 5 patients (5.4%) was observed. Among those with ileal CD, clinical remission

was achieved in 3 patients (43%), 2 patients responded to the therapy (28.5%) and another 2 patients did not respond. Among those with colonic CD, clinical remission was achieved in 25 patients (58%), 13 responded to the therapy (30%) and 5 patients did not respond (12%) Among those with ileo-colonic CD, clinical remission was achieved in 24 patients (56%), 14 responded to the therapy (32.5%) and 5 patients did not respond (11.5%).
11 out of 70 patients (12%) had adverse events (AEs); 8 of them (8.5%) had serious adverse events (SAEs) that forced the withdrawal of treatment: sepsis (1 patient 1%), allergic reactions (6 patients 6.5%), peritonsilar abscess (1 patient 1%) Other AEs were perianal abscess (3 patients 3.2%).
Conclusion: In analyzed population, biosymilar IFX CT-P13 seems to be effective and safe in patients with CD who are naïve to anti-TNF therapy.

Introduction: This analysis evaluated the impact of de-escalating therapy on mucosal healing 48 weeks (wks) after randomisation in patients with Crohn's disease (CD) in the CALM study.
Aims and Methods: In CALM, adult patients with moderate to severe CD naïve to immunomodulators and biologics were randomized 1:1 to a tight control (TC) or clinical management (CM) group after ≤ 8 wks of prednisone therapy. Treatment was escalated from no treatment to ADA induction+40 mg every other wk (EOW) to 40 mg ADA every wk (EW) to 40 mg ADA EW+2.5 mg/kg azathioprine (AZA)/day at 12, 24, and 36 wks after randomisation based on specific failure criteria (CD Activity Index [CDAI] ≥200 or decrease < 70 points (1 wk prior to randomisation) or < 100 points compared with baseline (at wk 11, 23, 35) and prednisone use for the CM group, and CDAI ≥150, C-reactive protein ≥5 mg/L, faecal calprotectin ≥250 µg/g, and prednisone use for the TC group). At 24 and 36 wks, if failure criteria were not met, patients de-escalated ADA EW dose to 40 mg ADA EOW. Patients would re-escalate to 40 mg ADA EW if the failure criteria were met at the following visit. In this subgroup analysis, the primary endpoint (mucosal healing [CD Endoscopic Index of Severity < 4] and no deep ulcers at 48 wks after randomisation) was evaluated in patients who de-escalated treatment. Analyses were performed in patients who completed the study and did not move to rescue therapy. Non-responder imputation was used for missing data.
Results: 15 patients in the CM group and 31 patients in the TC group de-escalated treatment during the study (CM, n = 15 from 40 mg ADA EW to 40 mg ADA EOW; TC, n = 21 from 40 mg ADA EW to 40 mg ADA EOW; TC, n = 10 from 40 mg ADA EW+2.5 mg/kg AZA/day to 40 mg ADA EOW+2.5 mg/kg AZA/day). Of those, 2 patients in the CM group and 8 patients in the TC group re-escalated to 40 mg ADA EW. Overall, 54% (7/13) of patients in the CM group and 61% (14/23) of patients in the TC group who de-escalated to 40 mg ADA EOW ± AZA achieved the primary endpoint (Table). Of the patients who re-escalated to ADA EW, 0% in the CM group, and 75% (6/8) in the TC group achieved the primary endpoint (Table). The overall adverse event rates in CALM have been previously reported.[1]
Conclusion: Our data suggest that repeated dose optimization (ADA de-escalation and re-escalation) based on tight control is a more refined approach resulting in mucosal healing compared with CM. Larger data sets are needed to confirm our observation on repeated dose optimization.

	CM n/N (%)	TC n/N (%)
De-escalated and remain de-escalated		
40 mg ADA EW to ADA EOW	7/13 (53.8)	7/13 (53.8)
40 mg ADA EW +2.5 mg/kg AZA/day to ADA EOW +2.5 mg/kg AZA/day	0	7/10 (70.0)
Re-escalated		
40 mg ADA EW to ADA EOW to ADA EW	0/2	6/8 (75.0)

P1615 ATTITUDES TOWARDS TREATMENT WITHDRAWAL IN IBD

N. O'Morain, S. O'Gorman, V. Doherty, C. Hanna, D. McNamara, N. Breslin, A. O'Connor, B. Ryan
Tallaght Hospital/Trinity College Dublin, Gastroenterology & Clinical Medicine, Dublin, Ireland

Contact E-Mail Address: neilmoran@gmail.com
Introduction: A recently published ECCO topical review on exit strategies in inflammatory bowel disease (IBD) has underlined the role of treatment withdrawal in selected cohorts with stable disease. As the disease course in IBD varies greatly, certain patients may well be over-treated with immunosuppressive agents. Identifying which patients can safely stop their treatment remains a challenge. Little is known regarding patients' own attitudes towards stopping long-term immunosuppressive treatment.
Aims and Methods: We invited patients undergoing immunosuppressive therapy, attending either out-patients or the infusion suite, during a 6-week period in March-April 2018, to participate in this prospective observational study. Participants were asked a series of questions regarding their disease and treatment history, compliance with treatment, awareness of risks of immunosuppression, concerns regarding long term treatment, concerns regarding treatment withdrawal and willingness to switch to generic medication.
Results: In total, 151 (female = 77, 51%) patients participated. The mean age was 41.5 years, with a range of 19–82 years. The majority of patients had a diagnosis of Crohn's disease (n = 117, 77%). The mean duration of disease was 12.2 years, with a range of 0.5–46 years. The breakdown of current treatments was as follows: 28% Adalimumab, 26% Infliximab, 22% combination therapy, 14% Imumunomodulator, 4% Ustekinumab, 4% Vedolizumab, 1% Golimumab, 1% Certolizumab. The mean duration of therapy was 4.67 years, with a range of 0.5–18 years. At least one course of glucocorticoids had been taken by 35% (n = 43) in the previous 12 months. Amongst the cohort there were 32 active smokers (21%) and 52 (34%) former smokers. Missed doses were reported most frequently for oral medications (80% IMM) and subcutaneous injections (78%). There were less missed doses in the intravenous treatment group (35%). Overall for the group the mean HBI was 6.3, with a range of 1–26, and the mean partial Mayo score was 1. There was very good awareness of the effect of therapy on the immune system (n = 147, 97%), with 100 (65%) expressing concern regarding same. There was general acceptance of life-long therapy (n = 115, 77%), however many (n = 91, 60%) would be happy to stop treatment if advised so by their Physician, particularly if the decision were based on suboptimal drug levels (n = 142, 93%). In terms of switching to a biosimilar drug, the majority (n = 111, 73%) had no objection. The main concerns expressed regarding treatment withdrawal included the risk of relapse (68%), loss of response (16%) or none (16%).
Conclusion: There is a good understanding amongst patients regarding the risks of long-term immunosuppression. Despite a long duration of disease and treatment, patients would be willing to stop immunosuppressive therapy if advised to do so. Objective measures such as drug levels may provide one tool to guide treatment withdrawal in patients with suboptimal levels. The main concern for patients when considering treatment withdrawal is the risk of future relapse.
Disclosure: Nothing to disclose

P1616 CLINICAL TRIAL: HIGH-DOSE VITAMIN D TREATMENT TO CROHN'S DISEASE PATIENTS WITH DISEASE ACTIVITY, A RANDOMIZED PLACEBO-CONTROLLED DOUBLE-BLINDED STUDY (MIRVIDIC)

M. Bendix[1], A. Dige[1], S.P. Jørgensen[1], J.F. Dahlerup[1], B. Deleuran[2], J. Agnholt[1]

Introduction: Vitamin D treatment may reduce the risk of disease activity in Crohn's disease (CD) [1]. Longitudinal studies have shown that vitamin D levels above 75 nmol/l are associated with reduced disease activity score, need for hospitalisation and surgery [2]. Yet it is unknown if CD patients with disease activity would benefit from high-dose vitamin D treatment and if it is well tolerated.

Aims and Methods: To investigate whether high-dose vitamin D treatment alone or combined with infliximab induction treatment to patients with active CD decreases inflammation markers and activity score compared to placebo.

Forty CD patients with disease activity were included. Patients were randomized to: 1) infliximab and high dose vitamin D (N = 8), 2) infliximab and placebo vitamin D (N = 8), 3) placebo infliximab and high dose vitamin D (N = 16), 4) placebo infliximab and placebo vitamin D (N = 8). Infliximab was given as 5 mg/kg week 0, 2 and 6 and vitamin D was given as 5 mg bolus week 0 followed by 0.5 mg/day in up to 7 weeks. Patients underwent colonoscopy week 0 and 7 and a Crohn's disease index of severity (CDEIS) score was measured. C-reactive protein (CRP), faecal calprotectin, leucocytes and Harvey Bradshaw Index (HBI) were measured week 0, 2 and 6.

After the 7 weeks of project treatment all patients were treated open with infliximab 5 mg/kg. Therefore during follow up the four groups were assembled into 2 groups: initial vitamin D treatment (group 1 and 3) or initial placebo-vitamin D treatment (group 2 and 4). Mixed model was used to test if the mean curves of the inflammation markers in the four groups were parallel. If the mean curves were not parallel, differences between respectively group 1 and 2 and group 3 and 4 were examined.

Results: During 26 weeks of follow up patients who had received high-dose vitamin D treatment during the project period had significantly less disease activity illustrated by 2.89 times lower calprotectin mean curves compared to placebo vitamin D (95% CI: 1.26–6.67, $p = 0.012$), and 2.19 times lower CRP mean curves compared to placebo vitamin D (95% CI: 1.11–4.32, $p = 0.024$).

During the 7 weeks of project treatment combined infliximab and vitamin D treatment reduced the CDEIS score compared to placebo (group 1 delta median -12.5, group 4 delta median -0.9, p = 0.04). However, single therapy with infliximab (group 2) did not reduce the CDEIS score significantly compared to placebo ($p = 0.11$). During the 7 weeks of project treatment the mean curves of the four groups differed over time regarding CRP ($p = 0.0024$), calprotectin ($p = 0.001$), HBI ($p = 0.045$), and leucocytes ($p = 0.028$). Single treatment with high dose vitamin D (group 3) decreased the leukocytes count compared to placebo (group 4) ($p = 0.039$), but significant differences were not reached regarding CRP, calprotectin and HBI.

Seven weeks of high-dose vitamin D treatment alone and combined with infliximab increased the calcium-ion levels over time compared to placebo-vitamin D treatment ($p = 0.013$) but within normal range of calcium. Phosphate levels were unaffected by treatments.

Conclusion: Patients who initially received high-dose vitamin D treatment had lower calprotectin and CRP levels during 26 weeks of follow up compared to placebo-vitamin D treatment.

Seven weeks of combined infliximab and high-dose vitamin D treatment reduced the CDEIS score compared to placebo. In patients with active CD, high-dose vitamin D treatment is safe and well tolerated and reduces the leukocytes count compared to placebo but not calprotectin and CRP.

Introduction: Vedolizumab (VDZ), a humanised monoclonal anti-$\alpha 4\beta 7$ integrin antibody, is effective for inducting and maintaining remission in both Crohn's disease (CD) and ulcerative colitis (UC). Secondary loss of response (LOR) can occur but there is limited information on its frequency and timing.

Aims and Methods: The aim was to assess the rate and timing of secondary LOR in patients with inflammatory bowel disease (IBD) treated with VDZ in a routine clinical practice at a large single university centre. A retrospective case-note review was undertaken of all patients who had received at least one infusion of VDZ from March 2015 – January 2018. Patients received VDZ 300mg intravenous infusion therapy at 0, 2 and 6 weeks and then 8 weekly for maintenance. Harvey-Bradshaw index (HBI) for CD and Simple Colitis Activity Index (SCAI) for UC were documented at each infusion. Clinical remission was defined as HBI < 5/SCAI < 3 and clinical response as a reduction in HBI/SCAI ≥3. Secondary LOR was defined as response followed by one of: an increase in HBI/SCAI ≥3, loss of clinical remission or treatment alteration required by: worsening of symptoms/radiological/endoscopic findings attributable to IBD. Chi square analysis was used to compare rates of response, LOR and recapture of response between those with CD and UC.

Results: 156 patients (102 CD, 50 UC, 4 IBD-unclassified (IBD-U) received VDZ. Two patients with IBD-U were grouped with CD and 2 with UC based on endoscopic and histological findings. Thirteen patients still in induction were excluded from analysis. 68/143 were on systemic corticosteroids at week 0 (37 CD, 31 UC). 138/143 had previous exposure to tumour necrosis factor (TNF) antagonists, 9 of these had not experienced failure of TNF antagonists. Twenty-one patients (16 CD, 5 UC) were in clinical remission at week 0. 122/143 patients (78 CD, 44 UC) were not in remission on starting VDZ and of these 56/78 (71.8%) patients with CD and 36/44 (81.8%) with UC responded. Of the 113 patients (72 CD, 41 UC) who showed response or were in remission on starting VDZ, secondary LOR occurred in 41/72 (56.9%) patients with CD (median 5 doses; 26 weeks (range 2–102)) and 21/41 (51.2%) patients with UC (median 6 doses; 41 weeks (range 5–98)). LOR occurred between weeks 0 and 16 in 18 (29.0%) patients, weeks 17 and 34 in 19 (30.6%), weeks 35 and 52 in 11 (17.7%) and after week 52 in 14 (22.6%). LOR tended to occur later in patients not on steroids at baseline (median 6 vs 5 doses and 36.5 vs 26.5 weeks). Clinical response was recaptured in 22 (53.7%) patients with CD, median of 1 dose and 8 weeks (range 1–54): 7 (31.8%) had a reduction in the dose interval, 5 (22.7%) received steroids and 10 (45.5%) had no treatment alteration. Clinical response was recaptured in 13 (61.9%) patients with UC, median 2 doses and 14 weeks (range 5–53): 7 (53.8%) had a reduction in the dose interval, 1/13 (7.7%) received steroids, 1 (7.7%) had both and 1 (7.7%) had a reduction in dose interval and azathioprine. There was no significant difference between CD and UC in rates of response, secondary LOR and recapturing of response.

Conclusion: LOR with VDZ occurred in over 50% of patients with IBD, median duration 5–6 doses in both CD and UC. However, clinical response could be recaptured without drug withdrawal in most patients. Early apparent LOR may represent relapse after steroid withdrawal and different mechanisms may be associated with later LOR. Further studies are required to understand mechanisms by which this occurs, including studies of antidrug antibodies.

Introduction: Vedolizumab is an alpha4beta7 integrin antagonist for the treatment of inflammatory bowel disease (IBD). The role of drug monitoring, based on the assessment of Vedolizumab trough levels (VTL) and anti-Vedolizumab antibodies (AVA) has not been clarified.

Aims and Methods: Consecutive IBD patients who started therapy with Vedolizumab were prospectively enrolled. Clinical activity was evaluated by Harvey Bradshaw Index (HBI) and partial Mayo score (pMayo). Endoscopic assessment was performed at baseline and during follow-up. VTL and AVA were assayed by ELISA (Theradiag) at weeks 6 and 14. Limits of detection for VTL and AVA were 2 ug/ml and 35 ng/ml, respectively. Clinical response was defined as at least 30% reduction of activity scores from baseline and remission was defined as HBI < 5 or pMayo < 2. Mucosal healing was defined as a Mayo score of 0 for ulcerative colitis (UC) and absence of ulcers for Crohn's disease (CD). Endoscopic response was defined as a reduction of at least 1 point of Mayo score for UC and improvement in mucosal inflammation for CD compared to baseline. Statistics was performed by Mann Whitney test, Spearman's rho, ROC curve analysis.

Results: We included 66 patients (mean age 46.1 y; male 61%) with CD (n = 32) and UC(n = 34). 87% of patients were anti TNF-alpha experienced. Baseline median C-reactive protein (CRP) levels was 6.7 mg/dl (cut-off < 5 mg/l). The median follow-up was at 59 week. Follow-up endoscopy was performed in 45 patients after a median of 50 weeks.

Median VTL measured at week 6 were significantly higher in clinical responders as compared to non-responders (41.3 vs 26.9 ug/ml, p = 0.003), and in patients in clinical remission at week 14 (45.9 vs 27.9 ug/ml, p = 0.03) and at week 22 (46 vs 27.6 ug/ml p = 0.009) compared to non-remitters. By ROC curve analysis we identified a cut-off value for VTL of 40,3 ug/ml for clinical response at week 6 (AUC 0.714, sensitivity 52%, specificity 85%, p = 0.0009). For remission at week 14 the identified cut-off was 24.4 ug/ml (AUC 0.682 sensitivity 93%, specificity 40%, p = 0.03) while for remission at week 22 the cut-off was 44.3 ug/ml (AUC

0.722 sensitivity 56%, specificity 82%, p = 0.005). Week 14 VTL were also significantly higher in patients being in clinical remission (20.6 vs 15.1 ug/ml p = 0.009) and also in remitters at week 22 (20.6 vs 15.4 ug/ml, p = 0.01). The cut off of week 14 VTL for week 14 and week 22 remission was 18 ug/ml (AUC 0.729 sensitivity 80% specificity 68%, p = 0.005 for week14; AUC 0.721 sensitivity 80% specificity 69%, p = 0.075 for week 22). Remission and response at later time points were not correlated with earlier VTL. AVA were detected in 1.5% of patients at week 6 and in 3% at week 14 and were not correlated with VTL and clinical response. Week 6 and 14 VTL were not predictive of mucosal healing. However, week 6 VTL were higher in those patients who obtained an endoscopic response (median of responders 40.3 vs 27.2 ug/ml, non-responders, p = 0.037). By ROC curve analysis a cut-off for week 6 VTL of 38.6 ug/ml was detected for week 50 endoscopic response. Week 6 but not week 14 VTL were negatively correlated with CRP levels.
Conclusion: Our data suggest that VTL at week 6 are correlated with early clinical response and remission and with endoscopic response. Week 14 VTL are correlated with clinical remission at week 14 and 22 and the identified cut off is 18 ug/ml. Immunogenicity of Vedolizumab is low in our patients.

Introduction: Thiopurines, represented by azathioprine (AZA) and 6-mercaptopurine (6-MP), are among the first treatments used in inflammatory bowel diseases (IBD). Their therapeutic effectiveness is perfectly established with, in particular, a major role of corticosteroid savings and a maintenance of the effect over time. However, nearly 20% of patients cease taking thiopurines because of its side effects.
Aims and Methods: The objective of this study is to evaluate the frequence of adverse effects of azathioprine (AZA) and 6-mercaptopurine (6-MP) in patients with IBD.
This is a retrospective and descriptive study conducted in the gastroenterology department of our hospital including 100 patients with chronic inflammatory bowel disease (IBD) treated with thiopurines (AZA or 6-mercaptopurine). The inclusion criteria are: age > 16 years, with a follow-up period of 3 months after the initiation of treatment.
Results: One hundred (100) patients with IBD were included, 64 patients (64%) had Crohn's disease. 24 (24%) ulcerative ulcerative colitis. And 12 (12%) indeterminate colitis. The average age was 36 years old [16–76]. The sex ratio M / F was 0.8, with an average duration of follow-up after the beginning of immunosuppressive treatment of 19 months [3–48]. 52 patients were on 6 mecartopurine and 48 were on azathioprine. The main indications for the prescription of thiopurines in Crohn's disease were: maintenance treatment after a first flush requiring corticosteroid therapy in 32% of cases, after severe acute colitis in 8.1%, postoperatively in 21.6%% of cases, ano-perineal lesions in 16% of cases, upper gastrointestinal tract involvement in 8.1% of cases, and corticodependence in 13.5% of cases. In ulcerative colitis the main indications were: treatment maintenance after severe acute colitis, inefficacy of 5-ASA, corticodependence with respectively: 50%, 33% and 16% of cases. Complete clinical and biological remission at 3 months was obtained in 65% of cases (65 patients). 32 patients experienced side effects with thiopurines (32%) occurring beyond six months of treatment in 45% of cases, they were mainly hematologic in 47.05% of cases (26% lymphopenia and 21% anemia), liver abnormalities in 41.16% of cases, and acute pancreatitis in 5.8% of cases. The occurrence of adverse effects resulted in discontinuation of treatment in 11% of cases
Conclusion: Our study has objectified a remission rate of 65%, which proves that the thiopurines still keep their place in the treatment of IBD at the same level of anti- TNF especially in our contexts.
Disclosure: Nothing to disclose

P1620 A MULTICENTER RANDOMIZED PROSPECTIVE STUDY ASSESSING THE EFFICACY OF SINERGIN IN INDUCTION AND MAINTAINING REMISSION IN MILD-MODERATE IBD

Introduction: The role of the gut microbiota, in addition to genetic factors, in the inititation and perpetuation of inflammatory processes is well established. There are studies that showed that the association between oligo-fructose and inulin (OF-IN) has the ability to modulate not only the composition of the intestinal microbiota but also its activity in a beneficial way, increasing the butyrate concentrations, which exhibits immunomodulatory and anti-inflammatory properties.
Aims and Methods: The main purpose of this multicentric prospective study was to highlight the anti-inflammatory effect of OF-IN (Sinergin) in patients with mild and moderate forms of active IBD. The patients were randomized into 2 groups as follows: group 1 received conventional therapy associated with 10 g/day of Sinergin and group 2 received only conventional therapy.
Clinical manifestations, CRP, faecal calprotectin were assesed in each patient at entry and at 3, 6, 11 months or in case of a flare. Colonoscopy was performed only when considered necessary.
Results: 82 eligible patients entered the prospective study (April 2017-March 2018) from which 8 of them abandoned the trial before the first control visit (3 months), one was excluded due to pregnancy and another due to severe flare, so a total of 72 patients were assessed. The studied group was divided almost even (37 patients without Sinergin vs 35 patients with Sinergin). There are 10 patients that underwent 6 months evaluation (4 with sinergin and 6 without). 25 patients underwent the 3 months evaluation (10 in group 1 and 15 in group 2). At 3 months there is no significant difference between the calprotectine drop down percentage from group 1 and 2 (36% vs 35%), but at the 6 months assessment we found a difference of 5% (45% vs 40%)(p < .05).
Conclusion: Group 1 (with OF-IN) maintained constant values of fecal calprotectin at 3, 6 months and registered a general decrease in CRP values
Group 2 (without OF-IN) has heterogenous results at 3,6 month-evaluation
The complex of oligofructose and inulin plays an important role on the long term in preventing high inflammatory flares in IBD.

Introduction: Adalimumab (ADA) is a well-established treatment for Crohn's disease (CD). Despite this limited data are available regarding the relationship of serum ADA levels, and antibodies to ADA (ATA) with clinical outcomes.
Aims and Methods: We performed a prospective cross-sectional study to investigate the association of serum ADA levels with deep remission (HBI < 5, CRP < 5mg/L and faecal calprotectin ≤200mcg/g). Inclusion criteria were a diagnosis of CD and minimum of 12 weeks therapy. Patients were written to in advance of their next clinic visit and advised to omit their ADA dose if due within 48 h from their appointment. Harvey Bradshaw Index (HBI), serum ADA levels / ATA, CRP and faecal calprotectin (FC) were simultaneously collected at clinic. Biochemical remission was defined as FC < 200 μg/g in addition to CRP < 5 mg/l.
Results: At the time of drug level testing, 259 patients were on ADA maintenance therapy. A total of 195 samples were available for analysis from 178 patients; matched HBI, FC and CRP were available for 171 patients. Median duration of ADA therapy was 2.4 years (IQR 1.2–4.3) with 37/178 (20.8%) patients receiving concomitant immunosuppression. Median ADA levels were higher in patients receiving weekly (n = 55) (14.0 μg/ml, 8.0–17.4) vs. fortnightly dosing (n = 123) (11.0 μg/ml, 7.0–14.5, p = 0.0095). 29/178 (16.3%) patients were positive for ATA. A clear negative correlation was observed between ADA levels and ATA (Spearman's r = −0.567, p < 0.0001). Median ADA levels were 11.4 μg/ml (8.0–15.0), 5.0 μg/ml (4.0–6-6) and 1.0 μg/ml (0.8–2.0) at ATA of < 10 AU/ml, 10–50 AU/ml and > 50 AU/ml, respectively (p < 0.0001). Patients in biochemical remission (n = 81/171; 47.4%) had significantly higher ADA levels (12.0 μg/ml, 10.0–15.7) than those with active disease (8.0 μg/ml, 4.8–12.5, p < 0.0001). ROC analysis revealed a positive correlation between ADA levels and biochemical remission [AUC (95% CI) 0.71 (0.63–0.79), p < 0.0001]. An optimum ADA level of > 8.8 μg/ml was identified for predicting biochemical remission (82.7% sens, 55.6% spec, positive LR 1.86). ADA levels but not ATA independently predicted biochemical remission in a multivariate logistic regression model.
Conclusion: Higher ADA levels were independently associated with biochemical remission; levels of > 8.8 μg/ml, higher than previously suggested, might be an appropriate target in the maintenance treatment of CD.

Introduction: Sexual health is part of the holistic WHO-concept of health. The World Health Association, WAS, defined in §7 "the right to the highest attainable standard of health, including sexual health". Thus, sexual health as well as dysfunction have to be respected and integrated in patients' treatment and disease management programs. Inflammatory bowel disease patients' quality of life is compromised including social engagement, sexual health, intimacy as well as fertility and reproduction caused by medication's side-effects, surgical procedures, reduced control of body function (enterostoma). Therefore, medical doctors were asked whether these aspects are integrated in routine medical treatment by addressing the topic in disease-management.
Aims and Methods: A 3-part questionnaire on health professionals' patient-treatment, health care structures as well as professional profile was distributed at the annual Austrian Crohn and Colitis symposium, Bad Ischl, September 2017. 50 of 190 congress-participants returned the questionnaire (26.3%).
Results: 58% of the health professionals addressed in up to 20% of the patients sexual health problems. 68% were asked by at most 20% of the patients about sexual issues. 46% of the participants assumed that up to 20% of their patients had troubled sexuality, 32% of the participants in even up to 40% of the patients but left the patients un-asked.
38% of the participants did not offer any help for troubled sexuality, 32% referred the patients to specialists such as internal medicine (70%), urologists (50%), gynecologists (48%), 30% evaluated the impact of medication on sexual dysfunction. 44% of the participants stated that lack of sexual-medicine expertise decreases the success of disease-management.
54% of the participants were male, 40% female. 52% of the participants worked in public hospital. 28% were clinically experience more than 21 years, 26% had between 10 and 20 years of clinical experience.
Conclusion: The participants of this survey were experienced in the field of inflammatory bowel disease. Despite this they did not integrate sexual health issues in routine treatment and disease-management-program so far: in up to 80% of the patients' sexual health including intimacy, fertility and reproduction-issues were left unaddressed and thus not treated. Sexual medicine competence was one of the aspects to increase the likelihood of successful disease management. Sexual medicine therefore may be an emerging field for experts in inflammatory bowel disease to be integrated in the near future.

Introduction: A substantial component of disease burden in patients with inflammatory bowel diseases (IBD) is due to frequent emergency department (ED) visits and hospitalizations. We hypothesized that an intervention by a dedicated IBD-nurse accompanied by a multidisciplinary team (MDT) at the ED may improve management and reduce admission rates.
Aims and Methods: We aimed to estimate the impact of proactive MDT care in the ED of a tertiary medical center. IBD-ED visits between November 2017 and April 2018 were identified by the ICD-9-CM codes. IBD patients that were proactively assessed by the MDT (intervention group) were compared to those not approached by the team (standard-ED group). Hospitalizations, exposure to CT scans, and recurrent admission rates within the first 30 days were detected.
Results: A total of 155 IBD patients' visits in the adults ED were identified. Of those, 50 patients (32.2%) were managed by the IBD-nurse and the MDT; average age at index ED visit: 36.1 ± 14.4 years (18–85), M/F 31/19 patients, disease duration 8.3 ± 9.0 years, 37/50 patients had Crohn's disease of whom 10 had a history of perianal involvement. The most common chief complaint (88%) was abdominal pain. Most patients (86%) were either referred by their primary care physician or self-referred. Seventeen patients (34%) underwent CT scan in the ED. MDT management was associated with ED discharge in 28/50 patients (56%). After discharge, most patients (26/28) were shortly followed by a phone call with the IBD-nurse (within 1–7 days), and then seen in the IBD clinic (median 5 [IQR 1–12] days post discharge). Nineteen out of 22 hospitalizations were directly IBD related. Of those, 12 (63.1%) were because of a surgical complication: either an obstruction or an abscess, requiring surgery in 7 patients (58%). The median duration of hospitalization was 3 days (IQR 1–6). Significant decrease in ED revisit within the first 30 days after discharge was observed in the intervention compared with the standard ED group (2% vs 18%, $P = 0.009$). However, there were no differences in rates of hospitalizations or CT scanning (44% vs 52.4%, P = NS, and 34% vs 20%, P = NS, respectably). Notably, patients in the standard ED group were older (36.1 ± 14.4 vs 50.1 ± 20.1, years $P = 0.001$). However, in logistic multivariate analysis the age at index ED visit was not associated with 30-days ED revisit (OR = 0.986, 95% CI 0.961–1.012, $P = 0.292$). In contrast, MDT intervention was associated with decreased ED revisit rates (OR = 0.77, 95% CI 0.01–0.607, $P = 0.015$).
Conclusion: MDT intervention for patients with IBD in the ED, improves patients management and reduces ED readmission in the first 30 days after discharge. This may suggest that MDT management should be a part of the care for patients with IBD visiting the ED.

Introduction: Anti-TNF therapy showed high efficacy in induction and maintain of remission in ulcerative colitis.
Aims and Methods: Study design: Retrospective data analysis using the National Health Insurance Fund social security databases including inpatient-, outpatient care, medications as well as the special drug reimbursement database of patients with the diagnosis of ulcerative colitis (UC) from 2010 to 2016. This is an observational / non-interventional, retrospective, epidemiological study. **Study population:** All of the adult – over 18 years of age – UC patients between 2010 and 2016. **Eligibility criteria:** Patients who have at least two events in all of relevant health care services or at least 1 inpatient event only with UC diagnosis (ICD codes: K51) K50 (Crohn's disease-CD) and K51 (UC) occurrence together: 80:20 distribution ratio. **Primary endpoint:** Analyze patient characteristics and therapeutic outcome of UC patients treated with anti-TNF agent in Hungary.
Results: 0.24% of total Hungarian population suffered from UC in 2016. This is more than 23.000 patients. The median age of the patients with UC is 51 (male 49, female 53) in the examined period. 1095 UC patients were treated with biologicals between 2010–2016. Annual prevalence of biological therapy was increasing continuously from 1.1% to 2.1%; 497 patients with UC were on anti-TNF alpha therapy at the end of 2016. The onset of biological therapy in UC is between 20 and 39, the average age is 37 years. This is 16 years less compared to the average age of total UC population.
Frequency of any type of extraintestinal manifestation was 29.8% among UC patients on biological therapy. The prevalence of different agents was 1.2% for infliximab and 1.1% for adalimumab in 2016. Anti-TNF alpha therapy was started within 3 years after the diagnosis in 35% of the patients, while disease duration was more than 10 years in every third cases. Primary non-response was observed in 9.7% of anti-TNF therapy. Ratio of dose escalation was 13.6%. Dose escalation was equally common among patients on infliximab and adalimumab therapy; however it occurred significantly later in case of infliximab. Frequency of switch was 15.7% and 83.1% of switch was performed after dose escalation. Ratio of adalimumab to infliximab switch was only 11%. Although frequency of hospitalization was as high as 71.7%, surgical intervention was needed in only 11.2% of patients on anti-TNF.
Conclusion: Both the prevalence and incidence of UC are high in Hungary. 3.4% of the UC population was treated with biological therapy in the last year of examination. Patients receiving biological therapy are typically from the younger part of the total UC population. Prevalence of using infliximab and adalimumab were the same in 2016. Primary non-response was observed about 10% of the cases, while ratio of loss of response was 16.3% (dose escalation 13.6% + 2.7% of switch without previous dose escalation). Need of surgical intervention was relatively low among Hungarian UC patients on biological therapy.

Introduction: The GEMINI trials and an increasing body of real-world data have demonstrated the effectiveness and safety of vedolizumab (VDZ) in IBD. However, there is limited available data about its effect on hospitalisations and steroid use. Our aim was to address this in a large real-world cohort of IBD patients from across Scotland.
Aims and Methods: A multicenter retrospective cohort analysis of medical records was performed across 7 Scottish healthcare trusts. Primary outcomes were hospitalisation rates and overall steroid use in patients remaining on VDZ. Secondary outcomes were safety and intention to treat steroid free remission rates in patients with active disease. All data were prospectively collected as part of routine clinical care. Baseline demographics, clinical scores (HBI or Partial Mayo), faecal calprotectin (FC), endoscopy and radiology at 3, 6 and 12 months was recorded where available. Active disease was defined as endoscopic or radiographic evidence of disease or FC >200 mcg/g. Clinical remission was defined as HBI <5 or Partial Mayo <2. Biochemical remission was defined as FC <200 mcg/g.
Results: 340 (137 UC and 203 CD) patients were included in the primary analysis with a median follow-up of 9.4 months. Hospitalisation rates per patient-year were 0.60, 0.67, 0.36 and 0.16 at baseline, 3, 6 and 12 months of treatment respectively. Total number of hospitalisations reduced by 52.5% from 204 (12 months prior to VDZ) to 97 (12 months after VDZ). Proportion of patients on concomitant steroids reduced from 39.7% to 16.7% (n = 332), 8.1% (n = 270), 9.3% (n = 194) at 3, 6 and 12 months respectively. In patients with active CD (n = 153, 75.4%) steroid free clinical and steroid-free biochemical remission rates were; 54.4% and 30.2% at 3 months; 47.7% and 32.1% at 6 months; 28.6% and 33.9% at 12 months. In patients with active UC (n = 112, 81.8%) steroid-free clinical and steroid-free biochemical remission rates were; 57.4% and 40.9% at 3 months; 51.6% and 39.1% at 6 months; 37.5% and 41.2% at 12 months. Our cohort received >2066 VDZ infusions, 2 (0.6%) patients developed infusion reactions, 9 (2.6%) patients developed serious infections and 17 (5.0%) serious adverse events.
Conclusion: VDZ is associated with reduced hospitalisation and steroid use over 1-year. Steroid-free remission rates and safety profile is in keeping with the published literature.

Introduction: Intestinal mucosal injury is supposed to cause liver disease and abnormal liver function tests are frequently observed in inflammatory bowel disease (IBD) patients.
Aims and Methods: We investigated the hepatic biochemistry abnormality and change during the treatment in IBD patients. IBD patients who were newly diagnosed and followed up in our hospital up to 2017 with the results of hepatic biochemistries at the both time points of diagnosis (before IBD treatment) and then at two years later (after IBD treatment) were enrolled. The biochemical profiles including aspartate aminotransferase (AST), alanine aminotransferase (ALT), total bilirubin (TB), direct bilirubin (DB), alkaline phosphatase (ALP), Gamma-glutamyltransferase (GGT) were analysed.
Results: One hundred forty-six (77 patients of Crohn's disease and 69 ulcerative colitis) patients were enrolled. HBs Ag positivity was found in 9 (6.2%) patients and anti-HCV antibody in 1 (0.7%). Radiologic diagnosis of fatty liver was found in 15 (10.2%) patients and gallbladder stone in 10 (6.8%). Within first year, 85 (58.2%) patients started and maintained azathioprine (AZA) therapy. At diagnosis, 45 (30.8%) patient revealed at least one abnormal hepatic biochemistry. AST was elevated than upper limit of normal (ULN) in 9 (6.2%) patients, ALT in 11 (7.5%), TB in 14 (9.5%), DB in 16 (11%), ALP in 21 (14.6%) and GGT in 15 (10.3%). At two years later, 59 (40.4%) patients showed at least one abnormal hepatic biochemistry. TB was elevated compared to baseline ($P < 0.001$) and absolute abnormal elevation of TB (>0.5 mg/dL) was significantly related with AZA ($P = 0.006$). In the AZA therapy group, hyperbilirubinemia (>1.2mg/dL) was found in 6 (7.1%) patients at initial diagnosis, but 19 (22.4%) patients at two years later. In this group, absolute TB abnormal elevation was found in 63 (64.1%) patients. Eighteen (21.2%) patients were within normal TB level at diagnosis and experienced newly developed hyperbilirubinemia after AZA therapy.
Conclusion: Abnormal hepatic biochemistry profiles were observed in nearly one-third of IBD patients at diagnosis. AZA therapy is related with elevation change of TB during the treatment of inflammatory bowel disease.

Introduction: Anti-TNF therapy is recommended as the first line for treatment of patients with Crohn's anal fistula. However, significant proportion of patients either fail initial trial or lose response to anti-TNF therapy. Reasons for this are likely multifactorial and related to metabolism of the drug as well as the development of antidrug antibodies. Currently, it is unknown whether fistula tissue levels play a role in this process.
Aims and Methods: We undertook a pilot study to measure fistula tissue levels of anti-TNF medication (infliximab and adalimumab) using a sensitive technique for peptide detection following trypsin digestion i.e. ultraperformance liquid chromatography mass spectrometry (UPLC-MS). Biopsies from two patients with infliximab and five patients on adalimumab for Crohn's anal fistula were obtained under general anaesthetic. The protein present in fistula's samples were extracted and digested by trypsin to obtain peptide fragments specific to each drug.[1] These were then analysed by UPLC-MS. The anti-TNF drug analysis was performed by ACQUITY UPLC (Waters Ltd., Elstree, UK) coupled to either a 'Xevo TQ-S' mass spectrometer (Waters, Manchester, UK). The MS system was equipped with an electrospray ionization source operating in positive ion mode (ESI−). The targeted UPLC-MS/MS detection and quantification method implemented was previously validated.[1] The chromatographic conditions were shortened to 7.2 min and consisted on mobile phase A (Acetonitrile with 0.1% formic acid) and mobile phase B (H2O with 0.1% formic acid) using a ACQUITY BEH 130 C18 1.7um 2.1×150 mm. MS parameters were optimised to detect specific peptide sequences from each drug. These multiple reaction monitorings (MRMs) also aimed to quantify the anti-TNF present in fistula tissue samples.
Results: The limit of detection (LOD) and linearity range of the method was assessed for each drug. Infliximab and Adalimumab were respectively with LOD of 0.096 and 1.92 mg/mL for linearity range over 4-fold. The peak area for each drug were normalised according to the weight of the fistula samples. Idiopathic (cryptoglandular) tissue samples were analysed as negative controls and anti-TNF drugs were spiked to these samples as positive controls.
Duplicated idiopathic and fistula samples were analysed. The anti-TNF drugs were not detected in fistula samples.
In addition, to validate the result samples were concentrated (x10) and still no detection of the drug was observed in the test samples.
Conclusion: Recent evidence suggests that higher infliximab trough levels are associated with perianal fistula healing in patients with Crohn's disease. In this study we have shown absence of detection of adalimumab / infliximab in all fistula biopsy samples from patients with Crohn's anal fistula. Furtherwork is required in greater numbers of patients biopsies to validate the findings observed and understand the correlation of tissue levels with serum levels of anti-TNF and clinical outcome.
Disclosure: Nothing to disclose

Introduction: Ustekinumab (UST) is an anti-IL-12/23 monoclonal antibody used for treatment of Crohn's disease (CD). We evaluated response to UST in a cohort

of patients with complicated course of disease and its association with serum trough levels (TLs).
Aims and Methods: Data from consecutive CD patients who previously failed at least one biologic agent and started UST with an i.v. dose between March and December of 2017 were included. Disease activity was assessed by Physician's Global Assessment (PGA) score as 0 (remission), 1 (mild disease), 2 (moderate disease) or 3 (severe disease) at week 0 and every following 8 weeks up to week 24 in a retrospective manner. At week 24, patients were considered as complete responders (CR) with PGA drop of at least 2 points, partial responders (PR) with drop of 1 PGA point or no responders (NR) with zero or negative decrease in PGA. C-reactive protein (CRP), fecal calprotectin (FC) and UST TLs were measured at every visit.
Results: Twenty-nine CD patients (37.9% males, 62.1% females) with mean age of 35.9 years were included. Mean disease duration was 15.2 years with 37.9% of patients classified as A1 according to Montreal classification. Proximal disease was present in 24.1% of patients and the same proportion of patients suffered from perianal disease. At least one previous surgery was performed in 86.2% of patients. In median, UST was administered as a 3rd biologic agent. Over half of patients had concomitant immunomodulators and 31% corticosteroids at week 0. At baseline, 20.7% of patients had severe disease activity, 62.1% had moderate and 17.2% mild or no current disease activity. Severe activity was present in 10.7% of patients, 50% had moderate and 39.3% mild or no activity at week 8. At week 24 the proportions were 8.7%, 47.8% and 43.5%, respectively, however, there was no decrease in mean CRP and FC between the two timepoints (CRP 11.2 ± 15.5 mg/L vs. 12.6 ± 16.5 mg/L, $p = 0.8838$; FC 1724 ± 1718 µg/g vs. 1611 ± 1830 µg/g, $p = 0.9277$). Patients with moderate to severe disease activity had significantly lower UST TLs at both week 8 and 24 (12.9 ± 10.1 µg/mL vs. 23.2 ± 11.8 µg/mL, $p = 0.0090$ at week 8 and 3.9 ± 1.9 µg/mL vs. 7.1 ± 3.8 µg/mL, $p = 0.0351$ at week 24). Fifty-two percent of patients experienced at least PR according to PGA decrease between baseline and week 24, while 48% didn't respond. There was no difference, and thus no predictive value, in UST TLs at week 8 between patients who did and didn't respond at week 24, however responders had significantly higher week 24 UST TLs (7.5 ± 3.7 µg/mL vs. 3.8 ± 1.9 µg/mL, $p = 0.0145$). Most frequent adverse events registered included fevers or arthralgias after application and there were 2 cases of periorbital rash at week 8. One patient developed demyelinating polyneuropathy during the follow-up, however, no patient had discontinued the treatment.
Conclusion: Despite no decrease in inflammatory markers, over 50% of the refractory CD patients experienced clinical benefit from ustekinumab after 24 weeks which was associated with its higher serum trough levels. No adverse event requiring the treatment to be terminated was registered.
Disclosure: Nothing to disclose

P1630 POTENTIAL THERAPEUTIC EFFICACY OF CURCUMIN IN THE TREATMENT OF EXPERIMENTAL COLITIS. MODULATORY ROLE OF PROSTAGLANDINS, NITRIC OXIDE, HYPOXIA INDUCIBLE FACTOR-1ALPHA AND INTESTINAL MICROBIOTA

S. Kwiecien[1], D. Wojcik[1], Z. Sliwowski[1], M. Magierowski[1], M. Surmiak[1], K. Magierowska[1], M. Hubalewska-Mazgaj[1], A. Targosz[1], A. Ptak-Belowska[1], P.C. Konturek[2], **T. Brzozowski**[1]

Introduction: Curcumin, a bioactive pleiotropic component derived from a rhizome of the *Curcuma longa* plant, exhibits antioxidant, anti-inflammatory, antiproliferative, analgesic and chemopreventive efficacy against various GI-tract disorders, however, its role in pathogenesis of IBD with respect to experimental colitis in animal models has been little studied. The potential proitective mediators such as prostaglandins, nitric oxide (NO) and the alterations in intestinal microbiota have been little determined.
Aims and Methods: We compared the effect of vehicle and curcumin on the intensity of inflammation in experimental colitis induced by TNBS (15 mg/kg per rectum) in rats with inhibited cyclooxygenase (COX)-1 and COX-2 activity by daily treatment with indomethacin (2 mg/kg i.p.), SC-560 or celecoxib (both at 5 mg/kg i.g.), and the inhibited NO-synthase activity by L-NNA (10 mg/kg i.p.). At day 9 upon TNBS administration, rats were euthanized with isoflurane and the macroscopic and microscopic damage and the colonic blood flow (CBF) was determined by disease activity index (DAI) and laser Doppler flowmetry, respectively, blood was withdrawn for the determination of the plasma proinflammatory cytokines IL-1b, TNF-a, IL-6, IL-13 and IL-17 by Luminex Multiplex platform and the accompanying alterations in mucosal MPO activity and the expression of mRNA and protein of proinflammatory and antioxidazing factors HIF-1α, IL-1β, TNF-α, HO-1 and SOD 2 were analysed by RT-PCR and Western blot. The composition in the intestinal microflora was determined by NGS in faecal samples.
Results: Intrarectal administration of TNBS resulted in macroscopic and microscopic colonic lesions accompanied by the significant fall in CBF, and the significant increase of colonic tissue weight, MPO and plasma IL-1b, TNF-a, IL-17, IL-6 and IL-17 levels ($p < 0.05$) and these effects were significantly increased by co-treatment with indomethacin (2 mg/kg i.p.), SC-560 or celecoxib (both at 5 mg/kg i.g.) ($p < 0.05$). Treatment with curcumin (20–200 mg/kg i.g.) dose-dependently reduced DAI and significantly raised the CBF suppressed MPO and plasma IL-1β, TNF-α, IL-6 and IL-17 levels ($p < 0.05$). The curcumin-induced reduction of DAI was mitigated by treatment with indomethacin, SC-560 or celecoxib and L-NNA, and further restored by concurrent treatment with 16, 16 dm PGE_2 (1 µg/kg i.g.) and L-arginine (200 mg/kg i.g.), the substrate for NO-synthase ($p < 0.05$ vs respective controls). In fecal samples, curcumin-treated rats had a higher ratio of phyla *Firmicutes* and *Bacteroidetes* and lower intestinal phylum levels of *Proteobacteria* compared to vehicle-control TNBS-treated rats. Curcumin downregulated mRNA and protein expression of Hif-1α, IL-1β and TNF-α and upregulated HO-1 and SOD 2 and these effects were reversed by L-NNA and further restored by co-treatment of L-NNA with L-arginine.
Conclusion: We conclude that 1) curcumin accelerates the healing of TNBS-induced colitis due to its antioxidazing and anti-inflammatory activities, possibly mediated by endogenous PG and NO, the inhibition of mRNA and protein expression of HIF-1α, IL-1β and TNF-α and the activation of HO-1 and SOD 2 expression and 2) curcumin caused changes in the distribution and structure of intestinal microflora and partially reversed changes in the diversity of gut microbiota in colitis.

Introduction: The herbal medicinal product Myrrhinil-Intest®, a combination of myrrh (*Commiphora molmol* E.), chamomile flower (*Matricaria chamomilla* L.) and coffee charcoal (*Coffea Arabica* L.) is used for the treatment of gastrointestinal complaints. Clinical data suggest its use for the maintenance therapy of inflammatory bowel disease [1]. Pharmacological investigations further revealed antispasmodic and immune-modulating activities of the herbal combination [2]. However, information regarding active substances remain insufficient.
Aims and Methods: The present investigation aimed to identify potential active components in the herbal combination with regard to their antispasmodic and ant-inflammatory activity.
Thus, HPLC/LC-MS analysis was performed to identify main plant compounds. Subsequently, the influence of the single compounds apigenin (API), trigonelline (TRI), caffeine (CAF), chlorogenic acid (3-CQA) and its isomers cryptochlorogenic (4-CQA) and neochlorogenic acid (5-CQA) on intestinal motility was determined using isometric tension measurement in isolated rat small intestinal preparations. Furthermore, cytokine (TNFα; IL-6) and chemokine (MCP-1) release from LPS-challenged human macrophages (THP-1) was investigated using an ELISA test system. Nimodipine and budesonide served as positive control for the antispasmodic and anti-inflammatory effect respectively.
Results: A spasmolytic effect indicated by inhibition of acetylcholine-induced contractions in rat small intestinal preparations was confirmed for apigenin ($IC_{50} = 31.1$ µM; 15.7% max. inhib.). Furthermore, cytokine TNFα and IL-6 as well as chemokine MCP-1 release from LPS-challenged human macrophages was inhibited concentration-dependently after apigenin incubation (IC_{50}-TNF$\alpha = 14.3$ µM, 2.9% max. inhib.; IC_{50}-IL6 = 12.79 µM, 5.7% max. inhib.; IC_{50}-MCP-1 = 10.43 µM, 23.4% max inhib.). Cryptochlorogenic acid (4-CQA) led to an inhibition of cytokine TNFα ($IC_{50} = 20.7$ µM, 7.9% max. inhib.) and IL-6 ($IC_{50} = 43.3$ µM, 30.7% max. inhib.) as well as chemokine MCP-1 (IC_{50}: 4-CQA = 13.9 µM, 22.5% max. inhib.) release. 3-CQA and 5-CQA were less effective (3-CQA: IC_{50}-TNF$\alpha = 51.0$ µM, 30.5% max. inhib.; 5-CQA: IC_{50}-TNF$\alpha = 14.3$ µM, 21.3% max. inhib.; no influence on IL6 or MCP-1).
Conclusion: Apigenin and 4-CQA – single components of chamomile flower and coffee charcoal – inhibited acetylcholine-induced contractions in rat small intestinal preparations and cytokine/chemokine release from activated human macrophages. These data reinforce the use of the traditional herbal medicinal product (Myrrhinil-Intest®) for the treatment of inflammatory intestinal disorders and the application of apigenin and 4-CQA as active markers for the antispasmodic and anti-inflammatory activity.

Introduction: Irritable bowel syndrome (IBS) is one of the most common clinical problems in gastroenterology with an estimated prevalence of between 10 to 25%

(1). Common co-morbidities include psychiatric disorders and both IBS and these comorbidities are associated with the gut microbiota and their metabolites (2,3). In particular there are compositional differences in the intestinal microbiota of IBS patients relative to healthy individual, and a depletion of faecal and mucosal bifidobacteria (4,5,6). Further, IBS patients have been reported to have a compromised gut barrier which may be linked to the microbiota and metabolites (7). Diet is one of the greatest determinants of gut microbiota composition and may offer a promising avenue for management of IBS. The challenge is to identify dietary modifiers of the microbiota which are specific. Human Milk Oligosaccharides (HMOs) are a family of complex carbohydrates found in high concentrations in human milk. In clinical studies, in both infants and adults, HMOs powerfully and specifically modulated the gut microbiota by increasing bifidobacteria and reducing certain detrimental bacteria (8,9). Further, beneficial metabolites such as short chain fatty acids are produced, which can improve gut barrier function, and potentially influence the pathogenesis of IBS and co-morbidities.

Aims and Methods: The aim of this study is to assess the *in vitro* mechanisms of i) the impact of HMOs on the microbial community and associated metabolites, and ii) the consequential improvement of gut barrier function. *In vitro* gut models were used to examine the impact of HMOs on the microbiota and bacterial metabolite production using faecal samples from healthy donors and IBS patients. Samples were analysed using flow cytometry coupled with fluorescent in-situ hybridization (FISH) for microbial composition and NMR spectroscopy for metabolite profiling. Intestinal cell lines were used to examine the impact of fermented HMOs on gut barrier permeability and immune response.

Results: The study showed (i) the microbiota of healthy and IBS patients to be different, (ii) a clear change in microbial composition and bacterial metabolites in IBS samples during HMO fermentation, (iii) an increase in bifidobacteria in the IBS samples to levels closer to healthy donors; and (iv) differential modulation of gut barrier function. Multivariate analysis on the NMR data revealed that the main cause of variation during the HMO fermentation was short chain fatty acids.

Conclusion: The results indicate that HMOs favourably impact the gut microbiota composition and associated bacterial metabolites of IBS patients and parameters of gut barrier function *in vitro*. This suggests HMOs as potential candidates for the dietary management of functional gastrointestinal diseases like IBS and associated comorbidities.

Disclosure: Louise Kristine Vigsnæs and Bruce McConnell are employed at Glycom A/S, Denmark, which funded this study.

P1633 DAY-TO-DAY VARIABILITY IN FECAL MICROBIAL RICHNESS AND ITS ASSOCIATION WITH STOOL CONSISTENCY: DO WE NEED MULTIPLE SAMPLE COLLECTION?

L. Vork[1], J. Penders[2], S. van Kuijk[3], J. Jalanka[4], M. Rajilic-Stojanovic[5], S. Bojic[5], C. Manichanh[6], M. Pozuelo[6], A. Masclee[1], D. Jonkers[1]

Introduction: Stool consistency has been associated with the fecal microbial composition. Temporal instability in stool consistency and microbial composition has been demonstrated in irritable bowel syndrome (IBS), raising the question of whether day-to-day variability in microbial composition and stool consistency should be taken into account in IBS microbiota studies.

Aims and Methods: We aimed to evaluate within-subject (day-to-day) variability in fecal microbial richness and its association with stool consistency in IBS patients and healthy subjects, over a period of seven days. Twelve IBS subjects (IBS) and 12 age- and sex-matched healthy subjects (HC) collected fecal samples once daily during seven consecutive days. Samples were frozen directly after collection. Microbial richness, as assessed by the observed number of species and Chao1 index (*i.e.*, alpha diversity), was analyzed by 16S rRNA gene sequencing. Fecal dry matter percentage, as a measure of stool consistency, was determined for each sample. Linear mixed-effects models were used to evaluate the association between microbial richness and stool consistency. To evaluate the within-subject variability in microbial richness, inter-item correlations and intra-class correlations (ICC) were calculated.

Results: Using linear mixed-effects models, significant associations were observed between stool consistency and microbial richness over time. However, regression coefficients were small for both Chao1 index (B:1.231, 95%-CI: 0.835;1.628) and observed species (B:1.066, 95%-CI: 0.725; 1.407), indicating a small change in alpha diversity per unit increase in stool consistency. Furthermore, in IBS and HC, microbial richness was highly correlated between subsequent samples (inter-item correlations >0.8; ICCs >0.850), for both measures of alpha diversity.

Conclusion: The small, but significant association between stool consistency and alpha diversity over time suggests that day-to-day variability in microbial richness might be influenced by stool consistency. The low within-subject variability in alpha diversity, however, indicates that the microbial richness of one single fecal sample is representative for a period of seven days and therefore, we consider collecting multiple fecal samples unnecessary.

Introduction: Human intestinal flora play an important role in the homeostasis of gastrointestinal tract. As one of the human intestinal commensal bacteria, Enterotoxin *Bacteroides fragilis* (ETBF) is an anaerobic Gram-negative bacterium which produces *Bacteroides fragilis* toxin (BFT). It has been found that ETBF colonization increases in colorectal cancer patients, and it may be associated with tumorigenesis.

Aims and Methods: We aimed to investigate the association between ETBF and the prognosis and chemotherapeutic effect of colorectal cancer. 242 cases of colorectal mucosa biopsy or resection, which had been made into paraffin tissue, were collected from Southern Medical University Affiliated Nanfang Hospital. These samples were divided into colorectal adenoma group (112 cases), colorectal cancer group ($n=80$) and mild inflammation group ($n=50$). Clinical data were collected from these patients, including sex, age, history antibiotics use within one week, radiotherapy history, chemotherapy history, biopsy location, pathology diagnosis, parenteral infection, carcinoembryonic antigen (CEA), C-reactive protein (CRP), white blood cell count (WBC), lymphocyte count (LYM), neutrophil count (NEU), monocyte count (MO), etc. Patients with colorectal cancer were followed up for one year and their clinical data such as surgery, chemotherapy, TNM staging, imaging data, relapse and death were collected. The total DNA(including host DNA and commensal bacteria DNA) from each group of paraffin tissues was extracted and then the endotoxin gene segment of ETBF were amplified by polymerase chain reaction. Then we analyze the relationship between ETBF infection and clinical data we collected.

Results: The positive rate of ETBF in colorectal adenoma group and colorectal adenocarcinoma group were both significantly higher than that in mild inflammation group ($p=0.008$, $p<0.000$). Positive rate of ETBF in biopsy from right colon was significantly higher than that from left colon ($\chi^2=14.13$, $P<0.000$). TNM tumor staging in patients with ETBF-positive colorectal cancer was significantly higher than that in ETBF-negative patients ($Z=-3.322$, $p=0.001$). There was no significant difference in inflammation index, such as WBC, LYM, NEU and MO between ETBF-positive and negative group ($p>0.05$). But the quantitative of CRP in ETBF-positive group was significantly higher than that in ETBF-negative group ($p<0.000$). The depth of tumor invasion ($Z=-2.892$, $p=0.004$) and distant metastasis of ETBF-positive patients ($Z=-2.881$, $p=0.004$) were significantly worse than ETBF-negative patients. There was no significant difference of recurrence and death within one year between ETBF-positive colorectal cancer patients and negative ones ($\chi^2=3.878$, $p=0.078$; $\chi^2=3.374$, $p=0.151$). Lymphatic metastasis, distant metastasis were significantly higher in ETBF-positive patients ($Z=-2.892$, $p=0.004$; $Z=-2.881$, $p=0.013$). Tumor-free survival rate of ETBF-positive patients was significantly lower than that of ETBF-negative ones ($\chi^2=12.836$, $p<0.000$). But there was no significant difference in tumor infiltration depth ($Z=-1.885$, $p=0.064$). Chemotherapy efficacy of ETBF-positive patients was significantly worse than ETBF-negative ones ($\chi^2=5.437$, $p=0.020$).

Conclusion: The ETBF infection was more prevalent in colorectal neoplasms patients. The higher colorectal cancer TNM stage, the higher positive rate of ETBF was. Prognosis and chemotherapeutic effect of colorectal cancer were worse in ETBF-positive patients, which may make ETBF detection an indicator of poor prognosis and chemotherapy efficacy.

Contact E-Mail Address: diliarik@yandex.ru

Introduction: Changes in human gut microbiota composition are often observed after the antibiotic therapy. Most of studies published recently paid attention to specific bacterial content, but there is limited data concerning functional roles of altered microbiota.
Aims and Methods: The aim of the study was to evaluate the influence of *H.pylori* eradication therapy on different functional groups of bacteria in the gut microbiota immediately after the eradication therapy and one month later.
Stool samples were collected from 83 patients before and immediately after eradication therapy (amoxicillin 1000 mg, clarithromycin 500 mg, proton pump inhibitor, bismuth subsalicylate 240 mg bid for 14 days), also 14 stool samples were collected one month after eradication therapy from the same patients. Samples were analyzed using shotgun metagenomic sequencing (SOLiD 5500 Wildfire platform). Relative abundance of bacterial groups in the gut microbiota was evaluated.
Results: We identified 5 functional groups of bacteria: butyrate-producing (*Eubacterium rectale, Roseburia hominis, Roseburia intestinalis, Roseburia inulinivorans, Eubacterium hallii, Faecalibacterium prausnitzii, Butyrivibrio crossotus, Coprococcus comes, Coprococcus eutactus, Subdoligranulum variabile*), propionate-producing (*Bacteroides fragilis, Bacteroides thetaiotaomicron, Bacteroides vulgatus, Veillonella parvula, Dialister succinatiphilus, Phascolarctobacterium succinatutens, Akkermansia muciniphila, Coprococcus catus, Megasphaera elsdenii, Roseburia inulinivorans, Ruminococcus gnavus, Ruminococcus torques*), hydrogen-utilizing (*Ruminococcus bromii, Blautia hydrogenotrophica, Blautia hansenii, Desulfovibrio piger, Methanobrevibacter smithii*), lactate-producing bacteria (*Bifidobacterium spp., Lactobacillus spp., Collinsella aerofaciens, Eubacterium rectale, Faecalibacterium prausnitzii, Roseburia spp., Bacteroides spp.*) and bacteria involved in vitamins biosynthesis (*Bacteroides thetaiotaomicron, Bacteroides vulgatus, Bifidobacterium longum*) as the most important for the maintenance of functional stability of the gut microbiota.
Significant reduction in the relative abundance of butyrate-producing and hydrogen-utilizing bacterial groups was observed immediately after eradication therapy compared to the baseline level: $(24.87 \pm 18.59)\%$ vs. $(32.81 \pm 16.77)\%$ ($p = 0.0048$) and $(1.6 \pm 2.74)\%$ vs. $(2.5 \pm 3.89)\%$ ($p = 0.0053$), respectively. One month after eradication therapy the relative abundance of hydrogen-producing bacteria almost completely returned to initial level, $(2.15 \pm 3.3)\%$ vs. $(2.5 \pm 3.89)\%$ ($p = 0.9878$). A tendency of increasing of the relative abundance of butyrate-producing bacterial group was also observed one month after the therapy, without significant differences compared to the initial level, $(25.21 \pm 13.69)\%$ vs. $(32.81 \pm 16.77)\%$ ($p = 0.2829$), but their number was still less than before the initiation of therapy.
No significant changes were observed in the relative abundance of bacteria involved in vitamins biosynthesis, as well as propionate-producing and lactate-producing bacterial groups immediately after eradication therapy as well as one month after the eradication.
Conclusion: So *H.pylori* eradication therapy leads to significant reduction of butyrate-producing bacteria abundance in human gut microbiota with a slight tendency to return to the initial level within one month after the end of treatment. This fact should be taken into account when prescribing eradiation therapy and predicting possible adverse events of therapy.

Introduction: Much evidence suggests the contribution of intestinal microbiota in the pathophysiology of irritable bowel syndrome (IBS). We characterized the intestinal microbial ecosystem (IME) by means of 16s ribosomal RNA (rRNA) gene profiling in fecal samples of IBS subtypes collected during a multicentre intervention trial with *Lactobacillus paracasei* CNCM I-1572 in IBS
Aims and Methods: To characterize the IME, we inluded in the study a total of 40 patients with IBS according Rome III criteria (12 IBS-C; 14 IBS-D; 11 IBS-M; 3 IBS-U). Biological specimens were collected every four weeks for five consecutive time points. Metagenomics DNA was extracted from about 200 mg of feces using the PowerSoil® DNA Isolation Kit. Subsequently, the bacterial community structure was profiled by 16s rRNA gene profiling, amplicons were sequenced using Illumina MiSeq System and the results were managed by means of the bioinformatic pipeline Quantitative Insights Into Microbial Ecology with the GreenGenes database.
Results: The taxonomic overview of the fecal sample analyzed revealed that the first 7 most abundant genera belong to the Firmicutes Gram positive order. Clostridiales accounted for about 75% of detected bacteria, while the relative abundance of members of the order Bacteroidales was lower than 10%. The analysis of median profiling data revealed 26 significantly different operational taxonomic units (OTUs) between IBS-M and IBS-C, while 19 OTUs distinguished IBS-M from IBS-D. Interestingly, the highest number of dissimilarities was found between IBS-C and IBS-D: 85 OTUs had, in fact, a significantly different relative abundance. Most of the discriminating OTUs were ascribed to the order Clostridiales; IBS-C were distinguished from IBS-D by numerous Clostridiales-associated OTUs belonging to the families Ruminococcaceae (in particular, the genus Ruminococcus) and Lachnospiraceae. Two OTUs ascribed to *Bifidobacterium adolescentis* were increased in IBS-C whereas OTUs associated to the order Bacteroidales and to the Firmicutes species *Eubacterium biforme* were enriched in IBS-D samples.
Conclusion: Our results indicate that the fecal microbiota of IBS-C and IBS-D is characterized by a different distribution of Clostridiales, whereas IBS-M samples possesse compositional features intermediate between IBS-C and IBS-D. The distribution of bacteria inside the Gram-positive order Clostridiales distinguishes the microbial ecosystem of IBS subtypes, suggesting that distinct therapeutic approaches targeting microbiota should be developed according to IBS subtypes.
ClinicalTrials.gov Identifier: NCT02371499

Contact E-Mail Address: cc@genetic-analysis.com
Introduction: The composition of intestinal microbiota is gaining importance in human health studies since there is increasing evidence that bacteria play a role in disease etiology. The composition of the gut microbiota is relatively stable throughout adult life, but can be transiently or permanently altered as a result of bacterial infections, antibiotic treatment, lifestyle, surgical, and a long-term change in diet.
Aims and Methods: To characterize normal Italian gut microbiota and identify factors shaping its composition, we conducted 16S rRNA analysis using GA-map™ Dysbiosis Test[1] of fecal samples collected from normal Italian adults residing in 3 regions of Italy (Milan, Rome, Palermo). Participants were recruited from subjects coming to the clinic for colonoscopy in connection to the national screening program, with no abnormal findings. Each participant also completed a 16-question questionnaire.
The GA-map™ Dysbiosis Test[1] is composed of 54 pre-selected highly specific 16S rRNA gene-targeted single nucleotide primer extension (SNuPE) probes, detecting at least 300 bacteria on different taxonomic levels, for detection and characterization of dysbiosis. The test reports a Dysbiosis Index (DI), where DI = 1–2 is considered normobiosis, and DI = 3–5 is dysbiosis. Fecal-Calprotectin (FCal) analysis was performed using BÜHLMANN fCAL® ELISA with a cut-off of ≤200mg/kg. Chi-square test was used to determine differences in proportions, with $p < 0.05$ for significance.
Results: We collected fecal samples from 78 normal Italian adults (39 females, 39 males; median age, 55; range age, 24–73; median FCal, 37; range FCal 6–190; median BMI, 23.4; range BMI, 18.4–28.4). 27 (35%) of study participants were smokers.
In total 60% (47/78) of normal Italian adults were determined to be normobiotic, 36% (28/78) were determined to have mild dysbiosis, and 4% (3/78) were determined to have severe dysbiosis. However, no subjects were found to have the highest degree of dysbiosis with DI = 5. Site-wise, the results show 58% normobiosis in Milan, 68% in Rome, and 38% in Palermo.
Of note, 15 (56%) of 27 smoking subjects versus 16 (31%) of 51 non-smoking subjects were determined to be dysbiotic ($p = 0.04$). No significant difference in proportion of dysbiosis between sites ($p > 0.01$) or gender ($p = 0.8$).
We observed high variability in the profiles of fecal microbiota among the Italian adults. The profiles were generally dominated by Actinobacteria (mainly the genus Bifidobacterium), Firmicutes (with diverse representation from numerous genera), Verrucomicrobia (*Akkermansia muciniphila*), and Bacteroidetes (mainly Bacteroides and Prevotella).
Conclusion: We used GA-map™ technology to characterize the gut microbiota in normal Italian adults. The present study showed that the composition of the fecal microbiota of normal Italian adults at the national level, while highly variable, was not strongly associated with subjectś area of residence or gender. However, smoking was found to be associated with dysbiosis. Altogether, our results indicate a 40% proportion of dysbiosis in normal Italian adults, which may possibly be caused by environmental factors such as dietary or smoking habits, as we observe a 25% higher proportion of dysbiosis among smokers as compared to non-smokers.
Disclosure: MKK and CC are employees of Genetic Analysis.

Introduction: The use of antithrombotics (antiplatelet agents and anticoagulants) is increasing with an ageing global population, there is lack of data and system to evaluate adherence to international practice guidelines and standard instructions prior to colonoscopy.
Aims and Methods: We aim to develop an automatic text-mining system to assess the instructions of antithrombotic medications in a retrospective cohort of patients who used antithrombotics and underwent elective colonoscopy in a large teaching hospital. The system first determined whether the clinician has ordered colonoscopy for a patient. If colonoscopy was arranged, the algorithm would search for keywords indicating modification of anti-thrombotic therapy. A list of keywords was created that carries the meaning of ''withholding'', such as ''stop'', ''withhold'' and its abbreviation ''w/h''. We matched these keywords with a list of relevant drug names, e.g. aspirin, warfarin and their abbreviations. Regular expressions were developed to extract the stoppage information using these concepts. Two investigators manually reviewed all consultation notes to determine whether instructions on modifying anti-thrombotic therapy were given. The manual review findings were used as a gold standard to assess the performance of the automated text-mining system.
Results: There were a total of 656 patients and 1,907 consultation notes identified. Manual review identified 108 relevant instructions in the notes. The text-mining system had an accuracy of 0.936, sensitivity of 0.843, specificity of 0.954, and an F1-score of 0.813. The computational and manual effort had 53 out of 656 patients with different results. Because of this discrepancy, the staff went through the consultation notes of those patients with different results. 42 patients were correctly labelled by the manual method but incorrectly labelled by the computational process; the sum of 42 came from false negative (FN)+ false positive (FP).
Conclusion: The computational text-mining tool was able to achieve a high accuracy of 93.6% in this pilot experiment. We can apply this automated tool to screen a larger population to understand the quality of instructions offered to patients. We can also relate this result of detection of drug stoppage instruction to other clinical outcomes, e.g. bleeding complications of the procedures and reversal instruction in future studies.

Introduction: Gastrointestinal bleeding (GIB) is one of the main causes of admission to the Emergency Department (ED) and with hospitalizations, responsible for health burden.
Aims and Methods: We studied all the readmissions by GIB in a tertiary hospital A retrospective study of all GIB admissions was made in the adult population during the year 2016. All patitents were caracterized by comorbilities and medication. Data was analized by Excell and SPSS.
Results: They were admitted to the ED with suspected GIB 690 episodes, reporting to 622 patients. A total of 68 readmissions, by 55 patients, 69% male and 31% female, the mean age being 62.58 ± 16.81 years. Using the Manchester triage protocol 75% of the patients were screened as urgent and 25% as very urgent. The presentation forms were: 43% Rectorragias, 24% Hematemesis, 23% Hematochesis and 10% melenas. In most readmissions (65%), the clinical form of presentation was different from the previous presentation, and agreement was observed in 35% of cases. Throughout the year, most (80%) of patients were readmitted only once, 16% 3 times and 2 patients 4 times. We found readmissions were 64.75 ± 73.17 days. In 50% of the cases were <30 days, with a average of 10.74 days. Analytically mean hemoglobin admission was 10.64 g / dL, with substancial loss at readmission 9,99 g / dL ($p = 0.035$). The hospitalization rate at readmission was 38% with a mortality rate of 15%.
Conclusion: Readmissions by GIB presented with clinical signs of severity, since in all cases they were stratified as urgent or very urgent by the Manchester triage. Taking into consideration that 50% of cases there was an early readmission (average time -10 days), we suggest a schedule reassessment of the most severe cases within 1 week after discharge.

Introduction: Lower Gastrointestinal bleeding (LGIB) is common and its incidence is increasing. There are well-validated predictive scoring models for upper gastrointestinal haemorrhage Rockall, Glasgow Blatchford Score (GBS) and AIM 65. There have been several attempts at identifying risk factors for developing severe LGIB. The BLEED criteria by Kollef et al[1] has not been found to be useful clinically. Strate et al[2] validated risk factors, triaging patients into low, moderate and high-risk groups. Unfortunately, the risk factors are likely to lack the sensitivity to be useful particularly at the low-risk end of the spectrum.
Aims and Methods: The aim of this multicentre review was to identify risk factors that predict adverse outcomes from LGIB. We retrospectively reviewed all patients admitted with LGIB from three large centres in the Midlands, UK between 2010 and 2017. Parameters collected included those that make up GBS, Rockall and AIM65 (Gender, age, co-morbidities, admission haemoglobin (Hb), Urea, Albumin, INR, blood pressure/heart rate, presence of melena, syncope and altered mental state). Adverse outcomes include red cell transfusion, endoscopic intervention, CT angiography, surgery, re-bleeding and mortality. Using regressional analysis all statistically feasible combinations of factors were used to predict adverse outcomes (both multivariate and univariate logistic regression models were fit) with cross-validation method repeated 100 times each combination. The model which exhibited the highest average AUROC value was identified. The factors with 95% CI for ORs containing value 1 were excluded. Then a multivariate logistic regression was fit again on the identified factors. Estimates of the Area Under the Receiver Operating Curve (AUROC) were calculated using a cross-validation method repeated 100 times.
Results: 473 patients were included. Admission Haemoglobin (Hb $<$ 72g/L 14 points, 73–95g/L 10points, 96–117g/L 7 points, 118–139g/L 4 points, $>$140 0 point, altered mental state 1 point, admission BP (Systolic blood pressure $<$ 90mmHg 1 point) and male gender (1 point) were the strongest predictors of the requirement of blood transfusion achieving an AUROC of 0.92 (95% CI 0.90–0.94), therefore giving The Birmingham Score (table 1).
This performed better than the Glasgow-Blatchford score (AUROC 0.89).
When predicting the risk of re-bleeding, the admission haemoglobin was the strongest predictor achieving an AUROC of 0.66 (0.60–0.72). Age, gender, co-morbidities, admission Hb/urea/albumin/INR, blood pressure and syncope predict a length of stay of more than four days with an accuracy of 80%.
Conclusion: Our study shows that admission haemoglobin, altered mental state, male gender best predict the need for blood transfusion after admission with LGIB, giving a novel LGIB score termed The Birmingham Lower GI bleed score. Therefore, this may act as a guide to initiate a more intensive treatment regimen and guide admission.

Score	Probability of requiring blood transfusion
≥12	≥90%
11	70%
9–10	45%
8	30%
6–7	15%
5	6%
≤4	≤3%

[The Birmingham score]

Introduction: The incidence of acute lower gastrointestinal bleeding (LGB) is increasing in Western countries. Recently the Oakland score has been developed for predict safe discharge after LGB.

Aims and Methods: The aim of this study was to compare the accuracy of Oakland score (OakS) with haemoglobin alone (Hb) for predicting outcomes after LGB. Safe discharge was the main outcome predicted by OakS. It was defined as the absence of all the following: a) rebleeding (need for additional red blood transfusion or a further decrease in haematocrit concentrations of 20% or more after 24 hours of clinical stability); b) red blood cell transfusion; c) therapeutic intervention (endoscopic therapy, vascular embolization or surgery); d) readmission with further LGB within 28 days and e) in-hospital death.

A retrospective study was performed from January 2013 to December 2015 in a university tertiary care hospital. Patients with acute LGB were identified using the International Classification of Diseases (9th Revision) and Clinical Modification codes for admission diagnosis. OakS was retrospectively calculated according to clinical reports data. Area under the receiver operating characteristic curve (AUROC), were calculated for OakS and Hb value. AUROCs were compared with the DeLong method by using STATA 14.1 software (StataCorp.2015).

Results: A total of 258 consecutive patients admitted to the hospital with acute LGB were identified retrospectively. Median age was 76.4 years (range 31.7–96.5), 178 (69%) of patients were older than 70 years, 54.3% were men. 154 (57.7%) patients were safely discharged. Six patients (2.3%) died, 50 (19.4%) rebleed, 84 (32.6%) needed transfusion, 20 (7.8%) were readmitted, 28 (11.2%) needed endoscopic treatment and 3 (0.8%) transcatheter arterial embolization. No patient required surgery.

The comparison of the AUROC for OakS and Hb are shown in table 1. Hb was equal or better than OakS for predicting all outcomes but readmission. AUROC were >0.8 for clinical intervention, transfusion, rebleeding and death for Hb and for clinical intervention, transfusion and death for OakS.

Conclusion: Hb seems non-inferior or even superior to OakS for predicting safe discharge, transfussion, rebleeding, haemostatic intervention or dead. OakS was better only for predicting readmission, but the predictive value for this outcome was low for both Hb and OakS.

	Oakland Score AUROC (95%IC)	Haemoglobin AUROC (95%IC)	P value
Safe Discharge n = 154; 59.7%	0.80 (0.74–0.86)	0.82 (0.77–0.88)	0.1516
Transfusion n = 84; 32.6%	0.87 (0.82–0.92)	0.90 (0.87–0.94)	0.0236
Rebleeding n = 50; 19.4%	0.76 (0.68–0.83)	0.81(0.75–0.87)	0.0409
Readmission n = 20, 7.8%	0.68 (0.55–0.77)	0.62(0.48–0.77)	0.0374
Haemostatic intervention n = 31; 12%	0.67 (0.55–0.77)	0.70 (0.61–0.80)	0.3852
Death n = 6; 2.3%	0.84 (0.73–0.95)	0.82 (0.72–0.91)	0.5066

[Table 1]

Introduction: Diverticular Disease (DD) is one of the most frequent benign gastrointestinal condition in older adults, is an asymptomatic condition, however, complications can occur in 5% of cases. The increasing use of non-steroidal anti-inflammatory drugs (NSAIDs), platelet anti-aggregators (PAAs) and oral anticoagulants (OACs) in this population raises the probability of hemorrhage associated with DD.

Aims and Methods: The aim of this study is to evaluate if the use of NSAIDs, PAAs and/or ACOs influence the presentation and the course of hemorrhage episodes associated with DD.

Retrospective analysis of patients admitted for DD complicated with hemorrhage between January 2015 and December 2017. Demographic, clinical, analytical and number of days of hospitalization were evaluated. Statistical analysis was performed using SPSS v24.

Results: 68 patients were included; average age was 80.85 ± 9.49 (53–97) years and 57.4% were male. At the entrance, average hemoglobin was 95.4 ± 25.1 (46–150) mg/dL, systolic blood pressure 115.10 ± 18.64 (80–159) mmHg and heart rate 79 ± 10.7 (50–99) bpm. The mean days of hospitalization was 6.56 ± 5 (2–40) days and the mean hemoglobin at discharge was 104.6 ± 16.9 (81–142) mg/dL. 22.1% of the patients were on NSAIDs; 45.6% PAAs and 42.7% on ACOs. Differences were found between patients with PAAs and ACOs and the highest INR (p-0.0 and p-0.00, respectively), as well as those with OACs with a higher number of days of hospitalization (p -0.036). In the categorization of the variables, it was verified that the patients who performed ACOs had HR at entry > 80bpm and > 6 days of hospitalization (OR 0.22, 95% CI 0.075–0.67, p-0.007 and OR 3.68, 95% CI 1.34–10.13, p-0.012, respectively). The use of NSAIDs did not present statistical significance in the influence of those variables.

Conclusion: The use of OACs influences the presentation and evolution of hemorrhage and is associated with a greater number of days needed for surveillance and treatment. Given the increasing use of these drugs, it is important to rethink the indications as well as the risk-benefit of use.

P1643 CAN METABOLIC AND LIFESTYLE RISK FACTORS PREDICT COLONIC ADENOMATOUS POLYPS?

A. Pisani, N. Azzopardi, K. Gatt, S. Santucci, Y. Abdilla, M.A. Barbara
Mater Dei Hospital, Msida, Malta

Contact E-Mail Address: anthea.b.pisani@gov.mt

Introduction: Recent studies have suggested that metabolic and lifestyle risk factors (including metabolic syndrome, obesity, diabetes mellitus and tobacco smoking) may increase the risk of developing colonic adenomatous polyps.[1–2] Strong evidence pointing towards an association between metabolic syndrome and colonic adenomas, may lead to new recommendations in colonic screening.

Aims and Methods: We analysed whether metabolic and lifestyle risk factors are associated with colonic adenomas. A prospective study on patients over the age of 50 undergoing a screening colonoscopy at Mater Dei Hospital was performed. Exclusion criteria included a history of inflammatory bowel disease, family history of colorectal cancer and previous colonic malignancy. We collected data on weight, body mass index (BMI), waist circumference, history of hypertension, diabetes and hyperlipidaemia, smoking, level of exercise done (using the Godin Leisure-Time Exercise Questionnaire), fasting glucose, triglyceride and HDL cholesterol level. A BMI ≥25 was considered as 'overweight.' The National Cholesterol Education Program (NCEP) Adult Treatment Panel III criteria were used to define 'metabolic syndrome.' Statistical analysis was performed using Fisher's exact test. *P*-value ≤ 0.05 was considered statistically significant. The presence or absence of colonic adenomatous polyps at colonoscopy was documented.

Results: 72 patients were recruited (51.4% were male). 40.3% of patients had one or more colonic adenomas. 40.3% patients had metabolic syndrome. 81.9% patients were categorized as overweight. 29.2% patients had diabetes mellitus. 18.1% patients were active smokers. 51.3% of patients had a sedentary or insufficiently active lifestyle (total leisure activity score < 14). See table 1.

Conclusion: Our study did not confirm the previously documented associations between metabolic and lifestyle risk factors and colonic adenomas. Further data from large screening centres may help establish the risk of adenomatous polyp formation in patients with metabolic syndrome.

Risk Factor	Present	Not present	Fisher exact test statistic value
Metabolic syndrome	10 (13.9%)	19 (26.4%)	0.47
Overweight	22 (30.6%)	7 (9.7%)	0.35
Diabetes mellitus	9 (12.5%)	20 (27.8%)	0.8
Active smokers	4 (5.6%)	15 (20.8%)	1
Sedentary lifestyle	15 (20.8%)	14 (19.4%)	0.81

[Table 1: Table showing the number of patients who had adenomas compared to the presence or absence of risk factors]

Introduction: How old is really old is a controversial topic in colorectal cancer. Whether the old patients did have different outcomes comparing with younger CRC.

Aims and Methods: Our study aims to determine an optimal cutoff age of defining older patients in CRC, and present a real-world impact of the factor of old on CRC, which could provide more evidence in future clinical practices.

A total of 76,858 eligible patients from Surveillance, Epidemiology and End Results (SEER) database were included in the study. Cox proportional hazards regression model and chow test were used to explore the suitable cutoff age. The propensity score matching method was performed to adjust the heterogeneity between the groups. Kaplan-Meier survival curves were plotted. Competing risk regression model was used to explore the impact of age on cancer-specific death (CCSD) and non-CSD. An external validation was performed based on the data from 1998 to 2003 from SEER database.

Results: The age of 70 years was determined as the optimal cutoff value. Based on the cutoff value, patients was divided into younger group ($n = 51,915$, < 70 years of old) and older group ($n = 24,943$, ≥ 70 years of old). Compared with younger patients, older patients were related with high rate of male, Caucasians, right CRC, mucinous carcinoma, poorer differentiated grade, and more likely to have less lymph nodes sampled, less possibility to receive chemotherapy and radiotherapy. After adjustment for covariates and propensity score weighting, older patients (age ≥ 70 years) remained associated with decreased CSS (HR, 1.67 95 CI, 1.60–1.74, $p < 0.001$). To account for competing risks (non-CCSD), the competing analysis indicated that older group did have more CCSD as well as increased non-CCSD. The external validation consistently showed that age of 70 years was a suitable cutoff value and older patients have poorer prognosis.

Conclusion: The age of 70 was a suitable cutoff value for defining "young". Old Ptients with CRC was not only associated with more non-CCSD but also more CCSD. Old patients might receive extra strengthened treatment if possible.

Introduction: The colorectal screening programmes based on the detection of FOBT (FIT – Faecal Immunological Test) in asymptomatic subjects between 50–69 years old, has proved its efficacy in the reduction of incidence and mortality of colorectal cancer (CRC). The established threshold in this context is 100 ng/mL. Given that values over 50 ng/mL are considered positive outside of the screening programme, there might be a percentage of asymptomatic individuals with values between 50–99 ng/mL that could have undetected lesions.

Aims and Methods: We aimed to analyse the endoscopic findings in patients included in the CRC screening programme with values of FIT between 50–99 ng/mL.

We retrospectively analysed the FIT results (OC-SENSOR, Biogen®) received at our hospital in the first round of screening between the years 2014–2016. We selected those patients with results between 50–99ng/mL that underwent a colonoscopy as indicated by their GP as screening. As a control group we used subjects from the same programme with FIT$\geq$100.

Results: A total of 989 subjects between 60–69 years old presented FIT results ranging from to 99ng/ml. 70 (7%) of them underwent colonoscopy. We detected adenomas in 32 (45.7%), high-risk adenomas in 14 (20%) and CRC in 2 (2.9%). In the table, we present the results comparing with the control group. Stratifying the analysis by sex, the% of adenomas (54.9%vs74.9%; $p = 0.13$) and high-risk adenomas (32.3%vs57.3%; $p = 0.05$) in male individuals differ with statistical significance from the control group.

Conclusion: The threshold of FIT established in the CRC population screening programme is efficient but can increase the percentage of false negatives. It is necessary to evaluate these results with wider series to find the risk factors associated to the false negatives and propose changes in the threshold or in the screening intervals.

	Screening group (FIT$\geq$100)	FIT 50–99	p-value
n	1270	70	
Age (years)	65.27	65.47	0.705
Sex (male)	744 (58.6%)	31 (44.3%)	0.018
Complete colonoscopy	1248 (98.3%)	69 (98.6%)	0.849
Adenomas	879 (69.2%)	32 (45.7%)	0.00
Male	557(74.9%)	17 (54.8%)	0.13
Female	322(61.2%)	15(38.5%)	0.05
High risk adenomas	608 (47.9%)	14 (20%)	0.00
Male	426 (57.3%)	10 (32.3%)	0.05
Female	182(34.6%)	4 (10.3%)	0.01
CRC	105 (8.3%)	2 (2.9%)	0.074
Male	71 (9.3%)	1 (3.3%)	0.212
Female	34 (6.5%)	1 (2.6%)	0.285

P1646 COLORECTAL CANCER INCIDENCE AND MORTALITY REDUCTION IN THE CZECH REPUBLIC – EFFECT OF THE NATIONAL SCREENING PROGRAM?

S. Suchanek[1], O. Ngo[2], T. Grega[1], O. Majek[2], M. Zavoral[1]
[1]*1st Faculty of Medicine, Charles University, Military University Hospital, Department of Internal Medicine, Prague, Czech Republic*
[2]*Faculty of Medicine, Masaryk University, Institute of Biostatistics and Analyses, Brno, Czech Republic*

Contact E-Mail Address: stepan.suchanek@uvn.cz

Introduction: The organized non-population based National Colorectal Cancer (CRC) Screening Program in the Czech Republic has been running since year 2000. In January 2014, the transition to population-based setting has been implemented. Currently, the annual immunochemical FOBT (FIT) is offered at the age 50–54, followed by FIT+ colonoscopy, if positive. In age of 55, there is a choice of either FIT biannually or screening colonoscopy in 10-years interval.

Aims and Methods: The main target lesions of the CRC screening program are the adenomas and early cancers. Therefore, the relation between number of colonoscopies/endoscopic polypectomies and CRC incidence and mortality decrease was evaluated. The analysis was based on the aggregate data from the Health Insurance Companies Databases, Preventive Colonoscopies Database and National Oncology Registry.

Results: Between years 2000 and 2015, there was significant reduction of the CRC incidence (18.4%) and mortality (32.4%) observed. The number of colonoscopies and endoscopic polypectomies has been raising continuously every year. In 2015, there were 264,399 colonoscopies performed from the following indications: 227,905 (86.2%) symptoms, follow-up and therapy; 23,463 (8.9%) FIT positivity and 13,031 (4.9%) screening at age $\geq$ 55. In the same year, overall 60,120 endoscopic polypectomies were done (22.7% of all colonoscopies) in following age groups: 5,272 in age $<$ 50; 5,627 in age 50–54 and 49,221 in age $\geq$ 55. In 36,494 colonoscopies performed within the organized CRC screening program in year 2015, there were 14,085 (38.6%) adenomas and 969 (2.7%) cancers diagnosed. 40.0% of the adenomas were advanced ($\geq$ 10 mm, villous component, high-grade dysplasia). Majority of the cancers found were in stage I (45%) and II (18%).

Conclusion: There is a very likely connection between the high number of diagnostic/therapeutic colonoscopies and CRC incidence and mortality reduction. To assess the benefit of the screening program to this effect, the comprehensive individual data from the new National Registry of Reimbursed Health Services needs to be evaluated.

Contact E-Mail Address: eunate.aranaarri@osakidetza.eus

Introduction: Colorectal cancer (CRC) is one of the most frequent cancer entities in Europe and most cases of CRC arise through malignant transformation of benign adenomas known as the adenoma-to-carcinoma-sequence. Screening colonoscopy is less effective in reducing the incidence of proximal compared to distal colorectal cancer, presumably because of missed adenomas and advanced lesions during

endoscopy. Thus, effectiveness and success of colorectal cancer (CRC) screening programs depend decisively on the quality of the endoscopic procedures.
Aims and Methods: We aimed to provide a detailed analysis of the epidemiology and survival of right-sided detection lesions (adenomas and CRC) in a population based screening programme with a high participation and colonoscopy compliance rates. We collected data retrospectively from 42,267 colonoscopies, 4,823 patients with adenomas and 2,180 with CCR were diagnosed, from January 2009 to December 2014. Data of clinical characteristics of patients, screening history, endoscopic procedure and histology results were collected.
Results: During the study period, 2,145 screening cancers (SCRC), 16 post-colonoscopy interval cancers (PCICRC) and 19 surveillance cancers (PCSCRC) were diagnosed. The rate of post-colonoscopy cancer (PCCRC) for the right-sided was 0.3% and for left-sided 0.6%. 20% of the SCRCs were located in the right colon. The mean age was 62.6 ± 5.4 years, slightly lower than left-sided, being 46.4% in the age range 64–69 years. 62.8% were men compared to 66.4% in left-sided. We did not find differences in the distribution in the deprivation index, nor in the stage at the diagnosis time. In the right-sided 68.1% were in early stage. The median µg Hb/g faeces detected by the immunochemical test in the right-sided was 234.9 (IQR = 1428), finding a significant difference with left-sided, 526.0 (IQR = 2105); $p < 0.0001$. The degree of differentiation was also different: 93.5% well-moderate in right-sided and 95.9% in left-sided; $p = 0.043$. We did not find difference in endoscopists adenoma detection rates (ADT). The 5-year survival for right-sided was 87.2% with an average of 7.86 years and 90.8% for left-sided with an average of 7.90 years; $p < 0.001$.
Regarding adenomas, 26.5% had right—side location. We did not find differences in endoscopists ADTs between locations. We found significant differences ($p < 0.0001$) regarding the histology of the adenomas, being mostly tubular in right-sided and tubulovillious in left-sided. The mean size of the largest polyp was somewhat higher in the left colon (13.9 ± 8.1 mm) with respect to the right colon (13.7 ± 12.6 mm).
The PCSCRC were located in right colon in 31.6% of the cases. 83.3% of right-sided were diagnosed at early stage. We did not find differences in mortality between both locations.
The PCICRC were located in 31.2% in right colon. 80% had good preparation in the previous colonoscopy. 20% had an incomplete resection of the polyps in a previous colonoscopy. 40% of the locations in the right colon were diagnosed at early stage. 2 patients have died, having the cancer in right location.
Conclusion: Available evidence is supporting the hypothesis that the natural history and survival of lesions in the right and left colon differ. Screening programs have greatly increased the detection of premalignant lesions. It is important to know the results and characteristics related to the locations of the lesions to implement measures that increase the effectiveness of the screening programs, improving survival, especially in right colon lesions.

Introduction: Colorectal cancer (CRC) is third most commonly diagnosed cancer worldwide. Dysregulation of mitosis and apoptosis contributes to the development of colorectal neoplasia.
Aims and Methods: The aim of the prospective study was to evaluate mitotic and apoptotic activity of epithelial cells at each stage of colorectal neoplasia.
A total of 61 persons were enrolled into the study: 18 patients with non-advanced colorectal adenoma (non-a-A), 13 patients with advanced colorectal adenoma (a-A), 13 patients with CRC and 17 controls: individuals with normal findings on colonoscopy. Biopsy samples were taken from pathology (patients) and healthy mucosa (patients and healthy controls). Samples were formalin-fixed paraffin-embedded and stained with haematoxylin-eosin. Mitotic and apoptotic activity were evaluated in lower and upper part of the crypts and in the superficial compartment. Apoptotic activity was also assessed using detection of activated caspase-3.
Results: In controls, mitotic activity was present in lower part of crypts, accompanied with low apoptotic activity. Mitotic and apoptotic activity decreased (to almost zero) in upper part of crypts. In superficial compartment, increase in apoptotic activity was observed. Transformation of healthy mucosa into non-a-A was associated with significant increase of mitotic activity in lower and upper part of the crypts and with significant increase of apoptotic activity in all three compartments; $p < 0.05$. Transformation of non-a-A into a-A did not lead to any further significant increase in apoptotic activity, but was related to significant increase in mitotic activity in upper part of crypts and superficial compartment. A significant decrease in apoptotic activity was detected in all three comparments of CRC samples compared to a-A; $p < 0.05$.
No differences in mitotic and apoptotic activity between biopsies in healthy controls and biopsy samples from healthy mucosa in patients with colorectal neoplasia were observed; $p > 0.05$.
Mitotic and apoptotic activity was not different in the left sided colonic neoplasia (distally from splenic flexure) compared to samples from right-sided colonic neoplasia; $p > 0.05$. No differences in mitotic and apoptotic activity were found in biopsies from normal tissue in patients with right-sided neoplasia when compared to normal tissue in patients with left-sided colonic neoplasia; $p > 0.05$. No differences in mitotic and apoptotic activity between females and males were observed; $p > 0.05$.
Detection of activated caspase-3 confirmed the above findings in apoptotic activity.
Conclusion: Significant dysregulation of mitosis and apoptosis during the progression of colorectal neoplasia, corresponding with histology, was confirmed. In patients with sporadic colorectal neoplasia, healthy mucosa does not display different mitotic and apoptotic activity compared to mucosa in healthy controls and therefore adequate endoscopic/surgical removal of colorectal neoplasia is sufficient.

Introduction: Early onset colorectal cancers (eoCRC), defined as arising before 50 years of age, are a growing health hazard in western and eastern countries alike. The incidence of colon and rectal cancers in young individuals is projected to increase by as much as 90% and 140%, respectively, by 2030. Although several known cancer risk factors have been investigated, there is no single compelling explanation for this epidemiological trend. While some eoCRC are associated with germline mutations in cancer predisposition genes, these appear to account for only a fraction of these cancers (~20%) and do not explain increasing incidence.
Aims and Methods: To investigate the role of exogenous risk factors (alcohol intake and smoking habits) and endogenous conditions (delays in diagnosis, gastrointestinal hereditary tumors) as associated factors of eoCRCs.
Clinical, anamnestic and pathological data were retrieved on eoCRC patients from June 2017 to April 2018. These patients were compared with a group of late onset CRC (loCRC) evaluated in the same period.
Results: We enrolled 33 eoCRCs and 48 loCRCs. According to definition, eoCRC patients were younger than loCRC, with a mean age of 40.7 ± 7.3 and 66.1 ± 9.8, respectively ($p < 0.001$). Gender was not different in the two groups with a prevalence of females (54.5% in eoCRCs and 52.1% in loCRCs). The diagnostic delay was higher in eoCRC group: only 42.4% of eoCRCs received the diagnosis in the 6th months from symptoms onset versus 100% of loCRC patients ($p < 0.001$). The syndromic familiarity (Lynch syndrome) was more frequent in eoCRC (12%) than loCRC group (0%), with a statistically significant difference ($p = 0.02$).
We also found a statistically significant difference in alcohol habit, with a percentage of no-drinker in 66.7% of eoCRCs and 41.7% of loCRCs ($p = 0.04$). Also, there was a trend through significance for no-smokers in eoCRCs.
Conclusion: CRCs should be considered earlier in the differential diagnosis in young patients. We confirmed alcohol as cofactor in the development of eoCRC and we underlined that familiar history should be collected to identify mutations carries.

Introduction: Epigenetic dysregulation plays essential roles in the tumorigenicity of *KRAS*-mutant colorectal cancer (CRC). However, the mechanism underlying epigenetic deregulation and its functional implications remain unclear. Our preliminary data revealed that *KRAS* gain-of-function mutations in colonic and CRC cells induced epigenetic reprogramming via methylation of DNA and histones; and that *SLC25A22,* a mitochondrial glutamate transporter, plays a key role in this process.
Aims and Methods: We aim to 1) investigate the role of SLC25A22 in the epigenetic reprogramming in *KRAS*-mutant CRC; 2) elucidate the mechanisms whereby epigenetic alterations mediate an oncogenic effect; and 3) devise a therapeutic strategy to target epigenetic reprogramming in *KRAS*-mutant CRC.
Results: Using isogenic cell lines harbouring wild-type and mutant *KRAS* ($DKS8^{WT}$ vs $DLD1^{G12D}$; $1CT^{WT}$ vs $1CT^{G12V}$), we demonstrated that mutant *KRAS* drives histone and DNA hypermethylation. Stable metabolomic analyses revealed that mutant *KRAS* drives glutaminolysis via TCA cycle, leading to increased succinate/fumarate to α-ketoglutarate (αKG) ratio. An altered metabolite ratio, in turn, suppressed histone/DNA demethylases, thereby inducing hypermethylation. We thus utilized the CRISPR-Cas9 approach to knockout *SLC25A22*, a mitochondrial glutamate transporter essential for glutaminolysis, in two *KRAS*-mutant CRC cell lines (DLD1, SW1116).
SLC25A22 knockout reversed *KRAS*-mediated glutaminolysis and reduced succinate/fumarate to αKG ratio, which consequently resulted in enhanced DNA demethylation, as evidenced by the increased levels of 5-hmC. Illumina 860K Methylation BeadChip was employed to profile the methylome of *SLC25A22* knockout DLD1 cells. Pathway analysis unveiled that WNT and cadherin signaling pathways as top pathways aberrant methylated in DLD1-control cells as compared to *SLC25A22* knockout cells. Of note, *SLC25A22* knockout initiated promoter demethylation and re-expression of genes within protocadherin cluster (*PCDHαβγ*), putative tumor suppressors that were shown to negatively WNT/β-catenin signaling. Consistently, *SLC25A22* knockout or ectopic expression of *PCDHαβγ* isoforms suppressed WNT/β-catenin signaling, as evidenced by decreased nuclear localization of active β-catenin, TOPflash activity and reduced expression of WNT target genes. Moreover, histone methylation profiling identified that *SLC25A22* knockout reduced H3K4 methylation, particularly H3K4me3, a histone mark that directs active transcription. Chromatin-immunoprecipitation revealed that *SLC25A22* knockout suppressed enrichment of H3K4me3 at the promoters of *ASCL2* and *LGR5*, WNT target genes that are markers of CRC stem cells. Accordingly, *ASCL2* and *LGR5* expression were diminished in *SLC25A22* knockout CRC cells. Corroborating our mechanistic findings, *SLC25A22* knockout suppressed tumorigenicity and stemness of CRC cell lines *in vitro* and in xenograft models.
Given that cancer can promote methylation of DNA/histone by either promoting methylation or inhibiting demethylation, we hypothesized that it may be possible to reverse aberrant DNA methylation and tumorigenesis by co-targeting methyltransferases (DNMT inhibitor) and glutaminolysis (GLS inhibitor). Concomitant administration of 5-Aza and GLS inhibitors (compound 968, BPTES, or CB839) synergistically inhibited growth of *KRAS*-mutant CRC cell lines.
Conclusion: *SLC25A22*-dependent glutaminolysis drives DNA/histone hypermethylation in CRC and promotes tumorigenesis and cancer stemness. A novel epigenetic therapy co-targeting DNMTs and GLS synergistically suppressed the growth of KRAS-mutant CRC cells.

Introduction: The unfolded protein response (UPR) is a cellular stress response activated upon accumulation of misfolded proteins in the lumen of the endoplasmic reticulum (ER). Activation of the UPR results in differentiation of intestinal epithelial stem cells and colon cancer stem cells via UPR kinase PERK, which results in increased chemosensitivity.
Activation of PERK and downstream phosphorylation of eIF2α attenuates protein translation. Transcriptional activity of XBP1 and ATF6 in contrast result in expansion of the ER. Previously, it was shown that knockout of XBP1 increases proliferation and tumor formation in mice. Therefore, we hypothesize that XBP1 signaling results in reduction of stemness and cellular proliferation in colon cancer cells. Since XBP1 and ATF6 have overlapping transcriptional targets, we additionally examine colorectal cancer cell proliferation upon ATF6 activation.
Aims and Methods: We generated LS174T colorectal cancer cell lines that stably carry transcripts enabling doxycycline inducible expression of the active form of XBP1 (XBP1s) or ATF6 (ATF6-373 truncated protein). In these cell lines, we measured downstream activation of UPR signaling or intestinal stem cell markers using quantitative RT-PCR or protein immunoblot. We determined proliferation using crystal violet and EdU incorporation. Global translation was measured with ^{35}S methionine incorporation.
Results: Enforced expression of transcriptionally active forms of XBP1 or ATF6 resulted in marked increase of downstream UPR target genes GRP78 and CHOP. Cellular proliferation was decreased significantly. We additionally found reduced expression of intestinal epithelial stem cell markers OLFM4 and LGR5. Interestingly, we found that XBP1s or ATF6 increased activation of PERK-eIF2α signaling, with decreased cellular translation as a result. Inhibition of eIF2α phosphorylation via constitutive expression of phosphatase GADD34 rescued XBP1 and ATF6 induced growth retardation.
Conclusion: Activation of UPR signaling in the intestinal epithelium, adenomas and colorectal cancer cells results in differentiation of stem cells. We observe that activation of transcription factors XBP1s and ATF6 inhibit proliferation and reduce translation in LS174T colon cancer cells. XBP1s and ATF6 induced proliferation inhibition exposed a novel interaction with PERK-eIF2α signaling. We identify eIF2α phosphorylation as responsible for XBP1s and ATF6 induced differentiation. Targeting PERK-eIF2α in colon cancer may thus be utilized for colorectal cancer cell differentiation and to increase chemosensitivity.

Introduction: The risk of colorectal cancer (CRC) is increasing with age, and cellular senescence plays an important role in tumourigenesis. We have previously showed that Klotho, an anti-senescence gene, was regulated by DNA hypermethylation and involved in the CRC cell proliferation.
Aims and Methods: This study was designed to determine the molecular mechanism of Klotho in cellular senescence and expression of senescence-associated secretory phenotype (SASP), and clarify its clinical significance and biological functions in CRC. Immunohistochemical staining was applied to identify Klotho expression in 143 CRC tissues. Senescent human mesenchymal cells were established and co-cultured with CRC cell lines. *In vitro* and *in vivo* studies were performed to determine the growth and metastatic phenotypes of colon cancer cells in response to senescent cells. Series of the senescence-associated secretory phenotype (SASP) molecules were screened after administration with recombinant Klotho. CCL-2, a candidate SASP, was validated and its functional role in CRC was studied.
Results: IHC staining showed that Klotho was down-regulated in CRC tissues and closely correlated with elderly age. High expression of Klotho was an independent prognostic factor for favorable survival in CRC patients. In addition, senescent mesenchymal cells significantly stimulated the proliferation of CRC

cells, enhanced their ability of cell migration and invasion *in vitro* and *in vivo* xenograft mouse models, while these effects could be partially blocked by the exogenous administration with Klotho. CCL-2, a SASP component, was validated to be upregulated in senescent mesenchymal cells. The pretreatment of recombinant Klotho blocked the DOX-induced senescence process, reduced the secretion of CCL-2 and restored the tumour-promoting effect of the senescent cells. Further investigations revealed that Klotho-mediated inhibition of NF-κB significantly suppressed CCL-2 expression.
Conclusion: Senescent mesenchymal cells may alter the tissue microenvironment via the secretion of SASP including CCL-2, promoting colorectal cancer growth and metastasis, which could be blocked by Klotho pretreatment. The inhibition of senescent stroma-cancer signaling pathways by Klotho has the potential to restrain colorectal cancer progression.

Introduction: A sessile serrated adenomas/polyp (SSA/P), one of the serrated polyps, is predominantly located in right-side colon. A SSA/P is recognized as a precursor lesion of colorectal cancer (CRC) characterized by BRAF mutation, CpG island methylator phenotype (CIMP), and microsatellite instability (MSI). However, the role of DNA hypomethylation during SSA/P-cancer sequence is unknown.
Aims and Methods: In this study, we aimed to investigate the biological relevance of DNA hypomethylation in SSA/P-cancer sequence. DNA hypomethylation array analysis of 7 SSA/Ps, and 2 cancer in SSA/P specimens were performed with a microarray-based integrated analysis of methylation by isoschizomers (MIAMI) method using normal colorectal epithelia as a reference. Levels of mRNA were determined by Taqman realtime PCR. The SSA/P organoid was established using biopsy specimens obtained from SSA/P with colonoscopy. The knockdown of the gene in SSA/P organoids and CRC cell lines with BRAF mutation (HT29 and WiDr) was performed using a lentiviral shRNA vector and siRNA respectively. The cell viability of SSA/P organoids and CRC cell lines were determined by ATP assay and BrdU colorimetric assay respectively. The DNA hypomethylation at CpG sites of the gene was quantitated by MassARRAY analysis. The protein expression was evaluated by immunohistochemistry and Western blotting.
Results: The mean number of hypomethylated genes in SSA/P and cancer in SSA/P were 41.6 ± 27.5 and 214 ± 19.8, respectively, showing astepwise increment of hypomethylation during the process of formation of SSA/P and subsequent cancer. The novel 4genes (S100P, S100α2, PKP3 and MUC2) were identified as most commonly hypomethylated genes in SSA/P. Of these, mRNA levels of S100P, S100α2, and MUC2 were significantly elevated in SSA/P than in normal epithelia. Particularly, the mRNA and protein expression levels of S100P were even higher than normal epithelia. The knockdown of the S100P gene in SSA/P organoids inhibited cell growth by 65% ($P < 0.01$). Similarly, the knockdown of S100P gene in HT29 and WiDr cells inhibited cell growth by 22 and 43% respectively ($P < 0.05$ respectively). The significant hypomethylation was detected at specific CpG sites in the intron 1, exon 1 and 5'-flanking promoter region of the S100P gene. The hypomethylation at the CpG sites in the intron 1 wasthe strongest among these regions.
Conclusion: Our results suggest that DNA hypomethylation including S100P, S100α2, and MUC2 hypomethylation is closely associated with SSA/P-cancer sequence. S100P, which is overexpressed probably due to hypomethylation at the specific CpG sites in the intron 1, exon 1 and 5'-flanking promoter region, plays an important role in cell proliferation of SSA/P. Thus, S100P may be a novel therapeutic target for colorectal carcinogenesis through SSA/P-cancer sequence.
Disclosure: Nothing to disclose

P1654 THE GUT MICROBIOTA INFLUENCES INTESTINAL EPITHELIAL PROLIFERATIVE POTENTIAL

J.P. Thomas[1], A. Parker[2], D. Divekar[2], A. Watson[3]

Introduction: The intestinal epithelium is comprised of a single layer of cells which serves a number of critical functions including the formation of a physical barrier to environmental pathogens and chemical substances, and the absorption of essential nutrients, electrolytes and water. It is also the site of the gut microbiota, a complex and diverse community of bacteria, viruses and fungi, which exists in a mutually beneficial relationship with the human host. The epithelial barrier is maintained through tightly regulated processes of stem cell renewal, epithelial maturation, cell migration and cell death. Failure to finely coordinate these processes can lead to disease states such as cancer.
Aims and Methods: In this study, we aimed to investigate and characterise the role of the intestinal microbiota on epithelial cell proliferation. We determined the rates of epithelial proliferation in the intestines of Specific-Pathogen-Free (SPF) mice and Germ-Free (GF) mice. We utilised a previously described method which integrates cell tracking using the thymidine analogue Bromodeoxyuridine (BrdU) in crypt-villus units, with a tailored mathematical model, to determine the spatiotemporal dynamics of epithelial cell behaviour in SPF and GF conditions.
Results: The rate of epithelial cell production in GF conditions was significantly slower in the colon, ileum and jejunum in comparison to SPF conditions. In the duodenum, there were no significant differences in proliferation rates in GF and SPF conditions. Cell production rates progressively decreased towards the distal part of the intestine, which inversely correlate with the concentration of organisms constituting the intestinal microbiota.
Conclusion: These findings indicate that the gut microbiota plays an important role in determining intestinal epithelial cell proliferation rates. This relationship may have important implications in disease states such as cancer and inflammatory bowel disease, where differences in microbial signatures are known to exist. In turn, it may be possible in the future to harness this knowledge to alter disease progression by modifying the host microbiota.
Disclosure: Nothing to disclose

Introduction: Molecular analysis of intestinal cancers is determined routinely in clinical practice. Data in the subgroup of tumors occurring in IBD population remain scarce. Two recent studies (1,2) suggest that colorectal tumors developed in IBD patients display different molecular profile than the sporadic ones and may vary considering the subtype of IBD.
Aims and Methods: We aimed to characterize the spectrum of genomic alterations in SBA and CRC in patients with IBD
We included retrospectively all the patients treated for both SBA and CRC in a French tertiary IBD unit from 2001 to 2017. Samples of the primitive tumor were extracted from biopsies made by colonoscopy or from a surgical specimen and analyzed on the same molecular biology platform. Samples were analyzed using Next-Generation Sequencing (NGS) with the Truesight Tumor 26 preparation Kit (Illumina) after DNA quality control testing. IDH1 status was determined using High Resolution Melting (HRM) analysis on the LightCycler 480 System (Roche).
Results: Among a cohort of 5716 IBD files (Crohn's Disease: CD, Ulcerative Colitis: UC), 51 (0.9%) patients were diagnosed with SBA or CRC during the study period and were all included. In 7 cases (14%), samples analysis didn't provide interpretable data (DNA deterioration n = 6; insufficient histological specimen n = 1). In 13 cases (25.5%) specimens are undergoing complementary quality control. Among the 31 remaining patients, 11 (21.5%) have reliable DNA support but are not fully interpreted yet. In total, 20 patients (39%) were analyzed (male 55%; CD 50%, colorectal cancer 90%, median age at cancer diagnosis: 42.7 years, median time between IBD and cancer diagnosis: 16.1 years). In the 10 CD patients, tumor was located to the colon in 6 cases, the rectum in 2 cases and the small bowel in 2 cases. In the 10 UC patients, tumor was colonic in 5 cases and rectal in the 5 other cases. At cancer diagnosis, IBD was active in 53% of the patients (symptoms and/or endoscopic lesions not related to tumor onset) and 30% were exposed to an immunosuppressive agent (azathioprine mainly) or anti TNF therapy (infliximab mainly). In 13 cases, tumor was initially localized (colonic n = 9; rectal n = 4). After a median follow-up of 36,3 months a remission was maintained in 7 cases (54%). Median overall survival of these patients with TNM I to III status was 27 months. In 13 cases, (relapsers n = 6; metastatic at diagnosis n = 7; colorectal n = 11) patients presented with metastasis. In those patients, all received double or triplet chemotherapy (first-line only: 31%). The drugs used were: 5FU (100%), Oxaliplatin (85%), Irinotecan (54%), Bevacizumab (54%), anti-EGF-R agents (54%). The median overall survival of these metastatic patients was of 21 months.
Of the 20 NGS analyses, 17 samples presented a known functional P53 mutation (85%). An APC mutation was found in 1 patient (5%). NRAS exons 2 and exons 4 were mutated in 4 (20%) and 1 (5%) cases respectively. Two PIK3CA (10%) and SMAD4 (10%) (Both in CD patients) mutations were found. There was no KRAS, GNAS, BRAF, HER2 and IDH1 mutation. No significant difference in genomic alterations was found between tumors developed on CD and those on UC.
Conclusion: In this preliminary descriptive study, the prognosis of intestinal IBD cancer patients seems poorer than sporadic ones. We observed a high P53 mutation and a low APC and RAS mutations rates, which seem to be different from sporadic colorectal cancers. Conversely to some data in the literature, no IDH1

alteration was found. Further prospective data are needed to confirm those results.

Introduction: Promoter hypermethylation plays a vital role in cancer through transcriptional silencing of tumour suppressive genes. Integrated epigenomic and transcriptomic analyses of the Cancer Genomic Atlas (TCGA) colorectal cancer (CRC) cohort showed that SCNN1B as an outlier gene aberrantly silenced in CRC. In this study, we investigated the function, molecular mechanism and clinical significance of SCNN1B in CRC.
Aims and Methods: In this study, we aim to 1) evaluate the clinical significance of SCNN1B in CRC; 2) investigate the biological function of SCNN1B in CRC; and 3) to elucidate the molecular pathways involved in tumor suppressive effect of SCNN1B. Clinical significance was validated by methylation-specific PCR (MSP), bisulfite sequencing (BGS) and real-time PCR analysis. In vitro functional assays were carried out by cell viability, colony formation, apoptosis, cell cycle, cell invasion and migration assays. Pathway analysis was performed by Gene Set Enrichment Analysis (GSEA), and validated by Western blot and luciferase reporter assay.
Results: Using volcano plots analyses of RNAseq and 450K methylation array dataset, we identified that SCNN1B is an outlier gene in TCGA CRC cohort which is silenced at mRNA level, but hypermethylated at its promoter CpG sites. RT-PCR showed that SCNN1B mRNA was silenced in all ten CRC cell lines tested compared to normal colonic tissues. MSP and BGS analysis confirmed SCNN1B promoter methylation in all ten CRC cell lines. SCNN1B expression was restored by demethylation treatment, suggesting that promoter methylation mediates its transcriptional silence. In a Hong Kong CRC cohort, we validated the silencing of SCNN1B mRNA and protein expression, by real-time PCR and immunohistochemistry (IHC), respectively, concomitant with its promoter methylation. Survival analysis of TCGA dataset demonstrated that mRNA expression of SCNN1B is independently associated with good outcome in CRC ($P < 0.001$); whereas its promoter methylation predicts poor survival ($P = 0.006$), indicating that SCNN1B might be a functional tumor suppressor in CRC. Ectopic expression of SCNN1B in two CRC cell lines inhibited cell proliferation and colony formation. SCNN1B exerted its effect by inducing apoptosis and cell cycle arrest. Consistent with this, Western blot analysis revealed that activation of caspase-7 and PARP, up-regulation of cell cycle inhibitors p21, p27 and p53, together with the down-regulation of cyclin D1. Moreover, SCNN1B suppressed cell migration, as determined by wound healing assay. To probe for pathways that can be regulated by SCNN1B, GSEA analysis was performed on TCGA CRC cohort. GSEA revealed a significant association of SCNN1B with down-regulation of KRAS oncogenic signature. Consistent with this observation, Western blot showed that SCNN1B overexpression decreased the expression of p-MEK and p-ERK, key downstream factors of oncogenic KRAS. Moreover, ectopic SCNN1B expression inhibited SRE luciferase activity, indicating suppression of RAS-MEK-ERK oncogenic signalling.
Conclusion: SCNN1B is a tumor suppressor silenced by promoter methylation in CRC. It inhibits colorectal tumorigenesis via inhibition of RAS-MEK-ERK signalling. SCNN1B mRNA expression and promoter methylation may serve as an independent prognostic biomarker for CRC patients.
Disclosure: Nothing to disclose

P1657 DIAGNOSTIC AND PROGNOSTIC ROLE OF CIRCULATING CELL FREE DNA (CF DNA) IN DIFFERENT STAGES OF COLORECTAL CANCER

M. Elnadry[1]
[1]*Al-azhar University, Tropical M., Cairo, Egypt*

Contact E-Mail Address: prof_nadry@yahoo.com

Introduction: Cell-free DNA (cfDNA) represents DNA originating from dying cells and from active release from viable cells. CfDNA reflect the genomic mutation profile of the tumor. The clinical utility of blood level of (cfDNA) in patients with metastatic colorectal cancer (mCRC) hasn't been much described before.
Aims and Methods: To assess the level of (cf DNA) as a serum biomarkers in diagnosis and progression of colorectal cancer (surgically resected and non-resected) at different tumor stages. A cross sectional study was conducted on 90 persons who fulfilling the designed inclusion criteria and classified into four groups, Group I include 30 patients with colorectal cancer (pre-operative), Group II : 30 patients with colorectal cancer (post-operative), Group III : 15 patients with colorectal polyps (low grade dysplasia), Group IV : 15 healthy volunteers as control group, All participant after detailed history, clinical examination, imaging study and endoscopic assessment were subjected to routine laboratory investigation, carcinoembryonic antigen (CEA) and serum level of circulating cfDNA.
Results: The mean DNA concentration was 2.46 μg/ml, for CRC(pre-operative), 0.519 μg/ml for CRC (post-operative), 1.684 μg/ml for colorectal polyps (low-grade dysplasia) and 1.068 μg/ml for healthy controls. DNA concentration was significantly higher in CRC (pre-operative) patients compared with healthy controls ($P = 0.05$). The mean DNA concentration was significantly higher in CRC (pre-operative) patients compared with CRC (post-operative) patients ($P = 0.01$) But the mean DNA concentration was non-significantly higher in CRC (pre-operative) patients compared with colorectal polyps ($P = 0.3$). The sensitivity, specificity, positive and negative predictive values of DNA concentration in distinguishing CRC patients from healthy controls were 36.7% and 100%, 100% and 50.5% respectively.
Conclusion: Cf-DNA is a useful non-invasive tumor biomarkers and can improve diagnostic and prognostic value for CRC disease at different tumor stages, and the results suggest that the combination of cfDNA with CEA could improve the diagnostic performance for benign tumor and CRC.

Contact E-Mail Address: eunate.aranaarri@osakidetza.eus

Introduction: Colorectal cancer (CRC) is one of the leading causes of cancer-related mortality worldwide. Most CRC develop via the adenoma-carcinoma sequence. Screening for colorectal cancer programmes with biennial fecal occult blood test has shown to increase early diagnosis and thereby decrease the incidence and mortality. With the screening programs the endoscopic resections as a potential curative treatment has increase. Nevertheless, some lesions are potentially missed or had potential incomplete resection.
Aims and Methods: The aim of our study is to determine the incidence of the metachronous CRC and their surveillance and characteristics in a population based screening programme with a high participation rate. We collected data retrospectively from a population-based screening programme registry with 54,746 colonoscopies and 1,835 CCR diagnosed, from January 2009 to December 2014. Data of clinical characteristics of patients, screening history, endoscopic procedure and histology results were collected.
Results: The rate of metachronous cancers ($n = 18$) over those detected in the screening programme was 0.98%. The mean age was 61.76 ± 6.49 years at diagnosis, being 77.8% females. Relevant medical history: dyslipidemia 27.8%, hypertension 38.9%, obesity 28.6%, diabetes mellitus 5.6%, tabaco smokers 11.1%, alcohol risk intake 16.7%, Charlson Comorbidity Index Score ≥ 2 76.5% and most deprived index 56.3%. In 94.4% of patients, their first cancer was diagnosed at the first participation in the programme. The location of first cancer was: 38.9% rectum, 22.2% rectosigmoid junction, 22.2% sigmoid colon, 11.1% descending colon and 5.6% transverse colon. 38.9% were diagnosed at an advanced stage. In the colonoscopy of the first cancer 76.9% of patients had polyps. 50% of the patients with polyps identified in the first colonoscopy had ≥ 3 polyps and size of the biggest polyp had a mean of 22.43 ± 11.6mm. 2 patients also had synchronous cancer at the first diagnosis. Different pre-operative systemic inflammation ratios were calculated, identifying in high-risk category: 13.3% for neutropil-lymphocyte ratio, 33.3% for lymphocyte-monocyte ratio, 40% for platelet-lymphocyte ratio and 60% for Systemic immnune-inflammation index. In 10 cases (55.6%) the second cancer appeared "de novo", in 7 cases (38.9%) after an incomplete resection and in 1 case (5.6%) with a previous polyp. The mean adenoma detection rate of the endoscopist at the first colonoscopy was $34.4 \pm 8.9\%$, presenting a 35.7% of them a rate higher than 35%. The location of the second cancer in 38.9% was in right side of the colon while in the first cancer only 5.6% had right location. The median time between first and second cancer was 21.49 months (IQR: 13.46–34.37). 44.4% of patients died and survival mean was 6.97 years (IQR: 5.64–8.29). 1 year survival was 94.1%, and 5 yr-survival 82.4%. We calculated the survival for interval cancer and screen-detected cancer at the programme. Interval cancer 1-yr survival 91.2%, 5-yr survival 76.3%; screen-detected 1-yr survival 97.8% and 5-yr survival 90.1%.
Conclusion: The incidence rate of metachronous cancers at the population-based screening programme is not very high; however, it should be noted that a significant percentage of them appear after complete resection or lack of resection of a potentially cancerous polyp in the screening colonoscopy. We also highlight how second cancers have a higher prevalence in the right colon. This suggests that in the screening programs the registration of quality indicators and the application of measures to control them are fundamental.

P1659 OVEREXPRESSION OF AT-RICH INTERACTIVE DOMAIN 3A CORRELATED WITH FAVORABLE PROGNOSIS IN PATIENTS WITH RESIDUAL RECTAL CANCER AFTER PREOPERATIVE CHEMORADIOTHERAPY

A.N. Seo, G. Yoon
Kyungpook National University, Pathology, Daegu, Korea (Republic of)

Contact E-Mail Address: san_0729@naver.com

Introduction: This study aimed to explore the clinical and prognostic impact of AT-rich interactive domain 3A (ARID3A) expression in patients with residual rectal cancer who underwent neoadjuvant chemoradiotherapy (NACRT).

Aims and Methods: Between January 2006 and December 2011, the surgical specimens of 146 patients with residual rectal cancer who underwent NACRT were analyzed. To assess ARID3A expression, immunohistochemistry was performed on whole tissue sections. *KRAS* exon 2 (codons 12 and 13) and *BRAF* V600E mutation status and microsatellite instability (MSI) were determined using polymerase chain reactions.

Results: Of the 134 eligible patients, overexpression of ARID3A was found in 64.5% ($n=91$) and inversely correlated with perineural invasion ($P=0.031$). However, overexpression of ARID3A had no correlations with *KRAS* and *BRAF* mutation status, or with MSI status (all $P>0.05$). In univariate analysis, over-expression of ARID3A was significantly associated with favorable cancer-specific survival (CSS) ($P=0.006$) and disease-free survival (DFS) ($P=0.039$). Multivariate analysis revealed that overexpression of ARID3A was independently associated with favorable CSS ($P=0.030$, hazard ratio [HR] = 2.640, 95% confidence interval [CI] = 1.098–6.345) but not DFS ($P=0.082$, HR = 1.676, 95% CI = 0.937–2.996).

Conclusion: Our study showed that high nuclear expression of ARID3A can predict favorable outcomes in patients with residual rectal cancer after NACRT.

P1660 OPTICAL TECHNOLOGIES FOR ENDOSCOPIC REAL-TIME HISTOLOGICAL ASSESSMENT OF COLORECTAL POLYPS – A SYSTEMATIC REVIEW WITH META-ANALYSIS

S. Mason, L. Poynter, Z. Takats, A. Darzi, J. Kinross
Imperial College London, Surgery and Cancer, London, United Kingdom

Contact E-Mail Address: sam.mason@imperial.ac.uk

Introduction: Accurate, real-time, endoscopic risk stratification of colorectal polyps would improve decision-making and optimise efficiency of endoscopy units. Several technologies exist to either manipulate or augment endoscopic optical outputs to enhance diagnostic accuracy. However, it is unclear how these technologies have improved over time, nor if they are sufficient for a safe 'resect and discard' or 'no resection' strategy (1, 2).

Aims and Methods: This meta-analysis aims to compare such technologies in the real-time histological prediction of colorectal polyps, documenting the current state and chronological progression of diagnostic accuracy. A systematic search strategy was applied to the databases MEDLINE, Embase and Cochrane Library in January 2018. Inclusion criteria were prospective deployment of a single endoscopic optical technology for *in-vivo,* real-time histological prediction of colorectal polyps; presenting the diagnostic accuracy in differentiating adenomas from hyperplastic or normal tissue after pathological assessment. Exclusion criteria were polyposis syndromes, inflammatory bowel disease, if the diagnosis was made *post-hoc* from images or if data were not primary. When three or more studies presented a similar technology, Bayesian bivariate meta-analysis using a binomial normal model was performed with a defined as 0.05 and 95% confidence intervals (CI) presented.

Results: Of the 3,984 studies identified, 92 were suitable for inclusion. Four types of optical technology were used on 31,337 colorectal polyps across 122 patient cohorts. Digital chromoendoscopy (n = 21,926) diagnosed adenomas with sensitivity of 0.922 (0.904–0.938) and specificity of 0.843 (0.819–0.866), with an area under the curve (AUC) of 0.86 (0.84–0.93). There was no difference between the constituent technologies of narrow-band imaging, Fuji Intelligent Chromo Endoscopy and iSCAN; or when only diminutive polyps (less than 5mm) were tested. Dye chromoendoscopy (n = 7 731) had sensitivity of 0.931 (0.904–0.952), specificity of 0.874 (0.838–0.906) and AUC 0.90 (0.81–0.96). This decreased with diminutive polyps AUC 0.74 (0.56–0.94), however this was not statistically significant. Spectral analysis of tissue fluorescence (n = 893) suffered from high false positives, with sensitivity of 0.915 (0.822–0.971), specificity of 0.625 (0.360–0.849) and AUC of 0.92 (0.72–0.97). Cellular imaging with endomicroscopy (n = 787) had sensitivity of 0.959 (0.915–0.987) and specificity of 0.939 (0.865–0.985). Subgroup analysis of high-confidence predictions, use of trained endoscopists and use of HD scopes did not significantly improve the accuracy of any technology. No single technology can currently demonstrate an estimated negative predictive value (NPV) for adenoma above 90%. Chronological aggregate meta-analysis was applied to all groups and shows a falling NPV over time. This holds when applied to trained endoscopists making high confidence predictions. Significant publication bias was evident across all technologies, appearing to over-estimate diagnostic value.

Conclusion: This is the most comprehensive meta-analysis assessing the ability of endoscopic optical technologies in real-time diagnosis of colorectal adenomas. Using a novel approach, it demonstrates that existing technologies are increasingly unlikely to meet the requirements for a safe 'resect and discard' strategy and that step-change innovation is required to disrupt clinical practice. It is likely that optical approaches may never be sufficiently accurate and that molecular data should be incorporated using techniques such as real-time mass spectrometry.

P1661 AUTOMATED EXTRACTION OF ENDOSCOPIC ADENOMA DETECTION RATES FROM ENDOSCOPIC-PATHOLOGICAL DATA IS AS SENSITIVE AND SPECIFIC AS MANUAL EXTRACTION

S. Zeki[1]
[1]*St Thomas' Hospital, Gastroenterology, London, United Kingdom*

Contact E-Mail Address: sebastiz@hotmail.com

Introduction: Medical data is increasingly moving into electronic formats. Endoscopic data in the UK is almost exclusively electronic. Pathology reporting of specimens taken at endoscopy is also electronic.

Although the data is digitalized much of it is captured in natural language, semi-structured formats. Furthermore pathology datasets are often stored separately to endoscopic datasets so that the merging a pathology report to a specific patients endoscopy date can be difficult. As a result, the data for one of the best validated indicators of endoscopic quality, the adenoma detection rate (ADR), is often done manually, and often inaccurately extrapolated from the endoscopy report only.

Automated extraction from text has become simplified using natural language tools. EndoMineR[1] is an open source software package written in R and is specifically designed to automate the process of extracting data from endoscopic and pathology datasets. Furthermore the package merges endoscopic and pathologic datasets by patient and (fuzzy) date and allows downstream analyses that depend on the merge between both datasets, such as the adenoma detection rate.

Aims and Methods: We aimed to determine the sensitivity and specificity of adenoma detection rates when using an automated process (EndoMineR) when compared to manual extraction.

For the manual extraction, the endoscopy reporting database was used to extract reports of all colonoscopic examinations carried out between July 1st 2017 and January 1st 2018 at St Thomas' Hospital. If the report mentioned a polypectomy having been performed, the pathology report for that endoscopy was accessed via the electronic patient record to determine whether it was an adenoma. The per endoscopist ADR was the calculated.

For the automated extraction, all pathology reports between the dates above were downloaded for all patients who underwent endoscopic examinations between the two dates. EndoMineR managed the merging of pathology and endoscopic reports for each patient at each time point. EndoMineR also extracted all adenomas, including the exclusion of reports mentioning the absence of adenomas, and calculated the per endocopist ADR.

Results: Between July 31st 2017 and Jan 1st 2018 2588 colonoscopies were performed. Endoscopic reports were available for all the endoscopies. Of the 1388 endoscopies where tissue was sent to histopathology, all the pathology reports were available. Manual extraction detected 499 endoscopies where an adenoma was detected and confirmed with histopathology. EndoMineR detected 501. Further examination of the dataset revealed that manual extraction had missed two cases such that the sensitivity and specificity of EndoMineR for this dataset was 100% and 100%. Manual extraction took 4.5 hours. The automated extraction took 5.3 seconds.

Conclusion: Automated adenoma detection rates can be calculated from semi-structured text reports accurately using merged endoscopic-pathology records. This technique should also be applicable to the detection of other pathologies detected at endoscopy and therefore has the potential to allow further metric development to assess endoscopic quality.

P1662 DELAYING AND DRYING EFFECTS ON THE RESULTS OF GUIAIC FAECAL OCCULT BLOOD TESTING

A. Field[1], J. Morling[1,2], C. Chapman[1], R. Logan[1,2]
[1]*Nottingham University Hospitals NHS Trust, Bowel Cancer Screening Hub, Nottingham, United Kingdom*
[2]*University of Nottingham, Epidemiology and Public Health, Nottingham, United Kingdom*

Contact E-Mail Address: andrew.field@nuh.nhs.uk

Introduction: In the UK guaiac-based faecal occult blood testing (gFOBt) is the primary means of national screening for colorectal cancer (CRC). However, variations in positivity rates not easily explained by background disease levels are seen across the country.
In particular, kits sent to the Eastern England Hub are 50% more likely to be tested positive than those sent to other hubs which has significant consequential affects for example on colonoscopy services.
Aims and Methods: We aimed to determine if delays in kit processing could be impacting positivity rates through the effects of sample drying.
In the Eastern Hub of the UK Bowel Cancer Screening Programme ~2500 gFOBt kits are processed daily.
1) For one month during winter 2017 received kits were randomly assigned to usual practice (test on day of receipt) or delay before testing of 2–3days. For 90% power (1 sided p = 0.05) 1,628 kits were required in each group.
2) For a further month received kits were randomly assigned to usual practice (test on day of receipt) or 'drying' with kits left for 24hrs spread out in a warm room (average temp 21°C).
Results: 1) The study consisted of n = 1783 in the no delay group and n = 1741 in the delay group.
Kit positivity of the control group was 18.4%, decreasing to 17.4% in the 2 day delayed group (n = 1192) and 16.7% in the 3 day delayed group (n = 221).
Window positivity was then investigated and showed a significant decrease in the positivity of windows 5 & 6 (the 3rd stool sample) when testing of the kit was delayed; particularly in window 6 where the proportion of positives decreased from 10.0% to 7.4%. Little effect was seen in the first 2 samples (windows 1–4).
2) In the second study n = 1793 in the control group and n = 1810 in the drying group.
Overall kit positivity was shown to decrease from 21.1% to 17.5%.
Window positivity showed a decrease in the positivity of windows 5 & 6 as with the 1st trial, but this time a larger decrease was experienced in those kits left in the warmer laboratory (10.5% to 8.4% and 11.4% to 8.0% in windows 5 & 6 respectively).
Conclusion: Positivity rates in kits delayed and dried were significantly lower than those processed quickly and whilst still moist. This was most notable for the 3rd sample from patients (i.e. the most recently sampled).
It is likely that variation in the timing of receipt and processing of samples will lead to variations in positivity rates found.
Further research is required to determine the positive predictive value of different delaying strategies for the detection of colorectal cancer in order to determine optimal operational protocols.

	Trial 1		*Trial 2*	
	0 DAYS DELAY (n = 1783)	ANY DELAY (n = 1741)	NO DRYING (n = 1793)	DRYING (n = 1810)
Total positive kits	18.4%	17.5%	21.1%	17.5%
Sample 1	6.7%	6.5%	6.8%	6.8%
Sample 2	7.1%	7.9%	8.4%	8.5%
Sample 3	11.6%	10.3%	14.2%	10.7%

Introduction: It has been demonstrated that colorectal cancer (CRC) screening program with faecal occult blood test (FOBT) reduces incidence and mortality. However, around 40% of colonoscopies performed in the setting of CRC screening program are normal or detect only benign pathology. Strategies to avoid non-pathological colonoscopies are highly necessary.
Faecal calprotectin (FC) test is an accepted biomarker for inflammatory bowel disease activity, but data about its value for CRC and adenoma detection are lacking.
Aims and Methods: We aimed to evaluate the accuracy of the combination of FOBT and FC compared with FOBT alone in a CRC screening program setting (with a previous positive FOBT) for reducing the number of colonoscopies with benign or no pathological findings.
Patients with previous positive FOBT who completed colonic investigations and returned stool samples the same of the colonoscopy were prospectively recruited.
FOBT was performed by FOB Turbilatex ® (Certest Biotec S.L, Zaragoza, Spain), with a cut-off of 29 μg/gr. FC was performed by Calprotectin Turbilatex® (Certest Biotec S.L, Zaragoza, Spain), with a cut-off of 50 μg/gr.
We considered as relevant pathology CRC and advanced adenoma (>3 adenomas, >1cm, high grade dyspasia, villious component).
Positive and negative predictive values, sensitivity, specificity and area under ROC curve (AURC) of FOBT, FC and the combination of both tests were calculated.
Results: 173 patients were prospectively recruited and included in the final analysis (109/173 63% male). 58 (33.5%) had relevant colonic pathology. 6 (3.5%) had CRC.
Diagnostic accuracy of FOBT, FC and combination of both test are summarized in table 1.
PPV: positive predictive value NPV: negative predictive value

Test	PPV	NPV	Sensitivity	Specificity
FOBT	47.5%	85.1%	81.0%	54.8%
FCP	32.3%	64.8%	56.9%	40.0%
Combination	38.4%	85.8%	91.4%	26.1%

[Table 1]
AUROC for CRC and advanced adenoma were 0.48 (95% CI:0.39–0.58) for FC; 0.76 (95% CI: 0.68–0.83) for FOBT and 0.71 (95% CI:0.62–0.80) for the combination of both tests, respectively. Neither FC nor the combination of both tests showed a better diagnostic accuracy that FOBT alone.
Conclusion: The combination of FOBT and FC in a CRC screening program setting does not improve the diagnostic accuracy for detection of advanced adenoma and CRC compared with FOBT alone
Disclosure: Nothing to disclose

P1664 INCREASING THE CUT-OFF VALUES OF FIT IN POPULATION BASED COLORECTAL CANCER SCREENING IMPROVES FALSE POSITIVE RATES AND HEALTH RESOURCE UTILIZATION IN A NATIONAL PUBLIC HEALTH SERVICE

A. Lanas[1,2,3], P. Carrera[3], M. Navarro[1], A. Ferrandez[1,3], M. Cano[4]

Contact E-Mail Address: angel.lanas@gmail.com

Introduction: Fecal immunochemical test (FIT) is commonly used in colorectal cancer (CRC) screening programs. These programs are planned based on assumptions of participation and positivity rates, population characteristics and country colonoscopy resources. We planned our regional CRC screening program based on data obtained from the COLONPREV study (Quintero et al. NEJM 2010) conducted in our community.
Aims and Methods: To analyse the results obtained 3 years after initiation of the program in order to accommodate and adjust current outcomes to available endoscopic resources of the current strategy. We have collected data from 128,412 average-risk individuals in Aragón (Spain), 60–69 years old, who were invited to a first round of a population-based CRC screening program with FIT. Fecal samples were collected, and levels ≥ 20 μg Hb/g feces (FOB-Gold® test) were considered positive. Subjects with a positive FIT were scheduled for colonoscopy within 4 weeks.
Results: In total, 64,989 (50.6%) individuals participated in the study; 9,329 (14.4%) had a positive test result and 97.0% underwent a valid colonoscopy. Colorectal cancer and advanced adenomas were detected in 5.7% and 29.7% of individuals respectively. The risk of cancer increased with increased levels of Hb in feces for both men and women, specially with the highest levels: Quartil (Q)1 = reference; Q2: 0.99; 95%CI (0.62–1.60); Q3: 1.82 (1.20–2.78); Q4: 6.54 (4.53–9.44). Attendance and positive test results were greater than those originally planned and overcame by far the planned regional colonoscopy resources (Table).

	Attendance	FIT + PPV	Expected number of colonoscopies per round	Detection of CRC	PPV Cancer + advanced adenoma
Estimated	38.2%	9.9%	11763	6%	45.6%
Current	50.6%	14.4%	17117	5.7%	43.1%

[PPV: positive predictive value]
Increasing the cutoff concentration of Hb in feces from 20 to 85.5 μg Hb/g feces would adapt current outcomes to available endoscopic resources by reducing the proportion of subjects who underwent colonoscopy evaluation by 42.4% (6.846 procedures). This would result in a reduction of false positive results for cancer

(from 94.3% to 52.8%) cancer + advanced adenoma (from 64.6% to 32.8%) with a 0.9% of cancer or a 10.6% cancer + advanced adenoma being missed, and an increase in PPV for cancer from 5.7% to 8.4% and for cancer+advanced adenoma from 35.4% to 43.1%
Conclusion: 1. Detection of cancer and advanced adenomas by FIT increase significantly with fecal Hb cutoff concentration for both men and women. 2. Participation and positivity FIT rates overcome the initial design of endoscopy needs. **3**. Increasing the cutoff concentration reduces the numbers of patients who undergo colonoscopy evaluation, adjust available endoscopic resources and improves results on positive predictive values at the expense of missing a small percentage of colorectal cancer and advanced adenomas.

Introduction: Because of its frequency and seriousness, colorectal cancer is a major challenge for public health. In our country it is the first digestive cancer according to the two major regional registers. Early detection allows better survival and certainly reflects the strength of the health system. Our work aims to analyze the reasons for late diagnosis of colorectal adenocarcinoma to provide solutions for improving early diagnosis.
Aims and Methods: We analyzed the preliminary results of a multicenter prospective cohort including 220 patients with colorectal adenocarcinoma between February 2016 and April 2017 in 5 hospital departments. A period exceeding 30 days between the appearance of first symptoms and the date of diagnosis is considered as delay of diagnosis. Factors related to this late diagnosis were analysed.
The descriptive and analytic study of the data was carried out with SPSS software version 16.0.
Results: The mean age of our patients was 56.72 years [22 -86] with a sex-ratio F / H of 1.12.
In 25% of cases, patients were under age of 45 (n = 55). The initial clinical symptoms were dominated by transit troubles (42.30%), abdominal pain in 36.54% of cases and lower bleeding in 21.16% of cases. Fifty-six percent of patients were diagnosed at the locally advanced or metastatic stage. The average time between onset of symptoms and diagnosis was 7 months on average with 79% of the time exceeding 30 days (n = 83). In 31% of cases (n = 68), an underestimation of the severity of symptoms was reported by patients as the cause of the consultation delay. In 36% of patients (n = 79) the symptoms were attributed to hemorrhoidal pathology and in 14% of cases (n = 30) the first visit indicated symptomatic treatment without any endoscopy investigation. Analysis of certain factors that explain the delay in diagnosisas age under 45, sex, location of tumor, lower bleeding, occlusion and advanced stage, has shown that only the absence of lower bleeding was correlated with a diagnosis delay with $p < 0.001$.
Conclusion: The late diagnosis of colorectal cancer is a real public health problem in our country with an average delay of 7 months. Only the presence of lower bleeding seems to alarm the patients. The reinforcement of public awareness campaigns could certainly shorten this diagnostic delay and improve the prognosis.
Disclosure: We would like to thank Hala AZZAM and his team for the workshops organized in Morocco on the capacity building that allowed this project to be launched We would also like to thank Dr. Karima EL RHAZI Dr. Anna R. GIULIANO and Dr. Peter A. KANETSKY for coordinating this project and follow-up workshops and Training. Introduction: Metformin might have the potential effect of reducing cancer risk and could improve response to radiotherapy in several malignancies.
Aims and Methods: We aimed to investigate whether metformin could have the beneficial effect in radiotherapy-induced tumor response in rectal cancer with diabetes. From January 2000 to November 2017, 91 patients with rectal cancer taking diabetes medication who were treated with neoadjuvant chemoradiotherapy followed by radical surgery were reviewed. Patients were divided into two groups: diabetics taking metformin (n = 56) and diabetics not taking metformin (n = 35). Tumor response and survival were compared between groups.
Results: The rates of T downstaging, N downstaging and tumor regression grades (TRG) 1–2 were significantly higher in diabetics taking metformin ($p = 0.018$, $p < 0.001$ and $p = 0.01$, respectively).
There were no significant differences between groups in terms of pathologic complete response, however, size of primary tumor and nodes decreased significantly in diabetics taking metformin ($p < 0.001$ and $p < 0.001$). The rates of T downstaging, N downstaging and tumor regression grades (TRG) 1–2 were significantly higher in diabetics taking metformin ($p = 0.018$, $p < 0.001$ and $p = 0.01$, respectively). There were no significant differences between groups in terms of pathologic complete response, however, size of primary tumor and nodes decreased significantly in diabetics taking metformin ($p < 0.001$ and $p < 0.001$).
Conclusion: Metformin is associated with higher tumor response rates and downsizing of tumor to radiotherapy in rectal cancer, especially in patients with diabetes

P1667 LONG-TERM RESULT OF "WATCH AND WAIT" WITHOUT RADICAL SURGERY FOR COMPLETE CLINICAL RESPONSE OF RECTAL CANCER AFTER NEOADJUVANT CONCURRENT CHEMORADIATION THERAPY IN A SINGLE INSTITUTION IN TAIWAN

C.W. Hsiao[1]
[1]*Tri-Service General Hospital, National Defense Medical Center, Colorectal Surgery, Taipei, Taiwan*

Contact E-Mail Address: dr.hsiao@msa.hinet.net
Introduction: Colorectal cancer is the most common malignancy in Taiwan, and rectal cancer was about 36.9% of these patients. Neoadjuvant concurrent chemoradiation therapy (CCRT) before radical surgery is the choice for advanced rectal cancer. Some lucky cases got complete clinical response after CCRT. Therefore, "watch and wait" without radical surgery could be the choice for the selected patient. We hereby presented the long-term result of "watch and wait" without radical surgery for complete clinical response of rectal cancer after CCRT in Tri-Service General Hospital in Taiwan.
Aims and Methods: This was a retrospective study in a single institution in Taiwan. The patients of advanced rectal cancer with complete clinical response after CCRT were included from Jan, 2007 to Oct, 2017.
Results: There were 40 patients diagnosed with rectal cancer following the "watch and wait" without radical surgery policy. Three residual tumors were found among 13 cases (13/40, 32.5%), who got transanal wide excision for obvious mucosal lesions, 3 months to 1 year later after CCRT. No local recurrence was noted after local excision. Among the 27 cases without local excision, 2 patients (2/40, 5%) had local recurrence and 1 (1/40, 2.5%) got distal metastases within one year after CCRT. Salvage radical surgery was successful for these patients and no associated morbidity or mortality.
Conclusion: According to our study, the long-term result revealed no mortality or morbidity in the selected patients of rectal cancer with complete clinical response after CCRT.
Therefore,"watch and wait" without radical surgery could be the choice for the selected case of rectal cancer with complete clinical response after CCRT.

P1668 ACID-RESPONSIVE DRUG-COMPLEXED POLYPEPTIDE NANOPARTICLE EFFECTIVELY AND SAFELY TREATS COLORECTAL CANCER

Q. Zhang[1], Q. Zhan[1], F. An[1], Z. Xie[1], Y. Lin[1]
[1]*Wuxi People's Hospital Affiliated to Nanjing Medical University, Department of Gastroenterology, Wuxi, China*

Contact E-Mail Address: zhang517068@126.com
Introduction: Colorectal cancer (CRC) is one of the most common malignant tumors worldwide, and in which chemotherapy plays an irreplaceable role. However, the efficacy is seriously unsatisfactory for the poor distribution specificity, short circular half-life and dosage-dependent side effects of traditional drugs. For this situation, a facilely prepared pH-responsive nanoparticle was prepared based on polypeptide to deliver antitumor drugs more efficiently and safely.
Aims and Methods: Epirubicin (EPI) as a model drug was loaded into nanoparticle (NP/EPI) via the electrostatic interaction between poly (ethylene glycol)-*block*-poly (L-glutamic acid) (mPEG-*b*-PGA) and EPI, and the subsequent

hydrophobic interaction among PGA/EPI complexes. The characterizations of NP/EPI were ensured by transmission electron microscopy (TEM) and Dynamic laser scattering (DLS). In vitro release experiment and nanoparticle stability assessment were employed to detect the pH-responsibility of NP/EPI. Subcutaneous C26-xenografted CRC murine model was established to evaluate the antitumor efficacy and security of NP/EPI with 4 times drug administration at EPI equivalent dose of 8.0 mg/kg. The tumor volumes and body weights of mice were measured every other day. Furthermore, the microscopic examinations were carried out by H&E staining and *in situ* apoptosis assay of isolated tumors.
Results: The loading nanoparticle appeared spherical with a medium hydrodynamic diameter of 93.71 ± 8.37 nm. The NP/EPI had faster release efficiency and higher cumulative release rate in intratumoral microenvironment of pH 6.8 than that in physiological condition (*i.e.*, pH 7.4), and in intracellular acidic microenvironment of pH 5.3 the difference was more significant. Similarly, the particles exhibited nearly constant diameters in solution of pH 7.4, which increased gradually with the decline of pH value, and further confirmed the pH-responsibility of NP/EPI. In vivo, the two drug formulations both inhibited the growth of CRC while the NP/EPI showed a significantly enhanced efficacy than that of EPI. Microscopic examinations displayed that nanoparticle could improve tumor tissue necrosis and cell apoptosis caused by EPI effectively. In the aspect of safety, the body weight of mouse in NP/EPI group was 22.08 ± 1.76 g, which was significantly higher than that in EPI group (*i.e.*, 18.02 ± 1.84 g). More meaningfully, only 30% mice survived with EPI administration while that with NP/EPI reached 70%.
Conclusion: With perfect pH-responsibility, drug-loaded nanoparticle based on mPEG-b-PGA could significantly enhance efficacy and reduce side effects of traditional drugs, and holds great potential for the CRC chemotherapy in clinic.

Introduction: Endoscopic self-expanding metal stent (SEMS) placement as a bridge to surgery is an option for obstructive colorectal tumors. SEMS could be used for definitive palliative treatment for unresectable or inoperable patients. Also SEMS are used as a bridge to elective curative resections. Although it is thought that emergency colorectal resections may cause worse oncological outcomes, the debate is still ongoing regarding to SEMS superiority and oncological safety. In this study, it is aimed to determine the benefits of SEMS placement in obstructive colorectal tumors.
Aims and Methods: Between 2012–2018, 136 patients admitted to University Hospital Emergency Clinic with acute obstructive colorectal tumors. Ninety-four of them were included in the study. Palliative SEMS placements for multi organ and/or peritoneal metastatic patients, patients whom undergone emergency surgery regarding to SEMS complications, palliative decompressive ostomy patients, patients with benign obstructive causes, patients with complications of previous surgery, were excluded.
Patients undergone surgical procedures immediately, were defined as Group 1 and patients who undergone elective surgery after SEMS placement were defined as Group 2.
The demographic data, signs in emergency service, operation techniques, ostomy entity, pathological results and oncological follow-up were reviewed retrospectively. Statistical analysis of groups with Chi-square test, Fisher Exact t test, student's t test, log rank and Kaplan-meier tests were done on SPSS Version 23.
Results: The demographic data, pathological results, clinical findings, and surgical outcomes were summarized in Table 1. The tumor localization of the Group 1 and 2 were, 53% and 10% right sided tumors, 8% and 29% descending colon, 33% and 43% sigmoid colon tumors, 6% and 38% for rectal tumors, respectively. There was no difference between groups as to distant organ metastasis (p:0.77).
End ostomy (without anastomosis) was created for 36 patients (49%) in Group 1. Only 36% of these ostomies were reversed.
Overall survival rates were significantly higher in Group 2 but there was no difference between groups according to disease free survival rates (p:0.041 and 0.1 respectively).
Conclusion: SEMS placement as a bridge to surgery provided better results in reference to permanent ostomy and overall survival.

	Group 1 (n:73)	Group 2 (n:21)	p
Female	39.7% (n:29)	42.9% (n:9)	0.79

P1670 ENDOSCOPIC FULL-THICKNESS RESECTION OF NEUROENDOCRINE TUMORS IN THE RECTUM – A SUBGROUP ANALYSIS OF THE GERMAN FTRD-REGISTRY

B. Meier[1], K. Caca[2]
[1]*Klinikum Ludwigsburg, Ludwigsburg, Germany*
[2]*Klinikum Ludwigsburg, Abt. für Innere Medizin, Ludwigsburg, Germany*

Contact E-Mail Address: dr.benjamin.meier@gmail.com
Introduction: Subepithelial tumors (SET) in the colorectum are rare and usually detected incidentally during colonoscopy. The incidence of SET in the colorectum was reported to be about 0.3% and up to 27% are described to be malignant or to have malignant potential. Neuroendocrine tumors (NET) and gastrointestinal stromal tumors (GIST) are the most common SET with malignant potential. Endoscopic ultrasound (EUS) allows further characterization of SET, but is associated with limited diagnostic accuracy. In consequence, histological examination should be performed but obtaining a diagnostically conclusive sample might be difficult as SET are originating from deeper layers than the mucosa. Management of colorectal SET depends on dignity, tumor size and presence of symptoms. Further surveillance, endoscopic resection (ER) or surgical resection (SR) are potential options. ER of SET using the standard techniques such as endoscopic mucosal resection (EMR) or endoscopic submucosal dissection (ESD) is difficult and associated with an increased risk of bleeding or perforation. Clip-assisted endoscopic full-thickness resection (EFTR) has shown to be feasible, effective and safe for smaller colorectal SET (1).
Aims and Methods: The FTRD-System (Full-Thickness-Resection Device) is available for clip-assisted EFTR in the lower gastrointestinal tract since 2014 in Europe. In September 2015 an online FTRD-registry has been created as part of a post-market clinical follow up (PMCF). FTRD-procedures of 31 German centers were entered into the database. This retrospective analysis further evaluates EFTR of rectal NET. The aim of this analysis is to show that EFTR with the FTRD-System is feasible, effective and safe for rectal NET and allows definite histological diagnosis and therapy (complete resection, R0).
Results: 501 procedures were entered from September 2015 to May 2017. 20 German centers contributed 35 cases of SET (7%). 10 cases were excluded (4 leiomyomas, 2 lipomas, GIST, MALT, inflammatory fibroid polyp, granular cell tumor) and 25 NET (24 rectum, 1 sigmoid) were included for this analysis. The median age of the patients (11 male, 14 female) was 57 years (range 28–81 years). The median size of the lesion was 8.3 × 7.5 mm (from 3 × 3 mm to 25 × 10 mm), mainly located in the middle rectum. EUS was performed in 9/25 patients (36%) and could not provide a definite diagnosis. Biopsies were taken before EFTR in 19/25 patients (76%) and all biopsies showed well differentiated (G1) NET. However, in all cases resection status was unclear or incomplete (Rx in 7 patients, R1 in 5 patients, missing statement in 7 patients). 5 NET (20%) were recurrent NET and had been treated previously (multiple forceps biopsies or snare resection). Mean procedure time of EFTR was 23 minutes (range 7–60 min). EFTR with the FTRD was macroscopical and histological complete (R0) in all cases. However in 7 cases (28%) a NET could no longer be proven. A full-thickness-resection specimen could be obtained in all cases. In 3 cases (12%) minor peri-interventional bleeding occurred and was managed endoscopically. Follow-up was available for 20/25 patients (80%) with a median of 17 weeks after EFTR (range 1–48 weeks). The OTSC was dislocated in 14/20 (70%) and in situ in 6/20 (30%) cases (no removal). No signs of a residual or recurrent tumor were observed.
Conclusion: EFTR with the FTRD for rectal NET is feasible, safe and effective and allows a definite diagnosis and therapy at once.

P1671 RED BLOOD CELL DISTRIBUTION WIDTH INDEPENDENTLY PREDICTS SURVIVAL IN R0 RESECTED COLORECTAL CANCER

A. Borda[1], **I. Fernández-Urién**[1], J.J. Vila[2], E. Albéniz[3], A. Guerra[1], J.M. Zozaya[1], F. Borda[1]

[3]*Complejo Hospitalario de Navarra (CHN), Universidad Pública de Navarra (UPNA), Gastroenterology, Pamplona, Spain*

Contact E-Mail Address: ifurien@yahoo.es
Introduction: Red blood cell distribution width (RDW) is related with inflammatory response and nutritional status in cancer patients, which could have a prognostic value in colorectal tumors. Nevertheless, studies in western countries are scarce
Aims and Methods: We aimed to study the possible prognostic value of RDW, determined at the moment of diagnosis, in long-term survival after a R0 colorectal resection.
Patients with haematological diseases and blood transfusion before diagnosis were excluded. We retrospectively studied 205 colorectal carcinomas, consecutively treated with R0 resection and with a minimum 5-year clinical controlled follow-up. The cut-off point of RDW was determined using ROC curves, considering "high" a RDW $\geq$ 17%: Cancer specific survival curves were analysed between both groups with a pretreatment RDW value $\geq$ and $<$17% (Kaplan Meier- log rank test), calculating hazard ratio (HR) and 95% confidence interval (CI95%). A multivariate analysis of cancer-specific survival rate (Cox model, stepwise) was performed, including in the model: RDW $\geq$ 17%, gender, age $>$ 70 years, (ROC curves), rectal or colonic localization, differentiation grade (1–3), pTNM stage (I-IV) (AJCC 7^{a}Ed.) and neoadjuvant and adjuvant treatment administration (yes/no).
Results: Median clinical follow-up was 40 months for deceased cases and 88 months for survivors. Tumor specific mortality was 23.9%. We registered 40/205 (19.5%) cases with RDW $\geq$17%. Survival curves were significantly worse in patients with pre-treatment RDW $\geq$ 17%: [p = 0.003; HR = 2.35; CI95% = (1.32–4.21)]. The multivariate analysis confirmed a lower survival in the RDW $\geq$ 17% group: [p = 0.009; HR = 3.07; CI95% = (1.33–7.08)].
Conclusion: 1.- In our series of R0 resected colorectal cancer, cases with "high" pre-treatment RDW values ($\geq$ 17%) show a significant worse cancer-specific survival curve,
2.- This unfavourable prognosis of an elevated RDW is independent of the rest of analysed parameters.
3.- If these data were confirmed, RDW could be a simple, low-cost and very easy to obtain parameter, useful to orientate the initial prognosis in the resected colorectal carcinoma.
Disclosure: Nothing to disclose

P1672 SURVEILLANCE PROTOCOL FOR ABDOMINAL DESMOID TUMOURS IN FAMILIAL ADENOMATOUS POLYPOSIS (FAP): EXPERIENCE OF A REGIONAL REFERRAL CENTRE

L. Sanchez Mete[1], E. Mannisi[2], A. Martayan[3], M. Caterino[2], V. Ferraresi[3], V. Stigliano[4]

[3]*Regina Elena National Cancer Institute, Rome, Italy, Rome, Italy*
[4]*Regina Elena National Cancer Inst. Dept. Gastroenterological Endoscopy, Rome, Italy*

Contact E-Mail Address: lupe.sanchez@ifo.gov.it
Introduction: Desmoid Tumours (DTs) are benign proliferations of stromal cells, rare in the general population and common in patients with Familial Adenomatous Polyposis (FAP) who have undergone prophylactic colectomy. In 10% of the cases DTs show a locally aggressive and rapid growth and are a main cause of death after prophylactic colectomy in FAP patients. Nevertheless International Guidelines have not defined a surveillance protocol yet.
Aims and Methods: Aims of the present study were: to define a surveillance protocol and to evaluate the best diagnostic tool between MRI and CT; to identify DTs with aggressive behavior.
From January 2010 to March 2018, patients who referred to the "Regional Referral Centre for FAP of Lazio Region" with a proven diagnosis of FAP were enrolled in the study. All patients underwent contrast-enhanced (CE) abdominal CT and MRI at least 1 year after prophylactic colectomy. Patients with DTs and without intestinal obstruction and ureteral compression received follow up examination after 6–12 month or alternatively after 2–3 month. Patients without DTs underwent follow up examination after 3 years. DTs growth assessment was performed by using RECIST criteria 1.1. The "average monthly growth rate" was also evaluated.
Results: One hundred patients (55F/45F) were enrolled in the study. DTs were detected in 13/100 (13%) cases (5F/8M): 2 abdominal wall DTs (AWD), 10 intrabdominal DTs (IAD), one patient presented lesions in both localizations. The average age at diagnosis was 32,5 years (range 19–53), the average time of onset after colectomy was 43,9 months (range 13–228). In 5/13 cases (38.5%) the IAD showed an aggressive behavior (asymptomatic intestinal obstruction and ureteral compression seen at imaging in 3 cases and symptomatic intestinal perforation in two cases). The "average monthly growth rate" was 0.58 cm (range 0.47–0.75 cm) for an average follow up of 11 months (range 4–20 months). The highest value was detected in the unique symptomatic case. CT was better than MRI for imaging IAD in 13 vs 9 cases.
In 18/100 patients (8F/10M), MRI and CT showed dubious alteration for DTs, describing an aspect of diffuse or localized mesenteric thickening. The average follow-up time for these patients was 15.1 years (range 1–35) and none of these patients presented any clinical symptom during clinical and radiological surveillance.
Conclusion: The proposed surveillance protocol allowed to detected early asymptomatic intestinal obstruction and ureteral compression in 3 cases improving clinical management. CT had a better diagnostic output than MRI and could play an important role for the first diagnosis of DTs. The evaluation of the "average monthly growth rate" could allow the identification of IAD with aggressive behavior, improving, thus, clinical management. The presence of a "mesentery thickening" at MRI or CT, does not appear predictive of desmoid development or disease aggressiveness. Therefore, these patients can be surveilled as negative ones.

P1673 HIGH EXPRESSION OF LONG NON-CODING RNA LINK-A ASSOCIATES WITH POOR SURVIVAL IN PATIENTS WITH COLORECTAL CANCER

Y. Ye[1], Z. Huang[1], J. Gao[1], C. Zhao[2], C. Tang[1]
[1]*West China Hospital, Sichuan University, Gastroenterology, Chengdu, China*
[2]*West China Hospital, Sichuan University, Chengdu, China*

Contact E-Mail Address: 2568284804@qq.com
Introduction: Long non-coding RNAs (lncRNAs) have been proved to be involved in the development of many diseases, including cancers. Long intergenic non-coding RNA for kinase activation (LINK-A), a newly discovered lncRNA, has been reported to enhance the occurrence and progression of breast cancer. LINK-A promotes breast cancer tumorigenesis via activating AKT or normoxic HIF-1α signaling pathway. AKT and HIF-1α pathway activation has been demonstrated to promote tumor formation, progression, and metastasis of colorectal cancer (CRC). However, whether LINK-A is related in the tumorigenesis of CRC is remained unknown.
Aims and Methods: To evaluate the expression of LINK-A in colon adenocarcinoma and establish the correlation between LINK-A and CRC prognosis. The expression of LINK-A was evaluated by qRT-PCR on cDNA tissue microarray, which contained 15 pairs of human colon adenocarcinoma and paracancerous tissues and another 65 colon adenocarcinoma tissues. The total 80 patients were devided into low and high expression groups according to the LINK-A levels. Then relationships between LINK-A expression and clinicopathological characteristics of colon adenocarcinoma were analysed between that two groups. Kaplan-Meier survival analysis was used to assess the LINK-A function on the survival of colon adenocarcinoma. Multivariable Cox regression analysis was also used to explore the risk factors for prognosis of colon adenocarcinoma between the high and low LINK-A expression groups.
Results: The expression level of LINK-A in colon adenocarcinoma was higher than those in paracancerous tissues (P = 0.047). Furthermore, overexpression of LINK-A was proved to be associated with advanced TNM stage (P = 0.013), positive lymph nodes (P = 0.024), low 5-year survival rate (P = 0.024) and even 10-year survival rate (P = 0.007). Besides LINK-A, advanced age (P = 0.036), high TNM stage (P = 0.023), deep infiltration degree (P = 0.032) and positive lymph nodes (p = 0.013) were also found to be positively related to poor overall 5-year survival by Kaplan-Meier survival analysis. Then, multivariable Cox regression analysis revealed that LINK-A was an independent risk factor for prognosis of colon adenocarcinoma (P = 0.047).
Conclusion: High expression of LINK-A associates with poor survival in patients with colorectal cancer. And LINK-A may serve as a candidate prognostic biomarker for colon cancer.

P1674 RISK OF METACHRONOUS ADVANCED NEOPLASIA IN PATIENTS WITH MULTIPLE DIMINUTIVE ADENOMAS

J.Y. Kim, S.-G. Lee, T.J. Kim, Y.-H. Kim, J.H. Song, E.R. Kim
Samsung Medical Center, Sungkyunkwan University School of Medicine, Division of Gastroenterology, Department of Medicine, Seoul, Korea (Republic of)

Contact E-Mail Address: jy1988.kim@samsung.com
Introduction: Individuals with advanced adenomas or three or more adenomas have a higher risk for metachronous advanced neoplasia (AN) and are recommended to undergo surveillance colonoscopy at shorter intervals. Recently, improvements of colonoscopy technology have resuled in higher detection rates for diminutive polyps. In more recent screening studies, adenoma detection rates of 40% or more have been reported. Therefore, it is questionable whether patients with multiple (three or more) non-advanced diminutive adenomas should be considered as high-risk.
Aims and Methods: We analyzed 5,482 patients diagnosed with 1 or more adenomas during their first colonoscopy screening and who underwent a follow-up colonoscopy. Patients were categorized into four groups based on adenoma characteristics at baseline: Group 1, 1–2 non-advanced adenomas; Group 2, $\geq$3 non-advanced, diminutive (1 to 5 mm) adenomas; Group 3, $\geq$3 non-advanced, small (6 to 9 mm) adenomas; and Group 4, advanced adenomas.
Results: During a median follow-up of 38 months, the incidence of metachronous AN at surveillance colonoscopy was 5.6%. The incidence of AN was 3.9% in

Abstract No: P1674

Table 1: Risk for metachronous advanced neoplasia based on baseline adenoma characteristics (different reference groups)

	Total number	Number of cases	Incident rate	aHR (95% cI)	P value	aHR (95% cI)	P value	aHR (95% cI)	P value
Group 1	4302	168	3.9	1.00 (reference)		0.19 (0.13–0.28)	<0.001	0.59 (0.34–1.01)	0.059
Group 2	472	28	5.9	1.71 (0.99–2.94)	0.059	0.32 (0.18–0.59)	<0.001	1.00 (reference)	
Group 3	378	40	10.6	2.76 (1.72–4.44)	<0.001	0.52 (0.31–0.89)	0.008	1.62 (0.84–3.12)	0.309
Group 4	330	73	22.1	5.23 (3.57–7.68)	<0.001	1.00 (reference)		3.07 (1.69–5.56)	<0.001

group 1, 5.9% in group2, 10.6% in group 3, and 22.1% in group 4. The adjusted hazard ratios (HRs) [95% confidence intervals (CIs)] for metachronous AN between group 2, group 3, and group 4, and low risk group 1 were 1.71 (0.99–2.94), 2.76 (1.72–4.44), and 5.23 (3.57–7.68), respectively. Compared with group 4, the adjusted HRs (95% CIs) for group 1, group 2, and group 3 were 0.19 (0.13–0.28), 0.32 (0.18–0.59), and 0.52 (0.31–0.89), respectively.

Conclusion: Risks for advanced neoplasia among individuals with high-risk features vary based on baseline adenoma characteristics. We found that patients with 3 or more non-advanced diminutive adenomas had a borderline increased risk of metachronous AN compared with patients with low-risk adenomas. The surveillance interval for patients with multiple diminutive adenomas may be lengthened from the recommended interval for patients at high risk.

P1675 ONCOLOGICAL RECURRENCE OUTCOMES AFTER STENTING AS BRIDGE TO SURGERY COMPARED TO EMERGENCY SURGERY FOR LEFT-SIDED MALIGNANT COLONIC OBSTRUCTION: RETROSPECTIVE BICENTRIC STUDY

C. Lara Romero[1,2], Á. Caunedo Alvarez[2], P. Hergueta Delgado[2], I. Lavin Castejon[1], R. Camargo Camero[1], R. Romero Castro[2], G. Alcain Martínez[1]

Introduction: Symptomatic left-sided malignant colonic obstruction is a medical and surgical emergency that requires an urgent intervention, which has been classically emergency surgery (ES), which still represents a high morbidity (30–60%) and mortality (10–30%).[1,2]

Stents bridge to surgery (SBTS) restore intestinal transit and allows to transform emergency surgery into elective surgery.

SBTS is widely accepted in palliation, but disagreement exists about its role in patients whose disease is potencially curable due to the possible risk of tumour spread.

At present, there are no consistent studies able to demonstrate that one strategy is superior to the other in terms of oncological benefit.[3]

Aims and Methods: Our aim is to evaluate the oncological outcome in terms of recurrence and recurrence-free survival of stented patients who went on to elective surgery compared to those who had ES. We retrospectively selected patients with clinically and radiologically left-sided malignant colonic obstruction between January 2006 to May 2012 in two Specialty Hospitals in the south of Spain.

Exclusion criteria were age under 18, tumour located in right or transverse colon, or in medium/inferior rectum; metastasic disease (stage IV of the American Journal Committee on Cancer (AJCC)) independently of the location or resecability of the metastases and perforation at the moment of the diagnosis.

Firstly, we analyzed demographic data, recurrence rate (RR) and recurrence-free survival (RFS) between both hospitals, without finding statistically significant differences and achieving an homogeneous sample for the analysis. Then we analyzed RT and RFS comparing SBTS vs ES groups. Multivariate analysis was made to find relative factors to oncological recurrence.

Results: We found a higher RR near statistical significance in the ES group compared to the SBTS group (34.8% vs 19.7; P = 0.072). The median follow-up time until recurrence was higher in the SBTS group, 58 vs 24 months (p = 0.053). We did not find differences between groups in recurrence location when distinguishing between local or distant recurrence (p = 0.999). Results are shown in table 1.

	SBTS (n = 71)	ES(n = 66)	P
Recurrence rate	14(19.7)	23(34.8)	0.072
Recurrence-free follow-up time (m)	58(14–85)	24(8.75–68)	0.050
Local Recurrence	8(57.1)	13(56.5)	0.999

[Table 1. Recurrence results. Values are presented as median (p25-p75) or n (%)]

Three-year and five-year RFS survival were lower for the ES group (67.5% and 60%), compared to the SBTS group (79.3% and 75.6%), but the Kaplan-Meier curve showed no difference in the RFS between two groups (log-Rank test, P = 0.220)

Stratifying according the AJCC stage, there are not statistically significant differences between groups for stage I(P = 0.317) or II(P = 0.884), but there is a lower RFS for stage III in ES group, where 3-years RFS suppose the 42.5% compared to 74.5% in the SBTS group; and 30% vs 69.7% according 5-year RFS (log-Rank test, P = 0.004; Fig. 2)

Performing a multivariate analysis, we find as hypothetical predincting variables of recurrence the type of emergency procedure and the AJCC stage, so that the patients who had ES have 2.12 [IC95%:(1.09;4.13); P = 0.027] more risk of recurrence than those who were treated with SBTS; and those with AJCC stage III have 2,97[IC95%:(1,53;5,78); p = 0,001) more probability of recurrence than those with a lower stage.

Conclusion: This study shows a clear trend to lower RR in patients who undergo SBTS compared to those who have ES for left-sided malignant obstruction and reaches statistically significant for recurrence-free follow-up time.

Patients who went to ES or was AJCC stage III had more probability of oncological recurrence.

Introduction: Women with Lynch syndrome (LS) have up to 71% lifetime risk of developing endometrial cancer (EC). Several studies evaluated the prevalence of Lynch Syndrome (LS) in young onset EC patients and the results were extremely variable (5%-22,8%). Molecular screening with Immunohistochemistry (IHC) for Mismatch Repair (MMR) proteins and/or Microsatellite Instability (MSI) analysis on cancer tissue have to be shown cost effective. Nonetheless, the approach of a universal vs a selective screening on tumor tissue is still debated. A pre-selection with family history criteria could improve the cost effectiveness of molecular screening.

Aims and Methods: The aim of our study was to evaluate the prevalence of LS in early-onset EC without family history compared with those with family history. Early-onset EC patients (≤ 50 years) were prospectively recruited in the study. Family history of Lynch-associated cancer (LAC) was recorded. IHC for MMR and MSI analysis were performed. Germ-line mutation analysis (GMA) was carried out in all MMR deficient tumors or when neoplastic tissue was not available. Results were compared with a published series of early -onset Colorectal cancer (CRC) undergone to molecular screening for LS and cathegorized according with family history of LAC.

Results: Twenty-two early- onset EC cases with a median age at diagnosis of 43 years were analysed. Patients were categorized in three groups according with family history of LAC: group A, Amsterdam II criteria fulfilled, 10 patients; group B, family history of LAC, Amsterdam Criteria not fulfilled, 3 patients; group C, no family history of LAC, 9 patients.

IHC and MSI were performed in 12 patients and showed MMR deficiency in 3/6 patients (50%) of group A, and 2/5 (40%) of group C. GMA was carried out in the 5 pts with somatic MMR deficiency and in the remaining 10 cases. It showed a deleterious mutation in 7/10 patients (70%) of group A, 1/3 (33.3%) of group B and 1/9 of group C (11.1%). 4/7 (57.1%) patients of group A with a deleterious mutation of MMR genes had a previous colorectal cancer.

The comparison between early onset CRC and early-onset EC showed significative differences for LS identification in group C only (0% vs 11.1%, p = 0.05).

Conclusion: Early-onset EC with or without family history of LAC are at high risk to develop LS. In our series we identified 40.9% LS cases. However, despite what reported for early onset CRC family history could not be used as a pre-screening tool to evaluate whether or not patients should undergo tissue molecular screening.

Introduction: Resection of obstructing left-sided colon cancer in the acute setting is associated with an increased risk of postoperative morbidity and mortality, especially in the elderly, frail patient (1–4). Bridge-to-surgery management with stent placement or decompressing colostomy may improve postoperative outcomes (5–6).
Aims and Methods: In this nationwide retrospective cohort study, our aim was to describe national practice and compare mortality and morbidity rates between acute resection and stent or stoma as bridge-to-surgery. All patients with curable obstructing left-sided colon cancer treated between 2009–2016 were included from the Dutch Surgical Colorectal Audit. Additional data including 90-day mortality and morbidity as primary outcomes were retrospectively collected.
Results: In total, 2587 patients were included of whom 2013 underwent acute resection and 574 bridge-to-surgery by stent (n = 229) and stoma (n = 345). Acute resection showed a 90-day mortality rate of 7.6% versus 1.4% with stoma ($p < 0.001$) and 5.2% with stent ($p = 0.2$). Complication rate was 38.4% in the acute resection group versus 31.9% in the stoma group ($p = 0.02$) and 39.7% in the stent group ($p = 0.7$). In patients ≥ 70 years, acute resection showed a mortality rate of 11.7% versus 3.2% with stoma ($p = 0.001$) and 8.3% with stent ($p = 0.2$). In patients with an ASA score of ≥ 3, mortality was 15.5% with acute resection versus 6.4% with stoma ($p = 0.03$) and 12.3% with stent ($p = 0.5$). The acute resection group showed a significantly lower primary anastomosis rate of 39.5% compared to the stoma group (84.9%, $p < 0.001$) and the stent group (74.1%, $p < 0.001$).
Conclusion: In this nonrandomized population, colostomy as bridge-to-surgery significantly reduced postoperative mortality and morbidity. Both decompressing colostomy and stent placement were associated with an increased primary anastomosis rate.

P1678 COLD SNARE PIECEMEAL ENDOSCOPIC MUCOSAL RESECTION (CSP-EMR) OF LARGE SESSILE COLONIC POLYPS ≥20 MM IS FEASIBLE, SAFE AND EFFECTIVE

D. Mangira[1,2], **K. Cameron**[2], B. (Ja Hyuk) Koo[2], A. Moss[1,2,3]

Introduction: Endoscopic Mucosal Resection (EMR) is the standard of care for resection of large (≥20 mm) non-malignant sessile colonic polyps. Serious adverse events are mostly due to electrocautery. This could potentially be avoided by cold snare EMR. Traditionally it was thought impossible to resect large polyps with cold snare. We hypothesized that aggressive wide field cold snare piecemeal EMR (CSP-EMR) could be as effective as conventional EMR, but with fewer adverse events.
Aims and Methods: The study aimed to evaluate safety and efficacy of CSP-EMR of sessile colonic polyps sized ≥20mm. All cases of CSP-EMR performed by a single endoscopist at two academic hospitals for sessile polyps ≥20 mm, from Jan 2016 – Dec 2017, were identified retrospectively. During this period, all lesions that were not suspicious for submucosal invasion, and were not very large Paris 0-Is lesions where cold snare resection would be technically very difficult, were performed by CSP-EMR. Efficacy was defined as the absence of residual or recurrent polyp tissue during the first surveillance colonoscopy. At surveillance, EMR scars were rigorously inspected using Olympus 190 series colonoscopes with high definition white light, then NBI, and then multiple cold biopsies of the centre and margins of the scar for histology. Adverse events including clinically significant intra-procedural or post-procedural bleeding, perforation, post-procedural pain requiring hospital admission, post-polypectomy syndrome, histological outcomes and surveillance colonoscopy findings were assessed by reviewing electronic medical records.
Results: 148 polyps sized ≥20mm were successfully excised by CSP-EMR in 133 patients (median age 67 yrs, IQR 56–74 yrs; men 31.1%). Mean polyp size was 25.3 mm (median 20mm, IQR 20–30 mm; range: 20–60 mm) and 137 (92.5%) polyps were Paris class 0-IIa. 85% of polyps were lifted with submucosal injection of Gelofusine with Methylene-Blue and Adrenaline (1:100,000) before resection. Histology was 90 (60.8%) sessile serrated adenomas, 42 (28.4%) tubular adenomas and 13 (8.8%) tubulovillous adenomas. Cytological dysplasia was absent in 89 (60.1%) polyps, low-grade in 57 (38.5%) and high-grade in 2 (1.3%). 110 of 133 patients had surveillance colonoscopy for 124 polyps over a median follow-up of 5 months (range: 2–16 months). EMR scar biopsies were taken in 113 of 124 polyps (94.2%). Residual or recurrent polyp was noted in 4 cases (3.2%). Clinically significant intra-procedural bleeding occurred in 2 patients (1.5%) and was successfully treated with clips. 4 patients (3%) experienced clinically significant post-procedural bleeding that settled spontaneously. 1 patient (0.7%) required overnight stay for post-EMR abdominal pain that settled spontaneously. None experienced post-polypectomy syndrome, deep mural injury or perforation.
Conclusion: CSP-EMR of sessile colonic polyps ≥20mm is technically feasible and potentially more effective than conventional EMR, but with a superior adverse event profile. We hypothesise that the enhanced safety of cold snare resection allowed for an aggressive and wide field resection that reduces recurrence rates. However, due to the likelihood of selection bias in terms of the polyps selected for CSP-EMR in this series, randomised controlled trials or large multicentre prospective observational studies are required to more rigorously demonstrate the non-inferiority and improved safety profile of CSP-EMR compared to conventional EMR, and to further determine which polyp morphologies are best suited to CSP-EMR.

Introduction: Enhancing the radio-responsiveness for locally advanced rectal cancer is important to local control and related long term prognosis. Despite the effectiveness of radiotherapy in treating cancer, harmful damage caused by radiation to the surrounding normal cells is often unavoidable. Therefore, it is necessary to treating tumor and minimizing side effects. Radiosensitizer can make cancer cells more sensitive to radiation using a low and safe radiation dose. Butyrate, one of the short chain fatty acid (SCFA), is used as energy source for histone acetyltransferase (HAT) activity in normal colonocyte. Due to the Warburg effect, cancer cells rely on glucose as their primary energy source, so butyrate is accumulated and function as a histone deacetylase (HDAC) inhibitor. There are reports that HDAC inhibitor enhance radiosensitivity, we assumed butyrate as a potential strategy for enhancing the radio-responsiveness for colorectal cancer patients.
For the test of the response to radiotherapy, the animal models have been used only due to the poor survival rate of patient-derived cell culture. However, the recently developed ex-vivo culture techniques for single crypt or a stem cell derived organoid with essential features of the in vivo tissue architecture has been demonstrated as useful and physiologically relevant tools to study the treatment response.
Aims and Methods: This study was aimed to prove the effect of SCFAs as radiosensitizer using the 3D-cultured organoids derived from colorectal cancer patients.
To culture organoids, normal mucosa fragments were cut into 3–5mm. Crypts were isolated by EDTA chelation and resuspended in matrigel and grown in culture media including EGF, Noggin, R-spondin, A83-01 and WNT. Tumor tissues were cut into pieces and incubated with Collagenase II, Dispase II and Y27632 at 37°C while shaking. Cells were incubated with culture media without Wnt and R-spondin for selecting only cancer cells. Organoids were treated with

1mM SCFAs and irradiated with 5Gy after 6hr. The evaluation of irradiated organoids was performed by measuring MTT assay, organoid size, and organoid-regenerating capacity.
Results: We screened SCFA for their anti-cancer effect on colorectal cancer organoid. Of the three SCFA, the butyrate only suppressed organoids proliferation and propionate and acetate had no effect. In the response of radiation, the butyrate significantly enhanced radiation-induced cell death in cancer organoids and it was more effective than treatment radiation or butyrate only. And also cancer organoid-regenerating capacity were decreased by radiation and butyrate treatment. Combination of radiation and butyrate reduced Ki-67 (proliferation marker) positive cells and decreased numbers of S phase cells in cancer organoids through expression of cell cycle regulator such as Cdkn1a, Cdkn1c and Gadd45b. Importantly, butyrate do not increase radiation-induced cell death and improve organoid-regenerating capacity after treatment with radiation on normal organoids. It suggest that butyrate have some tumor selectivity as radiosensitizer.
Conclusion: In this study, the butyrate increased radiosensitivity of colorectal cancer, whereas protected normal mucosa from radiation in patient derived organoids models. Considering their clinical application such as safety, they could be possible strategy for increasing radiotherapy efficiency without additional toxicity.

Introduction: The prevalence and mortality of colorectal cancer (CRC) are increasing worldwide. New strategies for prevention, such as chemoprevention, are needed to lower the burden of this disease. The most precise chemoprevention agent for CRC is NSAIDs, especially aspirin. However, the chemoprevention effect of aspirin is not so strong and has some adverse effect, such as gastrointestinal bleeding. We previously analyzed the chemopreventive effect of low dose metformin in rodent model and conducted clinical trial for adenoma prevention, and revealed good response for colorectal carcinogenesis both in rodent model and human. Furthermore, we reported there is no severe adverse events to use of low-dose metformin. However, the chemopreventive effect of metformin is also not strong. For the antihypertensive and antidiabetic treatment, we often use multiple low-dose agents with different mechanism of action for good response and avoid adverse effects. Then we analyzed the chemopreventive effect of combination treatment of aspirin and metformin for colorectal carcinogenesis.
Aims and Methods: We obtain normal colorectal tissue, adenoma and cancer from CRC patients by colonoscopy and cultured organoid in the matrigel. Then we treated both or with or without aspirin and metformin and analyzed the chemoprevention effects.
Results: Combination treatment of aspirin and metformin significantly suppressed cell proliferation in both in normal tissue, adenoma and cancer compared with single treatment of aspirin or metformin. Combination treatment significantly activated AMPK and suppressed mTOR pathway. The chemopreventive effect of combination treatment of aspirin and metformin for colorectal carcinogenesis is stronger than that of single use of aspirin or metformin.
Conclusion: The combination treatment of aspirin and metformin is one of the option for the CRC chemoprevention.

Introduction: Comprehensive characterization of the cancer genome provided important insights for development of new therapies. Current NGS-based personalized medicine requires the combination of the patients' molecular information with suitable databases and identifying appropriate publications to create a report. Here we report on 454 cancer patients with gastrointestinal (GI) tumors analyzed with MH Guide and highlight the importance of assessing the safety of suggested treatments.
Aims and Methods: We constructed an integrated database – the so-called Dataome®. Based on that, we have developed and registered an in-vitro diagnostic medical device MH Guide in Europe for clinical treatment decision support (TDS).
Results: In the 454 cases, MH Guide identified potential drug responses based on effective (4.5k), ineffective (0.7k) and toxic (1.6k) biomarker information in GI cancer cases. On average, about 16 distinct biomarker information were identified for each patient. MH Guide classifies biomarkers in germline and somatic lineage and categorizes them into three different levels of established clinical validity:
1) clinically endorsed (approved by FDA) (0.5k),
2) clinically observed (predictive effect observed in clinical trials) (3.1k), or
3) translational (supported by pre-clinical or computational evidence) (3.9k).
Furthermore, we evaluated different aspects e.g., recommended drugs, drug approval states, biomarker approval states, and clinical trial matching for off-label drugs.
Conclusion: To benefit from the comprehensive characterization of the cancer genome in the routine medical practice, technologies are required that efficiently interpret clinico-molecular patient data against all this rapidly advancing biomedical knowledge. MH Guide allows quick variant interpretation using referenced curated data including evaluation of quality parameters. Molecular Health technologies can assist clinicians in making informed decisions about the benefits of established therapies.
On this basis, we have concluded first contracts with statutory health insurances in Germany. The aim is to reduce the number of non-responders and toxic side effects, thus improving the overall cost of treatment as well as clinical outcomes and quality of life. Primary endpoint will be the change of the therapy recommendation in the tumor board after opening the MH side results in comparison to the previous recommendation.
Disclosure: The authors are employees of Molecular Health but for the senior author (JML) who is an advisor

P1682 LABORATORY PREDICTORS OF CLINICAL-PATHOLOGICAL RESPONSE AFTER NEOADJUVANT TREATMENT IN RECTAL CANCER

Introduction: In locally advanced rectal cancer, the ability to predict tumor response to neoadjuvant radiochemotherapy is of great clinical importance, since patients with complete pathologic response (CPC) have a better prognosis.
Aims and Methods: The objective of this study is to determine if there is an association between the laboratory variables and the clinical-pathological tumor response in patients with adenocarcinoma (ADC) of the rectum, submitted to neoadjuvant radiochemotherapy, followed by surgical tumor resection.
Retrospective study of patients with rectal ADC who received neoadjuvant radiochemotherapy, followed by surgical tumor resection between March 2012 and October 2017. Analysis of laboratory values (hemoglobin, platelets, creatinine, alkaline phosphatase, albumin, CEA and CA 19.9) from tumor downstaging and CPC. Statistical analysis was performed using SPSS v24.
Results: 89 patients were included, 60.7% were male, with a mean age of 63.8 ± 10.42 (40–86) and 79.8% of them was performance status 0. The majority of patients underwent surgery between 6 to 10 weeks after neoadjuvant radiochemotherapy (58.4%). There was a good response to neoadjuvant radiochemotherapy in 41.6% of the patients, tumor downnstaging in 83.1% and CPC in 23.6%. There was a statistically significant association between the lower levels of CA 19.9 pre-treatment and tumor downnstaging ($p = 0.032$), as well as in CPC ($p = 0.007$). In the categorization of CA 19.9 values (cut off ≤ 17 and > 17), there is an association between this variable and tumor downnstaging (OR 0.241; 95% CI 0.074–0.788; $p = 0.019$), as well as the complete pathological response (OR 0.189, 95% I 0.04–0.88, $p = 0.034$).
Conclusion: Of the laboratory variables commonly evaluated in the pre-treatment phase with neoadjuvant radiochemotherapy, the only one with association with tumor domnstaging and CPC are CA 19.9 levels. Lower CA 19.9 values can predict responses to neoadjuvant radiochemotherapy more favorable.
Disclosure: Nothing to disclose

Introduction: The gut barrier protects the body from potentially harmful compounds and microorganisms and a loss of gut barrier integrity can lead to increased intestinal permeability causing leaky disease such as irritable bowel syndrome. A key factor contributing to abnormalities in permeability is aberrant structuring of tight junction proteins that support gut barrier function. However, disruption of the intestinal barrier is associated with aging is uncertain.

Aims and Methods: The overall goal of the current study was to investigate the role of aging on colonic permeability and the relation between the change of sphingolipid which was known to be related with epithelial permeability and gut tight junction.

Colonic mucosal biopsies were acquired from old (≥65 years old) and young (20–40 years old) human, old IBS patients and young IBS patients. The change of inflammation (TNF-α, IL1ß, and IL-10) and tight junction (claudin2, occludin, and ZO-1) were measured by qreal-time PCR. Sphingolipid was measured by using a UPLC system. Data were expressed mean ± SE and analysed using Student's unpaired T-test for samples comparison. A p value < 0.05 was considered significant.

Results: The statistical difference was shown in IL-10 and claudin2 mRNA between old and young control group ($P < 0.05$). The IL-1ß, IL-10, occludin and ZO-1 mRNA was shown significant difference between young control and young IBS group ($P < 0.05$). The IL-1ß, IL-10, claudin2, occludin and ZO-1 mRNA was shown significant difference between old control and old IBS group ($P < 0.05$). Acid sphingomyelinase (ASM) was significantly increased in colonic mucosa as aging and patients with IBS ($P < 0.05$).

Conclusion: Overall, the data presented here show that increased ASM activity in aging and IBS patients might be related with the disruption of intestinal barrier. Further studies are needed to be clarify the relation between sphingolipid and gut tight junction.

Introduction: Irritable bowel syndrome (IBS) is conceptualized as a condition of visceral hypersensitivity and gastrointestinal motility abnormalities. Great number of studies have shown a higher prevalence of anxiety and depression in patients with IBS patients.

Aims and Methods: We aimed to assess correlation between presence and severity of clinical symptoms, severity of anxiety and depression and high resolution anorectal manometry (HRAM) data in patients with IBS with constipation (IBS-C) and IBS with diarrhea (IBS-D).

31 patients with IBS-D and 33 patients with IBS-C (according to ROME III) were examined for severity of abdominal pain and flatulence (by visual analogue scales), stool frequency (defecation per week), severity of depression and anxiety (by Hamilton Depression Rating Scale (HRDS) and Hamilton Anxiety Rating Scale (HARS) respectively). All patients were also analyzed by HRAM using 20 channel water-perfused catheter with a polyethylene balloon (Solar GI, MMS, the Netherlands).

Results: IBS-D patients showed positive correlation of stool frequency to amplitude and % of relaxation of internal anal sphincter ($\tau = 0.33$, $p = 0.023$; $\tau = 0.31$, $p = 0.023$; respectively) as well as duration of RAIR ($\tau = 0.36$, $p = 0.007$); negative correlation of stool frequency to threshold for first ($\tau = -0.33$, $p = 0.015$), permanent ($\tau = -0.36$, $p = 0.007$) and intense ($\tau = -0.28$, $p = 0.037$) urge to defecate.

Patients with IBS-C showed negative correlation of stool frequency to average and maximum resting pressure of the anal sphincter ($\tau = -0.28$, $p = 0.039$; $\tau = -0.32$, $p = 0.018$ respectively) and duration of RAIR ($\tau = -0.30$, $p = 0.028$).

All patients showed positive correlation of severity of anxiety to duration of squeeze of anal sphincter ($\tau = 0.36$, $p = 0.007$) and to threshold for the rectoanal inhibitory reflex (RAIR) ($\tau = 0.32$, $p = 0.017$); depression severity to threshold for first sensation ($\tau = 0.38$, $p = 0.004$) and to threshold for intense urge to defecate ($\tau = 0.29$, $p = 0.032$). The patients also showed negative correlation of depression severity to maximum of absolute anal squeeze pressure in both IBS group ($\tau = -0.27$, $p = 0.049$).

In addition, positive correlation of severity of anxiety to stool frequency and severity of flatulence ($\tau = 0.33$, $p = 0.008$ and $\tau = 0.44$, $p = 0.001$ respectively) was observed.

Conclusion: According to HRAM, rectal motility and sensitivity abnormalities correlate with severity of stool disorders, as well as flatulence intensity. Comorbid emotional disorders aggravate already existing motility and sensory abnormalities and enhance the clinical symptoms. This data allows to suggest that all IBS patients should be tested for anxiety and depression. Antidepressant and anxiolytic drugs might be an important part of IBS treatment for these patients.

Introduction: Constipation is a very frequent complaint in type 2 diabetic patients[1] and some authors believe that alterations in recto-anal thresholds may be present in individuals with these symptoms[2].

Aims and Methods: The aim of this study was to compare rectal sensorial and motor characteristics of type 2 diabetics with and without constipation.

Recto-anal manometry was performed in 35 type 2 diabetics, without signs of autonomic neuropathy, 15 with complaints of constipation and 20 without this symptom, matched by age and gender.

Results: In diabetics with complaints of constipation vs. without complaints, the values were the follow: rectal resting pressure, 11.5 ± 1.8 vs. 12.1 ± 2.3mmHg; $p = 0.8$; internal anal sphincter resting pressure, 40.0 ± 4.7 vs. 43.6 ± 6.1mmHg, $p = 0.6$; minimum rectal sensibility, 65.5 ± 6.8 vs. 78.6 ± 9.2ml, $p = 0.2$; first urge, 107.58 ± 14.1 vs. 119.3 ± 13.1ml, $p = 0.5$; intense urge, 132.0 ± 14.2 vs. 145.3 ± 15.5ml, $p = 0.5$; maximum tolerable rectal capacity, 197.0 ± 22.6 vs. 208.6 ± 19.0ml, $p < 0.7$. The relaxing percent during the recto-anal reflex was 40.9 ± 6.0% vs. 30.5 ± 4.5%, $p > 0.05$. The sphincter pressure during the squeeze was significantly lower in diabetics with symptoms 67.2 ± 11.2 mmHg than without it, 109.7 ± 16.4mmHg, $p < 0.03$; but during the squeeze endurance, 88.0 ± 11.7 vs. 114.9 ± 17.4mmHg, was statistically similar. The anal sphincter fatigue during the squeeze endurance, 0.29 ± 0.41 vs. -0.26 ± 0.40 mmHg/sec was similar. When comparing the recto-anal characteristics according to the severity of constipation, there were no statistic differences between diabetics with slight to moderate or severe to very severe symptoms.

Conclusion: 1-In type 2 diabetics with complaints of constipation the resting rectal pressure, the volume for minimum rectal sensibility, first urge, intense urge and maximum tolerable rectal capacity, and the relaxing degree during the recto-anal inhibitory reflex were statistically similar to diabetics without the symptoms. 2-The pressure augment during the squeeze was higher in diabetics without constipation. 3-In general recto-anal sensorial and motor thresholds were similar in type 2 diabetics with or without constipation.

Introduction: Irritable bowel syndrome (IBS) and bladder pain syndrome (BPS) often overlap, and are both characterized by visceral hypersensitivity reproduced by pelvic organ distension. Since pelvic organs share a common innervation, it is likely that those syndromes involve a cross-sensitization of the bladder and the colon in response to distension.

Aims and Methods: The aim of this project was to assess the involvement of spinal neuro-glial interactions in the development and the sustainment of bladder and colon cross-sensitization. Chronic cross-organ sensitization was obtained in C57BL/6 conscious mice using ultrasound-guided intravesical administration of acetic acid under brief isoflurane anesthesia. Colonic sensitivity was assessed in conscious mice by measuring abdominal contraction during isobaric colo-rectal distension. Myeloperoxidase (MPO), used as a marker of colonic inflammation, was measured on colon. Colonic permeability was measured using Ussing chamber. C-Fos protein expression, used as a marker of neuronal activation, was counted in the spinal cord (level L6-S1) using immunohistochemistery.

CX3CR1-GFP^{+}mice were used to identify and count microglia cells in the L6-S1 dorsal horn of the spinal cord. IL1beta mRNA was assayed on the spinal cord using qRT-PCR. Expression of NK1 receptor was quantified in the spinal cord by western-blot.
Results: We developed a chronic cross-sensitization model in conscious mice. In this model, intravesical administration of acetic acid induced a transient increase in colonic permeability, and a long lasting colonic hypersensitivity to distension, that involved neuroglial interaction and NK1 receptors.
Conclusion: We developed a chronic cross-sensitization model in conscious mice. In this model, intravesical administration of acetic acid induced a transient increase in colonic permeability, and a long lasting colonic hypersensitivity to distension, that involved neuroglial interaction and NK1 receptors.

Introduction: Intolerances to fermentable sugars, collectively referred to as FODMAPs, are common in functional gastrointestinal disorders (FGID), and reduction of the intake of these sugars results in significant symptom relief in selected patients (1). Breath tests are in widespread use for the diagnosis of sugar intolerances and have been shown to be useful in the prediction of the outcome of dietary modulation (2). However, studies of the repeatability of breath tests have not been reported.
Aims and Methods: The aim of this single-centre, prospective study was to assess the repeatability of the fructose breath test using appropriate statistical tools in successive patients with FGID. Sixteen male and female patients with functional dyspepsia and/or irritable bowel syndrome, as defined by Rome III criteria, received fructose 35g in the morning after a standardized 24h low-FODMAP diet on two separate days at least 14 days apart. At each occasion, breath samples for measurement of hydrogen and methane concentrations were collected (Quintron BreathTracker SC®, USA) and GI symptom intensities (abdominal bloating, flatulence, fullness, nausea, diarrhoea, abdominal cramps or pain, borborygmi, and gastroesophageal reflux) were scored hourly on a 3-point Likert scale for 5 hours after fructose ingestion. All patients, irrespective of symptom or gas responses, were evaluated. The areas-under-the-curve (AUC) of the aggregate GI symptom scores and of the breath hydrogen and methane concentrations were calculated and repeatability was assessed using limits of agreement and intraclass correlation coefficients (3). Additionally, the numbers of patients with intolerance (aggregate symptom score increased by >2) or malabsorption (rise in hydrogen >20ppm or in methane >10ppm) were determined and the absolute agreement and kappa values were calculated. The repeatability of measurements refers to the variation in repeat measurements made on the same subject under identical conditions, by the same instrument or method, the same observer and that the measurements are made over a short period of time.
Results: For the aggregate GI symptom score and the hydrogen and methane gas concentrations, repeatability was ''moderate'', with intraclass correlation coefficients of 0.7, 0.57 and 0.57, respectively. Fructose intolerance was present in 9 of 15 patients (60%) in the first and second breath tests, with an absolute agreement in classification between both breath testing sessions for 13 of 15 patients (87%), resulting in a kappa value of 0.72 ($p = 0.003$). Malabsorption of fructose occurred in 6 of 15 patients (40%) in the first test and in 7 of 15 patients (47%) in the second test. There was absolute agreement in malabsorption classification between both breath testing sessions for 8 out of 15 patients (53%), corresponding to a kappa value of 0.05 ($p = 0.42$).
Conclusion: The fructose breath test methodology shows repeatability in the range of what is considered adequate for clinical testing. When the arbitrarily defined thresholds used in clinical practice are applied, classification of intolerance based on symptoms shows good repeatability, while classification of malabsorption based on gas concentrations varies considerably. Based on these results, the fructose test can be recommended as a sensory provocation test, but current clinical definitions of malabsorption yield unreliable results and need to be revisited.

P1688 DIETARY FODMAPS SUCH AS FRUCTO-OLIGOSACCHARIDES AND LACTOSE CAN INCREASE ABDOMINAL SENSITIVITY AND THE NUMBER OF MUCOSAL MASTOCYTES IN MICE; A STUDY ON UNDERLYING MECHANISMS

Introduction: Irritable Bowel Syndrome (IBS) is characterized by abdominal pain, often associated with diet. Limiting the consumption of FODMAPs (fermentable oligos-, di-, mono-saccharides, and polyols), unabsorbed in the small intestine and fermented by the gut microbiota, improves symptoms in 70% of IBS patients. However, the mechanisms behind this effect remain unclear. Our hypothesis is that bacterial metabolites resulting from fermentation of FODMAPs, such as aldehydes (glycation agents), can cause symptoms via the formation of pro-inflammatory advanced glycation end-products (AGEs) in the tissue. In addition, mast cells, and specifically their proximity to nerve endings in the colon, have been strongly implicated in IBS. We used the FODMAP representatives lactose (disaccharide), and fructo-oligosaccharides (FOS) in an animal model to evaluate the effects of these dietary FODMAPs on gut sensitivity. We also aimed to evaluate the involvement of AGEs and the mucosal mast cell population in the effects induced by these interventions.
Aims and Methods: Three groups of mice (C57BL/6 ♀) were treated daily for 21 days with an oral gavage of saline or saline solution containing 5 mg of lactose and/or 5 mg of pyridoxamine for lactose experiments, additionally, three groups of mice (C57BL/6 ♀) followed diets for 21 days; control (AIN-93M), 10% FOS (AIN-93M; part of starch replaced by FOS), and 10% FOS + 1mg/ml pyridoxamine in drinking water. Visceral sensitivity in lactose-treated animals was measured using electromyography during a colorectal distension procedure. Abdominal sensitivity in FOS-treated animals was evaluated non-invasively by mechanical stimulations with von Frey filaments (0.16, 0.6 and 1.4 g). In both sets of animals, mucosal mast cell (MMC) numbers and Receptor of AGEs (RAGE) expression in proximal colon were evaluated by immunofluorescence.
Results: Lactose treatment led to an increased visceral sensitivity (average response +40% at distension 0,08ml compared to control, $p < 0.01$). The FOS-enriched diet induced abdominal hypersensitivity versus control (33% vs 15% for 0.6g stimulation, 52% vs 33% for 1.4g stimulation). Co-administration of pyridoxamine prevented these effects in both experiments. Proximal colon epithelial RAGE expression was higher in lactose-treated animals (± 40% increase in signal intensity), and mucosal mast cell numbers increased (0.74 v 0.54 mast cell/crypt). Similarly, RAGE expression and MMC numbers were higher ($p < 0.05$) in the FOS group compared to the control group (± 40% increase in signal intensity and 1.27 vs 0.67 mast cells/crypt respectively). No differences were observed between control and FOS+pyr groups. These increases were prevented by co-administration of pyridoxamine, in both treatment sets.
Conclusion: This study shows that an increased FODMAP intake induces an abdominal hypersensitivity and an increase in the number of mucosal mast cells in mice, two pathophysiological factors characteristic of IBS. The prevention of these effects by anti-glycation agent pyridoxamine implies the role of glycation processes and the generation of AGEs in the origin of these effects. Given the similar results obtained with both FODMAP representatives, this work suggests a common mechanism responsible for the adverse effects observed, namely, the generation of glycation agents derived from FODMAP fermentation by the gut microbiota.

P1689 ADENOSINE A_{2B} RECEPTOR REGULATES COLONIC FLUID SECRETION IN MICE

T. Asano, M. Takenaga
St. Marianna University School of Medicine, Institute of Medical Science, Kawasaki, Japan

Contact E-Mail Address: asano-ti@marianna-u.ac.jp
Introduction: Adenosine is an extracellular purine nucleoside signaling molecule responsible for diverse actions in gastrointestinal systems, such as intestinal secretion, motility, inflammation and sensation. Previous studies suggest that adenosine receptors, especially A_{2B} receptor regulate colonic water secretion (1, 2). However, the available evidences that A_{2B} receptor modulates fluid secretion have been limited and the results using pharmacological agents specific for its receptor or genetically modified mice have not been demonstrated.
Aims and Methods: Our aims in this study are to investigate the effect of adenosine receptors on colonic water secretion *in vivo* and to determine the genetic evidence for the involvement of A_{2B} receptor. Assessment of intestinal fluid content was examined by mouse intestinal loop model, as described previously with some modifications (3).
Results: Adenosine solution injected into lumen increased fluid volume in murine colon in a dose-dependent manner. Pharmacological analysis using specific receptor agonists showed that A_{2B} receptor agonist BAY60-6583 significantly stimulated colonic fluid volume. We also found that A_1 receptor agonist *N*6-cyclopentyladenosine (CPA) slightly increased water contents, while A_3 receptor agonist IB-MECA produced a small reduction in it. However, these results were not significant. CGS21680, an agonist for A_{2A} receptor did not affect intestinal fluid contents. Moreover, we confirmed that the adenosine injected into lumen

did not increase fluid volume in mice genetically deficient in A_{2B} receptors compared with the case of wild-type mice.
Conclusion: Taken together, these results suggest that A_{2B} adenosine receptor regulates colonic water secretion and this receptor could be a therapeutic candidate for constipation or diarrhea related diseases.
Disclosure: We belong to endowed research division of LTT Bio-Pharma Co., Ltd.

Introduction: Elongation of enteric neuron toward the gastrointestinal mucosal surface leads to visceral hypersensitivity, which is one of the pathogenesis of irritable bowel syndrome (IBS). Among a variety of physiological roles of enteric glial cell (EGC), we reported that activated EGC in the myenteric plexus of the colon contributes to motor hypercontraction according to the stress intensity (*Neurogastroenterol Motil*, 2015). However, it is unknown how submucosal plexus, particular in submucosal EGC involves in neuronal elongation. Although netrin-1 is a well-characterized chemoattractant involved in neuronal guidance in the developing enteric nervous system, it also remains unknown which layer of the colon netrin-1 has crucial roles in under stress circumstances.
Aims and Methods: We used the Wistar Kyoto rats (WKY), a model of visceral hypersensitivity, and Wistar rats (control). Distal colonic segments were obtained from each rat, and the respective layer (mucosa, submucosa, and muscle) were separately striped from the whole colonic tissues and prepared. According to the layers, we compared mRNA expression of glial fibrillary acid protein (GFAP), netrin-1, nerve growth factors (NGF), glial cell-line derived neurotrophic factor (GDNF), and GAP43, a neurogenesis marker by real-time RT-PCR. To analyze EGC morphology and its interaction with intrinsic primary afferent neuron (IPAN), whole mount submucosal plexus preparations were used for immunohistochemistry for EGC (GFAP), IPAN (calbindin), netrin-1, and a receptor of netrin-1 (DCC, deleted in colorectal cancer).
Results: mRNA expressions of netrin-1 (3.2-fold), NGF (2.2-fold), GDNF (1.6-fold), and GAP43 (3.0-fold) were significantly increased in submucosal layer in the WKY group compared to the control, while there were no changes in the mucosa and muscle layers between WKY rats and controls. GFAP mRNA expression was increased in the submucosal layer of the WKY rats (3.0-fold) compared to the control. In the submucosal layer of the WKY rats, hyperplasia of EGC processes dramatically appeared. In morphology of EGC processes, thick elongation, ramified and spine formation toward the IPAN (calbindin-positive) were remarkably found in the WKY group rather than the control. Netrin-1 was expressed in both EGC and the neuron, while netrin-1 receptor was expressed in the neuron alone.
Conclusion: Submucosal layer of the colon has important roles under stress circumstances. In the submucosal layer, both hyperplasia of EGC processes toward the sensory neuronal body and increased neuronal elongation factors (netrin-1, NGF, and GDNF) may be involved in peripheral mechanisms of visceral hypersensitivity in IBS.

Introduction: Some investigations shore up that there is an important overlap between the diverse functional disorders in the digestive tract.[1,2] In diabetics, gastro-oesophageal reflux and anorectal symptoms are frequent.
Aims and Methods: The aim of this study was to compare rectal sensorial and motor characteristics between type 2 diabetic individuals with and without complaints of gastro-oesophageal reflux.
Recto-anal manometry was performed in 32 type 2 diabetic, without signs of autonomic neuropathy, 12 with complaints of gastro-oesophageal reflux and 20 without this complaint, matched by age and gender.
Results: In diabetics with complaints, resting rectal pressure was slightly higher than others without complaints, 13.6 ± 1.2 vs 9.6 ± 1.6mmHg, but the difference was no significant, $p = 0.07$. In both groups, diabetics with complaints vs without complaints, other rectal manometric characteristics were the follow: minimum rectal sensibility, 56.7 ± 6.7ml vs. 80.0 ± 7.6ml, $p < 0.05$; first urge, 80.8 ± 6.1 vs. 132.3 ± 13.5ml, $p < 0.002$; Intense urge, 108.3 ± 6.0 vs. 152.8 ± 14.7ml, $p < 0.005$; maximum tolerable rectal capacity, 169.2 ± 15.6 vs. 225.5 ± 20.8ml, $p < 0.03$. The relaxing percent during the recto-anal reflex and the sphincters pressures during the squeeze and squeeze endurance were statistically similar. The anal sphincter fatigue during the squeeze endurance was 1.16 ± 0.55 vs. -0.53 ± 0.29 mmHg/sec. When comparing the characteristics according to the degree of reflux, slight to moderate vs. severe to very severe complaints, the resting external sphincter pressure was 31.0 ± 3.4 vs 58.3 ± 5.8mmHg, $p < 0.002$; and minimum rectal sensibility was 41.6 ± 6.0 vs. 63.7 ± 6.6mmHg, $p < 0.03$.
Conclusion: 1-In type 2 diabetics with complaints of gastro-oesophageal reflux the volume for minimum rectal sensibility, first urge, and intense urge and for maximum tolerable rectal capacity were lower than in diabetics without the symptoms. 2-The anal sphincter fatigue was higher in diabetics with complaints. 3-The volumes for minimum rectal sensibility and for maximum tolerable rectal capacity were higher in diabetics with more severe symptoms.

Introduction: Neuronal elongation toward the colonic mucosa leads to visceral hypersensitivity, which is one of the pathogenesis of irritable bowel syndrome (IBS). Activated enteric glial cell (EGC) in the myenteric plexus of the colon contributes to motor hypercontraction in maternally separated (MS) rats of IBS model (*Neurogastroenterol Motil*, 2015). Axon guidance molecules include attraction factors and repulsion factors, and interactively regulate the direction of neuronal sprouting in accordance with neurotrophic factor in the developing enteric nervous system. However, it is unknown how EGC, axon guidance molecules, and neurotrophic factor in the submucosal plexus involve in visceral hypersensitivity.
Aims and Methods: We used MS rats of IBS model (maternal separation stress for 3 hours starting on postnatal days 2–14). As an irritated condition, MS rats ($n = 4$–8) at the adulthood received intracolonic injections of acetic acid (2 mL, 0.6%) to cause the colonic mucosal irritation (irritated rats). One week later, distal colonic segments were obtained from each rat, and both mucosal layer and submucosal layer were separately stripped from the whole colonic tissues, and prepared to evaluate respectively. According to each layer, we compared mRNA expressions of glial fibrillary acid protein (GFAP), netrin1, an attraction factor, semaphorin3A, a repulsion factor, nerve growth factors (NGF), and GAP43, a neuronal outgrowth marker by real-time RT-PCR. To histologically analyze the submucosal plexus (network formation of EGC and neuron), whole mount submucosal plexus preparations were used for immunohistochemistry for GFAP (EGC), PGP9.5 (pan-neuronal marker), and netrin1.
Results: Glial processes were remarkably elongated and glia-glial connections were clearly enhanced in the submucosal plexus of the irritated rats, while they were faintly found in the non-irritated rats and control rats. Neuronal connections were also increased and enhanced along with the glia-glial connections. In the submucosal layer of the irritated rats, mRNA expressions of GAP43 (2.6-fold) and GFAP (3.4-fold) were higher than those in the non-irritated rats and untreated rats. As well as the submucosal layer, mRNA expressions of GFAP (2.3-fold) was tended to be increased in the mucosal layer of the irritated rats. However, there was no change in GAP43 mRNA expression in the irritated rats. In the submucosal layer of the irritated rats, mRNA expressions of netrin1 (1.7-fold) and NGF (2.5-fold) were significantly increased compared to those in the non-irritated rats. However, these expressions were not changed in the mucosal layer. Different from the attraction factor, mRNA expression of semaphorin3A was decreased in the mucosal layer of the non-irritated rats by chemical irritation, although it was significantly increased in the submucosal layer. Netrin1 was localized in the cytoplasm of neuron and EGC in the submucosal plexus. Neuronal outgrowth into the mucosa was histologically confirmed by GAP43 immunoreactivity in the acetic acid-treated rats.

Conclusion: Enhancement of glia-glial connections in the submucosal plexus in accordance with the axon guidance molecules both in the mucosa and submucosa affects neuronal outgrowth toward the colonic mucosa, which may lead to visceral hypersensitivity after mild irritation with chronic stress.

Introduction: Chronic constipation (CC) in Parkinson's disease (PD) is a severe, usually laxative-resistant condition often worsening the patient's quality of life. To date, the molecular mechanisms underlying PD/CC pathogenesis are only partially understood.
Aims and Methods: The present study aimed to investigate neuropathological and neurochemical features in colonic mucosal biopsies of PD/CC patients compared to non-parkinsonian CC patients and asymptomatic controls by examining markers of intestinal epithelial barrier (IEB) and of enteric submucosal neurons and glia. PD/CC patients (n = 6; 2F, 51–79 yrs), CC patients (n = 6; 4F, 31–60 yrs) and control subjects (screening colonoscopy) (n = 6; 3F, 33–64 yrs) were enrolled. Colonic biopsies (n = 6) were collected from each subject. Total proteins were extracted from n = 4 biopsies and analyzed by Western blot to quantify: glial fibrillary acid protein (GFAP, as index of glial activation) and vasoactive intestinal polypeptide (VIP) and its receptors VPAC1 and VPAC2 as markers of subsets of vaso-secretomotor neurons. In addition, n = 2 biopsies were analyzed by immunohistochemistry to evaluate tight junction (TJ) proteins, i.e. *Zonula occludens-1* (ZO-1) and occludin, as indicators of IEB structural integrity. The relative density of TJ immunofluorescence was scored as follows: 4, normal; 3, slightly modified; 2, altered; 1, markedly reduced; 0, no expression.
Results: Western blot data showed no significant differences in VIP protein expression levels in PD/CC *vs.* CC *vs.* controls (One-Way ANOVA, P = 0.3). Similarly, VPAC1 and VPAC2 expression did not appear significantly different among groups (P = 0.8 and P = 0.1, respectively). However, VIP and VPAC2 expression levels showed a trend to decrease in both PD/CC and CC groups vs. controls. Also GFAP expression did not show significant differences among the three groups (P = 0.5). ZO-1 immunoreactive pattern displayed a normal network in the mucosa of control subjects and PD/CC patients (score = 4), whereas in CC patients ZO-1 immunoreactivity was markedly decreased (score = 2). In contrast, occludin immunoreactivity in PD/CC patients was almost exclusively expressed at the base of the cells and it appears weaker (score = 1–2) than in CC patients and controls (score = 4).
Conclusion: The present study showed that occludin, but not ZO-1, is reduced in PD/CC and CC patients, whereas there were no significant changes in VIP, VPAC1, VPAC2 and GFAP protein expression in PD/CC and CC patients *vs.* controls. Taken together our data support the concept of selective protein abnormalities in IEB which may contribute to distinct mechanisms in PD/CC.

Introduction: Hypermobility Spectrum Disorders (HSD) are a continuum of connective tissue disorders characterized by joint hypermobility (JH). Recent studies demonstrated that HSD are often associated with gastrointestinal (GI) symptoms. A higher prevalence of HSD has been demonstrated in patients with functional compared to organic GI disorders, pointing towards neuromuscular dysfunction of the GI tract as a possible underlying mechanism.
Aims and Methods: We prospectively evaluated whether subjects with (undiagnosed) HSD present with different symptom patterns and GI motility compared to non-HSD subjects, in an unselected tertiary GI patient population in whom organic pathology had previously been excluded. Sixty-two subjects (53 female; mean age: 40), referred for comprehensive GI motility assessment using gastric emptying test, esophageal, antroduodenal, and/or colonic manometry study, were consecutively included. Brighton criteria were used to diagnose HSD, and JH was assessed using the Beighton score. A Beighton score ≥ 6 was used as the cut-off for clinically significant JH. GI and psychological symptom scores, and quality of life were assessed using the Gastrointestinal Symptom Rating Scale, Hospital Anxiety and Depression Scale, and Rand Health Survey Short Form-36.
Results: Eighteen subjects (29.0%) met criteria for HSD. No significant differences between HSD and non-HSD subjects were found for age, BMI, GI symptom severity, depression/anxiety, and mental as well as physical quality of life. Esophageal, gastric, antroduodenal, and/or colonic dysmotility was not significantly more prevalent in the HSD group vs. the non-HSD group (72.2% vs. 43.2%, p = 0.091). However, subjects with clinically significant JH (*i.e.*, Beighton score ≥ 6) more often showed abnormal GI motility compared to subjects with Beighton < 6 (83.3% vs. 46.8%, p = 0.028). The odds of having any form of GI dysmotility were 5.7 times higher (95%-CI: 1.121; 28.788) in cases with Beighton ≥ 6 than Beighton < 6.
Conclusion: In patients with functional GI disorders referred for extensive GI motility analysis, HSD patients did not present with gastric, esophageal, antroduodenal, and/or colonic dysmotility significantly more often than non-HSD patients. However, the clinical phenotype of JH was a significant predictor for GI dysmotility. Therefore, the present study supports a possible role for neuromuscular dysfunction as a pathophysiological mechanism underlying GI symptoms in HSD.

P1695 HISTOPATHOLOGIC SIGNS OF NEURON DEGENERATION IN INDIVIDUALS WITH GASTROINTESTINAL SYMPTOMS MAY BE FOUND IN CONVENTIONAL STAINING IN BOTH SUBMUCOSAL AND MYENTERIC NERVE PLEXA

B. Ohlsson[1], E. Englund[2]
[1]*Lund University, Department of Internal Medicine, Malmö, Sweden*
[2]*Lund University, Division of Oncology and Pathology, Dept of Clinical Sciences, Lund, Sweden*

Contact E-Mail Address: bodil.ohlsson@med.lu.se
Introduction: Gastrointestinal symptoms are common in the population, many times with unknown reasons. Previous research has described that enteric neuropathy may be the etiology in some cases. Parkinsonism is one disease which often presents itself with gastrointestinal symptoms, especially constipation, where enteric neuropathy may be suspected. Studies of the enteric nervous system and microscopic details of enteric neuropathy have often been performed and described in the myenteric plexa, using full-thickness intestinal biopsy and immunostaining. Since full-thicknes biopsy demands surgery or other advanced methods (Ohlsson et al 2017), and immunostaining is rather time-consuming, diagnosing of enteric neuropathy is often not performed. This leaves the patient without any diagnosis and explanation to the symptoms, and thereby without specific treatment.
Aims and Methods: The aim of the present study was to examine if pathologic changes are present also in the submucosal plexa, and whether these changes could be identified with conventional hematoxylin & eosin (HE) staining. In 20 deceased cases of Parkinson's disease/ Parkinsonism with gastrointestinal symptoms, the intestinal tract was investigated for potential neuroganglionic disease. Ten cases of non-Parkinson, intestinally asymptomatic individuals, were used as controls. Small specimens from the jejunum were sampled, as well as specimens from the colon. The material was treated with standard histopathological procedures, i.e. fixed in formaldehyde solution, dehydrated and embedded in paraffin, then sectioned at 4 μmeter thickness and stained with HE and with immunostaining for alpha-synuclein.
Results: In 15 of these cases of Parkinson's disease, there were atrophic/pycnotic nerve plexus cells, i.e. signs of ganglionic degeneration in the submucosal and/or myenteric plexa, mostly in both. In some of the cases, the degenerative signs were mild, however corroborated by findings of positive alpha-synuclein immunostaining. In the remaining 5 cases, there was no marked micromorphologic signs of degeneration in the HE staining, but immunostaining revealed minimal alpha-synuclein deposits in 3 of these cases. None of the controls showed any signs of ganglionic degeneration.
Conclusion: It seems possible to identify a morphologic intestinal disease substrate in individuals with Parkinson's disease, showing signs of ganglion cell pycnosis and degeneration, visible in both submucosal and myenteric plexa. This finding may serve to indicate a potential of diagnosing a dysfunction in the autonomic nervous system by conventional histopathological methods, which could be the target of a therapeutic approach. Pathologic changes also in the more easily available submucosal plexa which can be reached endoscopically, and not only in the deeper myenteric plexa, facilitate the diagnosing. These histopathologic findings have to be examined along with assessment of long-term gastrointestinal symptoms and autonomic dysfunction, not only in Parkinson's disease, but also in patients with idiopathic symptoms and dysfunction.
Disclosure: Nothing to disclose

Introduction: Postural tachycardia syndrome (POTS) is a heterogeneous clinical syndrome characterised by a rapid increase in heart rate ($\geq$ 30 bpm) that occurs within 10 minutes upon standing, in the absence of orthostatic hypotension and other medical conditions or medications. Gastrointestinal (GI) symptoms are common in patients with POTS and impact on their quality of life. Our objective is to evaluate common GI symptoms, diagnostic work up, final diagnosis and management strategy in POTS.

Aims and Methods: We reviewed the complete medical records of all patients (aged 16 years and older) referred to a District General Hospital Gastroenterology Clinic over a four year period (2014–2017) with GI symptoms and known or suspected POTS. Patients without confirmed POTS were excluded.

Results: A total of 85 patients were included, with a mean age of 28.4 years, 92.9% were female. Constipation, bloating and abdominal pain were the most common GI symptoms in POTS. Gastrointestinal endoscopy, high-resolution manometry, gastric emptying studies and colonic transit studies were most commonly performed investigations. Among 85 patients, 59 (69%) had confirmed or suspected GI dysmotility. Twenty four patients (28%) had delayed colonic transit studies.

Conclusion: Non-functional GI symptoms prevalence is high among POTS patient therefore careful evaluation is required to provide an adequate diagnosis. The majority of patients with POTS and GI symptoms have a functional disturbance and reduced GI motility, however a small proportion have organic disease which needs systematic evaluation. Dietary modifications and laxatives are the main of treatments. Novel laxatives such as prucalopride and linaclotide are effective in managing dysmotility symptoms in patient with POTS.

Introduction: Chronic constipation is categorized into normal- (NTC) and slow-transit constipation. Therefore, patients not responding to therapy are often referred to tertiary centers in order to evaluate colonic transit time (CTT) and colonic manometry (CM). Colonic manometry (CM) is of additive value in the diagnostic workup of colonic motility, however, CM is an invasive, demanding procedure and is not readily available in all centers. Colonic transit time (CTT) as measured with radio-opaque markers is a less invasive procedure but it is claimed that colonic motor disturbances occur in both normal- and slow-transit and therefore, the relationship between colonic motor disturbances on CM and colonic transit time remains unclear.

Aims and Methods: The aim of this study was to assess the predictive value of CTT for colonic motor abnormalities on 24-hours colonic manometry in patients with chronic constipation in order to evaluate whether CTT studies might be helpful in determining for which patients CM is indicated. Prospectively collected data from patients undergoing both a CTT study as well as 24-hours ambulatory CM in our tertiary referral center were reviewed. Healthy volunteers were studied to obtain control values. CTT was measured using radio-opaque markers (X ray at day 4 after ingestion of 20 markers at day 0). A catheter with 6 solid-state pressure sensors was positioned endoscopically and clipped to the mucosa in the right colon in order to perform 24-hours ambulatory CM. CM was defined as abnormal when less than three high-amplitude propagating contractions (HAPC's), i.e. propagating waves with amplitude $\geq$80 mmHg over at least three sensors, were identified. Results are shown as mean $\pm$ SD and proportions and were compared using independent-samples T-test and chi square statistics.

Results: Data of 88 patients (77 women; 42.9 $\pm$ 13.8 years) and 12 healthy controls (10 women; 47 $\pm$ 14.4 years) were evaluated. Slow colonic transit (SCT) was based on CTT. Mean number of HAPCs per 24 hours was significantly lower in patients showing SCT compared to patients with normal colonic transit and controls (1.9 $\pm$ 2.2 vs. 4.8 $\pm$ 1.6 and 5.3 $\pm$ 3.0, $p < 0.001$ and $p < 0.001$ respectively). In total, 70 patients showed SCT, of which 49 (70.0%) showed abnormal CM. All 18 patients with normal colonic transit at CTT had normal CM. Therefore, the positive predictive value (PPV) of CTT for colonic hypomotility was 70% and the negative predictive value (NPV) was 100%.

Conclusion: This study shows that in the evaluation of patients with chronic constipation normal colonic transit, as measured by radio-opaque marker study, excludes abnormal colonic manometry with a NPV of 100% (i.e. based on number of HAPCs), whereas slow transit is a strong indicator for finding motor disturbances on colonic manometry. Therefore, colonic transit studies appears to be helpful in selecting patients with chronic constipation for colonic manometry to further characterize colonic motility.

Introduction: Chronic intestinal pseudo-obstruction (CIPO) represents a severe form of chronic gut dysmotility. CIPO patients manifest with recurrent intestinal sub-occlusive episodes and severe symptoms causing significant morbidity and mortality. The intestinal microbiota is an important stimulator and regulator of gut motility. However, it is unknown whether gut microbiota is altered in CIPO and whether it is associated with the clinical presentation.

Aims and Methods: 1) To characterize the gut microbiota of patients with CIPO. 2) To identify demographic or clinical features associated with microbiota profiles. This is a prospective pilot study of CIPO patients and healthy controls at 2 tertiary centres in Hamilton, Canada and Bologna, Italy. Demographic and clinical data were collected by standardized questionnaires. Fecal microbiota analysis was performed using *Illumina* 16S rRNA gene sequencing.

Results: Fecal samples from 15 patients with sporadic CIPO (7 female, median age 38.6 $\pm$ 15 years) and 4 healthy age and sex-matched controls (2 female, 39.5 $\pm$ 9 years) were collected. Mean Body Mass Index was similar between groups (19.6 $\pm$ 3.3 vs. 21.7 $\pm$ 2.9 kg/m^2). A subset of CIPO patients (6/15) were on Total Parenteral Nutrition (TPN). Median age at onset of CIPO was 19 years (range 3–53). Most patients (11/15) had a history of intestinal resection. Overall, the microbiota profiles of CIPO patients were significantly different compared to healthy controls (Adonis test). CIPO patients exhibited marked dysbiosis, with a reduced relative abundance of Firmicutes, and a significant increase in Proteobacteria ($Q = 0.004$), mainly *Escherichia* species ($Q = 0.003$), compared to healthy controls. Bacterial richness (Chao index) and diversity (Shannon index) were significantly reduced in CIPO patients. There were no associations of microbiota profiles with clinical characteristics, as dysbiosis was present regardless of etiology, history of intestinal resection or TPN.

Conclusion: This is the first prospective series aimed at characterizing the intestinal microbiota of sporadic CIPO patients. We demonstrate that gut dysbiosis is a prominent feature of CIPO and is present regardless of clinical characteristics. It consists primarily in a predominance of the phylum Proteobacteria at the expense of Firmicutes. This provides a rationale for the evaluation of microbiota-based therapies for patients with CIPO.

Introduction: Small intestinal bacterial overgrowth (SIBO), with excessive and/or abnormal type of bacteria in the small bowel may play a role for the manifestation of Irritable bowel syndrome (IBS). We aimed to compare the prevalence of small intestinal bacterial overgrowth (SIBO) in patients with IBS and controls.

Aims and Methods: Using the search terms 'small intestinal bacterial overgrowth (SIBO)' and 'Irritable Bowel Syndrome (IBS)' or 'small intestinal bacterial overgrowth (SIBO)' and 'Functional gastrointestinal disorders (FGIDs)', 21 case-control studies that met inclusion criteria were identified when searching relevant databases. Prevalence rates for SIBO, relevant demographic and geographic data, and information on the diagnostic modalities were extracted and prevalence rates and 95% confidence intervals (CI) of SIBO in IBS and controls calculated. In addition, the influence of the diagnostic modality (breath tests, aspirate or biopsy and culture or both) was determined.

Results: The final dataset combined 21 independent studies that recruited 2,422 adult patients with IBS and 2,879 controls. Sixteen studies employed breath tests (five utilized glucose breath tests (GBT), seven utilized lactulose breath tests (LBT), two utilized xylose breath tests and one each utilized sucrose and fructose breath tests) and five studies utilized culture methods. Across all testing methods, the prevalence of SIBO in patients with IBS compared with controls was increased with an OR = 3.29 (95% CI 1.91–5.67), $p < 0.001$. In patients with IBS prevalence of SIBO was 37.04% (95% CI 35.11–38.96) as compared to 19.26% (95% CI 21.01–24.07) in controls. When the method of detection was

limited to breath tests, the prevalence of SIBO in IBS was 44.25% (95% CI 48.86–46.63) compared to 23.71% (95% CI 21.53–25.89) in controls. In contrast, based upon culture techniques, the prevalence of SIBO in IBS was 13.96% (95% CI 11.49–16.43) vs 5.03% (95% CI 3.9–6.17) in controls when the cut off value was 10^5 cfu/ml (colony forming unit/ml), and 33.51% (95% CI 30.14–36.88) vs 8.18% (95% CI 6.76–9.61) in controls when the cut off value was 10^3 cfu/ml. There was no evidence that the association between SIBO and IBS was influenced by publication bias. Only studies using culture and aspirate to diagnose SIBO have uniformly reported the prevalence of IBS in different subtypes. In IBS diarrhoea (IBS-D) the prevalence of SIBO was 25.91%, higher than that in IBS mixed (IBS-M) and IBS constipation (IBS-C) at 18.9% and 17.48% respectively.
Conclusion: Regardless of the diagnostic modalities, prevalence of SIBO is significantly increased in patients with IBS, especially in IBS-D when compared to controls. However, while culture-based diagnostic methods for SIBO are the gold standard, they yield substantially lower SIBO prevalence rates in IBS as compared to breath tests. This suggests that breath tests may overestimate the prevalence of SIBO and have insufficient diagnostic specificity for SIBO. While better diagnostic tests are required, it is critical to determine if SIBO in IBS is the cause for symptoms or a consequence of other abnormalities of gut function.

P1700 THE INFLUENCE OF THE DURATION OF THE DIABETES MELLITUS ON THE ANORECTAL FUNCTION

M. Reszczynska[1]
[1]*Wroclaw Medical University, Clinical Department of Gastroentrology and Hepatology, Wroclaw, Poland*

Contact E-Mail Address: g.reszczynska@gmail.com
Introduction: Diabetic enteropathy is one of the complications of diabetes. Long duration of the diabetes predisposes to different complications including those in the anorectal region.
Aims and Methods: The aim of the study was to evaluate the anorectal function with the use of the high-resolution anorectal manometry depending on the duration of the disease. Diabetic patients group with the disease history $\geq$ 10 years (group 1), the group with the disease history $<$ 10 years (group 2) and the control group included 35, 15 and 20 subjects, respectively. All patients completed the questionnaire (demographic and clinical data). The anorectal manometry was performed with the use of ManoScan 360 Sierra Scientific Instruments System. The following manometric parameters were evaluated: the maximum anal resting pressure (MRP), the maximum anal squeeze pressure (MSP), cough reflex, the push/strain maneuver, rectal sensation test and rectoanal inhibitory reflex (RAIR). Apart from the above mentioned parameters the following factors were also evaluated: length of the high pressure zone (HPZ), duration of sustain squeeze, anorectal pressure gradient, residual anal pressure (CR), rectal pressure during the push maneuver and the rectal compliance. Moreover, other parameters were calculated: MRP/MSP, MRP/CR (CR-residual anal pressure). Data are presented as mean $\pm$ SD.
Results: Patients with the diabetes history of $\geq$ 10 years reported anal region discomfort and incomplete evacuation more often than patients with the diabetes history of $<$ 10 years (13; 25 versus 1;6; $p < 0.03$, $p < 0.04$ respectively). MRP was 79.73 ± 23.52 mmHg, 96.85 ± 22.77 mmHg for group 1 and 2 patients respectively and 94.07 ± 12.96 mmHg for the control group; $p < 0.02$. MSP was 148.41 ± 62.51 mmHg, 203.31 ± 79.82 mmHg for group 1 and 2 patients respectively and 230.04 ± 59.79 mmHg for the control group $p < 0.01$. Group 1 and 2 patients had lower anorectal pressure gradient (-26.05 ± 26.33; -27.81 ± 38.01 respectively) and MRP/CR (1.19 ± 0.48; 1.29 ± 0.46 respectively) compared to the control subjects (-5.52 ± 29.56; 1.69 ± 0.56 respectively); $p < 0.05$; $p < 0.01$. Significant difference was found in the first sensation threshold between the group 1 and 2 patients (50.86 ± 28.11 ml, 38.00 ± 15.21 ml) and control group (28.50 ± 3.66 ml) $p < 0.01$.
Conclusion: Patients with the diabetes duration $\geq$ 10 years reported anal region discomfort and incomplete evacuation more often. Diabetic patients with the disease history $\geq$ 10 years had weakened function of external and internal anal sphincters than diabetic patients with diabetes history $<$ 10 years and control subjects. All diabetic patients had lower parameters used for the evaluation of push/strain maneuver (anorectal pressure gradient and MRP/CR) suggesting the appearance of dyssynergia more often. All had impaired visceral sensation manifested by higher threshold sense of the first sensation. The higher threshold of the above mentioned parameter was noted in the group of diabetic patients with the disease history $\geq$ 10 years compared to the group with the disease history $<$ 10 years.
Disclosure: Nothing to disclose

P1701 EVALUATION OF ANORECTAL FUNCTION IN DIABETES MELLITUS PATIENTS WITH DIABETES ENTEROPATHY SYMPTOMS

M. Reszczynska[1]
[1]*Wroclaw Medical University, Clinical Department of Gastroentrology and Hepatology, Wroclaw, Poland*

Contact E-Mail Address: g.reszczynska@gmail.com
Introduction: Diabetic enteropathy is one of the complications of diabetes. Symptoms such as chronic constipation, diarrhea or incontinence are important but often underestimated issues in interdisciplinary medical care.
Aims and Methods: The aim of the study was to evaluate the anorectal function with the use of the high-resolution anorectal manometry depending on the selected diabetic enteropathy symptoms.
Diabetic patients group with incontinence, constipation, chronic diarrhea and control group included 13, 15, 15, 20 subjects, respectively. All patients completed the questionnaire (demographic and clinical data).
The anorectal manometry was performed with the use of ManoScan 360 Sierra Scientific Instruments System. The following manometric parameters were evaluated: the maximum anal resting pressure (MRP), the maximum anal squeeze pressure (MSP), cough reflex, the push/strain maneuver, rectal sensation test and rectoanal inhibitory reflex (RAIR). Apart from the above mentioned parameters the following factors were also evaluated: length of the high-pressure zone (HPZ), duration of sustain squeeze, anorectal pressure gradient, residual anal pressure (CR), rectal pressure during the push maneuver and the rectal compliance. Moreover, other parameters were calculated: MRP/MSP, MRP/CR (CR-residual anal pressure). Data are presented as mean $\pm$ SD.
Results: MRP was 69.03 ± 26.15 mmHg, 81.89 ± 17.69 mmHg, 78.14 ± 26.49 mmHg for patients with incontinence, constipation and diarrhea respectively and 94.07 ± 12.96 mmHg for the control group; $p < 0.01$; $p < 0.04$; $p < 0.05$ respectively. MSP was 120.50 ± 72.57 mmHg, 140.63 ± 47.84 mmHg, 148.96 ± 77.10 mmHg for patients with incontinence, constipation and diarrhea respectively and 230.04 ± 59.79 mmHg for the control group; $p < 0.01$; $p < 0.01$; $p < 0.01$ respectively. Patients with diabetes and chronic constipation had lower anorectal pressure gradient (-30.64 ± 26.74) and MRP/CR (1.35 ± 1.69) compared to the control subjects (respectively -5.52 ± 29.56; 1.69 ± 0.56); $p < 0.03$; $p < 0.04$. Whereas patients with chronic diarrhea had only MRP/CR lower (1.28 ± 0.46); $p < 0.04$ from all the parameters used to evaluate the push/strain maneuver. Significant differences were found in the first sensation threshold between the symptomatic patients (50.00 ± 29.72 ml, 58.67 ± 37.20 ml, 38.00 ± 13.20 ml) and control group (28.50 ± 3.66 ml) $p < 0.01$; $p < 0.01$; $p < 0.02$ for incontinence, constipation and diarrhea respectively. Patients with diabetes and chronic constipation had higher threshold sense of urge to defecate (106.00 ± 47.48 ml) than control subjects (74.00 ± 9.40 ml) $p < 0.05$. RAIR was statistically significantly more often absent in the group of diabetic patients with incontinence, $p < 0.003$. Diabetic patients with incontinence and diabetic patients with chronic diarrhea had lower volumes of RAIR first time detection (31.54 ± 30.23 ml; 36.67 ± 30.39 ml) than the control subjects (52.50 ± 14.10 ml) $p < 0.01$; $p < 0.04$ respectively.
Conclusion: All diabetic patients with the symptoms of enteropathy had weakened function of external and internal anal sphincters. All diabetic patients had lower parameters used for the evaluation of push/strain maneuver (anorectal pressure gradient and MRP/CR) suggesting the appearance of dyssynergia more often. All had impaired visceral sensation manifested by higher threshold value of first sensation. Higher threshold value of urge to defecate was noted only in patients with chronic constipation. The absence of RAIR was more often noted in patients with incontinence.

Introduction: Irritable bowel syndrome (IBS) is one of the most common disorders among young adults. Various studies have demonstrated that use of probiotics can reduce the overall symptom of IBS, thus our aim was to evaluate the efficacy of probiotics products in the reduction of IBS symptoms after colonoscopy
Aims and Methods: Our patients were divided among three groups, including immediate probiotics users (21F, 12M, 32.97 ± 10.79 years old), start use of probiotics one month after colonoscopy (19F, 13M, 30.941 ± 8.52 years old), and placebo group (22F, 12M, 35.15 ± 11.20 years old). All the patients were interviewed for having common IBS symptoms (stool consistency and frequency, gas, abdominal pain, and flatulence) at baseline, 3rd month of follow up and 6th month of follow up.
Results: The mean reduction in abdominal pain was 3.05 ± 1.21, 3.86 ± 0.94 and 3.82 ± 0.63 in the control group, immediate probiotic users and one month after colonoscopy, respectively (P value $<$ 0.001). On the other hand, the symptoms of the disease, such as stool consistency, the frequency of defecation and flatulence (except gas) in the first quarter, in the two treatment groups were significantly improved more than in the control group (P value $<$ 0.05). In contrast, in the second quarter, stool consistency, abdominal gas and bloating were improved only in the immediate probiotics users compared to the control group (P value $<$ 0.05), but the frequency of defecation was not significantly different in the treatment group receiving the probiotics month after colonoscopy compared to the placebo users (P value $>$ 0.05).
Conclusion: According to our results, use of probiotics had the beneficial effect on IBS symptoms. Furthermore, it can be said, however, reductions in symptoms and pain in the two treatment groups were not significantly different, but after six months of treatment, the effect of probiotics in patients who immediately use it after colonoscopy was more visible and more stable.

Introduction: Patient-reported outcome measures (PROMS) are crucial to assess the efficacy of therapeutic interventions, especially for disorders such as Irritable Bowel Syndrome (IBS), without a well-defined organic substrate and lack of validated biomarkers. The reliability of paper diaries is often affected by recall bias and fake compliance. To acquire more valid data, electronic diaries have been developed and implemented in recent years. However, little has been reported on the compliance rates of these diaries so far, and when available, the rates vary widely between studies.

Aims and Methods: Our aims were 1) to determine the compliance rate to a smartphone application in a randomised placebo-controlled trial (RCT) and 2) to identify sociodemographic and clinical patient characteristics associated with compliance rate.

The PERSUADE study (peppermint oil versus placebo) uses a smartphone application for patients to register their daily symptoms. IBS patients (ROME IV) were instructed to fill out this digital dairy during a 8-week treatment period. In addition, patients were asked to complete electronic questionnaires (via email, not smartphone), regarding demographics and life style, symptom severity (IBS-SSS), Quality of Life (IBS-QoL), and anxiety and depression (GAD-7, PHQ-9). Compliance rate was defined as the percentage of days completed in the diary.

Results: 154 (79.1% female, mean age 33.8) patients have been included so far. The mean compliance rate was high (86.6%, 10.5 SD). No association was found between age, gender, educational level, and compliance. Interestingly, the number of adverse events was positively associated with compliance (B 0.01, $p = 0.04$), whereas anxiety was inversely associated with compliance (B -0.05, $p = 0.01$). Moreover, overall compliance declined over time ($F(5.8, 886.4) = 6.07$, $p < 0.00$).

Conclusion: This study demonstrates that compliance to this smartphone application is, on average, more than 80%. However, the compliance rate decreased over time, which might suggest that this method is less suitable to measure treatment efficacy over long periods of time.

Disclosure: The PERSUADE trial in part funded by WillPharma.

P1704 ADHERENCE TO DIET LOW IN FERMENTABLE CARBOHYDRATES AND TRADITIONAL DIET FOR IRRITABLE BOWEL SYNDROME: WHAT ARE THE CHALLENGES AND OPPORTUNITIES?

Introduction: Dietary interventions in irritable bowel syndrome (IBS) include a diet low in fermentable oligo-, di-, monosaccharides and polyols (FODMAPs) and a traditional IBS diet, which focuses on eating habits more than dietary composition.

Aims and Methods: We aimed to evaluate how well IBS patients adhere to common dietary guidelines, which specific food groups prove troublesome to replace, and which dietary shifts predicted a symptom response. This is a post-hoc analysis of a previously published RCT (Böhn *et al Gastroenterology* 2015), in which IBS patients ($n = 66$) were randomised to a 4-week low FODMAP diet or a traditional IBS diet. Participants completed 4-day diet diaries before and near the end of the intervention, and reported symptoms using the IBS symptom severity scale (cut-off for responder status was an improvement by 50 points). We evaluated compliance and general changes to the diet by principal component analysis, and described which specific food groups were reduced, replaced, or retained during the intervention. Discriminant analysis was used to investigate dietary changes predictive of responder status.

Results: Compliance with the low FODMAP guidelines was good and consistent: all patients had a comparable shift in the diet's principal components. High FODMAP fruits, nuts, and grains were largely replaced by low FODMAP equivalents (97%, 100%, and 54% of baseline consumption, $p < 0.001$, Table 1). Intake of confectionery and snacks was reduced by 69% ($p < 0.001$). High FODMAP vegetables were reduced by 88%, but poorly replaced, leading to a 17% loss of total vegetable intake. Total energy intake fell by 25% in the low FODMAP arm ($p < 0.001$). The traditional IBS diet did not lead to a major shift in the diet's principal components. Despite the traditional IBS guidelines, there remained high consumption of coffee (73% of baseline consumption), alcohol (54%), cabbage, onions, and legumes (67%, Table 1). Pizza and carbonated beverages were fully excluded. Total energy intake fell by 11% in the traditional IBS diet arm ($p = 0.15$). In both diets, responder status was predicted by reduced consumption of alcohol and coffee and increased consumption of water and tea ($p = 0.03$).

Conclusion: In both the low FODMAP diet and traditional IBS diet, certain food groups were difficult to replace. Close dietary guidance may enhance the efficacy of these diets.

Product	Reduced	Replaced	Retained	P-value	Main replacement
Low FODMAP diet					
Grains	17	54	29	<0.001	Gluten-free equivalents
Dairy products	48	28	24	<0.001	Lactose-free equivalents
Fruits (e.g. apples)	0	97	3	<0.001	Fruits (e.g. oranges)
Cabbage/onions/legumes	49	38	12	0.002	Leaf & root vegetables
Nuts (e.g. cashews)	0	100	0	<0.001	Other nuts & seeds
Confectionery	69	–	31	<0.001	–
Traditional IBS diet					
Coffee	27	–	73	0.004	–
Alcoholic beverages	46	–	54	0.005	–
Carbonated beverages	80	–	20	0.013	–
Cabbage/onions/legumes	0	33	67	0.08	Leaf & root vegetables
High-fat foods	12	2	86	0.002	Low-fat equivalents

Introduction: The purpose of this study was to investigate whether the ingestion of alkaline-reduced water (ARW) is helpful in improving the symptoms of diarrhea-predominant irritable bowel syndrome (IBS).

Aims and Methods: Twenty-seven patients (male, 25.9%; mean 41.7 years-old) with diarrhea-predominant IBS were randomly allocated to two groups. For eight weeks, the ARW group ($n = 13$) ingested at least 2 liters/day of ARW, while the control group ($n = 14$) ingested placebo water. IBS symptom scores (quality-of-life, abdominal pain/discomfort), stool form and frequency were assessed before and after treatment via questionnaires.

Results: Eight patients (61.5%) in the ARW group and six patients (42.9%) in the control group indicated that their symptoms had improved in more than four out of the eight weeks of treatment ($p = 0.449$). The IBS quality-of-life score significantly improved from 57.2 to 30.8 in the ARW group; this improvement was significantly greater than the slight improvement from 48.7 to 42.2 observed in the control group ($p = 0.029$). The abdominal pain score improved from 1.8 to 0.9 in the ARW group, and from 1.8 to 1.1 in the control group, with no significant group difference ($p = 0.232$).

Conclusion: Drinking ARW for eight weeks improves the quality-of-life in patients with diarrhea-predominant IBS.

Disclosure: Nothing to disclose

Introduction: Patient self-management is central to IBS therapy and recommended in most guidelines. Self-help allows better understanding of the condition and promotes patient implementation of evidenced-based diet, lifestyle and behavioural changes that can improve symptoms. However, co-existent anxiety may limit the response to self-help programmes. We report the impact of anxiety and IBS symptoms following a dedicated education program.
Aims and Methods: We present preliminary data from a randomised controlled trial of two forms of educational therapy in IBS, live group sessions versus individual online education. The educational programme involved six consecutive sessions over 10 weeks. Sixty nine patients (53 f, mean age 34, range 19–69) were invited to participate. All had baseline and post-treatment HAD score and IBS-SSS to assess anxiety/depression and bowel symptoms severity, respectively. Fourteen patients completed online education and 27 the live group sessions.
Results: Forty-one patients completed the educational programme. There were 14 patients with IBS-C, 14 IBS-D and 13 IBS-M. HAD scores at baseline demonstrated 36 patients had anxiety, 12 (29%) borderline and 24 (59%) overtly high scores; for depression there were 7 (17%) with borderline scores and 10 (24%) patients case-level scores. Fifteen (37%) patients had both anxiety and depression. Mean baseline IBS-SSS was 369 (range 160–480). There was no correlation between anxiety and symptom severity scores at baseline ($r = 0.17$, $p = 0.36$). Table 1: IBS subtypes.
At the end of treatment, anxiety had improved in 5/12 patients as well as in 10/24 borderline cases. No significant reduction in depression was recorded at the end of the internvetion (2/17 cases improved). Mean anxiety scores fell from 15 at baseline to 8 ($p < 0.001$). IBS-SSS fell from 369 at baseline to 273 ($p < 0.001$). There was an excellent correlation between reduction in anxiety scores and reduction in IBS-SSS scores ($r = 0.453$, $p = 0.23$).
Conclusion: Anxiety is highly prevalent in patients with IBS. Education is an effective means for reducing anxiety and improving symptom severity. Identifying and reducing anxiety is a key part of managing IBS patients. Self-management programmes are effective in addressing this objective and may be the key mechanism through which such programmes help.

Variable	Patients at baseline (69)	Patients at follow-up (41)
Age (mean)	34	32
Sex (f)	77%	91%
IBS-D	48%	35%
IBS-M	29%	32%
IBS-C	23%	33%

Introduction: Irritable bowel syndrome (IBS) is a disorder with brain-gut-microbiome alterations. Gut-directed hypnotherapy (GHT) has been shown to improve quality of life and symptoms in IBS. This therapy targets psychological coping, central nervous processing and brain-gut interaction. Studies have also demonstrated effects of hypnosis on the intestinal microenvironment, gastric functions such as intestinal transit, and the mucosal immune system. So far, no study has examined the effect of GHT on the intestinal microbiome.
This study aimed at examining psychological distress, IBS symptoms, and microbial alterations before and after GHT.
Aims and Methods: 38 IBS patients (Rome-III criteria, mean age 44 years, 27 female, 11 male, 22 diarrhea-dominant, 12 alternating-type and 4 constipation-dominant IBS) were assessed with validated questionnaires in psychological (perceived stress, PSQ; psychological distress, HADS-D; quality of life, visual analogue scales) and IBS symptom-related variables (IBS severity, IBS-SSS; single symptoms, visual analogue scales) and fecal samples were collected before and after 10 weekly sessions of GHT. Faecal samples underwent microbial 16S rRNA analyses (regions V1-2, Illumina MiSeq) via QIIME pipeline.
Results: Significant reductions in psychological distress (7.0 [5.0–10.5] Median [Q1-Q3] vs. 5.0 [3.0–7.3], $p = .001$) and symptom severity (322 [264–373] vs. 264 [184–333], $p = .001$), and increased quality of life (105 [91–134] vs. 151 [120–195], $p = .001$] were observed after GHT. No differences were observable in microbial alpha diversity before and after GHT (chao1 2591 vs. 2581, $p = .92$).
Conclusion: Reductions in IBS symptoms and psychological burden were observed after gut-directed hypnotherapy. No systematic alterations were found in intestinal microbiota. Hypnosis seems to act predominantly by central modulation.

Introduction: There are conflicting data concerning the association between diverticular disease and colorectal cancer (CRC).
Aims and Methods: The aim of this study was to determine whether colonic diverticula are associated with colorectal adenomas.
In a case-control, retrospective study, we analysed the colonoscopy reports of complete colonoscopies with the diagnosis of colonic diverticula of all patients referred for screening colonoscopy between January 2011 and January 2016. As a control group, a same number of complete colonoscopies performed for colorectal cancer screening and without the diagnosis of colonic diverticula were randomly selected in the same period of time. Patients who met any of the following criteria were excluded from study participation: positive fecal occult blood test, history of previous colorectal surgery, CRC, known colonic polyps or polyposis syndromes. Advanced adenomas were defined as adenomas $\geq$10 mm and/or villous architecture and/or high-grade dysplasia.
Results: A total of 414 patients were included in this study, 207 in each group. In the group with colonic diverticula, the mean age was 67.2 ± 8.9 years, 52.2% female ($n = 108$). In the control group the mean age was 63.3 ± 10.6 years, 48.8% female ($n = 101$). One or more adenomas were detected in 30.4% ($n = 63$) of the patients in the colonic diverticula group and 26.1% ($n = 54$) in the control group ($p = 0.326$). One or more advanced adenomas were detected in 10.6% ($n = 22$) of the patients in the colonic diverticula group and in 6.8% ($n = 14$) in the control group ($p = 0.293$). One or more adenomas were found exclusively in a proximal location in 10.6% ($n = 22$) of patients in the colonic diverticula group and in 7.7% ($n = 16$) in the control group ($p = 0.689$). One or more adenomas were found exclusively in a distal location in 15.9% ($n = 33$) of the patients in the colonic diverticula group and 11.6% ($n = 24$) in the control group ($p = 0.572$).
Conclusion: No significant association was found in this series between colonic diverticula and colorectal adenomas or advanced adenomas. There was no association between colonic diverticula and proximal or distal adenomas.
Disclosure: Nothing to disclose

P1709 ASSOCIATION BETWEEN COLONIC DIVERTICULA AND THE DETECTION OF ADENOMAS AND SERRATED POLYP SUBTYPES DURING SCREENING COLONOSCOPIES OF INDIVIDUALS WITH AN AVERAGE RISK FOR COLORECTAL CANCER

C. Schramm[1], F. Kütting[1], S. Lang[1], P. Kasper[1], S.-H. Chon[2], H.-M. Steffen[1]

Introduction: Colonic diverticular disease is one of the most frequently diagnosed diseases of the lower gastrointestinal tract and includes a broad spectrum of disease manifestations ranging from asymptomatic diverticula to diverticulitis with associated complications like abscess formation and perforation. Studies investigating the association between colonic diverticula and colorectal polyps and cancer (CRC) have reported conflicting results.
Aims and Methods: We aimed to evaluate this association for all relevant different histological polyp subtypes, i.e. hyperplastic polyps (HPs), sessile and traditionally serrated adenomas (SSAs and TSAs, respectively), clinically relevant serrated polyps (crSPs), non-advanced and advanced adenomas, in an exclusive colonoscopy screening cohort. We conducted a retrospective analysis of individuals $\geq$50 years with average risk for CRC who underwent a screening colonoscopy between 01/01/2012 and 14/12/2016 at a tertiary academic hospital and 6 community-based private practices. Exclusion criteria were conditions with increased risk for CRC (e.g. chronic inflammatory bowel disease, history of CRC, hereditary cancer syndromes), previous colonoscopy at the same institution, and incomplete procedures.
Results: 4196 colonoscopies were included (mean age 63.4 ± 7.6 years, 48.6% men). Individuals with diverticula were significantly older (65.6 ± 8.0 years vs. 62.0 ± 7.0 years, $p = 0.001$), whereas there was no gender difference (40.2% vs. 37.2%, $p = 0.093$). Detection rates of HPs and non advanced adenomas were significantly higher in patients with diverticula (19.4% vs. 15.8%, $p = 0.001$, and 32.3% vs. 27.4%, $p = 0.003$, respectively). No differences were found with respect to detection rates of SSA, TSA and crSP. Corresponding odds ratios (OR) were 1.340 (95%-CI 1.133–1.584, $p = 0.001$) for the detection of HPs overall and 1.459 (95%-CI 1.208–1.763, $p < 0.001$) in the distal colon as well as 1.355 (95%-CI 1.144–1.604, $p < 0.001$) for non advanced adenomas in the distal colon. The mean numbers of different histological polyp subtypes per person with at least one of the histological polyp subtype detected were not different in the presence or absence of diverticula.
Conclusion: Hyperplastic polyps and non-advanced adenomas, but not advanced polypoid lesions were detected more frequently in the presence of colonic diverticula during screening colonoscopies of individuals with an average risk for

colorectal cancer. Our results suggest careful inspection especially of the distal colon when diverticula are present during colonoscopy.

P1710 CHANGES IN ASSOCIATION BETWEEN INHIBITORY MOTOR NEURONS AND CALCITONIN GENE-RELATED PEPTIDE IN COLONIC DIVERTICULOSIS

J.I. Lukosiene[1], A.G. Pauza[2], K. Rysevaite[2], J. Kupcinskas[1], Z. Saladzinskas[3], A. Tamelis[3], N. Pauziene[2]

Introduction: Colonic diverticular disease (DD) ranges among the most common benign disorders of the gastrointestinal tract (GI). Despite its ever-growing burden on the national health systems, high prevalence and complicated clinical management, over the years DD has drawn relatively little research effort and has repeatedly been named the "neglected disease"[1].
The etiology of DD is known to involve structural remodeling of the enteric nervous system (ENS) [2]. The ENS is an integrative network located along the wall of the GI tract. More than 30 neurotransmitters have been identified in the ENS which then interact to intricate peristatltic movements, initiating local reflexes to regulate motility and secretion [3].
Calcitonin gene-related peptide (CGRP) is a potent smooth muscle relaxant playing a significant role in the non-adrenergic non-cholinergic regulation of the GI tract motility. CGRP acts through a heteromeric receptor composed of a G-protein coupled receptor called calcitonin receptor-like receptor (CRLR) and a receptor activity-modifying protein 1 (RAMP1) [4] resulting in a further activation ofvasoactive intestinal peptide (VIP) and nitric oxide (NO) – two of the primary relaxant neurotransmiters of the intestinal musculature [5].
Aims and Methods: The aim of the study was to reveal associations between CGRP and vipergic and nitriergic neurons within myenteric (MP), inner (ISP) and outer (OSP) submucosal plexuses of the ENS, suggesting an altered relaxation mechanism during DD.
Control (n = 10, age: 50–75 years) and asymptomatic DD (ADD) (n = 10, age: 57–76 years) sigmoid samples were obtained from patients undergoing surgery for non-obstructing colorectal carcinoma if colonic diverticula were present and patient had no previous anamnesis of DD associated symptoms. Symptomatic DD (SDD) samples (n = 10, age: 39–80 years) were obtained from patients who underwent sigmoid resection or left hemicolectomy after recurrent attacks of diverticulitis. Double immunohistochemical staining for NO synthase 1 (NOS1) or VIP and CGRP or its receptors – calcitonin receptor-like receptor (CRLR) and receptor activity modifying protein 1 (RAMP1) – was performed on full-thickness sections of sigmoid colon and analysed with quantitative fluorescence microscopy.
Results: According to our data, along the wall of the sigmoid colon NOS1 and VIP positive neurons were found to be distributed unevenly – NOS1 positive neurons were mainly located within the myenteric plexus, while VIP positive neurons predominated throughout submucosal plexuses. Both NOS1 as well as VIP positive neurons were found expressing a significant amount of CRLR and RAMP1, demonstrating a close association with CGRP positive fibers and susceptibility to CGRP activation.
Quantification of fluorescence intensity revealed decreased CGRP levels within the enteric ganglia of the sigmoid colon of DD patients. In the MP, as well as in the ISP, the amount of CGRP decreased by 51.7% ($p < 0.0001$) and 52.4% ($p < 0.0001$), respectively. In the OSP, the decrease was less expressed and reached 27.8% ($p = 0.04$).
CRLR levels were increased within the enteric ganglia of SDD patients. Compared to CGRP, this reflected an opposite trend between the experimental groups. The greatest increase of 41.3% ($p < 0.0001$) was found in the OSP, whilst in MP and ISP CRLR was increased by 29.3% ($p = 0.008$) and 22.7% ($p = 0.022$), respectively.
Conclusion: In conclusion, CGRP has all the necessary components for direct activation of nitriergic and vipergic neurons within both enteric plexuses and this disbalance in neuronal activation may cause the disordered myorelaxation in DD.

Introduction: Diverticular disease, a prevalent condition in the general population, is frequently asymptomatic, but may also cause abdominal pain, diarrhea, and occult as well as overt bleeding, which are also common indications for endoscopic evaluation of the lower gastrointestinal tract. The Diverticular Inflammation and Complication Assessment (DICA) endoscopic classification has been shown to constitute a valid parameter to predict the risk of diverticulitis occurrence/recurrence in patients suffering from diverticular disease of the colon[1].
Aims and Methods: The aim of the present study was to determine the prevalence of diverticular disease in the population that undergoes a colonoscopy, and to identify clinical and demographic factors that are associated with an increased risk for this condition. Prospectively recorded and codified data of all lower endoscopies performed in adult patients at our Endoscopy Unit from April 2009 to March 2018 was retrieved and the following variables were analyzed: age, sex, indication to perform endoscopy, exam completion (cecum visualization), and endoscopic findings. For patients who underwent several endoscopic examinations, only the index endoscopy was considered (complete colonoscopy). Incomplete evaluations (due to poor intestinal cleansing, exam suspension for all reasons, and cecum intubation failure) were excluded from the analysis.
Results: A total of 36981 colonscopies were performed at our tertiary hospital during the study period; 11019 cases of multiple endoscopic controls in the same patient or of incomplete exams were excluded from the analysis. Of 25962 patients (F = 13003, 50.1%), mean age 60.9 (range 18–102.55), who underwent lower endoscopy, diverticular disease was found in 7936 patients (30.6%), with similar frequencies in male vs female patients. With respect to patients without diverticular disease, patients with this condition were older (mean age 58.17 ± 14.3 vs 67.23 ± 10.8, $p < 0.001$, respectively); abdominal pain (20.4%vs 18.3%), positive fecal occult blood test (23.2% vs 20.1%), and anemia (5.3% vs 4.1%) were significantly more frequent indications for colonoscopy in patients with diverticular disease with respect to those without ($p = 0.0001$ for all), whereas significantly less patients with diverticular disease ($p < 0.05$ for all) had positive family history of colorectal cancer (4.0% vs 6.9%), diarrhea (5.3% vs 6.5%), lower gastrointestinal bleeding (18.8% vs 21.8%), constipation (9.5% vs 10.4%) and a change in bowel habits (1.8 vs 2.2%) as the indication for colonoscopy. DICA classification, used in our center since March 2017, was available for 1347 patients; 754, 379, and 214 patients were grouped in DICA 1, 2, and 3, respectively. Polyps were more frequently found in association with diverticular disease (27.1% vs 23.0%, $p = 0.0001$), but neoplasms were significantly more frequent in patients without diverticular disease (1.4% vs 2.2%, $p = 0.0001$) than in patients with diverticula.
Conclusion: A frequent finding in all-cause colonoscopy, diverticular disease is associated with increasing age and with a lower incidence of colorectal cancer. The latter is probably due to the fact that patients with diverticular disease usually undergo colonoscopy at an earlier age, and for symptoms such as rectal bleeding, which allow for prompt polyp detection and removal.

P1712 THE EFFICACY OF LACTOBACILLUS REUTERI 4659 IN REDUCING ABDOMINAL SYMPTOMS AND INFLAMMATORY BIOMARKERS IN ACUTE UNCOMPLICATED DIVERTICULATIS: A DOUBLE-BLIND, RANDOMIZED, PLACEBO-CONTROLLED TRIAL

C. Petruzziello, F. Franceschi, M. Covino, A. Migneco, **V. Ojetti**
Fondazione Policlinico A. Gemelli, Emergency Medicine, Roma, Italy

Contact E-Mail Address: veronica.ojetti@gmail.com
Introduction: Diverticular Disease (DD) is the most frequent abnormality in the digestive tract mainly in developed countries.
Acute Uncomplicated Diverticulitis (AUD) is defined as the inflammation of a colon diverticulum, often involving colic wall and pericolic fat. Conventional treatment of AUD includes antibiotic therapy, usually Ciprofloxacin and Metronidazole, fasting and fluid therapy.
At the state of the art, no RCT versus placebo studies have been performed aimed at evaluating the clinical efficacy of probiotics in AUD, and so no definitive results have been achieved yet.
Aim of our RCT study is to test the efficacy of *Lactobacillus Reuteri* 4659 (*L. Reuteri*), a specific strain with anti-inflammatory effect in association with conventional antibiotics in treating AUD compared to conventional antibiotic therapy plus placebo.

Primary outcome of the study is the reduction of abdominal pain and inflammatory markers (C-RP) in the group treated with *L. Reuteri 4659* supplementation compared to placebo.
Secondary outcome is the comparison of the days of hospitalization between the two groups.
Aims and Methods: A double-blind, placebo RCT was conducted in 88 (34M/54F mean age 61.9 +- 13.9 years) consecutive patients who came to the Emergency Department of Foundation Policlinico A. Gemelli Hospital with a diagnosis of AUD. All patients performed routine blood test, dosage of C – reactive protein value and they were randomly assigned to two groups:
- Group A (44 patients, 26F), treated with ciprofloxacin 400mg twice a day and metronidazole 500mg three times a day for one week, with a supplementation of L. Reuteri 4659 twice a day for 10 days.
- Group B (44 patients, 28F), treated with ciprofloxacin 400mg twice a day and metronidazole 500mg three times a day for one week plus placebo twice a day for 10 days.
All patients filled a daily Visual Analog Scale (VAS) for abdominal pain, with a range value from 0 (asymptomatic) to 10, and C-RP value was determined on admission and at discharge.
Results: All patients completed the study. No side effect were observed.
As regards the VAS values: between day 1 and 3, group A decreased 4.5 points of VAS scale, group B decreased 2.36 points of VAS scale ($p < 0.0001$); between day 1 and 5 group A decreased 6.6 points of VAS scale, group B decreased 4.4 points of VAS scale ($p < 0.0001$); between day 1 and 7 group A decreased 7.6 points of VAS scale, group B decreased 5.6 points of VAS scale ($p < 0.0001$); between day 1 and 10 group A decreased 8.1 points of VAS scale, group B decreased 6.7 points of VAS scale ($p < 0.0001$).
Regarding C-RP value, the difference between the admittance value and the discharge value was 45.3 mg/l for group A and 27.49 mg/l for group B ($p < 0.0001$).
Finally, group A has a mean of 4 days of hospitalization, meanwhile group B has a mean of 4.7 days of hospitalization ($p < 0.0001$).
Conclusion: Our RCT showed that the supplementation with *L. Reuteri 4659* in the standard AUD therapy, significantly reduce abdominal pain and inflammatory markers compared to placebo group, conducting also to a shorter hospitalization period, thus influencing also with an economical factor.
These interesting results could be due to the fact that *L. reuteri 4659* modulate cytokine production and reduce LPS-induced intestinal inflammation, expression levels of IL-6 and TNF-"mRNAs, and TLR4.

Introduction: Diverticular Disease (DD) has a chronic burden in Western aged people affected by other comorbidities. The multidimensional prognostic index (MPI) ia a validated non disease-specific prognostic index based on a comprehensive geriatric assessment in older patients. The aim of this study was assess the prognostic accuracy of MPI on long-term mortality in hospitalized elderly patients with DD.
Aims and Methods: In this prospective study with a 12-month follow-up, 41 hospitalized elderly patients (median 71 years, 33–92), affected by DD were enrolled. Within 48 hours since admission, the MPI score was calculated in all patients according to a validated algorithm that included information on basal and instrumental activities of daily living, cognitive status, nutritional status, the risk of pressures sores, co-morbidity, number of drugs and co-abithation. The patients were stratified in threee risk groups: low (MPI-1 value $\leq$0.33), medium (MPI-2 value 0.34–0.66), and high (MPI-3 $\geq$ 0.67) risk. The adjusted age-adjusted Charlson comorbidity index (ACCI) was calculated for all patients to assess the burden of comorbidities on survival. Kaplan-Meier curves of the survival probability according to the MPI was assessed to explore the association between MPI score baseline and mortality of the patient hospitalized.
Results: All patients had a median MPI of 0.44 (range 0.12–1.00). Patients were divided according their MPI grade: 11 patients (29%) were included in MPI-1 group, 16 patients (42%) in MPI-2 group, and 13 patients in MPI-3 group. Twelve-month mortality was significantly ($p < 0.05$) higher in MPI-3 group (9/11. 82%) than in MPI-2 (5/16, 31%) and MPI-1 (2/11, 18%) groups, with no difference between MPI-1 and MPI-2. Age, ACCI and MPI were predictive of mortality.
Conclusion: Our study demonstrated that MPI is a useful tool to estimate the risk of twelve-month mortality in hospitalized elderly patients affected by DD.

P1714 EVALUATING GASTROINTESTINAL MORPHOLOGY AND ENTERIC NERVOUS SYSTEM VIABILITY IN THE *DYSTONIA MUSCULORUM* MOUSE MODEL OF HEREDITARY SENSORY AND AUTONOMIC NEUROPATHY TYPE VI

Contact E-Mail Address: anisha.lg@gmail.com
Introduction: Hereditary sensory and autonomic neuropathy type VI (HSAN-VI) is a newly identified neuronal disorder caused by mutations in the human dystonin gene (*DST*). Patients may present with joint contractures, problems with eating and breathing, motor deficits, autonomic irregularities, as well as gastrointestinal symptoms such as chronic diarrhoea, and abdominal pain. Similarly, a mouse mutant known as *dystonia musculorum* (Dst^{dt}) also arises due to mutations in the dystonin gene. In our studies, we have also come to recognize certain gastrointestinal pathologies present within this mouse model. At the level of gross morphology, we have observed discolouration of the gastrointestinal tract, as well as an accumulation of gas, which often causes distension of the ileum, cecum, and colon.
Aims and Methods: As HSAN-VI and Dst^{dt} are primarily sensory neurone disorders, we hypothesize that the underlying cause for these gastrointestinal defects is due to impairments in the enteric nervous system. Here we aim to assess gut morphology by hematoxylin and eosin staining, evaluate the myenteric and submucosal plexuses by wholemount immunofluorescence staining, and assess function by GastroSense 750 tracking via *in vivo* imaging system.
Results: In late stage Dst^{dt} mice (postnatal day 15) we have observed small, but significant reductions in ileum villi width and crypt length, as well as decreased smooth muscle wall thickness at all levels of the gastrointestinal tract. Despite the reduced muscle size, motility as assessed by tracing of the fluorescent GastroSense 750 marker appears to be normal in Dst^{dt} mice. Investigation of the enteric nervous system also reveals no difference in markers for cell death (as determined by cleaved caspase 3, FluoroJade C, and TUNEL staining), though total number of neurones per ganglia still remains to be characterized.
Conclusion: Thus far we have observed no major changes to the enteric nervous system of Dst^{dt} mice. Although we have determined that dystonin isoforms are expressed in the enteric nervous system, their role my not be as critical to neuronal survival as in dorsal root sensory neurones. It may also be that autonomic dysfunction (possibly by the vagus nerve) could be responsible for observed gastrointestinal defects. Investigation into higher nervous system centres inputting onto the gut will be performed in future work.

P1715 GASTROINTESTINAL BLEEDING AFTER LEFT VENTRICULAR ASSIST DEVICE IMPLANTATION IS ASSOCIATED WITH A SHIFT TOWARD A PRO-ANGIOGENIC PHENOTYPE IN THE ANGIOPOIETIN AXIS

A. Edwards[1], C.M. Wilcox[1], S. Pamboukian[2], P. Mannon[1], **S. Peter**[1]

[2]*University of Alabama at Birmingham, Department of Medicine, Division of Cardiovascular Disease, Birmingham, AL, United States*

Contact E-Mail Address: ssugandha@uabmc.edu
Introduction: Gastrointestinal bleeding (GIB) occurs in approximately 20% of continuous-flow left ventricular assist device (CF-LVAD) recipients after device implantation, predominantly from angioectasias in the upper GI tract or small intestine. While a higher risk of GIB has been observed in CF-LVAD recipients with lower device pulsatility, a mechanism linking changes in hemodynamics to an increased rate of GIB has not been established. In a recent study LVAD implantation was associated with increased angiopoietin-2 (Ang-2) levels, a growth factor that promotes vascular destabilization, suggesting that alterations in the molecular regulation of angiogenesis may play a role in GIB in this population.
Aims and Methods: The aims of our study were to:
1. Compare levels of angiopoietin-1 (Ang-1), a growth factor with vascular protective effects, vascular endothelial growth factor A (VEGF-A), an inducer of angiogenesis, and Ang-2 in (a) CF-LVAD recipients vs. control patients and (b) in CF-LVAD recipients that developed GIB after device implantation vs. those who did not;
2. Assess whether CF-LVAD pulsatility and pulse pressure are correlated with levels of Ang-1, VEGF-A, and Ang-2.
To achieve our aims we recruited 24 participants from our institution, 12 with CF-LVADs (six of whom developed GIB after device implantation) and 12 age-matched controls with no history of heart failure or GIB. Each participant provided a peripheral venous blood sample. We measured VEGF-A and Ang-2 levels in serum samples with a magnetic bead immunoassay panel (MILLIPLEX®, EMD Millipore) and Ang-1 levels with an enzyme-linked immunosorbent assay kit (Abcam). Statistical analyses were performed with SPSS version 22.
Results: In CF-LVAD recipients as compared to controls, Ang-2 levels were higher (9674 pg/mL vs. 4456 pg/mL, respectively; $P = 0.001$) and Ang-1 levels were lower (5639 pg/mL vs. 8239 pg/mL, respectively; $P = 0.023$). There was no

difference in VEGF-A levels between the two groups. In CF-LVAD recipients who developed GIB after device implantation as compared to those who did not, Ang-1 levels were lower (4021 pg/mL vs. 7258 pg/mL; $P = 0.028$). Neither levels of Ang-2 nor VEGF-A differed between the two groups. While there was no correlation between CF-LVAD pulsatility index and levels of Ang-2, Ang-1, or VEGF-A, pulse pressure was negatively correlated with levels of Ang-2 ($r = -0.578$, $P = 0.003$) and positively correlated with levels of Ang-1 ($r = 0.496$, $P = 0.014$). There was no correlation between pulse pressure and VEGF-A.
Conclusion: CF-LVAD recipients in our study demonstrated a shift toward a pro-angiogenic phenotype in the angiopoietin axis, a main regulatory pathway of angiogenesis, with increased serum levels of Ang-2 and lower serum levels of Ang-1 as compared to controls. Additionally, lower serum levels of Ang-1 were associated with GIB following CF-LVAD implantation, suggesting a role for alterations in the regulation of angiogenesis in GIB in this population. Lastly, lower pulse pressure was associated with higher Ang-2 levels and lower Ang-1 levels, suggesting a link between the lower pulse pressures that follow CF-LVAD implantation and changes in the regulation of angiogenesis.

Introduction: Achalasia is an esophageal motor disorder characterized by incomplete relaxation of the lower esophageal sphincter (LES) and by the absence of esophageal peristalsis. Patients typically present with regurgitation, dysphagia, retrosternal pain, and marked weight loss. Exact pathogenesis of the disease still remain to be clarified while it has been known for more than 300 years. However, the most widely accepted hypothesis of the development of achalasia is that a viral infection or some other environmental factors trigger autoimmune response resulting in chronic inflammation that leads to myenteric neuronal loss and neuronal fibrosis in susceptible subjects who may be genetically predisposed. Therefore genetic factors may play an important role in its pathogenesis.
Aims and Methods: The aim of our research was to reveal candidate genes involved in pathogenesis of achalasia. We obtained 12 achalasia and 5 intact esophageal resection tissues from patients operated on because of achalasia and esophagus cancer respectively. We characterized whole-transcriptome profiles (47.231 gene transcripts) by using Illumina Human HT-12 v4.0 Expression Beadchips. Expression data were analyzed with Genome Studio data analysis software.
Results: We detected that 733 differentially expressed genes, of these, 519 were up-regulated in cases. Pathway analysis by KEGG online tool revealed that mostly upregulated genes were involved in the pathways of focal adhesion and smooth muscle contraction. Moreover miR-targeted genes expressed in muscle cell, epithelium and lymphocytes were also mostly upregulated.
Conclusion: To the best of our knowledge, our research is first transcriptomic study in Turkish patients with achalasia. We here firstly identify the candidate genes in pathogenesis of achalasia. However, further analysis is needed to reveal the gene interactions with each other and other pathways.
Disclosure: this study was supported by grants from Marmara University, Scientific Research Research Projects Committee (Project No:SAG–B-030114-0005)

P1717 CIRCULAR RNA_009414 /MIR-30C-2-3P AXIS PROMOTES GASTRIC CANCER VIA BCL9/WNT/β-CATENIN SIGNALING PATHWAY

X. Li[1], G. Zhang[2]
[1]*Nanjing Medical University The First Affiliated Hospital Dept. of Gastroenterology, Nanjing, China*
[2]*Jiangsu Province Hospital, Gastroenterology department, Nanjing, China*

Contact E-Mail Address: lixuan20091225@163.com
Introduction: Circular RNA (circRNA) _009414 is emerging as a vital regulatory molecule in the progression of different types of cancer and miR-30c-2-3p is reported to be embedded in BCL9's first exon. However, their function and specific mechanisms of action have not been fully elucidated.
Aims and Methods: The aim of this study was to identify a novel circRNA-microRNA-mRNA functional network in gastric cancer. Quantitative real-time polymerase chain reaction (qRT-PCR) was used to assess the relative expression of circRNA_009414 and miR-30c-2-3p in normal (GES-1) and gastric cancer cell lines (SGC-7901, AGS) as well as in tumor tissues. Gain and loss of function approaches were carried out to investigate the potential roles of circRNA_009414/miR-30C-2-3P in cell proliferation and apoptosis. Moreover, BCL9 was validated to be the target of miR-30C-2-3P, and miR-30C-2-3P targeted circRNA_009414 via luciferase reporter assay and RNA-pulldown. Western blotting was used to evaluate the protein expression of related signaling pathway. Finally, we confirmed the function in nude mice.
Results: In our study circRNA_009414 and BCL9 were increased in gastric cancer cell lines and tissues, while miR-30c-2-3p was decreased in gastric cancer cell lines and tissues. Overexpression of circRNA_009414 and BCL9 promoted cell proliferation and inhibited cell apoptosis, whereas knockdown them inhibited these effects. Overexpression of miR-30c-2-3p inhibited cell proliferation and inhibited cell apoptosis, while knockdown it promoted these effects. By further examining the underlying mechanism, we showed that circRNA_009414/miR-30c-2-3p axis inhibited expression of BCL9. RNA-pulldown confirmed that circRNA_009414 could bind to BCL9 and thus further suppress the expression. BCL9 downregulation subsequently inhibited the Wnt/β-catenin including c-myc and β-catenin.
Conclusion: Taken together, our results point to a novel regulatory pathway circRNA_009414/miR-30C-2-3P/ BCL9/ Wnt/β-catenin in gastric cancer which may be potential target for cancer therapy.

Introduction: MicroRNAs are a class of small non-coding RNAs involved in post-transcriptional regulation of gene expression. Deregulated microRNA profiles and their contribution to carcinogenesis have been observed in different types of cancer, making them a promising tools for cancer diagnosis and targeted therapy. However, their involvement in pathogenesis of the most common mesenchymal tumors of gastrointestinal tract – gastrointestinal stromal tumors (GISTs) – is not well defined yet.
Aims and Methods: The aim of this study was to evaluate the role of highly deregulated microRNAs in pathogenesis of gastric GISTs. Investigated microRNAs (hsa-miR-375, hsa-miR-200b-3p, hsa-miR-490-3p) were selected from sequencing and TaqMan Low Density Array validation data from our previous study on microRNA profiling in GIST. Potential targets of selected microRNAs were predicted using TargetScan (Release 7.1) database. Further functional analysis in GIST representing GIST-T1 cell line was performed after transfections of microRNA mimics and mimic negative control using a lipofection approach. Changes in target gene expression were detected using TaqMan primers and probes, protein expression analysis was performed using Western Blot technique. Alterations in cell viability and migration rate were evaluated by MTT and Wound Healing Assays. Statistical analysis was performed using the computing environment R.
Results: Increased amounts of hsa-miR-375 significantly reduced expression of its potential target gene *KIT* ($FC = 0.57$, $p < 0.05$), however KIT protein expression remained unchanged in GIST-T1 cell line. Overexpression of hsa-miR-200b-3p significantly reduced *EGFR* and *ETV1* gene expression ($FC = 0.7$ and $FC = 0.81$, respectively, $p < 0.05$) and significantly reduced levels of EGFR protein ($FC = 0.55$, $p < 0.05$). Analysis of physiological changes of GIST-T1 cells revealed that only hsa-miR-375 significantly reduced both viability and migration rate of GIST-T1 cells, while hsa-miR-200b-3p significantly reduced cell migration rate and showed slight, but not significant impact on cell viability. Hsa-miR-490-3p did not affect expression of its predicted target genes and was not further investigated.
Conclusion: Analysis of highly deregulated microRNAs in GIST-T1 cell line showed that microRNA hsa-miR-375 potentially targets known GIST associated oncogene KIT and therefore affects cell viability and motility. Another microRNA hsa-miR-200b-3p might be involved in GIST pathogenesis by targeting oncogenes EGFR and ETV1. Therefore, microRNAs hsa-miR-375 and hsa-miR-200b-3p should be further investigated as a potential components of GIST pathogenesis and a promising tools for targeted therapy in GIST.
Disclosure: Nothing to disclose

P1719 GRANULOMATOUS GASTRITIS : CLINICAL AND PATHOLOGICAL FEATURES

B. Raoua[1], A. Gueddiche[1], F. Aisseoui[1], S. Ben Amor[1], W. Ben Mansour[1], W. Bouhlel[1], H. Loghmeri[1], L. Safer[1]
[1]*Faculty of Medicine Monastir, Monastir, Tunisia*

Contact E-Mail Address: raouaraoua2009@outlook.fr
Introduction: Granulomatous gastritis is an infrequent lesion characterized by the presence of granulomas in the gastric mucosa. Etiopathogenic diagnosis is obtained only by combining morphological examination with clinical and laboratory investigations. The purpose of our study is to evaluate the clinical features and to determine the etiologies of granulomatous gastritis.
Aims and Methods: This is a retrospective study of all cases of granulomatous gastritis noted in the histopathological examination of gastric biopsies, collected between 2012 and 2016 in the department of gastroenterology in the university hospital of Monastir. The clinical, endoscopic, histological characteristics as well

as the associated lesions and the etiology retained of gastritis granulomatosis were noted.
Results: Fourteen cases of gastric granulomatosis included 6 men (42.9%) and 8 women (57.1%) with an average age of 39 years (21–65 years). The indication for endoscopy was dominated by epigastric pain in 6 cases (42.9%), chronic diarrhea in 4 cases (28.6%), anemia in 2 cases (14.3%) and vomiting in 1 case (7.1%). The discovery of granulomatous gastritis was fortuitous in 1 case.
Oeso-gastro-duodenal fibroscopy was abnormal in the majority of cases (92.8%), it showed antral gastropathy in 12 cases (erythematous gastritis in 6 cases and nodular gastritis in 6 cases). The granuloma was unique in 4 cases (28.6%) and multiple in 10 cases (71.4%). The location of the granuloma was antral in 8 cases, fundic in 1 case, and antro-fundic in 5 cases. Associated chronic gastritis was noted in 13 cases (92.9%). Regarding the etiology, eight of our patients (57.1%) had Crohn's disease and two, gastric tuberculosis (14.3%). In two cases, *H. pylori* was the cause of granulomatous gastritis. In the remaining patients, the final diagnosis was sarcoidosis (n = 1), lichen planus (n = 1). Six patients (42.9%) had Hp positive histological status.
Conclusion: In our series, Crohn's disease and tuberculosis dominate the etiologies of granulomatous gastritis. An association between *H. pylori* and granulomatous gastritis cannot be excluded and the confirmation of this link is based on the disappearance of this histological lesion after the eradication of this bacterium.

Introduction: Autoimmune atrophic gastritis (AAG) is an organ-specific autoimmune disease affecting the corpus-fundus mucosa of the stomach. Little is known regarding the pathogenic mechanisms underlying AAG. Chronic T cell-induced activation of B cells seems to be responsible for the local production of antiparietal cell autoantibodies, peripheral hallmark of AAG.
Aims and Methods: Aim of our study was to characterize immune cells infiltrating the gastric corpus mucosa of patients with AAG in comparison to control subjects. We isolated lamina propria mononuclear cells (LPMCs) from gastric corpus of six patients with AAG (mean age 58.3 ± 13.5 years, F:M ratio 2.0:1) and ten patients with functional dyspepsia (mean age 56.1 ± 15.1 years, F:M ratio 2.3:1) enrolled as controls. Freshly isolated LPMCs were stained with the following antibodies: CD45, CD3, CD4, CD8, CD19, CD56, CD66b and CD68, then analyzed by flow cytometry in order to identify $CD4^+$ and $CD8^+$ T cells, B cells, natural killer cells, neutrophils and macrophages.
Results: As shown in Table 1, the percentage of gastric B cells was significantly ($p < 0.05$) higher in patients with AAG (mean 26.7 ± 6.4%) than in those with functional dyspepsia (mean 9.9 ± 1.7%). Conversely, the frequency of all other immune cell types did not significanty differ between AAG and those with functional dyspepsia (Table 1).

Cell type	Autoimmune atrophic gastritis (n = 6)	Functional dyspepsia (n = 10)	P value
CD45+ LPMCs, mean ± SEM	39.8 ± 7.0%	29.6 ± 2.6%	NS
CD3+ T cells, mean ± SEM	41.5 ± 10.3%	61.9 ± 8.9%	NS
CD3+ CD4+ T cells, mean ± SEM	15.2 ± 3.1%	14.8 ± 2.3%	NS
CD3+ CD8+ T cells, mean ± SEM	43.6 ± 13.2%	48.2 ± 7.6%	NS
CD19+ B cells, mean ± SEM	26.7 ± 6.4%	9.9 ± 1.7%	< 0.05
CD56+ natural killer cells, mean ± SEM	2.3 ± 0.9%	4.5 ± 1.5%	NS
CD66b+ neutrophils, mean ± SEM	7.6 ± 3.1%	11.9 ± 2.8%	NS
CD68+ macrophages, mean ± SEM	4.3 ± 0.5%	10.2 ± 2.5%	NS

[Table 1. Frequencies of the main immune cell type subsets in the lamina propria of gastric corpus]
Conclusion: Amongst all the main gastric immune cell type subsets, we here described an increased frequency of lamina propria B cells in the gastric corpus of AAG patients. Further studies are needed to better clarify the putative pathogenic role of gastric B cells in AAG.

P1721 EVALUATION OF A NEW ASSAY FOR THE QUANTITATIVE DETERMINATION OF CALPROTECTIN IN HUMAN FECES (CALIAGOLD)

C. Paparella, A. Barazzutti, F. Vespasiani, G. Longo, J. De Giorgio, R. Lucini
Sentinel CH SpA, Milan, Italy

Contact E-Mail Address: cesarepaparella@sentinel.it
Introduction: The objective of this study is to evaluate the analytical and clinical performances of a new assay for the quantitative determination of calprotectin in human feces (CALiaGold) on SENTiFIT 270 analyzer. The presence of calprotectin in human stool specimens is intended as an aid in the assessment of intestinal mucosal inflammation. The assay results can be useful in distinguishing organic, inflammatory disease of the gastrointestinal tract (inflammatory bowel disease, IBD, e.g. Crohn's disease or ulcerative colitis, UC) from functional disease (irritable bowel syndrome, IBS), in patients with chronic abdominal pain, and as an aid to IBD monitoring.
Aims and Methods: The CALiaGold test is a particle enhanced turbidimetric immunoassay (PETIA) and allows quantification of calprotectin in fecal extracts. Fecal samples are dissolved in the extraction buffer using the CALiaGold Tube device. The extracts are incubated with reaction buffer and mixed with polystyrene nanoparticles coated with calprotectin-specific antibodies (immunoparticles). Calprotectin in the sample mediates immunoparticles agglutination. Sample turbidity, measured by light absorbance, increases with calprotectin-immunoparticle complex formation and is proportional to the calprotectin concentration. The detected light absorbance allows quantification of calprotectin concentration via interpolation on an established calibration curve.
Results: The Limit of Blank (LOB) (1 saline sample × 20 replicates × 3 runs) was 12.2 ug/g. The Limit of Detection (LOD) (1 sample at 4-fold LOB concentration × 20 replicates × 3 runs) was 18.3 ug/g. The Limit of Quantitation (LOQ) (8 dilution levels starting from sample at concentration 100 ug/g × 10 replicates × 1 run) was 21.3 ug/g at%CV lower than 20%. The Intra Assay (3 runs × 3 samples × 20 replicates) gave 6.6% CV at 50.7 ug/g (Level 1), 4.3% CV at 115.5 ug/g (Level 2), and 6.7% CV at 1576.4 ug/g (Level 3). Total imprecision study (44 testing days × 2 runs × 2 observations × 4 level samples – during total time of 66 days) gave 6.7% CV at 59.1 ug/g (Level 1), 3.3% CV at 161.3 ug/g (Level 2), 2.0% CV at 509.9 ug/g (Level 3), and 2.3% CV at 1435.2 ug/g (Level 4). The test was linear up to 2249.5 ug/g, considering the% bias versus theoretical concentration lower than ± 10% for each dilution point of linearity curve. Reagent on board stability was up to 66 days, obtaining% bias versus Time 0 (mean value) -4.6% at 60.0 ug/g (Level 1), 0.0% at 161.4 ug/g (Level 2), -0.6% at 509.5 ug/g (Level 3), and -0.2% at 1433.2 ug/g (Level 4). This test (y) was compared with Bühlmann fCAL turbo on Architect c16000 (x) that uses the same methodology and gave the following results: y = 8.17 + 1.00x; correlation coefficient (r) = 0.979; number of samples = 114. The test is not affected by the presence of conjugated bilirubin up to 0.5 mg/L, hemoglobin up to 0.07 g/L, lipids up to 1.2 g/L. There is not Hook effect/antigen excess up to 1323.9 ug/g. High concentration samples (up to 10000 ug/g) were flagged by the instrument (no false negative results).
Conclusion: Analytical and clinical performances of CALiaGold assay on SENTiFIT 270 analyzer meet the requirements for its use as quantitative determination of calprotectin in human feces. Specificity and precision make this assay very suitable for routine measurement of this analyte.

Introduction: *H. pylori* may not the only one that could colonize in the gastric mucosa, and the other potential pathogens may trigger gastric disease except for *H. pylori*. [1] Hosts select gastrointestinal microbiota mainly by secretary of immunoglobulin A (IgA). [2] IgA binds those bacteria invading into the mucosal epithelium and threating the host, therefore identifying the IgA-coated bacteria can give an insight into the potential pathogens in the stomach. [3]
Aims and Methods: To investigate the IgA-coated gastric bacteria, gastric juice specimens without bile, blood and other contamination were collected from 12 individuals during endoscopy examination. Six cases were diagnostic with chronic atrophic gastritis and the others were non-atrophy gastritis. We used Flow Cytometer to separate the IgA positive and IgA negative bacteria in gastric juice. Firstly, bacterial flora from the gastric juice were extracted by centrifugation. Then gastric microbiota were strained with FITC-conjugated Goat Anti-Human IgA alpha chain (Abcam) and Goat IgG FITC – Isotype control after fixing and washing. Sorting of IgA+ and IgA- bacteria was performed by flow cytometer (BD FASC Aria III). V4 region of 16S rDNA gene sequencing was performed by MiSeq sequencer (Illumina). Species relative abundance in the IgA positive (P group), negative (N group) and the total bacterial flora (T group) was acquired by bioinformatics analysis. IgA-coating index (ICI) was use to assess the affinity of bacteria with IgA.
Results: The proportion of IgA positive bacteria in the gastric juice of atrophic gastritis was higher than that from non-atrophic gastritis juice (35.55% vs. 23.15%), though there was no statistical difference. ICI of *Rothia aeria* and *Rothia dentocariosa* were as high as 19.2 and 18.2 respectively, while the ICI of *H. pylori* was about 6.8. And other species with a higher ICI than *H. pylori* were *Streptococcus anginosus* (8.6), *Streptococcus infantis* (7.9), and *Prevotella*

melaninogenica (6.9). The average relative abundance of those species in T group were higher than *H. pylori*. And Kruskal test indicated significant different average relative abundance of those species between group N and P.
Conclusion: The high affinity of *Rothia aeria, Rothia dentocariosa, Streptococcus anginosus, Streptococcus infantis and Prevotella melaninogenica* with IgA in the stomach indicates that they may be the potential pathogens in the stomach.
Disclosure: Nothing to disclose

Introduction: Reactive oxygen Species (ROS) are physiologically produced within the organism but, when their concentration increases, exceeding the physiologic capacity of repair, they induce ''oxidative stress'', a condition that can be seen in many chronic inflammatory processes and in autoimmune diseases as well. The most relevant damage, hitting genomic DNA, involves the formation of 8-hydroxydeoxyguanosine (8-OHdG), a biomarker identified in gastric carcinogenetic processes and gastric cancer[1].
Aims and Methods: This study, which, in our findings, is the first one to consider the relation between oxidative stress and gastric autoimmune disease, was aimed at investigating the presence, the entity and the characteristics of oxidative stress in autoimmune atrophic gastritis (AAG) compared with multifocal *H.pylori* related gastritis (MAG) and superficial non atrophic gastritis (SG).
The study included 90 patients sub-grouped in 40 with AIG, 24 with MAG and 26 SG. dROMs test for the detection of ROS was performed in the serum of 37 AIG and 9 MAG patients and the test levels were subclassified in borderline, mild, moderate, high and very high. The levels of 8-OHdG were investigated by HPLC in gastric biopsies of 40 AIG patients, 24 MAG and 26 SG. The OLGA staging system was used for staging gastric damage. Levels of PgI, PgII and gastrin (ELISA) were evaluated in AIG patients. Statistics was performed using Kolmogorov-Smirnov test, t test, chi square and Fisher's exact test. We also performed linear regression, ROC curves, Odds Ratios, sensitivity and specificity tests.
Results: ROMS levels in AIG and MAG were similar, with medium/high levels in 62% and 55.5% of the cases, respectively. 8-OHdG values were lower in AIG and SG with respect to MAG (mean ± SEM: 17 ± 3, 20 ± 3 and 32 ± 6 adducts/105dG, respectively), with a statistically significant difference overall ($p = 0.016$), strongly supported by the difference between AIG and MAG ($p < 0.01$). A trend towards a significant difference ($p = 0.06$) was found comparing OLGA 1–2 AIG vs OLGA 2–3. Lastly, a cut-off for 8-OHdG between AIG/SAG and MAG was calculated (AUC 68%, sensitivity 83%, specificity 50%, positive predictive value 82%, negative predictive value 52%), with 93% of AIG and 50% of MAG presenting levels lower than the cut-off. The OR of patients with 8OH-dG above the cut-off of having AIG was 0.08 ($p = 0.0002$).
Conclusion: Both AIG and MAG present high levels of oxidative stress. However, when the genomic oxidative damage is expressed as 8-OHdG, a carcinogenesis biomarker, AIG presents much lower levels of oxidative genomic damage than MAG that, conceptually, could correlate with the lower risk of neoplastic evolution of AIG.
Disclosure: Nothing to disclose

Introduction: We aim in this study to compare the effectiveness of eosinopenia in predicting response to cholangitis treatment with C-reactive protein and procalcitonin which are the other inflamatory reagents.
Aims and Methods: Patients who applied to our unit between September 2016 and September 2017 who have cholangitis diagnosis (cholangitis group) and who do not have cholangitis but have undergone ERCP by reason of choledoch stone (control group) were prospectively examined in our study. After having compared both groups in terms of eosinophil counts at time of application, additionally the relationship between eosinophil level and other inflamatory reagents (CRP and Procalcitonin) of the patients in cholangitis group during the period they are hospitalized at time of application was examined.
Cholangitis diagnosis and severity classification have been performed with Tokyo criteria (1) and examined in 3 groups according to disease severity. The patients with eosinohil count < 100 were considered as eosinopenic.
Results: 62 patients in cholangit group [(age average 66.9 ± 1.85 years old; 21 female (%41.2)], and 57 patients in the control group [(age average 57.3 ± 2.3 years old; 31 female (%73.8)] were examined (For age $p < 0.05$; For type $p < 0.05$). The average eosinophil count in the cholangitis group at time of application was 55.7 ± 10.5 10^3/uL while this count was significantly higher in the control group (201.8 ± 19.2 10^3/uL) ($p < 0.001$). 25 of the patients were Grade-1 (40%), 27 were Grade-2 (17%) and 10 were Grade-3 (17%) according to cholangitis severity. The higher the disease severity, eosinophil levels decrease and any statistical significance was not determined. (respectively 86.4 ± 22.4 10^3/uL, 40.1 ± 10 10^3/uL, 21.3 ± 7.6 10^3/uL; $p = 0.19$). ERCP process was applied on all patients (median 0 within (0–5) days) and the patients were followed-up for 3.5 ± 0.1 days in average after the ERCP. All patients were discharged with full recovery, eosinophil values tended to increase while CRP and Procalcitonin values tended to decrease to a statistically significant extent beginning from the second day.
ROC curve analysis suggested that the optimum eosinophil level cut-off point for cholangitis was 100.5 10^3/uL, with sensitivity, specificity, positive and negative predictive value of 87, 65, 72, and 81%, respectively (area under the receiver-operating characteristic curve = 0.877). According to this evaluation, eosinophenia is existing in 87% of the patients with cholangitis and this ratio was determined as 36.8% in the control group when the eosinopenia threshold is taken as < 100.510^3/uL ($p < 0.001$).
CRP upper limit was taken as 5 mg/L and this was taken as 0.15 ng/mL for Procalcitonine in the hospital laboratory where the study was performed. According to this, there was a distinct recovery in the number of patients whose eosinopenia recovered in 1st, 2nd, 3rd day beginning from hospitalization and at time of discharge (last day) (percentage of patients with eosinopenia is respectively 87, 68, 45, 45, 39%) while the ratio of patients whose CRP and Procalcitonin values became negative and recovered was determined lower (1.6% for 1st day, 3.2% for 2nd day, 3.2% for 3rd day, 4.8% at time of discharge for CRP and PCT).
Conclusion: Eosinopenia is an inflamatory reagent that may be used in patients with cholangitis. Its inexpensiveness and applicability everywhere are the most significant advantages.

P1725 EFFICACY OF HEMOSPRAY AND ENDOCLOT IN THE TREATMENT OF GASTROINTESTINAL BLEEDING: RESULTS FROM A TERTIARY REFERRAL CENTER

F. Vitali, A. Naegel, J. Siebler, M. Neurath, T. Rath
Ludwig Demling Endoscopy Center of Excellence, Department of Medicine, Division of Gastroenterology, University Hospital Erlangen, Erlangen, Germany

Contact E-Mail Address: harmf4@hotmail.com

Introduction: Gastrointestinal (GI) bleeding frequently leads to hospital admission and is associated with relevant morbidity and mortality, particularly in the elderly. Due to the increasing administration of direct oral anticoagulants in the last years and the emerging role of antiplatelet agents treatment of gastrointestinal bleeding may be challenging. Hemostatic powders (HP) represent novel ''touch-free'' and easy to use items for the management of gastrointestinal bleeding.
Aims and Methods: Our aim was to analyze the short-term (ST-within 72 hours-) and long-term (LT-within 30 days-) success for achieving hemostasis with HP and to directly compare the two agents Hemospray (HS) and Endoclot (EC) in their hemostatic efficacy. Data were prospectively collected on patients who received HS and EC between September 2013 and September 2017 for endoscopic hemostasis in our center. Patients were followed-up for at least one

month after index endoscopy and data analysis was performed after follow-up was completed.
Results: HP was applied in 154 consecutive patients (mean age 67 years) with GI bleeding in our center. Patients were followed up for at least 1 month (mean FU: 3.2 months). The majority of HP applications were in the upper GI tract (89.0%) with the following bleeding sources: peptic ulcer (35%), esophageal varices (7%), tumor bleeding (11.7%), reflux esophagitis (8.7%), diffuse oozing bleeding and erosions (15.3%). Overall ST success with HP was achieved in 125 pts (81.2%) and LT success in 81 patients (67%). Re-bleeding occurred in 26.6% of all patients treated with HP. In 72 patients (47%), HP was applied as a salvage hemostatic therapy, here ST and LT success were 93.1% and 64.3%, respectively, with re-bleeding in 31.9% of patients. As a primary hemostatic therapy, ST and LT success were 81.7% and 69.2%, respectively, with re-bleeding occurring in 21.9%. Subgroup analysis showed a ST and LT efficacy for cancer bleeding of 83.3% and 86.7%, for peptic ulcer disease of 81% and 56.2% and in patients under therapeutic anticoagulation of 80% and 60.5%. There was no statistical difference in the ST or LT efficacy between EC and HS for the various indications; however, HS was more frequently applied for upper GI bleeding ($p = 0.04$).
Conclusion: Both HS and EC allow for effective hemostasis with high ST success when applied as primary or salvage therapy. No differences in ST, LT success and re-bleeding between HS and EC were detected.

Introduction: Upper GI bleeding (UGIB) has a mortality of about 10% in United Kingdom (UK) despite advances in treatment. The current guidelines recommend dual modality of treatment which could include injection of adrenaline, argon photocoagulation or using endoscopic clips to achieve haemostasis. A recent addition to therapeutic options is Hemospray. Since June 2013, there have been reports from UK that it is useful as an adjunct in treatment of UGIB with most reporting success rates of 77%-85%. It has been suggested that it may not be reliable when used as the only mode of treatment.
Aims and Methods: We aimed to report our experience of using Hemospray in our centre over last 4 years (2013 to 2017). A retrospective review was carried out to select relevant patients between July 2014 and July 2017, using the trust endoscopy database. We looked at electronic records of patients who underwent an endoscopy & needed Hemospray as a mode of treatment for managing an acute gastrointestinal (GI) bleed. All relevant clinical data was compiled using electronic records.
Results: 45 consecutive patients (M = 31), with median age 72 years (range 35–91y) were included. The mean haemoglobin prior to endoscopy was 92 g/L. 40% were on anticoagulants or anti-platelets on admission. Of all patients who needed Hemospray, 43 had gastroscopies, 1 ERCP and 1 had colonoscopy. The details of diagnosis are in Table 1.
- 39 (86%) patients had Hemospray as adjunct therapy & all patients had complete haemostasis documented at the end of index procedure.
- It was used as the only modality of therapy successfully in 6 patients (4 with malignancy and 2 iatrogenic bleeds).
- Overall, 6/45 patients had a documented rebleed after discharge but within 4 weeks; 4 had bleeding vessels and were on warfarin or Ticagrelor; 2 patients had tumour related recurrent bleeding.
- Forrest classification applicable to 22 patients -1A (n = 3, 15%), 1B (n = 10, 46%), 2A (n = 3, 15%), 2B (n = 3, 15%), 2C (n = 2, 9%).
- 100% (n = 7) of UGIB related to malignancy responded to Hemospray (adjunct and monotherapy included).
- 30-day mortality was 24%(n = 11) with 3 deaths directly attributed to GI bleeding, 4 palliative secondary to malignancy and 4 multifactorial in elderly patients.

Conclusion: Our 4-year experience suggests that Hemospray can be a useful adjunct to conventional endoscopic therapy for acute GI bleed with success rates comparable to previous reports (nearly 85% in our cohort), with a rebleed rate of 14%. Rebleeding was observed to be higher when patients were on antiplatelets or anticoagulants. Our findings also suggest it could be useful as monotherapy for bleeding related to malignancies where other therapy may be impractical. More studies with larger numbers are needed to add to the evidence base.

Diagnosis	Number (n = 45)
Duodenal Ulcer	14 (32%)
Oesophageal/gastric ulcer	4(9%)
Malignancy related	7(15%)
Iatrogenic bleeding	7 (15%)
Other including unclear cause of bleed	13(29%)

P1727 70-DAY MORTALITY OF ADMISSIONS TO INTENSIVE CARE UNIT WITH UPPER GASTROINTESTINAL BLEEDING

J. Beig[1], V. Rajakrishnan[2], M. Stretton[3], M. Ow[4]
[1]*Hawkey Bay hospital, Gastroenterology, Hawkeys Bay, New Zealand*
[2]*Auckland, Auckland, New Zealand*
[3]*Northshore, ICU, Auckland, New Zealand*
[4]*Auckland City Hospital, Gastroenterology, Auckland, New Zealand*

Contact E-Mail Address: drjunaidyaseen@gmail.com
Introduction: Acute upper gastrointestinal bleeding (AUGIB) is a common hospital presentation. The incidence of UGIB in New Zealand is reported as 59.2 per 100,000 adults per year (1). The estimated mortality rate ranges between 6% and 10% (2), but can be even higher in patients admitted to the intensive care unit (ICU). There is very little data on what predicts outcomes of patients with UGIB requiring intensive treatment.
Aims and Methods: The aim of this study is to determine the 30-day mortality of UGIB post-ICU admission and potential risk factors that predict an outcome.
A retrospective analysis of all patients admitted to ICU at Middlemore Hospital with AUGIB from 2010 to 2015 was performed. The following characteristics were examined – demographics; comorbidities; mode of presentation; haemodynamic; urea, lactate, and coagulation profile at presentation; Rockall score; precipitating factors (anti-platelets; anticoagulation, NSAID's); cause of UGIB; endoscopic findings; and transfusion requirement. The primary outcome was 30-day mortality post-ICU admission. The secondary outcome was risk factors that independently predicted mortality.
Results: A total of 80 patients with AUGIB were admitted to ICU. Median age was 61 years (interquartile range 52–72). Bleeding from peptic ulcer was the most common endoscopic diagnosis (70%), followed by oesophageal varices (17.5%). Overall 30-day mortality was 11% (9/80), of which 78% (7/9) had UGIB as their primary cause of death. Logistic regression revealed high Rockall score and high lactate were significant independent predictive factors for 30-day mortality. On Receiver Operating Characteristic (ROC) analysis, these two variables, when combined, had the greatest accuracy (area under ROC curve 0.94, sensitivity 90%, specificity 90%) for predicting 30-day mortality
Conclusion: Patients presenting with AUGIB requiring intensive treatment have a high mortality rate of 11% at 30 days and, in the majority, this was due directly to GIB. High Rockall score and lactate at admission to ICU were the strongest independent predictors of 30-day mortality in patients presenting with AUGIB and should be used as prognostic markers to predict an outcome.
Disclosure: Nothing to disclose

Introduction: Antithrombotic (AT) drugs increase the risk of overt gastrointestinal bleeding (GIB) but their effects on clinical outcomes are not well established.
Aims and Methods: The aim of this study was to determine the effect of antiplatelet (AP) and anticoagulant (AC) drugs on rebleeding and mortality in patients with gross GIB.
This was a prospective study on all patients admitted to the American University of Beirut Medical Center with melena, hematochezia, hematemesis, or coffee ground emesis between Jan. 2013 and Feb. 2018. The patients' characteristics and clinical outcomes were compared among the following groups: (a) patients on any one or more antiplatelet (AP) only (aspirin, clopidogrel, ticagrelor, prasugrel, and dipyridamole), (b) patients on any anticoagulant (AC) only (warfarin, heparin, low molecular weight heparins, direct acting oral anticoagulants), (c) patients on combination therapy (AP and AC), and (d) patients on no AT therapy.
Clinical features associated with rebleeding and mortality were assessed using the Chi-Square and Student's t-tests, respectively. Stepwise Cox proportional hazards regression analysis was used to adjust for potentially confounding variables when assessing the association between mortality, rebleeding, and the following: type of AT therapy, age, Charlson Comorbidity Index (CCI), blood transfusion, severe GIB (systolic blood pressure < 100 mmHg, > 2 units of blood transfused or ≥ 2 units drop in Hb), stigmata of recent hemorrhage (SRH), and endoscopic therapy.
Results: Complete follow-up information for a mean of 22 months was available for 447 patients. The clinical characteristics of patients are shown in table 1. Patients on any AT were significantly older and had higher CCI than controls.

Abstract No: P1728

Table 1: Clinical characteristics and outcomes of patients based on antithrombotic medications on admission

		No antithrombotics (Control group) (170)	Antiplatelets only (148)	Anticoagulants only (75)	Antiplatelet and anticoagulant (54)	Total (447)
Age (SD)		60 (19)	74 (11) **	72 (17) **	75 (10) **	
Charlson Comorbidity Index (SD)		1 (2)	2 (2) *	2 (2) *	2 (1) *	
Male	N (%)	106 (62%)	104 (70%)	44 (59%)	30 (56%)	284 (64%)
Upper GIB	N (%)	105 (62%)	70 (47%)	41 (55%)	26 (48%)	242 (54%)
Lower GIB	N (%)	48 (28%)	60 (41%)	22 (29%)	19 (35%)	149 (33%)
Blood Transfusion	N (%)	83 (49%)	87 (59%)	55** (73%)	40** (74%)	265 (59%)
Severe Bleeding	N (%)	77 (45%)	76 (52%)	40 (53%)	30 (56%)	223 (50%)
Stigmata of recent hemorrhage	N (%)	50 (29%)	52 (35%)	26 (35%)	9 (17%)	137 (31%)
Endoscopic Therapy	N (%)	42 (25%)	47 (32%)	24 (32%)	21 * (39%)	134 (30%)
Rebleeding	N (%)	39 (23%)	23 (16%)	19 (25%)	8 (15%)	89 (20%)
Death	N (%)	22 (13%)	30 (20%)	31 ** (41%)	19 ** (35%)	102 (23%)

*: $p < 0.05$; ** $p < 0.01$ compared to control

The overall rebleeding and mortality rates were 20% and 23%, respectively. Of 277 patients admitted on AT drugs, 23 died in-hospital, and 169 were discharged on AT drugs.

After adjusting for confounders, predictors for mortality were: older age (HR = 1.037 per year increase, $p < 0.0001$), higher CCI (HR = 1.442, $p < 0.0001$), severe GIB (HR = 1.83, $p = 0.007$), and being on AC only (HR = 1.9, $p = 0.037$), while independent predictors of rebleeding were: older age (HR = 1.03 per year increase, $p < 0.0001$), higher CCI (HR = 1.4, $p < 0.0001$), severe bleeding (HR = 2.0, $p = 0.002$), and being on AC only (HR = 1.8, $p = 0.07$).

Compared to patients on AP only, patients on AC only were more likely to receive blood transfusions ($p = 0.03$) and to die ($p = 0.001$) (table1). After adjusting for confounders, the AC only group had a higher rebleeding rate (HR = 2.3, $p = 0.003$) and higher mortality (HR = 2.3, $p = 0.002$) compared to the AP only group.

Discharge AT drugs had no independent effect on mortality or rebleeding.

Conclusion: Overall re-bleeding and mortality in patients with GIB remain high and seem to be associated with AC therapy. The findings may inform risk stratification and decisions regarding continuation or discontinuation of AC.

Introduction: Gastric antral vascular ectasia (GAVE) is a rare cause of gastrointestinal bleeding (GIB). Patients often require regular blood transfusions and long-term oral or intravenous iron supplementation to manage symptomatic anaemia impacting on quality of life. Endoscopic therapy (ET) for GAVE includes argon plasma coagulation (APC), laser therapy and endoscopic band ligation. In some patients, these measures are not successful with significant effects on their health and quality of life. Radio-frequency ablation (RFA) may provide a solution in these patients.

Aims and Methods: A single-centre prospective study to evaluate the efficacy and safety of RFA in patients with GAVE refractory to first line ET.

The primary outcome was an increase in haemoglobin (Hb) 3 months after treatment. Secondary outcomes were a reduction in frequency of blood transfusions and/or iron (PO or IV) in the 3 months before and after RFA treatment. Endoscopic surface area (SA) regression of GAVE was analysed by 3 experts estimating % change in SA following treatment by examining images before and after treatment.

Methods: Patients who remained anaemic and/or transfusion or iron dependent after other ET were eligible. Other causes of GIB were excluded. Treatment with RFA was with focal RFA at 12J/cm2 with 3 applications to visible areas of GAVE under conscioussedation. Patients had up to 2 RFA treatments 6 weeks apart. Data were collected before and after treatment.

Results: 20 patients had RFA for refractory GAVE. The median age was 69 years (IQR 62–82). 17/20 (85%) were female. 13 were previously treated with APC, 4 with laser and 3 with band ligation. In the 3 months prior to treatment, 11/20 were on oral iron, 6/20 were on IV iron. 14/20 required regular blood transfusions prior to treatment, with 11 of these on both iron supplementation and blood transfusions. The median number of RFA treatments was 2 (IQR 1–2).

No patients had recorded complications of RFA. The mean pre-treatment Hb was 95.1g/L (95% CI 87.4–102.6g/L). The mean Hb at 3 months after final RFA treatment was 112g/L (95% CI 103.9 -120.1g/L). The mean change in Hb was +12.6 g/L (95% CI 11.7–24.3g/L) ($p < 0.0001$) (paired t-test)).

Post treatment, only 3/14 (21%) of the patients who required blood transfusions prior to the procedure had ongoing transfusions. Only 5/17 (29%) patients who were previously on iron had ongoing iron needs.

The mean surface area regression when scored by 3 expert endoscopists was 64.2.% (95% CI 56.3–72.1).

Conclusion: RFA for patients with symptomatic anaemia secondary to GAVE refractory to previous ET is a novel treatment therapy for a difficult cause of GIB. This feasibility study shows that this approach can significantly reduce blood transfusion dependence and iron supplementation in some patients with improved Hb after treatments. The required number of treatments is small and it appears safe.

P1730 MANAGEMENT OF ANTIPLATELET AND ANTICOAGULANT THERAPY IN PATIENTS WITH NONVARICEAL UPPER GASTROINTESTINAL HEMORRHAGE

C. Vogt[1], G. Allo[1], M. Bürger[1], P. Kasper[1], S.-H. Chon[2], U. Töx[1], T. Goeser[1], H.-M. Steffen[1], **C. Schramm**[1]

Introduction: Acute nonvariceal upper gastrointestinal hemorrhage (NVUGIH) is a frequent event with an estimated incidence of 40–150/100,000/year. The European Society of Gastrointestinal Endoscopy (ESGE) has published guideline recommendations on the management of antiplatelet (APT) and anticoagulant therapy (ACT) in patients with NVUGIH [1].

Aims and Methods: Patients who underwent esophago-gastro-duodenoscopy (EGD) at a single university hospital between 01/01/2016 and 31/12/2017 were screened for cases of NVUGIH. Inclusion criteria were endoscopically diagnosed NVUGIH and prior exposition to antiplatelet agents (APA) and/or anticoagulation (AC). Exclusion criteria were variceal bleeding, negative findings in EGD, and outpatient setting because of missing information on follow-up.

Following definitions were used to assess the management of APA and AC according to the ESGE guidelines:

Primary prophylaxis: APA should have been withheld. Resumption of APA was not included in the definition.

Secondary prophylaxis: APA should have been withheld and then resumed in case of high-risk endoscopic stigmata, or continued without interruption in case of low-risk endoscopic stigmata.

Dual antiplatelet therapy (DAPT): Both APAs should have been continued without interruption in case of low-risk endoscopic stigmata, or in case of high-risk endoscopic stigmata and high thrombotic risk. In case of high-risk endoscopic stigmata and low thrombotic risk, the second APA should have been withheld and low-dose acetyl salicyl acid (ASA) as first APA should have been continued without interruption.

ACT should have been withheld and then have been resumed within 15 days irrespective of thrombembolic risk.

Endoscopic stigmata were classified as high risk in case of Forrest Ia, Ib, IIa, and IIb and as low risk in case of Forrest IIc and III. High arterial thrombotic risk was defined as acute coronary syndrome < 12 months, elective implantation of a bare metal stent < 4 weeks, or drug eluting stent < 6 months. Major bleeding was defined as haemoglobin ≤8 g/dl on the day of endoscopy (day 0), drop of haemoglobin of ≥2 g/dl between day 0 and day 1 or need for transfusion of packed red blood cells. Blood products included platelets, fresh frozen plasma, and single or combination of coagulation factors. Follow-up was defined as time period between index endoscopy and hospital discharge or death.

Results: 316 out of 9,948 (3.2%) patients met inclusion criteria. Of these 68.4% were male, median age was 70.5 years (IQR 62–78). Management of APA for primary or secondary prophylaxis was assessed as not following guideline

recommendations in 37/83 (45%) patients. Age, gender, treating specialty, major bleeding, use of blood products, Charlson comorbidity index, admission to intensive care unit, need for reendoscopy, rebleeding or endoscopic stigmata were not associated with management of APA. Management of ACT was assessed as not following the guideline recommendations in 68/127 (53.5%) patients. After including the use of heparin in therapeutic dosage, number decreased to 61/127 (48%). In univariate analysis, age (66 years, IQR 57–74.75, vs. 73 years, IQR 66–78, $p=0.005$) and treating specialty (internal medicine 61.8% vs. 88.1%, $p=0.003$) were significantly associated with inappropriate management of ACT. All other patients received combination therapy.
Conclusion: Management of APA or AC in patients with NVUGIH was not according to current ESGE guidelines in a significant number of patients. Efforts need to be made to improve management of these patients as they are at an increased risk for cardiovascular events.

P1731 COFFEE GROUND VOMIT: DOES IT JUSTIFY AN URGENT ENDOSCOPY?

A. Khani, Y. Maksunova, M. Patel, K. Besherdas
Royal Free NHS Trust, Gastroenterology, London, United Kingdom

Contact E-Mail Address: aria.mkhani@gmail.com
Introduction: Coffee ground vomit is vomit that looks subjectively like coffee grounds. It is thought to occur due to the presence of coagulated blood in the vomit and hence is a common indication for inpatient admission and thereafter endoscopy. In an increasingly stretched inpatient endoscopy service it is important not to over burden it with endoscopies that could be performed safely as an outpatient.
Aims and Methods: Therefore, our aim is to evaluate the need for inpatient gastroscopy in patients who are deemed to have coffee ground vomiting. We hypothesize that patients with coffee ground vomiting do not have significant upper gastro intestinal bleeding requiring endoscopic intervention.
A single-center, retrospective analysis was performed on patients endoscopied for the primary indication of coffee ground vomiting. Data was collected and scrutinized from the Electronic Patient Records (EPR) and Unisoft endoscopy-reporting tool at Barnet and Chase Farm Hospitals, Royal Free London for 12 months of 2017. Gastroscopy reports were studied to see whether endoscopic therapy was required (defined as use of adrenaline injection, banding, clips, haemospray or gold probe). EPR was subsequently used to assess whether these patients had a significant drop in their haemoglobin (Hb) defined as a Hb drop $\leq$20g/dl. Two independent researchers carried this out.
Results: There were 2618 gastroscopies during the study period. Of these, 37 were indicated due to coffee ground vomiting with 29 being performed as an inpatient. Of these 29 patients, 27 (93%) had a significant drop in their Hb level prior to gastroscopy. One (3%) patient required endoscopic therapy. This patient had significant co-morbidty of ischaemic heart disease, hypertension, aortic valve replacement as well as a drop in Hb.
In total, 12 patients had a diagnosis of oesophagitis, 3 had erosive gastritis, 3 non erosive gastritis, 1 oesophageal ulcer, 3 duodenal ulcers, 3 non erosive duodenitis, 1 pyloric ulcer and 1 hiatus hernia. 4 gastroscopies were completely normal. There were no patients with cancer diagnosis. Each diagnosis was reported separately if the report contained more than one diagnosis.
Conclusion: From this study we conclude that in the majority of patients endoscoped for coffee ground vomit do not require intervention during endoscopy. This study confirms our hypothesis and adds weight to the notion that patients with coffee ground vomiting do not necessarily require inpatient gastroscopy despite a significant Hb drop. If findings from this study were to be repeated in other centers we may be able to discharge stable patients with coffee ground vomiting to early OPD endoscopy thus reducing length of stay and pressure on already stretched inpatient emergency workload.
Disclosure: Nothing to disclose

P1732 ORAL ANTICOAGULANTS AND UPPER GASTROINTESTINAL BLEEDING: POTENTIAL RISK FACTORS AND OUTCOMES – A SINGLE-CENTRE EXPERIENCE

Introduction: Acute nonvariceal upper gastrointestinal bleeding (AUGIB) is a common medical emergency requiring prompt management. Available data suggest that use of oral anticoagulants (OAC) is associated with more frequent AUGIB, mostly peptic ulcer-related, and more severe outcomes.
Aims and Methods: To identify patients with AUGIB who use OAC and determine the severity of bleeding, outcomes and potential contributing factors for adverse outcomes. Retrospective, prospective analysis of all patients over 18 years of age consecutively admitted for AUGIB in a tertiary centre in Latvia – Riga East Clinical University Hospital from November 2013 to December 2014. Patients were asked to complete a questionnaire regarding their history of OAC use and INR control. Data were collected on bleeding-related interventions, length of hospital stay and outcomes. Bleeding severity on endoscopy was evaluated according to Forrest classification. Data was analysed using SPSS 20.0.
Results: Two hundred thirty-six patients with AUGIB were identified (138 (58%) men and 98 (42%) women, mean age 62 ± 17.36 years). Twenty-seven (11.4%) patients used OAC (mean age 73 ± 11.3 years), mostly warfarin (n = 22, 82%). Only 5 (18%) of OAC users were on new OAC – dabigatran (n = 3, 11%) and rivaroxaban (n = 2, 7%). Sixty-seven percent of OAC users received this therapy for $>$ 2 years, most commonly because of permanent atrial fibrillation. Among OAC users 8 (30%) were on double antithrombotic (OAC+antiplatelet) therapy. The most common diagnoses in patients using OAC were haemorrhagic gastropathy (n = 5, 17%) and Mallory-Weiss syndrome (n = 5, 17%) and peptic ulcer disease (PUD), with Forrest IA, IIA and IIB bleeding with equal frequency (n = 4, 14% in each). Despite previously experienced spontaneous haemorrhages (n = 5, 18%) and episodes of severe bleeding, such as gastrointestinal bleeding, epistaxis and post-traumatic bleeding, (n = 8, 29.6%), most OAC users with AUGIB were not regularly controlling INR levels. One hundred eight patients (45.7%) were hospitalized in intensive care unit (ICU), most often with Forrest IIB PUD bleeding – 36 (33.3%). Of those hospitalised in ICU one was using OAC. There was no statistically significant difference in severity of PUD bleeding between OAC users and non-users ($r=-0.189$, $p=0.004$, *Pearson Correlation)*. There was also no statistically significant difference between OAC users and non-users in length of ICU stay ($p>0.05$, *Chi-Square Test*) and total length of hospital stay. Transfusion of red blood cells was required in 133 (56.3%) cases, fresh frozen plasma in 106 (44%) cases and cryoprecipitate in 39 (16.5%) cases. Surgery was performed in 37% of patients. Ninety-seven (41,1%) of all patients received vitamin K intravenously. Twenty-four (10%) patients died, two of them (8.3%) were OAC users.
Conclusion: OAC use was not associated with more severe ulcer bleeding, longer hospitalization in ICU or longer total hospital stay. OAC use-related bleeding could be minimised with thorough patient education about risks and regular INR control.

P1733 GASTROINTESTINAL BLEEDING, A SERIOUS COMPLICATION OF PATIENTS WITH ACUTE CORONARY SYNDROME

A. Ben Slama, M. Ksiaa, S. Hamdi, H. Jaziri, H. Aya, N. Elleuch, A. Jmaa
CHU Sahloul Faculty of Medecine, Gastroenterology, Sousse, Tunisia

Contact E-Mail Address: aida.benslama@yahoo.fr
Introduction: Gastrointestinal bleeding (GIB) is frequent in patients receiving anti thrombotic treatment. This situation is more delicate in patients with an acute coronary syndrome (ACS). There is no specific recommendation whether antiplatelet medications should be interrupted or not. The aim of this study is to evaluate the clinical outcome and therapeutic features of patients who developed a GIB during an ACS.
Aims and Methods: We retrospectively reviewed the medical files of patients with ACS who were complicated with GIB from January 2012 to December 2017. Clinical, biological and endoscopic findings were collected.
Results: One hundred sixty-five patients were included in our study. There were 68% males and 32% females. The median of age was 52 years. The average time between the ACS onset and GIB was 5 days. All patients had dual antiplatelet therapy (DAPT). Haemorrhage was externalized by hematemesis in 72% of the cases, melena in 28% and rectal bleeding in 12%. Upper endoscopy showed: erosive gastritis (24%), bulbar ulcer (28%), antral ulcer (16%), œsophagitis (20%), erosive duodenitis (2.6%),esophageal ulcer (8%), esophageal varices (2.6%), gastric varices (4%) an portal hypertensive gastropathy (2.6%). Colonoscopy revealed: diverticulosis coli (20%), angiodysplasia colic (45%) and colic polyps (35%). DAPT was maintained in all patients because of the high thrombotic risk. Patients had intravenous proton pump inhibitors and endoscopic management (adrenaline injection, argon plasma coagulation, variceal banding). Bleeding stopped in the majority (89.3%) of patients. Eight (10.7%) patients died after endoscopic haemostasis failure or because of an early recurrence.
Conclusion: GIB is a severe complication that can occur in patients with ACS. Management is based on medical treatment and endoscopic haemostasis.

P1734 ENDOSCOPIC APPLICATION OF HIGHLY MUCO-ADHESIVE POWDER (NEXPOWDER) FOR TREATMENT OF DIFFUSE OR REFRACTORY ACTIVE UPPER GASTROINTESTINAL BLEEDING (UGIB): PRELIMINARY RESULTS

D.H. Lee[1], B.W. Bang[1], S.-J. Hong[2], Y.-W. Shin[1], H.-K. Kim[1], K.S. Kwon[1]
[1]*Inha University Hospital, Division of Gastroenterology, Department of Internal Medicine, Incheon, Korea (Republic of)*
[2]*Soonchunhyang University College of Medicine Dept. of Internal Medicine, Bucheon, Korea (Republic of)*

Contact E-Mail Address: ldh@inha.ac.kr
Introduction: Upper gastrointestinal bleeding (UGIB) frequently leads to hospital admission and is associated with relevant morbidity and mortality. Although the conventional endoscopic hemostasis was usually effective in controlling UGIB but some have difficulty in achieving successful hemostasis depending on the location and severity of hemorrhage. Conventional endoscopic hemostasis require targeted therapy on bleeding focus. However hemostatic powder do not require target approach and can apply easily to bleeding site.
Nexpowder (Nextbiomedical Co., Incheon, South Korea) is a novel highly muco-adhesive hemostatic powder designed to be a simple endoscopic technique in applying to large surface areas even in difficult positions. Nexpowder consists of oxidized dextran and modified amino acid, and is thus, biodegradable and biocompatible. When Nexpowder contacts water, the oxidized dextran reacts with the amino acid, and becomes a highly muco-adhesive gel. The gel physically adheres to the ulcer base creating a mechanical barrier to achieve hemostasis.
Aims and Methods: The aims of the current study were to evaluate 1) the feasibility of the application of the highly muco-adhesive hemostatic powder inpatient with diffuse or refractory UGIB 2) re-bleeding rate on second-look endoscopy at 1 or 3 days after the procedure, 3) persistent rate of hydrogel on ulcer base at follow-up endoscopy.
The muco-adhesive hemostatic powder (3~6g) was sprayed endoscopically onto the bleeding site using a 7.5-Fr catheter passed through the operative channel of the endoscope.
Results: Eleven patients with diffuse or refractory active UGIB requiring endoscopic hemostasis were treated with Nexpowder. The etiology of bleeding was a post-ESD bleeding in 5 patients, ampullary bleeding in 2, ulcer bleeding in 2, and tumor bleeding in 2 patients. Application of the highly muco-adhesive hemostatic powder on the bleeding source was successful in all patients with no therapy-related adverse events (AEs). Immediate hemostasis was achieved in 11/11 (100%) patients. Recurrent bleeding within 3 days was observed in 1/11 patients 9.1%. The persistence rate of Nexpowder gel was about 80% at 1 day and 20% at 3 days after the procedure.
Conclusion: Despite the small number of patients in this study, we can find that Nexpowder is an effective method in achieving immediate hemostasis when used in diffuse or refractory UGIB. Nexpowder seems to have a successful hemostatic effect because the highly muco-adhesive gel attaches to the bleeding site to form a mechanical barrier and then the adhesive gel protect the bleeding site for more than one day. Therefore, muco-adhesive Nexpowder seems to be good option in patients with diffuse or refractory UGIB.

Introduction: Aortic esophageal fistula (AEF) can be classified as primary in the absence of previous surgery of the esophagus or aorta, and secondary in the presence of one of them. AEFs classically present with the Chiari triad: chest pain, sentinel hematemesis followed by exsanguinating hematemesis.
Aims and Methods: The aim of the study was to evaluate and characterize the clinical presentation and endoscopic findings and prognosis of AEFs detected by upper gastrointestinal endoscopy (UGE).
Between October 2014 and January 2018, 5 patients with AEFs were detected by UGE. The clinical presentation, comorbidities, endoscopic appearance, management and outcome of the patients were evaluated. Descriptive statistical analysis was performed.
Results: The mean age was 59.5 ± 11.9 years of which 4 (80%) were men.
Clinical presentation: Toracalgia-2 (40%), hematemesis-2 (40%), melena-1 (20%), abdominal pain-2 (40%) and anemia-1 (20%). In patients presenting with gastrointestinal hemorrhage, 3 (60%) cases had no hemodynamic repercussion. The lowest median value of hemoglobin in the first 24 hours was 8 g/dL.
Etiology: Primary – 3 (60%); secondary – 2 (40%).
All patients had cardiovascular comorbidities and 1 (20%) had oesophageal neoplasia. Antiplatelet agents were documented in 3 (60%) and antiplatelet agents in combination with anticoagulants were noted 1 (20%) patients.
Endoscopically, the median distance of the ulcer in the esophagus from the dental arch was 30 (Range – 22–35) cm. Active arterial bleeding was noted in 1 (20%), adherent clot to the base of the ulcer in 2 (40%) and an ulcer with evident endovascular stent mesh visible in the ulcer base in 2 (40%) patients.
The AEF were confirmed by computed tomography of the chest in all patients. Management of patients involved endovascular stent placement in 4 (80%), esophageal and endovascular stent in 1 (20%) and esophageal stent in 1 (20%) in the patient with esophageal neoplasia. There was a recurrence of bleeding in 3 (60%) patients. Mortality was documented in 4 (80%) patients after a median of 3.6 (Range – 2.9–7.5) months.
Conclusion: Aortic esophageal fistulas detected by endoscopy were more frequent in men in the 6th decade of life presenting as an ulcer in the middle third of the esophagus. The prognosis is poor despite endoscopic and endovascular interventions.

Contact E-Mail Address: joleonart@yahoo.com.ar
Introduction: Gastric varices are founded in 20% of patients with portal hypertension. Their bleeding rates ranges between 55 to 78%, associated to high mortality (45%). According to literature, management with N-butyl-2-cyanoacrylate shows initial hemostasis rates between 87% and 100%, while the rebleeding rates ranged between 24% and 50%. Severe complications related to the procedure (sepsis, thromboembolism, fistulas, adherence of the needle to the varix) are rare. Even though prospective studies are lacking, the linear echoendoscopy placement of coils associated to N-Butyl-2-Cyanoacrylate is a promising therapeutical option for the varix obliteration and the achievment of hemostasis. Besides, it enables to use less cyanoacrylate doses and thus decreases the risk of any complications
Aims and Methods: Retrospective, observational study of 106 patients having gastric varices who were treated in our unit with butyl-cyanoacrylate. A 0.5 ml of N-butyl-2-cyanoacrylate + 0.5 ml of lipiodol solution was used. 21 gauge sclerosis needles were used, and Olympus endoscopes. Procedures were performed under sedation with propofol.
Results: 106 patients were included, 41 women and 65 men, with a 54 year old average age (16–92 years). Portal hypertension (HTP) causes were: cirrhosis HTP (87.7%), non cirrhotic HTP (0.9%) and segmentary HTP (2.8%), 49% were Child A, 36.7% Child B, 9.4% Child C, 5 patients were not classified. Esophageal varices were classified as esophagogastric (GOV) or isolated gastric (IGV) in accordance with the classification of Sarín: 17.9% GOV-1, 44.3% GOV-2, 11.3% GOV-1 Y GOV-2, 22.6% IGV-I, 2.8% IGV-I and GOV-II).
In 94 patients having gastrointestinal bleeding, primary hemostasis was 88.6% successful, while the rest of the patients required one or more sessions, including 1 therapy combined with coils and surgical shunt after the 4 session failure. In the latter case, the endoscopic finding included active bleeding in 21 cases (19.8%), sticking clot in 11 (10.3%), red dots in 12 (11.3%), platelet plug in 34 (32%), ulcer on varix in 12 (11.3%), tumoral varices in 14 (13.2%).
Rebleeding rate during the 6-week follow-up period was 11.3%, they were re-treated with N-Butyl-2-cyanoacrylate, thus achieving the final hemostasis. In one patient, the greatest complication of treatment was thrombosis of the splenic vein.
Conclusion: The use of N-butyl-2-cyanoacrylate is a safe and efficient option for gastric varix management. To our knowledge, in accordance with the international literature, the achievements were as follows: primary hemostasis (88.6%); final hemostasis (99%), and rebleeding low risk and complications (1%). In order to obtain good results, it is essential to follow the technical recommendations during the injection methodology.

Introduction: In the treatment of peptic ulcer bleeding, various endoscopic treatment modalities are used depending on ulcer size, localization and clinical status of the patient. These modalities are; injection treatments (sclerotherapy etc), thermal treatments (argon plasma coagulation, soft coagulation, bipolar or monopolar cautery etc.) and mechanical treatments (hemoklips etc.). These treatment methods have advantages or disadvantages among themselves and there isn't a recommended standard treatment approach.
Aims and Methods: The aim of this study is to compare a relatively new method monopolar hemostatic forceps soft coagulation (MHFSC) and commonly used hemoclips (HC).
Between September 2016 and February 2018, patients with upper gastrointestinal bleeding who were diagnosed with Forrest 1a, 1b, 2a stomach or duodenal ulcer on endoscopic examinations were included in the study. Proton pump infusion therapy was started at the time of diagnosis to all patients and continued until 72 hours after the procedure. Patients were randomized to MHFSC and HC groups. The rates of primer hemostasis with MHFSC and HC were approximately 96% and 78.5%, respectively and we planned a total of 56 patients per group, considering an alpha error of 0.05 and to achieve statistical power of 80%. In patients who do not have adequate haemostasis with the first method, the other method applied. Rebleeding was defined as hemorrhage within the first 7 days after endoscopic hemostasis. Patients with stomach operation history, malignant ulcers, and patients who could not be followed for 7 days after discharge were excluded. Both groups were compared in terms of initial hemostasis

success, rebleeding rate, endoscopic procedure time to achieve hemostasis, and hospitalization time.
Results: During the study period, a total of 245 patients were referred to our clinic with hematemesis or melena. Emergency endoscopy was performed within 24 hours after the presentation of 238 patients. According to the study protocol, 126 patients were excluded from the study. 112 patients were randomized to the MHFSC (n = 56) and HC (n = 56) groups. The mean age was 61.36 ± 19.3 years and 80 (71.4%) were male. There was no statistically significant difference between the two groups in terms of demographic and laboratory parameters, drug use and underlying chronic diseases.
The initial hemostasis was achieved in MHFSC alone in 55 patients (98.2%) and HC group in 45 patients (80.4%) in HC group, higher in MHFSC group (p = 0.004). All 11 patients who were not able to receive the first hemostasis in the HC group were successfully treated with hemostatic forceps. One patient who could not undergo hemostasis with hemostatic forceps was stabilized by medical treatment and hemorrhage was not observed at 24th hour control endoscopy. Rebleeding was detected in ten patients (2 MHFSC, 8 HC). In the MHFSC group, the duration of endoscopic procedure (302 ± 87.8 vs 568 ± 140.4 s, p < 0.0001) and the length of hospital stay were shorter (3,50 ± 1,03 vs 4,37 ± 1,86 days, p = 0.016). None of the patients needed transcatheter embolization or emergency surgical treatment.
Conclusion: MHFSC method is is more effective and safe treatment method than HC and can be applied more rapidly in the endoscopic treatment of peptic ulcer bleeding.

Introduction: Opioid-induced constipation (OIC), a common side effect of opioid utilization in treating chronic non-cancer pain, is caused by the action of opioids on peripheral μ-opioid receptors in the enteric nervous system. Naldemedine (NAL), a peripherally acting μ-opioid receptor antagonist (PAMORA), has demonstrated consistent efficacy and safety in the treatment of OIC from two phase 3, randomised, placebo-controlled, double-blind clinical trials [NCT01965158 (COMPOSE-1) and NCT01993940 (COMPOSE-2)]. In both studies there were significant improvements in the frequency of Spontaneous Bowel Movements (SBMs) and in the OIC symptoms of incomplete evacuation and straining with NAL. Study subjects in these studies, who must have discontinued previous laxative therapy, were assigned to a once-daily, oral 0.2 mg dose of NAL or placebo (PBO) for 12-weeks. Other elements of study design, study participants, eligibility criteria, clinical characteristics, clinical assessments, and outcome measures, as well as results are reported by Hale et al (Hale et al. 2017). However, the effect of naldemedine on the treatment of OIC in laxative inadequate responders (LIR) has not been reported.
Aims and Methods: To understand the therapeutic effect of naldemedine in LIR relative to PBO as well as non-LIR subjects. A post-hoc analysis from pooling two phase 3, randomised, placebo-controlled, double-blind clinical trials (COMPOSE-1; COMPOSE-2) was performed in the LIR and Non-LIR subgroup. LIR was defined as subjects who were on laxative therapy prior to entering the study and those who stopped its use within 30 days prior to screening, and who signed the informed consent which required the subject to have self-reported OIC (ie, incomplete bowel movement, hard stools, straining, or false alarms). Non-LIR was defined as those subjects who did not receive laxatives or only received rescue laxatives at or after screening. SBM responders, defined as having ≥3 SBM/week with ≥1 SBM/week increase over baseline for ≥9 of 12 weeks and ≥3 of the last 4 weeks, were compared between groups. Treatment emergent adverse events (TEAEs) were defined as those that were reported after randomization and were assessed as well.
Results: A significantly higher proportion of SBM responders was observed in the NAL group as compared to PBO in both the LIR and non-LIR groups for both studies (Table 1). TEAEs were comparable between the NAL and PBO in both LIR and non-LIR groups. The most common TEAEs were gastrointestinal-related.
Conclusion: These data demonstrate that NAL is efficacious and well tolerated in the treatment of OIC in those subjects who were LIR or non-LIR. These results suggest that the effect of NAL is independent of previous laxative utilization and is a useful treatment option in the management of OIC in patients with chronic non-cancer pain.

Introduction: The interactions occurring in the gut microenvironment following gut microbiota manipulation are believed to play an important role in the pathophysiology of irritable bowel syndrome (IBS) and yet to be studied. A previous study demonstrated the role of mucosal factors in the pathobiology of IBS by conducting RNA sequencing of colon samples showing transcriptomic changes that affect neurotransmitters, ion channels, cytokines, immune function, cell adhesion and barrier function in IBS-diarrhea (IBS-D) patients [1]. The use of fecal microbiota transplantation (FMT) in IBS-D patients improves their symptoms and manipulates their gut microbiota [2].
Aims and Methods: In this study we conducted RNA-sequencing to evaluate disease biology in Formalin-Fixed Paraffin-Embedded (FFPE) tissue samples of duodenal mucosa of the same cohort of IBS-D patients before and after FMT. Twelve IBS-D patients received freshly donated feces from their family members' donors and were instilled via a gastroscope into the descending part of the duodenum. Biopsy samples were collected before and three weeks after FMT. They were fully characterized with full transcriptome next-generation RNA sequencing (NGS) of duodenal samples, both before and after FMT. Half of the patients had idiopathic etiology (n = 6) and the remaining half had post-infectious (PI) etiology. NGS libraries were prepared with the illumina TruSeq® RNA Access protocol and sequenced on an illumina HiSeq 4000 apparatus [3]. Assembly of reads and alignment was guided by Tophat and Bowtie. Comparative analysis was done using voom/Limma package in R software version 3.4. Quality expression filter for all mRNA species was set at 3 counts per million for at least 50% of the samples evaluated. Differentially expressed genes (DEGs) were considered significant with a p-value cut-off at 0.05 and fold change greater than 1,5.
Results: Both subgroups of IBS-D patients showed different characteristics of gene expression following FMT with 85 and 108 DEGs in the idiopathic and post-infectious group, respectively. Table 1 shows the differentially expressed *common* changes in gene expression and some known gastroregulatory hormones between the two subgroups of IBS-D patients before and after FMT, and their respective up- or down-regulation after FMT.
Conclusion: RNA sequencing appears to be complementary in identifying changes in mucosal mRNA expression of genes of interest. This is the first study to show that RNA sequencing of duodenal mucosa samples demonstrates transcriptomic changes that affect immune function, cell adhesion, ion channels,

Introduction: Interstitial cells of Cajal (ICC) are known as the pacemaker cells of gastrointestinal tract that regulate gastrointestinal motility. It was reported that small intestinal bacterial overgrowth induce intestinal dysmotility by decreasing ICC through antibody to vinculin, a cytoskeletal protein in gut, and it can be used as a biomarker for irritable bowel syndrome. However, there are no data on relationship between ICC and anti-vinculin antibody in human stomach. Thus, this study aimed to investigate correlation between levels of circulating anti-vinculin antibody and ICC density in inner muscular layer and myenteric plexus of human stomach.
Aims and Methods: Paraffin-embedded gastric specimens from 46 patients (mean age 65.1 years ± 11, male 78.3%, female 21.7%, Diabetes Mellitus 21.7%), with gastric cancer who received gastric surgery at Kangwon National University Hospital from 2013 to 2017 were used for immunohistochemistry. Each specimen was stained with c-Kit and DOG-1 specific antibodies, then number of positive cells in inner circular muscle, and myenteric plexus were counted. Corresponding patient's blood samples were used to determine the amount of anti-vinculin antibody by enzyme-linked immunosorbent assay (ELISA).
Results: The median concentration of anti-vinculin antibody was 0.12μg/mL (IQR 0.04–0.45), the median number of ICC in inner circular muscle with positive c-Kit stain was 93 per 2.5mm^2 (IQR 54–155), the median number of ICC in myenteric plexus with positive c-Kit was 60 per 2.5mm^2 (IQR 32–89), while the number of ICC in inner circular muscle with positive DOG-1 stain was 161 per 2.5mm^2 (IQR 25–337), and the number of ICC in myenteric plexus with positive DOG-1 stain was 31 per 2.5mm^2 (IQR 7–81). Level of circulating anti-vinculin antibody correlated significantly with density of ICC in myenteric plexus ($p = 0.008$; Spearman correlation). Increased level of circulating anti-vinculin antibodies were significantly associated with reduced number of ICC in myenteric plexus, but not inner circular muscle.
Conclusion: Increased level of circulating anti-vinculin antibody was significantly correlated with decreased density of ICC in myenteric plexus of human stomach, which suggest regulation of ICC expression by anti-vinculin antibody in patients with gastrointestinal dysmotility. Further studies are needed to determine such relationship in functional dyspepsia.

Introduction: Relamorelin (RLM) is a pentapeptide ghrelin receptor agonist with prokinetic effects, shown in Phase 2 trials to accelerate gastric emptying significantly and improve symptoms in patients with diabetic gastroparesis (DG). Ghrelin agonists may increase appetite and glycaemia.
Aims and Methods: The aim was to assess overall safety and tolerability of RLM in adults with DG using Phase 2 trial data. Randomised, double-blind, placebo-controlled Phase 2a and 2b trials (NCT01571297, NCT02357420; results published previously) were conducted in DG patients aged 18–75 years over 4 weeks (RLM 10 μg once or twice daily [BID] or placebo BID) and 12 weeks (RLM 10, 30 or 100 μg or placebo BID) with 1- and 2-week, single-blind placebo run-in periods, respectively. Safety assessments included weight, adverse events (AEs) and laboratory tests, including blood glucose and HbA1c. Analysis of covariance on the change from baseline (CFB) values was used post hoc to assess the effect of treatment on HbA1c and glucose; a test for linear trend was also performed. All other data were summarised descriptively.
Results: Among 204 Phase 2a and 393 Phase 2b patients, mean age was 56 years, 64% were female, 90% had Type 2 diabetes and mean (range) body mass index was 32 (18–60) kg/m^2. Proportions of patients with ≥1 treatment-emergent AE (TEAE) were generally similar across treatment groups (Table). TEAEs occurring in ≥5% of RLM-treated patients included headache and dizziness in Phase

Weight, kg, mean (SD) CFB[a]	−0.01 (1.6)	0.20 (1.6)	0.17 (2.0)	0.25 (2.6)	−0.07 (2.7)	0.59 (3.0)	0.46 (2.2)

[a]Study duration was 4 weeks for Phase 2a and 12 weeks for Phase 2b

2a, and hyperglycaemia, urinary tract infection and diarrhoea in Phase 2b. No cardiac TEAEs occurred in ≥2% of any RLM-treated group. In Phase 2b, discontinuations due to TEAEs were higher in RLM-treated patients compared to placebo. Incidence of serious TEAEs was generally similar between treatment groups. No specific serious TEAE was experienced by ≥1 Phase 2a patient; in Phase 2b, impaired gastric emptying was documented in two patients on placebo, one on RLM 30 μg and one on RLM 100 μg, and unstable angina was reported in two patients on RLM 30 μg, all assessed by the investigator as unrelated to study drug. One 100 μg RLM-treated Phase 2b patient died from urosepsis, unrelated to study drug. Treatment-emergent diabetic ketoacidosis (DKA) was experienced by three RLM-treated Phase 2b patients (one in each group), unrelated to study drug. In Phase 2a, one case of DKA occurred during the placebo run-in period (not considered treatment emergent). Over the Phase 2b study, the mean CFB to Week 12 HbA1c levels increased with RLM dose: mean (SD) values were -0.03 (0.86), 0.48 (1.03), 0.92 (1.53) and 0.81 (1.77) for placebo, RLM 10, 30 and 100 μg, respectively (test for linear trend $p < 0.0001$). A dose-related linear trend was also observed for fasting blood glucose ($p = 0.0043$). No clinically relevant changes in weight were observed (Table).
Conclusion: Phase 2 results indicate that RLM 10–100 μg BID is generally safe and well tolerated in adults with DG. Proactive glycaemic management will be incorporated into the planned Phase 3 trial due to increased blood glucose and HbA1c levels observed in RLM-treated patients.
Disclosure: MC (with compensation to his employer) and AL have received research funds to study relamorelin and serve on the Rhythm Pharmaceuticals advisory board. RM has received grants and consulting fees from Rhythm Pharmaceuticals. ST, LK, MM, KB and AI are employees of Allergan plc and own stock and stock options in the company.

P1742 COLD SENSATIONS AND HEARTBURN EVOKED BY ESOPHAGEAL INFUSION OF L-MENTHOL INDICATE EXPRESSION OF THE TRPM8 RECEPTOR IN ESOPHAGEAL C-FIBERS IN HUMANS

P. Banovcin[1], M. Duricek[1], P. Liptak[1], R. Hyrdel[1], M. Kollarik[2]
[1]*Jessenius Faculty of Medicine in Martin, Comenius University in Bratislava, Gastroenterology Clinic, Martin, Slovakia*

Introduction: The TRPM8 receptor is best known for its responsiveness to cold and menthol, however, TRPM8 was also implicated in amplification of nociceptive sensory signals. Recent studies in animals showed that C-fibers innervating the esophagus express TRPM8. Here we evaluated the translatability of this finding in humans.
Aims and Methods: We hypothesized that the infusion of the TRPM8 activator L-menthol into the esophagus induces cold sensation in healthy subjects and that this sensation is exaggerated in patients with chronic heartburn. We used L-menthol because of its higher potency on TRPM8 compared to R-menthol or racemic mix. L-menthol (3mM), vehicle (0.05% ethanol) or acid (HCl solution, $pH = 1$) was infused (8ml/min) into the esophagus via a transnasal tube with the opening placed 5 cm above the manometrically determined LES. The intensity of sensations was recorded every 2 min. by visual analogue scale (VAS, range 0–10). The subjects were also asked to describe the quality of the sensations. 12 healthy subjects and 27 patients with chronic heartburn (> 6 months, burning sensation behind the sternum with frequency at least one day per week) were enrolled. Each subject received only one esophageal infusion.
Results: Esophageal infusion of L-menthol evoked a cold sensation behind the sternum in 11 of 12 healthy subjects (mild heartburn in the remaining subject). The intensity of sensations was relatively modest, it fully developed during the 10 min. and did not increase further during the rest of infusion. VAS score in healthy subjects at 20 min. was 1.9 ± 0.3 ($N = 12$). Surprisingly, in 11 of 12 patients with chronic heartburn, esophageal infusion of L-menthol evoked typical heartburn (cold sensation in the remaining one). The intensity of heartburn increased gradually during the whole duration of L-menthol infusion and the VAS score at 20 min was 6.0 ± 0.7 ($N = 12$, $P < 0.01$ compared to healthy subjects). Infusion of vehicle failed to evoke similar sensations ($N = 3$). For comparison, in a separate group of patients with chronic heartburn ($N = 12$) the VAS score at 10 min of acid infusion was 7.1 ± 0.8 indicating that the intensity of heartburn evoked by L-menthol is comparable to that evoked by acid infusion.
Conclusion: Cold sensations evoked by esophageal infusion of menthol in healthy subjects indicate the expression of TRPM8 in esophageal sensory nerves. A relatively intense heartburn evoked by menthol in patients with chronic heartburn indicates that TRPM8 is expressed in C-fibers and suggest that the role of TRPM8 in amplification of visceral painful sensations in humans deserves a closer look.

Introduction: Gastric electrical stimulation (GES) via high-frequency, low-energy pulses can provide an effective treatment for gastroparesis and obesity; however, the current available device requires surgical implantation for long-term stimulation and repeated surgical procedure after a period of time. We aimed to describe and test endoscopic implantation of newly developed wireless gastric electrical stimulator.
Aims and Methods: We developed a novel and miniature wireless gastric electrical stimulator. Endoscopic gastric implantation techniques were implemented on healthy weaner pigs under general anesthesia. We made endoscopic submucosal pocketing and inserted gastrostimulator as previously mentioned. In vivo gastric slow waves were recorded and measured during electrical stimulation. A multi-channel recorder (Acknowledge 4.4, MP150; Biopac Systems, Santa Barbara, CA) was used to record gastric myoelectrical activity throughout the study.
Results: Electrogastrogram recordings demonstrated that gastric slow waves became more regular and of constant amplitudes when stomach tissues were stimulated, in comparison with no stimulation. The frequency-to-amplitude ratio also changed significantly with stimulation.
Conclusion: Gastric electrical stimulation is feasible by our endoscopically implanted, wireless GES device. This technique have the potential to increase the utility of GES as a treatment alternative.

P1744 OESOPHAGO-GASTRIC JUNCTION OUTFLOW OBSTRUCTION: OUTCOMES OF 45 PATIENTS FROM A TERTIARY REFERRAL CENTRE

A. Mari[1], **K. Patel**[1], H. Martin[2], A. Raeburn[1], R. Sweis[1]

[2]*UCLH, Gastroenterology, London, United Kingdom*

Contact E-Mail Address: kalp.patel@nhs.net
Introduction: Oesophago-gastric junction outflow obstruction (OGJOO) is characterised by a raised integrated relaxation pressure (IRP) with preserved oesophageal peristalsis. Although in some series OGJOO is being reported more frequently than achalasia, challenges still remain understanding its aetiology, clinical significance, natural history and appropriate therapy.
Aims and Methods: From June 2015 to November 2017, a retrospective analysis of patients undergoing high-resolution manometry (HRM) using 36-channel solid-state catheter (Manoscan 360, Sierra Scientific Instruments) was performed in a tertiary referral centre in London. Patients who fulfilled the diagnostic criteria for OGJOO as per version 3.0 Chicago Classification were included. 10 single water swallows were followed with 5×1cm cubed of bread. Medical files of patients meeting the diagnosis were reviewed to determine patient demographics; clinical history, endoscopic and barium swallow findings as well as therapy and response.
Results: 45 patients were included, 28 females (62%), mean age 56 ± 2 (range 33–83 years). Most patients (84%) reported symptoms of dysphagia and chest pain (Eckardt score >3), while the others complained of heartburn, epigastric pain and/or cough. 18 patients were diagnosed based on single water swallows alone (IRP >15mmHg), 7 based only on solid swallows and 20 on both. 43 patients had Oesophago-Gastro-Doudenoscopy (OGD) recorded, 3 had Endoscopic Ultrasound (EUS) and 25 had Timed Barium Swallow (TBS). 9 patients (21%) had possible explainable aetiology: 2 Schatski ring, 2 peptic stricture, 3 slipped fundoplication, 1 Eosinophilic Oesophagitis and 1 extrinsic compression at the OGJ (seen on EUS). The rest were idiopathic. 12 patients reported regular use of opioids, including morphine, codeine and/or tramadol. Thus far, 12 patients have been treated within the same tertiary institution: 9 had botulinum toxin (botox) injections into the OGJ and 7 had Rigiflex balloon dilation to 30 and/or 35mm (4/7 of who were previously treated with botox with no response). 4 of those who were treated with botox and all patients who underwent Rigiflex dilatation improved significantly when assessed between 3 and 12 months following therapy. The median height of the barium column at 5 minutes prior to treatment was 8.2 cm (IQR = 0;11.4cm) while the median height following treatment was 0cm (IQR = 0;0cm). Overall, mean Eckardt scores for the 12 treated patients dropped from 9 (range 4–12) prior to therapy to 2 (range 0–3) after treatment.
Conclusion: : OGJOO is an increasingly recognised manometry-defined disorder. In patients who are symptomatic with no explainable cause, treating as one would achalasia with botox or Rigiflex dilatation, is associated with excellent clinical response.
Disclosure: None

P1745 OESOPHAGEAL APERISTALSIS IS UNDER INVESTIGATED IN THOSE WITHOUT ACHALASIA OR REFLUX

P. Visaggi[1], H. Ibraheim[2], T. Wong[2], J. Dunn[2], J. Jafari[2], S. Zeki[2]

Contact E-Mail Address: pierfrancesco.visaggi@gmail.com
Introduction: Oesophageal aperistalsis (OA) is the absence of oesophageal motility with water swallows at high-resolution manometry (HRM). Symptoms include dysphagia, regurgitation, globus, chest pain and heartburn. The main causes are achalasia and acid reflux although in many patients no cause is found. There is no consensus for the investigation of OA without achalasia; this will depend on how common the underlying aetiology is.
Aims and Methods: The objective of this study was to investigate the number of patients with an identifiable cause of OA and to investigate the number of patients in whom the most common aetiologies of OA have been determined.
We examined the reports of all patients who had undergone HRM at Guy's and St. Thomas' NHS Trust from January 2008 to July 2017. 492 patients had OA as per the Chicago Classification 2014; achalasia was defined as an integrated relaxation pressure (IRP) of >15mmHg or IRP 12–15mmHg and a barium swallow or other imaging or a previous myotomy for achalasia was identified. For those without achalasia, Gastroesophageal reflux disease (GORD) was defined according to any pH study off proton pump inhibitors. Patients without GORD or achalasia were classified as non-achalasia, non-reflux aperistalsis (NANRA). Non-achalasia patients without a pH study were excluded (n = 35). The electronic patient record of NANRA patients was then consulted to look specifically for evidence of autoimmune disorders (AD), eosinophilic oesophagitis (EoE) or previous oesophageal surgery.
Results: Among 457 included patients we defined three categories: 183 (40%) had achalasia, 185 (41%) had GORD and 89 (19%) had NANRA.
Of the 89 NANRA patients, 29% had an AD including Systemic Lupus Erythematosus, Scleroderma, Sjögren syndrome and Antisynthetase syndrome (n = 25, M:F 3:7, average age = 48). One had Myotonic Dystrophy (n = 1); 11% (n = 10) had hypersensitive oesophagus; 6% (n = 5) had surgery for atresia, oesophageal spasm, or gastric cancer; 2% (n = 2) had EoE and in 2% (n = 2) of patients AD screen and EoE screen were normal. The remaining 50% of NANRA patients (n = 44) had an unknown cause but incomplete investigations (no screen for AD: 97.7%; no biopsy: 67.4%).
Conclusion: 1. The principal cause of OA is achalasia; it shouldn't be dismissed as a cause even if the IRP is <15mmHg as 6.5% (n = 12) of patients with achalasia and OA had IRP <15mmHg but typical radiological findings.
2. GORD is present in 41% of patients but it is unclear whether it is a cause or effect of OA, therefore the finding of GORD should not stop further investigation.
3. Patients with OA are under investigated for AD and EoE. Incomplete investigations occurred in 50% of patients with NANRA, potentially losing the opportunity to identify other aetiologies. It is unclear whether NANRA patients should be routinely tested for AD or for EoE, or whether this should be done only in selected cases.

Introduction: Esophageal motility abnormalities (EMAs) are often seen in patients with systemic sclerosis (SSc). Several studies have shown a relationship between EMAs and skin involvements, while other studies have not.
Aims and Methods: The aim of the study was to identify predictive variables for EMAs in patients with SSc. A total of 109 patients with SSc who underwent esophageal high-resolution manometry (HRM) between May 2009 and August 2016 at Gunma University Hospital were enrolled. Esophageal motility was assessed retrospectively according to the Chicago Classification v3.0. HRM and clinical data, including the presence of autoantibodies and skin involvements, were collected. The association between EMAs and skin involvements was evaluated. SSc was divided into two types, diffuse cutaneous SSc (dcSSc) and limited cutaneous SSc (lcSSc), based on the presence or absence of the proximal extent of skin thickness. The severity of skin thickness was assessed by a modified Rodnan total skin thickness score. Chi-square or rank sum tests were used to compare variables between patients with EMAs and those with normal esophageal motility. Variables were categorized as age: <65 or ≥ 65 years, disease duration: <5 or ≥ 5 years and skin score <11 or ≥ 11; and multiple logistic regression analysis was performed. Data was expressed as median values (25%, 75%) unless stated otherwise.
Results: Forty-four patients had normal esophageal motility, eight had esophago-gastric junction outflow obstruction, one had distal esophageal spasm, 27 had ineffective esophageal motility and 29 had absent contractility. Although the prevalence of dcSSc did not differ between patients with EMAs and those with normal esophageal motility (34% vs. 20%, respectively; $p = 0.19$), patients with EMAs had a significantly higher skin score than those with normal esophageal motility [7.0 (4.0, 16.0) vs. 4.0 (2.0, 9.0), respectively; $p < 0.05$, Table]. Other variables such as age, sex, disease duration, and the presence of digital ulcers, Raynaud's phenomenon, or autoantibodies did not differ between patients with EMAs and those with normal esophageal motility. Although a significant predictive variable for EMAs was not found by multiple logistic regression analysis, a high skin score was a significant variable for absent esophageal contractility (Table).
Conclusion: A significant correlation between severe skin thickness and absent contractility was found in patients with SSc. Consequently, if such patients have a high skin thickness score, esophageal motility should be evaluated.

	Normal esophageal motility (n = 44)	Esophageal motility abnormarlity (n = 65)	Odds ratio [95% confidence interval] for absent contractility
Sex (male/female)	6/38	11/65	1.570 [0.582, 4.235]
Age (years)	60 (50, 68)	63 (55, 67)	1.216 [0.326, 4.541]
Disease duration (years)	2 (0, 6)	2 (0, 11)	1.701 [0.566, 5.112]
SKIN INVOLVEMENT			
dcSSc	9/44 (20%)	22/65 (34%)	0.771 [0.145, 4.103]
Raynaud's phenomenon	42/44 (95%)	61/65 (94%)	1.393 [0.134, 14.500]
Digital pitting ulcer or scars	12/44 (27%)	18/65 (28%)	1.082 [0.365, 3.204]
Total skin score	4.0 (2.0, 9.0)	7.0 (4.0, 16.0)	7.203 [1.614, 32.144]
AUTOANTIBODIES			
Anti-nuclear	31/44 (70%)	46/65 (71%)	0.818 [0.213, 3.136]
Anti-centromere	19/44 (43%)	26/65 (40%)	1.334 [0.305, 5.836]
Anti-topoisomerase I	8/44 (18%)	3/64 (33%)	0.837 [0.167, 4.196]

Introduction: Per-oral endoscopic myotomy (POEM) has revolutionized the management of esophageal achalasia and other spastic disorders of esophagus. In the absence of large studies with long-term follow-up, the role of POEM remains uncertain for the management of esophageal motility disorders. In this study, we aimed to analyse the safety and efficacy of POEM in a large cohort of patients with esophageal motility disorders.
Aims and Methods: The data of consecutive patients with achalasia and non-achalasia esophageal motility disorders who underwent POEM at a single tertiary care center from January 2013 to March 2018 were analysed. Technical and clinical success, adverse events, and operative time were analysed in all the patients.
Results: Overall, 775 patients (40.37 ± 4.39 years, Males 428) with esophageal motility disorders underwent POEM during the study period. The type of achalasia as per Chicago classification were: type I (219), type II (481), type III (30). 15 patients were classified as non-achalasia spastic motility disorder including Jackhammer esophagus in 4 and diffuse esophageal spasm in 11 patients. Overall, 356 patients had history of prior treatment. Majority of patients (71.35%) underwent anterior POEM. POEM was successfully performed in 98.45% patients. The most common reason for technical failure was submucosal failure (1.16%) followed by excessive extension of mucosal incision (0.4%). Mean operating time was 64.8 ± 31.26 minutes (16–240). Mean length of myotomy on esophageal and gastric side was 8.23 ± 2.91 cm and 3.01 ± .49 cm, respectively. Major adverse events were noticed in 9 patients (1.1%). Post-procedure Eckardt score (6.89 ± 1.52 vs 0.86 ± 0.77) and lower esophageal sphincter pressures (37.45 ± 15.14 vs 13.16 ± 5.61) were significantly lower than prior to the procedure. Clinical success was evident in 92% and 90% at 1 and 2 years, respectively. Long-term clinical success (≥3years) was achieved in 87.6% of patients. Gastroesophageal reflux disease was noticed in 58 patients (40.5%) on 24-hour pH impedance analysis. Clinical symptoms of reflux and erosive esophagitis were found in 22.4% and 18.9% of patients, respectively.
Conclusion: POEM is safe, effective and durable for the treatment of esophageal motility disorders. However, gastroesophageal reflux disease occurs in a substantial number of patients and needs to be considered while considering POEM for the management of achalasia.
Disclosure: Nothing to disclose

P1748 ABNORMAL DISTENSIBILITY ON ESOPHAGEAL ENDOLUMINAL FUNCTIONAL LUMEN IMAGING PROBE (ENDO-FLIP) IDENTIFIES ESOPHAGEAL OUTFLOW OBSTRUCTION AND DIRECTS MANAGEMENT WHEN INTEGRATED RELAXATION PRESSURE (IRP) ON HIGH-RESOLUTION MANOMETRY (HRM) IS NORMAL OR BORDERLINE

Introduction: An important clinical role for esophageal HRM is to diagnose esophageal outflow obstruction, typically identified when IRP is higher than the upper limit of normal. However, achalasia and esophageal outflow obstruction can manifest with IRP within the threshold of normal, and borderline elevated IRP may not be clinically relevant in some instances. Evaluation of EGJ distensibility and esophageal body contractility with endo-FLIP may refine diagnosis of esophageal outflow obstruction.
Aims and Methods: Our aim was to evaluate the value of endo-FLIP in identifying EGJ outflow obstruction when IRP values are normal or borderline on esophageal HRM. Adult patients undergoing both HRM and endo-FLIP testing at a tertiary care institution were eligible for inclusion. Patients with incomplete HRM or endo-FLIP data were excluded. Patients completed questionnaires defining presenting symptoms. Endo-FLIP was performed using sequential volumetric distension of a compliant balloon placed in the distal esophagus during sedated endoscopy. Primary metrics were distensibility index (DI) from endo-FLIP (≤ 2.8 mm^2/mmHg = abnormal), and IRP from HRM (≥ 15 mmHg = abnormal; 15–20 mmHg = borderline). Chicago Classification 3.0 diagnoses, results from provocative testing during HRM (rapid drink challenge or RDC, multiple rapid swallows or MRS), and esophageal body contractility were additionally assessed. Data was analyzed to assess concordance and discordance between HRM and endo-FLIP assessments of the EGJ, and final diagnoses from each assessment.
Results: Of 85 patients (61.4 ± 1.6 yr, 61.2% F) identified over an 18-month period, 78 presented with dysphagia or suspected esophageal outflow obstruction, and the remainder had unexplained symptoms. Both IRP and DI were abnormal in 25 patients (29.4%); this was true for all patients with achalasia (6 patients). Among patients with a normal IRP, DI was normal in 21/53 (40%), while abnormal (discordant) in 32/53 (60%, p = 0.0007). When IRP was borderline, DI was also abnormal in 9/12 (75%, p = 0.3 compared to normal IRP). In borderline and normal IRP cohorts, esophageal pressurization on provocative testing was seen more often with abnormal DI (69.4% vs. 37.5%, p = 0.02); mean IRP (p = 0.6) and MRS IRP (p = 0.8) were not discriminative between abnormal and normal DI. High GERDQ scores suggesting reflux disease in the normal IRP cohort were associated with normal DI (p = 0.005), but other symptom assessments were not different between abnormal and normal DI cohorts. Of 10 patients with absent contractility and normal IRP, 5 patients (50.0%) had features of achalasia on endo-FLIP with mean DI 1.3 ± 0.4 and mean IRP 6.8 ± 0.6 mmHg, compared to true absent contractility (mean DI 5.4 ± 0.8, p = 0.007, mean IRP 7.6 ± 1.3, p = 0.6). Endo-FLIP findings resulted in a change in management in 67.8% with normal IRP, and in 75% with borderline IRP.

Chicago Classification diagnosis	Distensibility index ≤2.8 mm2/mmHg	Distensibility index >2.8 mm2/mmHg
IRP < 15 mmHg (n = 53)	***n = 32***	***n = 21***
Normal	14/24 (58.3%)	10/24 (41.7%)
Hypermotility (Jackhammer, DES)	7/9 (77.8%)	2/9 (22.2%)
IEM, fragmented peristalsis	6/10 (60.0%)	4/10 (40.0%)
Absent contractility	5/10 (50.0%)	5/10 (50.0%)
IRP 15–20 mmHg (n = 16)	***n = 12****	***n = 4****
Achalasia	2/2 (100%)	0/2
EGJOO	9/12 (75%)	3/12 (25%)
IRP≥20 mmHg (n = 16)	***n = 13***	***n = 3***
Achalasia	4/4 (100%)	0/4
EGJOO	9/12 (75%)	3/12 (25%)

*[*two patients had DES, one each with normal and abnormal DI]*
Conclusion: Endo-FLIP evaluation provides prominent gains over HRM when IRP is normal or borderline in symptomatic patients, with management implications.
Disclosure: Nothing to disclose

P1749 FOOD RHEOLOGY AND NUTRITIONAL ASSESSMENT OF DIET IN ACHALASIC PATIENTS: AN OBSERVATIONAL STUDY

E. Ribichini, A. Cesarini, S. Rossi, M.C. Sacchi, D. Badiali
La Sapienza University of Rome, Internal Medicine and Medical Specialities, Rome, Italy

Contact E-Mail Address: emanuela.ribichini@uniroma1.it
Introduction: Esophageal Achalasia (EA) is a rare disease of still uncertain etiology, characterized by absence of peristalsis and absence or incomplete relaxation of the Lower Esophageal Sphincter (LES) in response to swallowing. Dysphagia, food regurgitation and chest pain are the main symptoms of the disease with negative impact on the quality of life (QoL) and lead patients to limit food intake with possible nutritional consequences. There are no specific dietetic advices for this kind of dysphagia resulting in self-management.
Aims and Methods: Aims of the study was to evaluate diet, eating habits and nutritional status of achalasic patients, and to assess association, if any, between food rheology and symptoms. Twenty-five achalasic patients (F14, M11, mean age 54 ± 18 yrs) were enrolled in the outpatient office of gastrointestinal Pathophysiology of Policlinico Umberto I, Rome. EA was diagnosed by manometry, 19/25 patients had been previously treated by endoscopic dilatation (n = 13), Heller myotomy (n = 4), both treatments (n = 2), 6/25 patients had not yet undergone any treatment. Clinical data were collected using a symptom and QoL questionnaire, divided in two parts (MD Anderson Dysphagia Inventory and Modular Questionnaire Roma III). Patients filled in a diary for 15 days (a total of 990 meals), where they reported ingested food for each meal and the presence of symptoms according to ESS. Estimated caloric intake and composition of macronutrient were compared to Mediterranean Diet. Patients were classified according to the Eckardt Symptom Score (ESS) considering the ESS value ≥3 as a cut-off to identify the need for (re) treatment.
Results: Seventeen patients (68%) had a ESS≥3 with dysphagia and chest pain as main symptoms, 16 patients (64%) reported no weight loss, 6 (24%) reported weight loss < 5 kg and 3 (12%) reported weight loss ranging from 5 to 10 kg. ESS correlated with disability (r = 0.7; p < 0.05), and was inversely correlated with BMI (r = −0.59; p < 0.05). The mean score of QoL was 19.08 ± 12.94, corresponding to a mild degree of disability perception.
Evaluation of the usual diet in comparison with estimated caloric need showed an intake of 1620 ± 382 vs 2201 ± 546 Kcal and in comparison with the recommended macronutrient assumption the following subdivision: carbohydrates 45.4% ± 5.9 vs 55–59%, protein 20.3% ± 3.9 vs 15–18%, total fat 33% ± 3.8 vs 26–27% and fiber 14.9 ± 4.2 vs 25–30 g. Solid food caused more frequently symptoms than semiliquid and liquid ones: dysphagia (26.2% vs 3.6% vs 1%), chest pain (13.6% vs 2.1% vs 0.3%), regurgitation (7.8% vs 1.8% vs 0.5%).
Spaghetti, pizza and bread were associated with dysphagia in >50% of the meals, dry food and vegetables caused symptoms in ~30% of meals; 40% of patients reported a worsening of symptoms with cold foods, 36% of patient improvement with hot foods. Full meals were achieved by 68% of patients; 32% stopped meals for vomiting, chest pain or regurgitation (64%, 27%, 9%, respectively). The most frequent intervention to overcome symptoms was

drinking (52%), followed by repeated swallowing (21%), waiting (14%), regurgitation (13%).
Conclusion: The results of this observational study suggest that dysphagia and chest pain are main symptoms in achalasic patients even after treatment and they affect mildly the QoL. However, patients conform their diet to avoid symptoms reducing the intake of solid food and food rich in carbohydrates, leading to a hypocaloric and unbalanced diet in favour of fat and protein.

Introduction: Recent studies reported that pyloric distensibility is altered in 30–50% (1) of gastroparetic patients. Pyloric distensibility has also been shown to correlate with gastric emptying and symptom severity.
Aims and Methods: The aim of the present study was to assess whether pyloric distensibility measurement is predictable of the symptomatic response after intra-pyloric toxin botulinum injection in gastroparesis.
Pyloric distensibility has been measured using the ENDOFLIP® system in 25 consecutive gastroparetic patients before intra-pyloric toxin botulinum injection (Botox, 200 UI). Altered pyloric distensibility was defined as a distensibility below 10 mm^2/mmHg as previously reported (1). Dyspeptic symptoms and quality of life have been prospectively investigated before and 3 months after intra-pyloric toxin botulinum injection. Dyspeptic symptoms (vomiting, nausea, gastric fullness, early satiety, bloating, epigastric pain and regurgitation) have been evaluated using a 5 point likert scale (0 = non symptoms; 4 = most severe symptoms). Total symptomatic score (TSS) was defined as the aggregation of individual symptomatic scores. Quality of life was measured using the GIQLI score ranging from 0 (worst quality of life) to 144 (best quality of life). Gastric emptying was assessed using the C13 octanoic acid breath test.
Results: Using the threshold of 10 mm^2/mmHg, 17/24 patients had altered pyloric distensibility while 8 patients had normal pyloric distensibility. In patients with altered pyloric distensibility, TSS dropped at 3 months from 13.6 to 11.0 ($p = 0.02$), while it remained unchanged in patient with normal pyloric distensibility (from 14.0 to 14.2; $p = 0.77$). Among dyspeptic symptoms, vomiting (from 1.3 to 0.5; $p = 0.03$) and gastric fullness (from 3.3 to 2.4; $p < 0.01$) were the only symptoms to be improved in patients with altered pyloric distensibility, while none of the dyspeptic symptoms were improved in patients with normal pyloric distensibility. GIQLI score improved from 65 to 74 in patients with altered pyloric distensibility ($p = 0.06$) while GIQLI score remained unchanged (from 70 to 70; $p = 0.94$) in patients with normal pyloric distensibility. In patients with altered pyloric distensibility, gastric emptying half time was 249 min before and 222 min 3 months after injection ($p = 0.18$). In patients with normal pyloric distensibility, gastric emptying half time was 227min before and 214 min 3 months after injection ($p = 0.93$). When threshold was set at 9 or 8 mm^2/mmHg, similar findings were observed.
Conclusion: Pyloric distensibility measurement before intra-pyloric toxin botulinum injection predicted symptomatic and quality of life response 3 months after injection in gastroparetic patients.
Disclosure: Nothing to disclose

Introduction: History of gastric surgery is found in 10% of gastroparesis. A vagal lesion is often suspected to be responsible of pylorospasm, although there was until recently no routine test to diagnose such alteration. Recently, pyloric distensibility measurement using the ENDOFLIP® system showed that pylorospasm was found in 30–50% of gastroparetic patients (1).
Aims and Methods: The aim of the present study was to assess whether pylorospasm, diagnosed using the ENDOFLIP® system is observed in 3 different types of gastric surgeries, namely antireflux surgery, sleeve gastrectomy, and esophagectomy.
Pyloric distensibility and pressure were measured using the ENDOFLIP® system in 43 patients (19 antireflux surgery, 16 sleeve gastrectomy, and 8 esophagectomy) with dyspeptic symptoms after gastric surgery, and in 21 healthy volunteers. All patients had delayed gastric emptying, except in sleeve gastrectomy in the absence of normal values established in asymptomatic controls. Altered pyloric distensibility was defined as distensibility below 10 mm^2/mmHg as previously reported (1).
Results: Different patients groups were not different in demographic characteristics, except for body mass index that was increased in the sleeve gastrectomy group and age that was older in the esophagectomy group. Compared to healthy volunteers (distensibility: 25.2 ± 2.4 mm^2/mmHg; pressure: 9.7 ± 4.4 mmHg), pyloric distensibility was decreased in the antireflux surgery (14.5 ± 3.4 mm^2/mmHg; $p < 0.01$) and esophagectomy (10.8 ± 2.1 mm^2/mmHg; $p < 0.05$) groups, while pyloric pressure was only increased in the antireflux surgery group (18.9 ± 2.2 mmHg; $p < 0.01$). Pyloric distensibility and pressure were similar in healthy volunteers and the sleeve gastrectomy (distensibility: 20.3 ± 3.8 mm^2/mmHg; pressure: 15.8 ± 1.6 mmHg) groups. Altered pyloric distensibility was found in 18% of patients from the sleeve gastrectomy group, 58% ($p < 0.05$) of patients from the antireflux surgery group and 67% ($p < 0.05$) of patients from the esophagectomy group.
Conclusion: Antireflux surgery and esophagectomy are associated with pylorospasm although pylorospasm is not found in all these patients. Sleeve gastrectomy was not associated with altered pyloric distensibility nor altered pyloric pressure.

Introduction: Traditional treatment of functional dyspepsia (FD) is unsatisfactory, and the potential role of antidepressant medications also hasn't been definitely clarified.
Aims and Methods: This study aimed to evaluated the efficacy and safety of antidepressant medications for management of annoying symptoms of FD. Adult FD patients (identified by Rome III criteria) and not remitted using routine treatments were selected for this study. All patients had undergone appropriate gastrointestinal (GI) diagnostic tests and ruled out organic GI diseases seemed possible explanations for the symptoms. The symptom patterns of included patients were divided into three subtypes at initial visit: postprandial distress syndrome (PDS), epigastric pain syndrome (EPS) or both. Patients were treated with different antidepressant agents and dosage according to individual illness features. An established 4-point Likert-type scale was used to measure the response of antidepressant therapy at follow-up according to the clinical records. Patient demographics, clinical symptoms, medication history, GI diagnostic tests, and antidepressant therapy were collected. Antidepressant treatment data extracted contained the type and dose used, treatment response, and self-reported adherence.
Results: Among the total patients ($n = 1524$) referred to this specialist clinic because of refractory GI symptoms or asked for physical examination, 9.4% ($n = 144$) met the inclusion criteria for study cohort. Fourteen patients were subsequently excluded for failure to return after initiation of antidepressant therapy and 130 cases were left for analysis. The mean patient age was 50.5 years over a range of 18–83 years, and 88 patients (67.7%) were female. Thirty-eight patients (29.2%) had EPS, 64 (49.2%) had PDS, and the remaining 28 (21.6%) complained of both EPS and PDS. The mean duration of GI symptoms prior to initial evaluation was 3.8 years. Thirty-three subjects (25.4%) of all had been treated with only one antidepressant; 91 (70%) were treated with two, and 6 (4.6%) had changed medication consecutively. Antidepressant agents, in descending order of frequency were: fluoxetine, flupenthixol melitracen, sulpiride, paroxetine, citalopram, mirtazapine, sertraline, duloxetine, amitriptyline, and venlafaxine. Following initiation of antidepressants, symptom improvement was attained in 122 patients (93.8%) at some time in follow-up: remission of symptoms (score = 3) occurred in 71 patients (54.6%), and the average time to obtain remission was 3.4 months; moderate improvement (score = 2) was obtained in 33 patients (26.2%). No significant difference was detected in remission rate in relation to symptom pattern and no antidepressant regimen was significantly different for management of three FD types. Complete symptom remission occurred in 46.9% of subjects with PDS vs. 57.9% for subjects with EPS and 67.9% with both. When subjects with symptom remission were compared with the reminder, young patients ($P = 0.065$) tended to lead a poor outcome. Furthermore, when given sulpiride or fluoxetine, patients with younger age were associated with a poor outcome ($P = 0.001$ and $P = 0.005$, respectively).

However, there was no any association between gender, FD subgroups, or dyspepsia duration and response to antidepressants.
Conclusion: Low dose of antidepressant medications achieved a high response rate in FD patients, especially for older patients. Symptom remission was not related to symptom patterns or antidepressant regimens.

P1753 INVESTIGATION OF AUTOIMMUNE GASTRITIS DIAGNOSED BY ENDOSCOPIC FINDINGS

M. Kishino, S. Nakamura, K. Tokushige
Institute of Gastroenterology, Tokyo Women's Medical University, Tokyo, Japan

Contact E-Mail Address: kishino.ige@twmu.ac.jp
Introduction: Endoscopic features of autoimmune gastritis (AIG) are based on severe spread of atrophic gastritis in the stomach body. The endoscopic findings are different from those of atrophic gastritis associated with *H.pylori*, which is frequently found in Japan. Diagnosis of AIG is meaningful clinically because AIG can complicate autoimmune polyendocrine syndrome (APS) and can cause anemia and gastric tumor.
Aims and Methods: We investigated the significance of endoscopic findings as a lead for AIG diagnosis. Thirty-nine cases with appreciatively severe atrophic gastritis in the stomach body on endoscopic examination between January 2009 and March 2018 were studied. Gender, laboratory data (serum gastrin, parietal cell antibody (PCA), intrinsic factor antibody (IFA), pepsinogen (PG) I and II, Hb, Vit.B12, Fe), complications, *H.pylori* infection, and reason for endoscopic examination were evaluated as retrospective cohort study.
Results: We defined patients who satisfied all these criteria — severe atrophic gastritis in the stomach body, hypergastrinemia (>200pg/ml), positive reaction of PCA and/or IFA, low level of serum PG-I (<40mg/ml) — as "AIG fix". All except "AIG fix" were defined as "AIG suspect (sus)". "AIG fix" were 17 patients (43.6%). Males in "AIG fix" were 17.6%. Mean serum gastrin, PG-I, and PG-II were 3184 ± 1986pg/ml, 6.6 ± 4.5mg/ml, and 8.2 ± 2.4mg/ml. PCA- and IFA-positive rates were 88.2% and 35.3%. Low serum Vit.B12 and Fe levels were 64.7% and 29.4%, respectively, in this group. Five patients (29.4%) were complicated by some autoimmune diseases. Five patients (29.4%) were complicated by NET (Neuroendocrine tumor). Two patients (11.8%) were complicated by gastric cancer. *H.pylori*-positive by urea breath test were 3 patients (17.6%). Among "AIG sus" several patients with autoimmune disease and pernicious anemia were included.
Conclusion: It was suggested that correct diagnosis of atrophic gastritis predominating in the stomach body differing from *H.pylori*-related gastritis may be the first step in the diagnosis of AIG. However, many cases were not examined even if findings were correct. Dissemination of the diagnostic significance of AIG will be needed in the future.

P1754 COMPARATIVE STUDY BETWEEN ROME III AND IV DIAGNOSTIC CRITERIA AMONG COLLEGE STUDENTS' FUNCTIONAL GASTROINTESTINAL DISORDERS EPIDEMIOLOGICAL INVESTIGATION IN CHINA

K. Zhao, M. Li, B. Lu
The First Affiliated Hospital of Zhejiang Chinese Medical University, Department of Gastroenterology, Hangzhou, China

Contact E-Mail Address: zhaokj1228@163.com
Introduction: FGIDs are common and important disorders of the digestive system and have a worldwide distribution. Its incidence in the general population is approximately 36.1%. Rome IV criteria published in 2016 redefines FGIDs as brain-intestinal interactions, varying from a single gastrointestinal motility abnormality to neuro-gastroenterology and brain-intestinal interactions abnormality. Compared with Rome III, Rome IV has a more stringent and precise definition of FGIDs. For example, Rome IV revised frequency threshold and the nature of IBS symptoms. Rome IV adjusted and refined diagnostic criteria might impact the clinical diagnosis of FGIDs. Therefore, on the basis of the previous survey performed by our research team regarding FGIDs epidemiological investigation in students from the colleges in Zhejiang province, we compared the two criteria regarding FGIDs diagnosis, to explore the difference between the two criteria and evaluate the value, if present, in the clinical FGIDs diagnosis using Rome IV criteria.
Aims and Methods: This research was aimed at investigating the differences and the similarities between Rome III and IV diagnostic criteria in the diagnosis of Functional Gastrointestinal Disorders (FGIDs) among college students in China. According to FGIDs database of college students in Zhejiang Province established by our previous research team, further epidemiological analysis and comparisons were made using Rome IV and Rome III criteria.
Results: Among 1870 students' database information, 54.81% FGIDs met Rome IV criteria and 59.41% FGIDs met Rome III criteria. Rome IV-positive students showed a higher scoring of obsessive-compulsive, depressive and anxiety. In Rome IV group, belching disorders, irritable bowel syndrome (IBS), functional abdominal bloating/distension (FAB/D) and postprandial distress syndrome (PDS) detection rates were lower than that of Rome III group. In Rome IV group, functional diarrhea (FDr) and epigastric pain syndrome (EPS) detection rates were higher than in Rome III group. Some of the original PDS patients (11 cases, 11.11%) were included in the EPS, some of the original IBS patients (43 cases, 33.33%) were included in the FDr, and 12 cases (9.30%) of the original IBS patients were included in FC according to Rome IV criteria. A significant difference was observed in the distribution of different subtypes (PDS, EPS) of FD between two criteria ($\chi^2 = 25.63$, $P < 0.01$).
Conclusion: Rome IV criteria has more strict and accurate FGIDs definition, allowing a more accurate identification of the disease and those patients who really need treatment, resulting in a more efficient and feasible application in clinical practice and scientific research.

Introduction: Acid exposure time (AET) and reflux-symptom association (RSA) on pH-impedance monitoring can stratify esophageal syndromes into nonerosive reflux disease (NERD), and functional esophageal disorders (FED), including reflux hypersensitivity (RH, normal AET with positive RSA) and functional heartburn (FH, normal AET and negative RSA). Low mean nocturnal baseline impedance (MNBI) is now a recognized marker of impaired mucosal integrity that can predict therapeutic outcome from antireflux therapy. We hypothesized that MNBI could differentiate between NERD and FED, particularly FH.
Aims and Methods: Our aim was to evaluate the discriminative value of MNBI within FED categories, both conventional (diagnosed off PPI) and overlap (diagnosed on PPI therapy), compared to conventional NERD (diagnosed off PPI). Adult patients undergoing pH-impedance testing at two tertiary academic centers were approached for enrollment in this prospective study. Patients with proven GERD were tested on PPI therapy, while those with unproven GERD were tested off PPI for 7–10 days. Patients completed questionnaires defining symptoms (Reflux Diagnostic Questionnaire, RDQ), affective state (Hospital Anxiety and Depression Scale, HADS; Visceral Sensitivity Index, VSI), and functional diagnoses (irritable bowel syndrome, IBS; functional dyspepsia, FD on ROME diagnostic questionnaire). Patients with incomplete symptom data were excluded. Based on AET and RSA, FED patients were designated RH and FH, and were compared to NERD (AET > 6% off PPI therapy). MNBI was calculated by averaging baseline impedance from 3 stable 10-minute periods (1AM, 2AM, 3AM) at the 5 cm impedance channel, low if < 2292 ohms. Data were analyzed to assess differences between FED categories segregated by MNBI thresholds, and NERD.
Results: Of 93 patients (51.8 ± 1.5 yr, 74.2% F), 26 had NERD, and 67 had FED (RH = 15, FH = 52) based on ROME IV definitions. Within FED, proportion of acidic reflux episodes were higher off PPI, compared to proportion of weakly acidic reflux episodes ($p < 0.001$ for each comparison). Symptom burden, HADS, VSI and proportions of IBS and FD were similar between RH and FH, both within conventional and overlap subgroups. When MNBI was available (n = 45), FED could be subdivided into two categories using a threshold of 2292 ohms. Within RH, numbers were too small to make meaningful comparisons. Within FH, when MNBI was normal, symptom burden, depression and anxiety scores were higher compared to FED with low MNBI ($p \leq 0.04$ for each comparison). Proportions with FD were numerically higher in FH with normal MNBI ($p = 0.08$ across groups); proportions with IBS were similar. In particular, 30% with normal MNBI FH had evidence of depression on HADS compared to none with low MNBI FH ($p = 0.002$).

	FH with normal MNBI	FH with low MNBI	NERD
RDQ score	81.6 ± 8.1	59.5 ± 17.4	61.6 ± 7.7
Acid exposure time	0.6 ± 0.2*	0.9 ± 0.3*	10.9 ± 1.5
Acid reflux episodes	7.4 ± 1.4*	8.1 ± 2.1*	34.6 ± 5.8
All reflux episodes	45.3 ± 4.9	33.5 ± 4.4	53.7 ± 9.8
Mean MNBI (ohms)	3178 ± 167.4*	1443 ± 134.2*†	927.7 ± 124.2
HADS depression score	5.0 ± 0.8	1.8 ± 0.5*†	4.6 ± 0.7
HADS anxiety score	8.7 ± 0.9	5.5 ± 1.1†	7.4 ± 0.8
VSI	54.7 ± 4.5	65.8 ± 6.2	65.1 ± 4.1

*[*p≤0.05 compared to NERD; †p≤0.05 compared to FH normal MNBI]*

Conclusion: Within the ROME IV FH category, heartburn with normal MNBI defines a subgroup with higher symptom burden, and higher anxiety and depression scores despite similar metrics on pH-impedance monitoring. Our findings suggest that normal MNBI may augment diagnosis of FH by identifying absence of reflux induced mucosal injury. Further research using normal MNBI values in defining FH is warranted.

Introduction: Recent years, functional dyspepsia is treated by two major categories of drugs; acid inhibitors such as H_2-receptor antagonists and proton pump inhibitors (PPIs), and prokinetic drugs that accelerate disturbed GI motility by modifying altered visceral sensitivity. Although PPIs are widely used as the initial treatment of choice in patients with epigastric pain, several randomized controlled studies have suggested that the efficacy of PPI therapy for FD is limited and may be confined to FD patients with co-existing EPS. Acotiamide may act directly on the gut and also indirectly through the brain-gut axis via actions in the central nervous system. Thus, it may be difficult to improve both PDS and EPS symptoms by using a single-agent therapy because of the complexity of FD. The aim of this study is to clarify whether acotiamide and rabeprazole combination therapy can improve clinical symptoms, gastric emptying and satisfaction with treatment in FD patients more effectively than acotiamide or rabeprazole monotherapy alone. We also aimed to determine whether acotiamide affects these changes via its effect on gastric emptying and appetite-related hormones such as ghrelin and leptin, and on the hypothalamic-pituitary-adrenal (HPA) axis.

Aims and Methods: We used Rome III criteria to evaluate upper abdominal symptoms, and anxiety by the State-Trait Anxiety Inventory. Gastric motility was evaluated by the ^{13}C-acetate breath test. Eighty-one FD patients were treated with acotiamide (300mg/day) (n = 35), acotiamide (300mg/day) and rabeprazole (10mg/day) (n = 28), or rabeprazole (10mg/day) (n = 18) for a period of 4 weeks and evaluated after 4 weeks of no treatment. ACTH, cortisol, leptin and ghrelin levels were measured in all FD patients.

Results: Acotiamide and rabeprazole combination therapy significantly improved PDS-like symptoms (postprandial fullness, p = 0.018; abdominal fullness, p = 0.04; early satiety, p = 0.041), epigastric pain (p = 0.024) and STAI-state scores (p = 0.04), compared to rabeprazole monotherapy. Both acotiamide monotherapy, and acotiamide taken in combination with rabeprazole, significantly (p = 0.001 and p = 0.02, respectively) improved satisfaction with treatment, compared to rabeprazole monotherapy. Acotiamide and rabeprazole combination therapy had no significant effect on ACTH or cortisol levels in FD patients. Of interest, acotiamide monotherapy, and acotiamide and rabeprazole combination therapy, significantly ($p < 0.0001$ and p = 0.018, respectively) increased acylated ghrelin/total ghrelin ratios and significantly (p = 0.04) improved impaired gastric emptying compared to rabeprazole monotherapy.

Conclusion: Further studies are warranted to clarify how acotiamide treatment improves clinical symptoms in FD patients.

Introduction: Autoimmune gastritis (AIG) is an organ-specific autoimmune and inflammatory disorder. It is characterized by reduction and loss of parietal cells and formation of autoantibodies against H^+/K^+-ATPase and intrinsic factor. Oxidant radicals increase secondary to inflammation in autoimmune and autoinflammatory disorders. The increase in reactive oxygen species can react with cellular macromolecules and causes in lipid peroxidation, nucleic acid damages and protein modifications. Thiols are functional sulfhydryl groups and consist of a sulfur atom and a hydrogen atom bound to a carbon atom and capable of reacting with free radicals in order to provide protection against tissue damage caused by reactive oxygen products. Thiol groups of proteins are oxidized by oxygen molecules and are reversibly converted to disulfide bonds. These disulfide bonds can be reduced to thiol groups in a condition of decreased oxidative stress. In case of oxidative stress, thiols form a number of products as a result of oxidative stress. These formed disulfide bonds can again be reduced to thiol groups, and therefore thiol-disulfide homeostasis is maintained. An abnormality in this homeostasis process may result in a variety of disorders. Since AIG is an autoimmune and inflammatory disorder, abnormal thiol/disulfide homeostasis may have a role in the pathogenesis of this condition.

Aims and Methods: Direct measurement of thiol-disulfide levels with a novel and automated method is already available. Therefore, the aim of this study was to investigate dynamic thiol/dislfide homeostasis in patients with AIG and identify possible factors associated with this oxidation. Also to determine whether thiol oxidation may have a role in the gastric emptying time in patients with AIG. Forty-nine patients with AIG and 52 healthy volunteers were enrolled in the study. Venous blood samples were collected from the subjects after overnight fasting. Serum samples were separated and stored at -80°C. Serum thiol-disulfide homeostasis was determined with a colorimetric method recently developed developed by Erel and Neselioglu (1). Native thiol and total thiol were measured directly, and disulfide level, disulfide/total thiol ratio, disulfide/native thiol ratio were obtained with calculation.

Results: Mean native thiol (330.65 ± 33.437 mmol/L *vs* 369.71 ± 21.73 mmol/L, P = 0.001) and native thiol/total thiol ratio total thiol levels (90.61 ± 98 vs 95.1 ± 26.7%, P < 0.001) were determined lower in AIG patients, compared to the control group. Mean disulphide level (21.47 ± 4.0 mmol/L *vs* 16.73 ± 2.4 mmol/L,respectively; P = 0.007), and disulphide/native thiol (5.1 ± 1.1 ± 1.2% *vs* 4.0 ± 1.2%, respectively, P < 0.001) were determined higher in AIG patients compared to the control group.

Conclusion: In this study, thiol/disulphide balance was shown to shift towards disulphide form in AIG patients, compared to the control group. According to these results, weakened thiol/disulphide equilibrium in AIG patients was thought to be associated with autoimmunity and inflammation. Determination of abnormal thiol/disulfide homeostasis in patients with AIG suggested that abnormal thiol/disulfide homeostasis may be related to the pathogenesis of AIG.

Introduction: In vitro studies have highlighted that the dissolution of levothyroxine sodium tablet (LT4) is inversely correlated to pH increase. An increased dose of LT4 is needed to reach therapeutic target of serum TSH in different gastric hypochlorhydric conditions as *Helicobacter pylori* infection, chronic autoimmune gastritis and chronic Proton pump inhibitors treatment. At present, a correlation between intragastric pH and required therapeutic LT4 dose is lacking.

Aims and Methods: The aim of our study was to determine *in vivo* a correlation between the pH of gastric juice and the effective dose of LT4 needed to restore euthyroidism.

Sixty-one dyspeptic hypothyroid patients (9M/52F; median age 51yrs range 26–73y) treated with LT4 were enrolled in this prospective study. In this cohort, 32 patients that required an excess of LT4 individually- tailored dose to normalize serum TSH value were screened for extraintestinal (drugs and food) and/or

gastrointestinal non-acid-related causes (celiac disease, Crohn disease, lactose intolerance, SIBO, gastric surgery) of LT4 malabsorption. All patients underwent gastroscopy with sampling of gastric acid secretion and multiple gastric biopsies to assess Sydney System-related gastritis patterns. Chronic atrophic gastritis (GCA) was defined as the presence of oxyntic glandular atrophy in fundus and corpus, pangastritis (PNG) when the active and chronic inflammation involved both the antrum and corpus, antritis (A) when inflammation was limited to the antral region. pH and [H^+] concentrations in gastric juice samples were measured by direct NaOH titration. According to the in vitro study by Pabla et al. (1), gastric pH value >2.4 was used as a cut off of established decrease of LT4 percentage dissolution in the stomach. Data are expressed as median (IQR range) and $p < 0.05$ considered statistically significant.
Results: In patients with gastric pH values ≤ 2.4, the median value of excess drug dose (+14%, IQR = 0–19) was significantly lower than that in patients with pH values >2.4 (+50%, IQR = 33–63) ($p < 0.0001$). Only 7/34 (20.6%) patients with pH values ≤ 2.4 required an excess drug dose compared with 25/27 (92.6%) patients with pH values > 2.4 ($p < 0.0001$). The increase in LT4 dose needed was differently distributed according to gastritis patterns. Indeed, 90.5% GCA patients (19/21) required an increased LT4 dose compared with 75% PNG (6/8) patients and only 22% with A or without histological alterations (7/32) (GCA vs A $p < 0.0001$, PNG vs A $p < 0.05$); these differences were strictly depended on pH value in relation to gastritis pattern (GCA median pH 6.6, IQR = 6–7.1; PNG median pH 3.1, IQR = 1.85–6.8; A or no histological alterations median pH 1.5; IQR = 1.3–1.9) (GCA vs A $p < 0.0001$, PNG vs A $p < 0.05$). The required therapeutic dose of LT4 was directly correlated with intragastric pH ($r^2 = 0.4850$; $p < 0.0001$) and inversely with gastric juice H^+ concentration ($r^2 = 0.4618$; $p < 0.0001$). Multivariate analysis including anthropometric characteristics (BMI, age, gender) of the patients revealed that gastric pH acts as independent variable in determining the dose of LT4 ($p = 0.029$).
Conclusion: *In vivo*, intragastric pH and gastritis patterns influence the required therapeutic dose of LT4. Therefore, in clinical practice, dyspeptic hypothyroid patients that need an increased LT4 dose to restore euthyroidism should be screened for any condition that impairs gastric acid secretion. The knowledge of gastritis patterns could speed up the tailoring of individual daily LT4 dose.

Introduction: There is increasing evidence that small intestinal bacterial overgrowth (SIBO) plays a role for the manifestation of a variety of gastrointestinal (GI) and non-GI diseases. While breath tests measuring H_2 and methane (CH_4) after ingestion of a glucose test meal are widely used to diagnose SIBO but they lack sensitivity and specificity, and are time-consuming.
Aims and Methods: To determine the mucosa-associated bacterial density in mucosal biopsies collected from the second part of duodenum. The patient groups were: i) "asymptomatic": referred for diagnostic work-up of a positive faecal occult blood test (FOBT) and/or iron deficiency anaemia (IDA) but with normal endoscopic findings; ii) patients with functional gastrointestinal disorders (FGIDs) and; iii) patients with inflammatory bowel disease (IBD). We also assessed the influence of smoking and proton pump inhibitor (PPI) intake on the bacterial densities. Biopsies were collected from 283 patients (170 female, mean age 50.5, range 17 to 78 yrs). Of these 70/283 were "asymptomatic", 94/283 with FGIDs of whom, 69 functional dyspepsia/Irritable bowel syndrome (FD/IBS) overlap, 22 FD only, 2 IBS only; 111/283 with IBD (69 UC and 42 CD); and 9/283 patients with other organic disease (OD) such as GERD. Data on demographic characteristics, type and severity of GI symptoms, psychological comorbidities and medications were assessed. During endoscopy, mucosal samples were collected utilising the Brisbane Aseptic Biopsy Forceps (MTW, Germany) to avoid the luminal and working channel contamination of tissue, and total DNA was extracted. In 98 randomly selected subjects, additional biopsies were taken with standard biopsy forceps, to allow for comparison between biopsy collection methods. Bacterial density was assessed and normalised to human DNA in each sample by qPCR, using bacteria-domain 16S rRNA gene-specific primers, and primers targeting the human beta-actin gene.
Results: Utilising the aspetically obtained biopsies, overall bacterial densities were significantly higher in patients with FGIDs (0.20 ± 0.49) compared to the controls (0.09 ± 0.29 $p < 0.02$). Bacterial density was significantly greater in patients using PPI (0.26 ± 0.61) compared to those without PPI use (0.05 ± 0.12; $P < 0.01$). However, the increased bacterial density in FGID patients compared to the asymptomatic control group was maintained, even if those patients using PPI in both groups were excluded. The bacterial densities on duodenal tissue from both UC (0.01 ± 0.02) and CD (0.02 ± 0.03) patients were significantly less relative to both FGID and the asymptomatic control group ($p < 0.05$). Smoking did not influence bacterial density ($p > 0.4$). Results from samples taken with standard biopsy forceps (and thus susceptible to cross-contamination) were only poorly correlated with the results produced from matched samples obtained with the aseptic biopsy device ($r < 0.1$; $p > 0.6$).
Conclusion: Bacterial density on duodenal tissue collected from FGID patients was significantly greater in comparison to asymptomatic controls, while the duodenal bacterial density in IBD patients was lowest of the three patient cohorts. In addition, PPI use appears to result in an increase in the bacterial density on duodenal tissue, irrespective of patient diagnosis. Measurement of both bacterial density and diversity on duodenal tissue are warranted to improve our understanding of the pathophysiology of digestive diseases and to identify patients that will respond positively to microbe-directed therapies.

Contact E-Mail Address: sabine.rabini@bayer.com
Introduction: Functional dyspepsia (FD) is one of the most prevalent GI diseases. It involves epigastric pain or burning, fullness and early satiety in the absence of organic systemic or metabolic diseases and it frequently overlaps with other upper gastrointestinal (UGI) symptoms (Stanghellini 2016). It recognizes a multifactorial pathohysiology and no single therapy has been shown to control all typical and overlapping symptoms.
STW 5 is a fixed herbal multicomponent preparation, that is indicated in FD with proven efficacy is several randomized controlled clinical trials (RCTs) and more than 5 decades of clinical experience.
The preparation was shown to beneficially affect different pharmacological targets associated with the pathogenesis of FD and hence is believed to improve a broad spectrum of symptoms displayed by FD patients. However, its efficacy on single symptoms was not clinically investigated until now. The current study closes this gap, as the available RCTs were specifically analyzed to investigate STW 5's effects on individual FD symptoms.
Aims and Methods: Data from previously conducted RCTs were pooled for the analysis. Of the 25 studies screened for eligibility, 6 were included [Madisch 2014; Caspary 2006; Malfertheiner 2003; Rösch 2000; Goebell 2000; Melderis 1994] which met the following: 1) 10 UGI symptoms assessed on a five-point Likert scale by the validated GIS sum score [Adam 2005], 2) Assessments of GIS items at baseline and after 28 days of treatment, 3) dosage used was 3x20 drops per day, 4) adult FD patients were included.
Results: Overall 637 patients were treated in 6 studies (STW 5: 351, placebo: 286). The full analysis set comprised 618 patients (STW 5: 346, placebo: 272). The STW 5 and placebo groups were comparable with regard to baseline characteristics, disease history, mean patient age, weight and gender distribution. Mean baseline GIS sum score was 11.8 (±4.1 SD, range: 1 to 27). Overall there were no structural differences between treatment groups with respect to baseline characteristics and length of treatment.
The mean improvement of GIS sum score from baseline observed after 28 days of treatment was 7.1 points for STW 5 and 4.9 points for placebo. The ANCOVA results (adjusted for baseline score) showed a statistically significant difference of 2.07 points between the treatments regarding improvement of GIS sum score in favor of STW 5 (95%-CI: 1.37, 2.76; $p < 0.0001$). Furthermore, the improvement of mean score for the single items comprising the GIS was consistently and significantly in favor of STW 5 for every single item.
Conclusion: In conclusion, the analysis stresses the clinically proven efficacy of STW 5 and shows that the preparation significantly improves every single FD symptom assessed in the GIS score. Theses study results substantiate STW 5's multitarget activity and ascertains its suitability for all subtypes of FD.

P1761 ROUTINE OESOPHAGEAL BIOPSIES IN THE INVESTIGATION OF DYSPHAGIA: ARE THEY COST EFFECTIVE?

M.H. Minto[1], D. Neal[1]
[1]*East Sussex Healthcare NHS Trust, Gastroenterology, Eastbourne, United Kingdom*

Contact E-Mail Address: moeedminto@hotmail.com

Introduction: Eosinophilic oesophagitis (EO) is a chronic immunogenic-antigen mediated disease of the oesophagus, histologically defined by over 15 eosinophil counts seen in a high-power microscopic field, without gastro-oesophageal reflux disease. It causes symptoms including dysphagia, regurgitation and food bolus impaction. Oesophageal biopsies are necessary to diagnose EO. We evaluated the results of routine oesophageal biopsies to investigate patients with dysphagia.
Aims and Methods: We studied the endoscopy records and oesophageal biopsy results of 160 consecutive patients who were referred with a new diagnosis of dysphagia to the endoscopy departments of East Sussex Healthcare NHS Trust, over a 3 month period. Data collection sources included the EndoBase reporting tool and patient case notes.
Results: 23 of the 160 patients had a diagnosis at endoscopy of oesophageal cancer or Barrett's oesophagus. These did not have routine biopsies taken for assessment of EO and were excluded from analysis. Of the remaining 137 patients who had biopsies taken at different levels in the oesophagus to screen for EO, 5 were consistent with a diagnosis of EO, representing 3.6% of patients. 61.3% were normal and 35.1% showed changes of reflux related inflammation. The case notes of the patients with EO were reviewed. All revealed a history of either food bolus impaction or repeated episodes of dysphagia. Two patients had a history or family history of asthma and eczema.
Conclusion: In this series 5 of 137 patients with symptoms of dysphagia were diagnosed with EO. The cost of biopsies at two different levels in the oesophagus was £46.68 per patient. £1279 was spent to diagnose one case of EO.
A selective strategy for taking oesophageal biopsies to diagnose EO would be more cost effective. This needs evaluation but restricting biopsies to those with a history of episodic food bolus obstruction, a family or past history of asthma or atopy and endoscopic signs such as mucosal furrowing and prominent concentric rings merits further assessment.

P1762 VARIATION IN THE INVESTIGATION AND DIAGNOSIS OF EOSINOPHILIC OESOPHAGITIS IN DAILY CLINICAL PRACTICE

A.V. Hadjinicolaou[1], S. Beg[1], G.S.Z. Tun[2], L. Warburton[3], S. Sansone[3], S. Riley[2], K. Ragunath[3], I. Modolell[1]

Introduction: Eosinophilic oesophagitis (EoE) is a recognised cause of dysphagia, with an estimated annual incidence of 6–13 cases/100,000 persons. Diagnosis can only be definitively established by endoscopic biopsy and as such, societal guidelines advocate the acquisition of six non-targeted oesophageal biopsies.
In this study, we aim to determine whether these recommendations are adhered to in routine clinical practice, and whether this practice is influenced by scope operator, patient age and referral pathway.
Aims and Methods: We performed a retrospective database review of all OGDs performed to investigate dysphagia or food bolus obstruction between 1st July 2016–31st June 2017, within three tertiary referral centres serving a total population of approximately 3.2 million people. We collected information on age, gender, endoscopy operator, referral pathway, endoscopic features and diagnosis, number of biopsies taken and histopathological diagnosis. Statistical comparisons were made using the Fisher's exact test or Chi-square test with Yates' correction to calculate odds ratios and evaluate their significance.
Results: During this time period a total of 4056 (15.9% of total) OGDs were performed as part of the investigation of dysphagia. Following exclusion criteria, 3712 (91.5%) OGDs remained eligible for our analysis. An endoscopic diagnosis for the cause of dysphagia was made in approximately one-third of cases (n = 1286; malignancy 5.1%, oesophagitis 15.7%, benign stricture 8.4%, candidiasis 2.9%, achalasia 1.1% and other 0.2%). In the remaining 2468 cases (66.5%) normal endoscopic appearances were described. Biopsies to exclude EOE were taken in 923 (37.4%) of these cases. The recommended 6 (or more) biopsies were received by histopathology in only 87 cases (9.43%).
When specifically comparing gastroenterologists to surgeons (total of 2193 normal endoscopies), we noted that gastroenterologists were 5.6 times more likely to obtain biopsies than surgeons (46.7% vs 13.6%, $p < 0.0001$, Table 1). In cases where biopsies were in fact taken, gastroenterologists were 8.6 times more likely than surgeons to obtain the recommended 6 or more biopsies (10.7% vs 1.4%, $p < 0.01$, Table 1). They were also 4.7 times more likely to consider a diagnosis of EOE at the time of endoscopy. Overall, in the 12-month period, 83 histologically confirmed cases of EOE were diagnosed of which 79 (95.2%) were made by gastroenterologists. The mean age of EOE cases was 46.2 years (range 21–85; 32.5% age > 50 years) with a M:F ratio of 2:1.

Normal Endoscopies	Total (n = 2193)	Gastroenterologists (n = 1648)	Surgeons (n = 545)	Comparison between groups
Endoscopies with biopsies taken (% of normal endoscopies)	843 (38.4%)	769 (46.7%)	74 (13.6%)	$p < 0.0001$
Endoscopies with 6 or more biopsies taken (% of endoscopies with biopsies taken)	83 (9.8%)	82 (10.7%)	1 (1.4%)	$p < 0.01$

[Table 1. Comparison of practice between gastroenterologists and surgeons]
When patient age was considered, we observed that biopsy acquisition was more than twice as likely in patients younger than 50 years old compared to older patients (52.4% vs 33.2%, $p < 0.0001$). Interestingly, we also observed that EOE was over three times more commonly diagnosed in patients referred routinely compared to those under urgent referral (5.0% vs 1.5%) although these results were possibly influenced by the proportion of patients biopsied.
Conclusion: In conclusion, our findings show that there is variable adherence to the investigation of EOE. The hospitals included serve a combined population of approximately 3.2 million, giving rise to a below average incidence of 3.32 cases per 100,000/yr. Our findings suggest that under-diagnosis may be secondary to under-investigation as a result of disparities in biopsy acquisition amongst gastroenterologists and surgeons, as well as influenced by patient age and referral pathway.

P1763 BRAVO WIRELESS PH MONITORING CAN SAVE TIME WHEN INVESTIGATING PATIENTS WITH EOSINOPHILIC OESOPHAGITIS

I.M. Bell, S.S. Zeki
St Thomas' Hospital, Gastroenterology, London, United Kingdom

Contact E-Mail Address: iona.bell@gstt.nhs.uk
Introduction: The incidence of eosinophilic oesophagitis (EoE) is increasing. Following diagnosis, the initial therapy is to place patients on protein pump inhibitors (PPI) and repeat oesophageal biopsies, as 30% of patients will be PPI responsive. As acid reflux is known to cause eosinophilic oesophagitis, pH impedance and manometry is also carried out to aid management. This is usually carried out as a separate hospital visit. An alternative test is wireless pH monitoring with a BRAVO device during which a pH monitoring chip is attached to the distal oesophagus at the same time as a gastroscopy. This is also an opportunity to take the repeated biopsies to assess PPI response; pH monitoring could therefore be integrated into the repeated endoscopic pathway and avoid the extra appointment for standard pH impedance. The fragile ''crêpe-paper'' mucosa of EoE has been raised as a potential source of early detachment of BRAVO capsules thereby limiting their use in this condition.
Aims and Methods: We aimed to assess whether there is any difference in the detachment day of the BRAVO capsule in patients with EoE when compared to other conditions and thereby determine its use in the pathway for the investigation of EoE patients.
The electronic records of patients with EoE who also had a BRAVO were examined retrospectively between June 2008 and January 2018 at a single centre. The total time of recording of the BRAVO capsule was noted and whether reflux was significant. In addition the number of eosinophils per high power field on the oesophageal biopsies taken prior to or at the same time as the BRAVO study was recorded.
Results: Ten patients with EoE underwent 12 BRAVO studies (M: F 1:1, age range 18–56). One study detached within one day, three after two days and eight after four days. The patient whose capsule detached early went on to have a second BRAVO study lasting 4 days. Detachment times were compared to those for non-EoE in our department for a single calendar year (December 2016-December 2017). There was no significant difference in detachment rates between these two groups ($p < 0.1$). The range of eosinophils per HPF was 20 to 71 (average 38.1, standard deviation 20.5).
Conclusion: Bravo pH manometry is a useful investigation in patients with EoE and beneficial to the patient; reducing the number of invasive procedures by allowing the attachment of the BRAVO capsule at the same time as taking post-PPI biopsies. The detachment was not significantly greater in patients with EoE although the numbers are small. There was no correlation between eosinophil count per HPF and attachment times. The only drawback is that patients are expected to stop PPI 7 days prior to the BRAVO being placed with a theoretical risk of a recrudescence of oesophageal eosinophilia in that time although the standard time for redevelopment of EoE is around 6–8 weeks.

P1764 ESOPHAGEAL COMPLIANCE IN PATIENTS WITH EOSINOPHILIC ESOPHAGITIS MEASURED BY ENDOFLIP BEFORE AND AFTER TREATMENT WITH TOPICAL BUDESONIDE

S. Casabona-Francés[1], M.T. Pérez-Fernández[1], M. Pérez-Romero[2], A. Sanz-García[2], G.J. Ortega-Rabbione[1], J. Fernández-Pacheco[1], P.L. Majano[2], C. Santander[1]

Introduction: Esophageal compliance is decreased in eosinophilic esophagitis (EoE). The reduction of compliance due to fibrosis has been shown to be a strong predictor of the risk of impaction and esophageal dilatation in patients with EoE. There is a lack of correlation between the eosinophil count and distensibility, revealing the dissociation that is sometimes observed between inflammatory and clinical activity. The reduced esophageal compliance correlates with the intensity of the endoscopic esophageal trachealization.
The functional endoluminal imaging probe (EndoFLIP®, Crospon Ltd., Galway, Ireland) for the study of esophageal distensibility and diameter uses the impedance planimetry technique and allows the analysis of volume-controlled esophageal compliance, obtaining three-dimensional images of the esophageal light.
The goal of the treatment of eosinophilic esophagitis is not only the clinical, endoscopic and histological improvement, but also the reduction in the degree of fibrosis, and therefore an improvement in esophageal compliance.
Aims and Methods: A pilot study to compare the esophageal compliance of patients diagnosed with active EEo before and after treatment with topical Budesonide.
We analyzed the esophageal compliance data of the first patients undergoing EndoFLIP at the Gastroenterology Department of the Hospital Universitario de La Princesa in Madrid. These patients presented active EoE and the esophageal compliance data were obtained before and after the treatment with Budesonide orodispersible tablets 1 mg every 12 hours for 6 weeks.
Results: Five patients were included in which clinical and histological improvement was observed (<15 eos/hpf), as well as an increase in diameter and statistically significant esophageal compliance ($p = 0.02$) after 6 weeks of treatment with topical Budesonide. The functional endoluminal imaging probe (EndoFLIP) for the study of esophageal distensibility was performed during the same endoscopic procedure, under sedation, and there were no complications associated with the procedures in any patient.
Conclusion: With topical budesonide treatment, the clinical and histological response and increased compliance in patients with EoE are achieved. More studies are needed with a greater number of patients and comparing with control subjects to know the clinical benefit of EndoFLIP in the follow-up of patients with EoE, and thus be able to establish its usefulness in the diagnostic-therapeutic algorithm of EoE.

Introduction: Eosinophilic Esophagitis (EoE) is a chronic immune-mediated disorder characterized by symptoms of esophageal dysfunction due to an inflammatory eosinophilic infiltrate in the esophageal lamina propria. Today the diagnostic gold standard is the histologic sampling of the esophagus and the recognition of at least 15 eosinophils for high power field (hpf). Up to 50% of patients with esophageal eosinophilia responds to a Proton Pump Inhibitor (PPI) therapy twice a day as first-line treatment. In order to confirm response to treatment, histologic sampling is necessary, and therefore according to international guidelines repeating upper endoscopy is mandatory. However, few data are available of the value of symptom reporting in predicting disease activity and response to PPI treatment.
Aims and Methods: We aimed to evaluate whether symptom remission due to PPI therapy may predict histological remission in patients with EoE responding to acid suppressive treatment. Patients with symptoms suggestive of EoE (i.e. dysphagia and bolus impaction) were prospectively enrolled in different Gastroenterology units in Italy. At baseline, an esophagogastroduodenoscopy (EGD) was performed to confirm the presence of inflammatory eosinophilic infiltrate (>15 oes/hpf) in the proximal and distal esophagus and to establish the diagnosis of EoE. Then, according to international guidelines, PPI-therapy was administered b.i.d. for eight weeks and a second EGD with biopsies was repeated to assess the endoscopic and histological remission due to acid-suppressive therapy. Esophageal symptoms including dysphagia, bolus impaction, heartburn and regurgitation were assessed before and after therapy by mean of a 4-point Likert scale, from 0 (absent symptom) to 3 (severe symptom). Histological remission was considered if esophageal samples presented less than 15 eos/hpf. A value of zero for each symptom after PPI therapy was indicative of clinical response.
Results: Thirty-one (25 Male; Age 18–68) patients with symptoms suggestive of EoE were enrolled. All of them presented dysphagia, 16 (52%) regurgitation and 19 (61%) heartburn. After 8 weeks PPI-therapy, 23 (74%) patients well responded to acid suppressive therapy and 8 (26%) subjects did not. Dysphagia disappeared in all of the subjects with a positive response to PPIs and only in 4 out of 8 refractory to PPIs. Moreover, regurgitation and heartburn resolved in 14/15 (93%) and in 16/17 (94%) of patients responding to PPIs, respectively, and in 1/1 (100%) and 1/1 (100%) of subjects refractory to PPIs, respectively. Using Fisher's test, we calculated sensitivity, specificity, positive and negative predictive values (PPV and NPV) of symptom disappearing in order to segregate PPI responders from PPI-non responders without performing an EGD. Disappearance of dysphagia presented a sensitivity of 100%, a specificity of 50%, a PPV of 80% and NPV of 100[ES1]% in detecting EoE-PPI responders ($p = 0.002$), whereas the disappearing of heartburn and regurgitation were not statistically significant ($p = 0.9$).
Conclusion: Clinical response to PPI therapy as assessed by the resolution of dysphagia is useful, but does not suffice to predict histologic response to PPI treatment. On the other hand, lack of disappearance of dysphagia after PPIs seems to justify starting steroid therapy without histological confirmation of persistent esophageal eosinophilia during upper GI endoscopy.
Disclosure: Nothing to disclose

P1766 POOR CORRELATION BETWEEN ENDOSCOPIC FINDINGS, EOSINOPHILIC INFILTRATION AND REFLUX BURDEN IN PATIENTS WITH EOSINOPHILIC ESOPHAGITIS

Introduction: Eosinophilic Esophagitis (EoE) is a chronic immune-mediated disorder characterized by symptoms of esophageal dysfunction due to an inflammatory eosinophilic infiltrate in the esophageal lamina propria. Currently, the endoscopic appearance of patients with EoE is defined by using the Endoscopic Reference Score (EREFS), whereas esophageal eosinophilic infiltration is used to diagnose EoE (i.e. >15eos/ high power field) and to estimate disease severity. The relationship between EoE and gastroesophageal reflux disease (GERD) has been demonstrated, although the magnitude of it is unknown and scant data have been published to date. Moreover, no sufficient data exist about the correlation of eosinophilic infiltrate with clinical presentation, endoscopic findings and reflux burden.
Aims and Methods: We aimed to correlate eosinophilic infiltration with clinical presentation, endoscopic findings as expressed by the EREFS score and reflux burden as assessed by impedance-pH studies. Patients with symptoms suggestive of EoE (i.e. dysphagia and bolus impaction) were prospectively enrolled in different Gastroenterology units in Italy. At baseline, an esophagogastroduodenoscopy (EGD) was performed to confirm the presence and entity of inflammatory eosinophilic infiltrate (>15 oes/hpf) in the proximal and distal esophagus and to establish the diagnosis of EoE. Endoscopic findings were expressed by using the EREFS score, describing the presence of edema, rings, exudates, furrows and stricture, whereas esophageal symptoms including dysphagia, bolus impaction, heartburn and regurgitation were assessed by mean of a 4-point Likert scale, from 0 (absent symptom) to 3 (severe symptom). Moreover, each patient underwent 24-hour pH-impendance testing off-medication in order to measure reflux burden. In particular, we measured the acid exposure time (AET; abnormal if greater than 4.2%), number of total reflux episodes (TRE; abnormal if higher than 54) and post-reflux swallow-induced peristaltic wave (PSPW) index and of mean nocturnal baseline impedance (MNBI).
Results: Forty-one (34 males, mean age 38, mean BMI 24) patients with a definite diagnosis of EoE were enrolled. Patients complained of dysphagia (mean score 2, range 1–3), heartburn (mean score 1, range 0–3) and regurgitation (mean score 1, range 0–2). The mean EREFS score was 2 (range 0–4), while the mean number of eosinophils were 33 (range 15–78). Impedance-pH feature are reported in the Table. Correlation was assessed by means of linear regression analysis and no statistically significant correlation was found between pick of eosinophils or EREFS score and AET, TRE, PSPW, MNBI and symptom score ($p = ns$).

Neither a correlation between pick of eosinophils count and value of EREFS score was observed (p = ns).
Conclusion: Eosinophils pick count in the esophageal mucosa of patients with EoE does not correlate with the severity of disease in term of endoscopic findings, symptomatic presentation and reflux burden. It seems that these factors are independently associated and additional phenomena are likely to be involved in determining the entity of eosinophilic infiltration.

Introduction: The incidence of erosive reflux esophagitis has increased sharply in Japan, probably due to falling prevalence of *Helicobacter pylori* (HP) infection. HP-associated atrophic gastritis, which reduces gastric acid secretion, is known to be protective against erosive reflux esophagitis. Therefore, both gastric acid secretion level and HP infection status should be taken into consideration when analyzing the risk factors of erosive reflux esophagitis. Pepsinogen I/II ratio is reported to correlate significantly with not only gastric atrophy grade but also gastric acid secretion level. Hence, we performed comprehensive analyses of the risk factors of erosive reflux esophagitis by using pepsinogen I/II ratio as a surrogate marker of gastric acid secretion level.
Aims and Methods: A total of 959 consecutive subjects who underwent esophagogastroduodenoscopy and measurement of serum pepsinogen level at the same day were enrolled. The following subjects were excluded to avoid the influence on pepsinogen levels; 1) those who had received successful HP eradication therapy in the past, 2) those who had undergone gastrectomy, 3) those who were taking proton pump inhibitors for various reasons, and 4) those having renal failure (Creatinine > 3.0 mg/dl). HP infection status was determined by the titer of serum HP-IgG. Erosive reflux esophagitis was defined as grade M or more reflux esophagitis according to Los Angeles classification. Univariate and subsequently multivariate logistic regression analyses were performed to identify the factors of erosive reflux esophagitis. The following factors were evaluated: sex, age, body mass index (BMI), pepsinogen I/II ratio, drinking status, smoking status, and HP infection status.
Results: The 959 enrolled subjects comprised 466 males, with a mean age of 52. To neutralize an influence of HP infection status on erosive reflux esophagitis, the entire cohort was divided into 2, HP-infected (HP-IgG positive, n = 236) and HP-noninfected (HP-IgG negative, n = 723) subjects. In HP-infected subjects, univariate analysis showed that factors significantly associated with erosive reflux esophagitis were pepsinogen I/II ratio (Odds ratio (OR) 1.45, 95% confidence intervals (CI) 1.10–1.91) and BMI (OR 1.12, 95%CI 1.01–1.91). Multivariate analysis showed that pepsinogen I/II ratio was only a significant factor of erosive reflux esophagitis (OR 1.41, 95%CI 1.06–1.86). On the other hand, in HP-noninfected subjects, univariate analysis showed that male sex (OR 4.17, 95%CI 2.94–6.25), BMI (OR 1.13, 95%CI 1.07–1.19), everyday drinking (OR 3.38, 95%CI 2.16–5.31), and current smoking (OR 2.83, 95%CI 1.76–4.56) were significantly associated with erosive reflux esophagitis. Multivariate analysis showed that male sex (OR 2.70, 95%CI 1.69–4.35), BMI (OR 1.07, 95%CI 1.01–1.13), and everyday drinking (OR 1.78, 95%CI 1.07–2.96) were statistically significant.
Conclusion: The factors for erosive reflux esophagitis differ between HP-infected and HP-noninfected subjects. In HP-infected subjects, pepsinogen I/II ratio was the only significant factor. On the other hand, in HP-noninfected subjects, demographic/lifestyle factors such as male sex, BMI, and everyday drinking were significant. These results suggest that although gastric acid secretion ability is fundamentally important for erosive reflux esophagitis, demographic/lifestyle factors are more important in HP-noninfected subjects whose ability to secrete gastric acid is reserved. In the era of falling prevalence of HP infection in Japan, lifestyle modification may be promising for preventing erosive reflux esophagitis.

Introduction: Gastric bypass (GBP) is considered an effective surgical treatment option for co-existing gastroesophageal reflux and obesity. However, previous studies examining GBP and reflux have had small sample sizes, short follow-up, and substantial loss to follow-up. This study aimed to assess how GBP influences reflux in a large study with long and complete follow-up.
Aims and Methods: This nationwide and population-based cohort study included 2,805 obese individuals with preoperative reflux who underwent GBP in Sweden in 2006–2015, with follow-up until 2016. Reflux was defined as dispensation of >6 months of antireflux medication, excluding other indications for such medication. Poisson regression was used to assess cumulative incidence and risk factors of postoperative reflux.
Results: Reflux re-occurred in 48.5% of patients within two years of GBP (48.5/100 person-years, 95% confidence interval [CI] 46.6–50.5). The re-occurrence of reflux remained stable around 50% during 3 to 10 years after GBP (yearly change in incidence rate ratio [IRR] of 1.00, 95% CI 0.99–1.02). Risk factors for postoperative reflux were high preoperative dose of antireflux medication (IRR = 1.83, 95% CI 1.67–2.01 comparing high with low dose), older age (IRR = 1.11, 95% CI 1.01–1.22 comparing age >50 with <40 years), female sex (IRR = 1.26, 95% CI 1.15–1.39), and comorbidity (IRR = 1.23, 95% CI 1.11–1.35 comparing Charlson comorbidity index ≥2 with 0).
Conclusion: Reflux re-occurs in approximately half of patients after GBP, and the rate is higher rates in individuals using high preoperative dose of antireflux medication, and in those of female sex, older age, and with comorbidities. These results suggest that the treatment effect of GBP may have been overestimated.

	Number (%)		
	Total	Women	Men
	2,805 (100.0)	2,301 (82.0)	504 (18.0)
Age (years) – mean (SD)	46.5 (9.8)	46.3 (9.8)	47.6 (9.6)
Comorbidities			
No comorbidity	1,752 (62.4)	1,486 (64.5)	266 (52.8)
1 comorbidity	762 (27.2)	604 (26.3)	158 (31.3)
≥2 comorbidities	291 (10.4)	211 (9.2)	80 (15.9)
Dose of antireflux medication prior to GBP* – mean (SD)	452.2 (240.7)	444.5 (231.8)	487.1 (275.1)
Low dose	1,227 (43.7)	1,021 (44.4)	206 (40.9)
Intermediate dose	1,256 (44.8)	1,038 (45.1)	218 (43.2)
High dose	322 (11.5)	242 (10.5)	80 (15.9)
Previous bariatric surgery	318 (11.3)	266 (11.6)	52 (10.3)

Introduction: Decrease in the lower esophageal sphincter pressure with increased gastro-esophageal pressure gradient and the hiatal hernia have been reported to be induced by high intra-abdominal pressure due to abdominal fat accumulation and obesity are related to the high prevalence of reflux esophagitis. Moreover metabolic syndrome is diagnosed by the factors of visceral fat accumulation, dyslipidemia, hypertension, and hyperglycemia, and all 4 factors have been suggested to correlate with the occurrence of GERD.

Aims and Methods: This study was performed to clarify the association between metabolic syndrome and erosive esophagitis and to find out which one of the diagnostic criterion of the metabolic syndrome is mostly correlate with erosive esophagitis. The study subjects were an adult population who visited a National Health Insurance Ilsan hospital for Korean National Cancer Screening Program from January 2011 to December 2016. Among 101,435 screened, 9,117(8.98%) subject diagnosed with erosive esophagitis. One to one propensity score-matched 8,537 pairs of with and without esophagitis subjects were compared.

Results: Mean age was 58.8 years old. Two-third were male (70.7%). A half of the subjects were non-smokers (48.3%) and one-third were moderate alcohol consumer (32.3%, >80g of ethanol per week) based on the questionnaire. Proportion of subjects accompanied with hiatus hernia was about 8.4%. Metabolic syndrome was more prevalent in esophagitis group (45.3% vs. 53.6%; $P < 0.001$). Unadjusted odds ratio of metabolic syndrome for esophagitis tended to increase, but not statistically significant (OR = 1.512, 95% CI 0.944–2.244; $P = 0.085$). The esophagitis group showed higher rate of obese subjects defined as waist circumference, one of diagnostic criteria for metabolic syndrome (27.3% vs. 35.9%; $P < 0.001$). As waist circumference increased, the Los Angeles grade of reflux esophagitis became more severe, assessed by the trend test ($P = 0.003$). Adjusted odds ratios of waist circumferences for esophagitis was 1.355 (95% CI 1.017–1.807; $P = 0.038$).

Conclusion: Waist circumference, rather than metabolic syndrome is a reliable predictive factor for the prevalence and severity of erosive esophagitis.

Introduction: Gastroesophageal reflux disease (GERD) is prevalent worldwide, which causes esophageal mucosal injury or reflux symptoms.[1] It not only affects people's health and quality of life, but also becomes a source of substantial burden and cost.[2] A variety of factors have been reported to be relevant to GERD such as body mass index (BMI), *Helicobacter pylori* infection and a certain diet.[3–5] Many studies have reported that drinking is associated to various digestive diseases.[6–8] However, there is still no comprehensive article to assess the correlation between alcohol consumption and GERD. To summarize the evidence on the effect of alcohol on GERD, we conducted a meta-analysis of observational studies. In addition, the drinking frequency and alcohol consumption were further classified and the dose response analysis was also conducted to explore the correlation.

Aims and Methods: This study aimed to investigate the association between alcohol consumption and GERD by meta-analysis. Two investigators searched for relevant studies respectively on PubMed, Cochrane and EMBASE published before December 2017. The summary odds ratios and 95% confidence intervals were calculated by random effects model to assess the association. Heterogeneity and subgroup analyses, sensitivity and publication bias analyses were also performed.

Results: Twenty-six cross-sectional studies and three case-control studies were included in the meta-analysis. Alcohol consumption was significantly associated with an increased risk of GERD in cross-sectional studies (OR, 1.55; 95%CI, 1.36–1.76; $I^2 = 89.1\%$). The case-control studies did not reveal any association between alcohol intake and GERD (OR, 1.08; 95%CI, 0.73–1.60; $I^2 = 87.2\%$). In two subtypes of GERD, the correlation between alcohol drinking and reflux esophagitis (OR, 1.78; 95%CI, 1.56–2.03; $I^2 = 87.5\%$) was stronger than that of non-erosive reflux disease (OR, 1.15; 95%CI, 1.04–1.28; $I^2 = 0.3\%$). The pooled OR for drinkers that drinking less than 3–5 times or days per week was 1.29(95%CI, 1.14–1.46; $I^2 = 35.5\%$), and 2.12(95%CI, 1.63–2.75; $I^2 = 55.1\%$) for those who drink more frequently. Dose-response analysis showed a linear association between alcohol consumption and GERD (P for nonlinearity = 0.235). The pooled OR for a 12.5g/day increment of alcohol was 1.162(95%CI, 1.065–1.268; $P = 0.001$).

Conclusion: This meta-analysis provides evidence for the association between alcohol intake and GERD. The increase in alcohol consumption and frequency showed a stronger correlation with GERD.

Introduction: Gastro-oesophageal reflux disease (GORD) is a common condition with a prevalence of up to 28%, often causing impaired quality of life [1]. Avoidance of lifestyle factors such as tobacco and alcohol is often recommended in GORD management; mostly based on tradition and only to some degree on epidemiological findings. Hence, smoking is associated with an up to two-fold increased risk of GORD as well as Barrett's oesophagus (BO), whereas the effects of alcohol are less well known [1]. Physiologically, lower oesophageal sphincter pressure (LOSP) decreases during tobacco smoking and after alcohol intake [1]. Correspondingly, smoking cessation has been shown to improve reflux symptoms, but only in normal-weight GORD patients, whereas the effect on acid exposure is less clear [1]. For alcohol, any immediate effect on oesophageal function in regard to reflux symptoms and/or reflux monitoring is doubtful [1]. In the long-term however, alcohol may lead to neuropathy [2] and possibly even have positive effects on chronic pain [3]. Only one study has addressed the association between smoking and oesophageal sensitivity, finding no relation, likely due to the inclusion of only three smokers.

Aims and Methods: We aimed to characterize the impact of alcohol and tobacco consumption on experimental oesophageal sensitivity, and hypothesized that both of these are associated with hyposensitivity. Twenty-three patients with BO (mean age: 64.2 ± 7.8 years) and 12 healthy controls (mean age: 54.9 ± 10.8 years) were included. At baseline, all subjects reported consumption of alcohol (standard drinks per week) and tobacco (accumulated pack years). At a later visit, experimental oesophageal pain sensitivity was assessed by placing a multimodal stimulation probe in the lower oesophagus. The probe was then used to apply mechanical distension, thermal stimulation, electrical stimulation, and acid perfusion with 0.1 M hydrochloric acid (a Bernstein test). All stimulations were stopped when the subject felt moderate pain.

Results: Tolerated acid volume (hyposensitivity) increased with greater tobacco exposure and alcohol consumption in healthy controls (tobacco: $P < 0.001$, alcohol: $P = 0.001$), but not in patients with BO (all $P > 0.3$). Concerning mechanical stimulation, a greater tolerated bag volume was associated with greater tobacco exposure only in patients with BO ($P = 0.02$). For healthy controls in relation to tobacco smoking and for alcohol use in both groups, no significant associations with sensation to mechanical stimulation were found (all $P > 0.6$). For electrical and thermal stimulation, neither alcohol nor tobacco use showed any significant associations in any of the groups (all $P > 0.1$).

Conclusion: Oesophageal sensitivity decreased with greater reported consumption of alcohol and tobacco. Previous findings of a strong association to smoking in asymptomatic patients with oesophagitis support this [4]. Hyposensitivity in smokers could be due to a direct nociceptive effect of nicotine [5], whereas other factors might explain hyposensitivity related to alcohol. Further evidence is needed to support these findings.

Introduction: Some recent studies suggested that reflux esophagitis is positively correlated with asthma. However, there are debates on this issue.
Aims and Methods: The aim of this study is to clarify the true association between reflux esophagitis and asthma in a large population. Medical records of subjects who received health surveillance checkup between January 2005 and December 2011 were reviewed. There endoscopic finding, medical history, body mass index, smoking history were analyzed. Reflux esophagitis was defined as endoscopically detected mucosal break at the Z-line irrespective of reflux symptom. Information about patients' history of asthma was obtained from their questionnaire and medical records.
Results: Out of the total 15,999 patients, 986 had reflux esophagitis and 376 had asthma. In this population, reflux esophagitis was inversely related with asthma in univariabe analysis (OR, 0.586; 95% CI, 0.342–1.003, $p = 0.049$). In multivariable analysis, asthma was demonstrated as an independent negative risk factor for reflux esophagitis (OR, 0.472; 95% CI, 0.257–0.869, $p = 0.016$), under adjustment with age (OR, 0.472; 95% CI, 0.257–0.869, $p = 0.016$), male sex (OR, 2.092; 95% CI, 1.683–2.601, $p < 0.001$), body mass index (OR, 1.115; 95% CI, 1.090–1.141, $p < 0.001$), smoking (OR, 1.584; 95% CI, 1.318–1.902, $p < 0.001$), and urban residence (OR, 1.363; 95% CI, 1.149–1.616, $p < 0.001$). Likewise, reflux esophagitis was shown to be an independent negative risk factor for asthma (OR, 0.558; 95% CI, 0.324–0.960, $p = 0.035$) under adjustment with age (OR, 1.025; 95% CI, 1.015–1.034, $p < 0.001$), male sex (OR, 0.861; 95% CI, 0.691–1.074, $p = 0.185$), BMI (OR, 1.067; 95% CI, 1.030–1.106, $p < 0.001$) in multivariable analysis.
Conclusion: Contrary to previous studies, this large-scale data showed inverse association between reflux esophagitis and asthma. Further studies investigating the clear mechanism of this phenomenon are warranted.

P1773 CLINICAL CHARACTERISTICS OF GASTROESOPHAGEAL REFLUX DISEASE IN SUBJECTS WITH SLEEP-DISORDERED BREATHING

J.-H. Oh, M.-J. Cho
The Catholic University of Korea, Internal Medicine, Seoul, Korea (Republic of)

Contact E-Mail Address: ojhmed@gmail.com

Introduction: There is insufficient evidence for a relationship between gastroesophageal reflux disease (GERD) and obstructive sleep apnea (OSA). The purpose of this study was to determine whether OSA patients proven by polysomnography would be related to GERD.
Aims and Methods: A total of 424 subjects was evaluated in St. Paul's Hospital, Catholic Medical Center, Korea, between September 2009 and September 2015. Nocturnal polysomnography was performed and a GERD questionnaire was asked. The apnea-hypopnea index < 5 was defined as non-OSA subjects. Subjects with heartburn or acid regurgitation at least once a week were classified as having GERD.
Results: Among 424 subjects who underwent polysomnography, 320 were OSA and 104 were non-OSA. There was no difference in the prevalence of GERD between OSA and non-OSA (10.6% vs 13.1%, P = 0.609). There was no relationship between the percentage of subjects with GERD and the severity of OSA (Non-OSA: 11, mild OSA:8, moderate OSA:12, severe: 22, P = 0.549). Subjects with GERD had the higher scores in Stanford sleepiness scale (SSS) (P = 0.001), Epworth sleepiness scale (ESS) (P = 0.003), and depression (P < 0.001) than non-GERD subjects. GERD subjects had higher waist-to-height ratio and waist circumference to height index than non-GERD. The multiple logistic regression showed that SSS, ESS, and depression were independent factors associated with GERD.
Conclusion: There may not be little relationship between GERD and OSA. SSS, ESS, and depression are associated with GERD in subjects with sleep-disordered breathing.

Introduction: Gastroesophageal reflux disease (GERD) is a disease determined by several concomitant factors. The pathophysiology is particularly linked to obesity, smoking habits and the secretive activity of the stomach; the variability of endoscopic findings depends on different resistance and sensitivity of the individual patient's mucosa.
Aims and Methods: Aim of this study was to evaluate the influence of epidemiological risk factors (age, sex, obesity, smoking habits) and gastric acid secretion status in the development of esophagitis in a *H.pylori*-negative population.A group of 320 patients (M = 234, F = 86, mean age = 42.7 ± 11.6 range = 18.80) with symptoms of the upper GI tract was recruited. They underwent gastroscopy in order to assess the presence of esophagitis: 150 had esophagitis (Group A) in comparison with 170 without lesions (Group B). All patients underwent to gastric acid aspiration test for measuring basal acid output (B.A.O.) and maximal acid output (M.A.O.) after stimulation with pentagastrin (i.m., 6 μg/kg). All of them underwent a blood sampling for serum pepsinogen I and G17 determination. Statistical analysis were performed by means of Mann-Whitney test for the comparison of demographic characteristics and endoscopic diagnoses. An univariate analysis was used to evaluate risk factors such as age, sex, smoking habit, BMI, M.A.O., PGI, G17. All patients underwent a 15-years follow-up using gastroscopy when symptoms occurred to assess the onset of a feature of esophagitis.
Results: Univariate analysis demonstrated a significant association between the feature of esophagitis, lasting the follow-up, and M.A.O. (p = 0.0001), PGI (p = 0.0001), G17 (p = 0.0001), BMI (p = 0.014), while no association was found with age, gender nor smoking habit.
Conclusion: Our study demonstrated a positive association between high gastric secretion (M.A.O., PGI and G17) as well as BMI and the onset of esophagitis in an H.p. negative population lasting a long 15-years follow-up.

Introduction: There are great difficulties for the diagnosis of laryngopharyngeal reflux disease (LPR). Reflux finding score (RFS) and reflux symptom index (RSI) were proposed for the diagnosis however their value is questionable. We propose a new diagnostic tool with the measurement mucosal impedance in different areas of larynx and pharynx in patients with LPR and controls.
Aims and Methods: The objective of the study was to assess the relation of laryngeal mocusal impedance values with LPR. In total 78 patients (38 female) were included who were operated for different ENT pathologies other than laryngeal diseases. Exclusion criteria; previous upper gastrointestinal or laryngeal surgery, on-going proton pump inhibitor treatment, other laryngeal disorders, previous radiotherapy in the head and neck, laryngeal carcinoma. Patients were divided into four groups according to RSI, RFS (Table). Normal values were accepted < 13 for RSI and < 7 for RFS. After the general anesthesia and intubation, the mucosal impedance measurements of band ventricle, arytenoid, vallecula, posterior comissure, endolaryngeal surface of epiglottis and buccal area (as control) were recorded using Ohmega (Laborie) MII-pH equipment with an impedance catheter (Unisensor). A mean value from a stabile measurement was taken from each area.
Results: It was possible to achieve stabile and reliable values from all measured areas. Mean mucosal impedance values of the band ventricle, arytenoid, posterior comissure, endolaryngeal surface of epiglottis, vallecula and buccal area were given in the table. A statistically significant difference was found for band ventricle, arytenoid, vallecula and endolaryngeal surface of epiglottis ($p < 0.05$) within all groups but especially between groups I (both RFS & RSI pathologic) and IV (both normal). 51 non-smokers exhibited higher but insignificant

Abstract No: P1775
Table 1: Mean impedance values of the laryngeal areas and buccal area (ohms) (* $p < 0.05$; comparison of four groups).

Groups	Band ventricle*	Arytenoid*	Posterior commissure	Endolaryngeal surface of epiglottis*	Valleculae*	Buccal area
I (n = 30) (RFS+/RSI+)	835 ± 270	793 ± 302	1153 ± 300	566 ± 147	1520 ± 346	2268 ± 369
II (n = 8) (RFS-/RSI+)	1047 ± 385	1293 ± 308	1302 ± 208	733 ± 214	1843 ± 421	2192 ± 553
III (n = 11) (RFS+/RSI-)	1182 ± 125	1043 ± 153	1304 ± 165	727 ± 95	1651 ± 246	2145 ± 341
IV (n = 29) (RFS-/RSI-)	1203 ± 325	1191 ± 317	1278 ± 374	740 ± 253	1850 ± 241	2484 ± 406

measurements compared to 27 smoker patients in all measured areas except band ventricle (1183 vs 779 ohms). Binary logistic regression analysis revealed that a model using measurements from ventricular fold (OR 0.995, 95%CI 0.991–0.999), arytenoid (OR 0.991, 95%CI 0.984–0.998) and endolaryngeal surface of epiglottis (OR 0.993, 95%CI 0.988–0.999) was able to distinguish especially between group I and group IV with a sensitivity of 93% and a specificity of 83%.
Conclusion: Mucosal impedance measurement of the larynx and pharynx can be used as a promising diagnostic tool. Smoking, as a possible strong confounding factor, has very limited impact on measurements. When our findings were evaluated with the parameters of RFS, posterior commissure hypertrophy should not be taken into consideration however ventricular obliteration should be more emphasize. Considering the results of logistic regression more attention should be paid also to the arytenoids and endolaryngeal surface of epiglottis. It is possible to create a new diagnostic scoring system with this more objective technology. Outcome data and thinner catheters are needed for office-based measurements.

Introduction: Impedance-pH monitoring, providing a comprehensive assessment of reflux independently of the pH of refluxate, allows to reliably distinguish non-erosive reflux disease (NERD) from functional heartburn, and thus represents a valuable test for investigating proton pump inhibitor (PPI)-refractory patients.
Aims and Methods: We aimed to investigate whether impedance-pH off- or on-therapy may better identify patients with NERD responding to PPI treatment. In this prospective, multicenter study, 64 patients complaining of heartburn and with a negative upper endoscopy, underwent impedance-pH testing off-therapy. Then, patients with proven NERD based on traditional parameters (i.e. abnormal AET and/or positive symptom association analysis) were treated with PPI for 8 weeks and repeated the impedance-pH testing on-therapy. Tracings were blindly and manually reviewed and we measured conventional reflux testing parameters, such as esophageal acid exposure time (AET), number of reflux episodes and symptoms association analysis (symptom index, SI, and symptom association probability, SAP), and novel impedance-detected features, including the post-reflux swallow-induced peristaltic wave (PSPW) index and mean nocturnal baseline impedance (MNBI).
Results: Thirty-two individuals (16 male, mean age 48) had PPI-refractory heartburn (i.e. < 50% of symptom relief after 8-week high-dosage PPI therapy), and thirty-two (18 male, mean age 56) had PPI-responsive heartburn. Demographic and clinical characteristics were not different between the two groups at baseline (p = ns). At off-therapy impedance-pH monitoring, no differences were found between PPI-refractory and PPI-responsive patients in terms of median AET, number of reflux episodes, symptoms association analysis, PSPW and MNBI, as illustrated in the Table. At on-therapy reflux testing, median esophageal AET and symptom association analysis did not differ between the two groups. However, the total number of refluxes, weakly acidic refluxes and bolus exposure were significantly higher, while PSPW index and MNBI were significantly lower in PPI-refractory cases ($p < 0.05$), as shown in the Table.

Impedance-pH Features	PPI-refractory N = 32	PPI-responsive N = 32	P Value
Off-Therapy			
Mean AET,%	6.2 (4.2–9.9)	5.0 (3.3–8.9)	0.471
PSPW index (%)	24 (19–31)	29 (20–32)	0.378
Mean MNBI, Ohms	1321 (889–1861)	1127 (741–1655)	0.214
Total Refluxes, n	53 (39–77)	42 (31–68)	0.053
Total Refluxes, n	46 (33–63)	41 (26–50)	0.076
Weakly Acidic Refluxes, n	7 (4–13)	3 (1–13)	0.087
Mean Bolus Exposure Time (%)	2.3 (2.0–3.2)	1.4 (0.8–2)	0.568
On-Therapy			
Mean AET (%)	0.4 (0.1–1.9)	0.1 (0.0–0.8)	0.190
PSPW index (%)	26 (19–37)	46 (35–51)	<0.001
Mean MNBI, Ohms	2129 (1615–2742)	2779 (2199–3122)	0.012
Total Refluxes, n	53 (35–81)	29 (14–47)	0.002
Acid Refluxes, n	9 (3–16)	4 (1–9)	0.061
Weakly Acidic Refluxes, n	34 (17–64)	23 (8–37)	0.018
Mean Bolus Exposure Time (%)	2.3 (1.2–5.0)	0.9 (0.4–1.9)	0.008

[Baseline off- and on-therapy impedance-pH features of 32 patients with PPI-refractory and 32 patients with PPI-responsive heartburn]
Conclusion: Our data showed that only on-therapy impedance-pH monitoring is able to differentiate patients with NERD who are responding to PPI therapy from those who are refractory to acid-suppressive treatment. In particular, impedance-detected characteristics (i.e. total number of refluxes, bolus exposure, PSPW index and MNBI) seem to better correlate with response to PPI therapy. This study provides additional evidence on the value of impedance-pH testing as compared to pH-metry alone in investigating reflux disease patients and evaluating therapeutic outcome

Introduction: There are reports about the relationship between baseline impedance level and oesophageal mucosal integrity by endoscopic findings such as erosive and non-erosive reflux oesophagitis. However, many children with symptoms of GORD have normal findings or minor changes on oesophagogastroduodenoscopy (OGD). We would like to examine whether trivial changes in OGD study can be evaluated by multichannel Impedance monitoring as an alternative measure.
Aims and Methods: Patients (ages 0–18 years) with symptoms related to GOR who underwent OGD and pH-MII monitoring in Women's and Children's Hospital in Adelaide, Australia, between 2014 and 2016 were retrospectively studied and the following data were collected: demographics (age, gender), pH-MII data (acid exposure (pH), included reflux index (acid exposure time), mean acid clearance time, longest episode of acid exposure). Impedance data included: the number of acid and non-acid reflux events, and baseline impedance (distal channels; 5,6 was objectively calculated using software created using Matlab (MathWorks, Natick, MA)). Endoscopic findings were classified by modified Los Angeles grading, LA-N as normal, LA-M as with a minimal change such as the reddish or whitish mucosa, or friability in the mucosa. Patients on proton pump inhibitors were excluded. Other exclusions were the presence of esophageal anatomical anomaly, eosinophilic esophagitis, and previous anti-reflux surgery.
Results: Seventy patients (43 boys 61%) were enrolled with a mean of age of 7.9 years (range 10 months to 17 years) in this study. Fifty-one patients (72.9%) were allocated to LA-N, while LA-M evident in 19 patients (27.1%). Statistical differences were observed in four parameters: frequency of acid ($p = 0.034$) and non-acid reflux ($p = 0.022$), baseline impedance in channel 5 ($p = 0.024$) and 6 ($p = 0.005$). The mean values ± SE of the data were LA-N: 22.16 ± 2.94 episodes,

21.86 ± 2.26 episodes, 2574.8 ± 97.60 Ω, 2491.1 ± 109.3 Ω, In LA-M: 32.68 ± 3.84 episodes, 40.4 ± 7.21 episodes, 2163.2 ± 130.7 Ω, 1897.3 ± 169.2 Ω.
Conclusion: In children with GOR Minor oesophageal endoscopic findings were associated with lower baseline impedance. It is therefore reasonable to relate the number of acid and non-acid reflux episodes to minor changes in the distal oesophagus.
Disclosure: Nothing to disclose

P1778 THE CONSISTENCY OF LOS ANGELES CLASSIFICATION OF GASTROESOPHAGEAL REFLUX DISEASE ACCORDING TO THE INSERTION/WITHDRAWAL PHASES OF ESOPHAGOGASTRODUODENOSCOPY

S.-J. Nam, S.J. Lee, C.D. Kang, S.C. Park, J.M. Park, S.H. Lee

Introduction: During esophagogastroduodenoscopy (EGD), patients often belch and retch. Gastroesophageal junction (GEJ) is a narrow area easily affected by endoscopic manipulation and belching or retching of patients during endoscopy. But there is no consensus on optimal timing of grading esophagitis during EGD, and no study was performed to assess the effect of these factors on the Los Angeles (LA) classification of reflux oesophagitis.
Aims and Methods: We performed prospective observational study to investigate the effect of endoscopic movement and patients' belching/retching during EGD on the GEJ appearance. Still images of GEJ were captured during both insertion and withdrawal phases of EGD and analyzed separately. All the image sets of GEJ (each subject has two image sets, one during insertion and the other during withdrawal) were mixed randomly, and reviewed by two expert endoscopists (who had performed more than 3000 upper gastrointestinal endoscopy), who are unaware of the relationship of mixed image sets. LA classification was recorded as normal, minimal change, A, B, C, and D. Simplified working definition of minimal change lesion (i.e., white turbid discoloration and Z-line blurring) was adopted in this study [1]. LA classifications determined by two reviewers were compared. For incongruent results, final grading was made by mutual agreement after discussion. During EGD, patients' belching and retching were scored by endoscopist as follows: none, mild (no significant but presence of any event), moderate (able to complete examination but difficult and prolonged examination due to the event), and severe (cannot evaluate completely due to the event).
Results: We prospectively enrolled 369 consecutive subjects, and 11 subjects were excluded due to unclear GEJ image for LA classification. Finally, 358 subjects (183 males and 175 females, mean age 59.6 years, range 17–87 years) were analyzed in this study. Belching occurred in more than 70% of subjects (none: 29.7%, mild: 52.1%, moderate: 15.7%, severe: 2.5%). Retching occurred in 7.5% of subjects (none: 92.4%, mild: 3.4%, moderate: 4.2%, severe: 0%). LA classifications graded from image sets during withdrawal phase were upgraded significantly compared to classifications graded from image sets during insertion phase ($p < 0.001$; Wilcoxon signed ranks test). Totally, LA classification change was occurred in 49 subjects (13.7%). The most common change between insertion and withdrawal phase was from 'normal' to 'minimal change' (Table 1). Even though LA classification was not affected, there were several cases developing mucosal erosions and minor bleeding on GEJ during withdrawal phase (N = 12, 3.4%). Belching and retching was not significantly associated with LA classification change ($p = 0.075$ and $p = 0.128$ for each; Linear by linear association).

		Withdrawal phase				
	normal	minimal	LA-A	LA-B	Total	
Insertion phase	normal	159	38	4	0	201
	minimal	5	81	2	0	88
	LA-A	0	0	62	0	62
	LA-B	0	0	0	7	7
	Total	164	119	68	7	358

[Relationship of LA classifications between insertion and withdrawal phase]
Conclusion: LA classification of gastroesophageal reflux disease can be affected by endoscopic manipulation during EGD. We suggest taking pictures of GEJ during insertion phase rather than withdrawal phase for exact classification of reflux esophagitis.
Disclosure: Nothing to disclose

Introduction: The spectrum of esophageal motor function, and reflux burden within obese subjects is not fully known. We compared esophageal questionnaire data, esophageal motor function and reflux metrics on pH-impedance monitoring among symptomatic and asymptomatic obese subjects presenting for bariatric surgery.
Aims and Methods: Our aim was to describe esophageal motor function and esophageal reflux metrics in symptomatic and asymptomatic obese subjects (BMI > 30). Patients undergoing esophageal function testing (HRM, pH-impedance monitoring off medications) over 1.5 years prior to bariatric surgery were eligible for inclusion. Prior foregut surgery, lack of symptom data and incomplete esophageal tests were exclusion criteria. Patients completed standardized questionnaires evaluating reflux symptoms (GERDQ). HRM studies were evaluated using Chicago Classification 3.0 and GERD classification metrics; acid exposure time (AET, physiologic < 4%, pathologic > 6%), numbers of reflux episodes and mean nocturnal baseline impedance (MNBI, normal > 2292 ohms) recorded 5 cm proximal to the lower esophageal sphincter (LES), and post-reflux swallow-induced peristaltic wave index (PSPW index) were extracted from pH-impedance monitoring. Data were analyzed to determine the discriminative value of esophageal physiologic testing in identifying patients with pathologic esophageal acid exposure in obese patients.
Results: 34 obese patients (43.0 ± 2.3 yr, 85%F, BMI 49.6 ± 2.7) fulfilled study inclusion criteria; 28 (82.4%) reported heartburn or regurgitation on questionnaires, and 17 had a positive GERDQ (≥8). Demographics, esophageal motor diagnoses and esophageal pH-impedance metrics were similar regardless of symptom status. Using AET > 6% and MNBI < 2292 as indicative of pathologic reflux, the two metrics were concordant in 21/34 (61.8%), discordant in 11/34 (32.4%); AET was borderline (4–6%) in 2 patients. Compared to AET < 4%, patients with AET≥4% had higher numbers of reflux episodes (43.5 ± 4.0 vs. 66.3 ± 10.3 respectively, $p = 0.02$), and lower mean MNBI (2184 ± 219 vs. 1128 ± 206 respectively, $p = 0.003$) and a trend toward a higher proportion with low MNBI (84.5% vs. 52.4%, $p = 0.06$), but similar BMI, symptom burden and motor characteristics. When the study cohort was segregated by MNBI, those with low MNBI (<2292 ohms) had lower BMI, higher total AET, supine AET, and a lower PSPW index compared to patients with normal MNBI ($p \leq 0.04$ for each comparison, Table). In the normal MNBI cohort, there was 1 patient (8.3%) with AET > 4 and no patients with AET > 6%, compared to 10 patients (45.5%) with AET > 4 and > 6 when MNBI was low ($p = 0.005$). Symptom assessment (GERDQ, MDQ), EGJ morphology and barrier function, esophageal body contraction vigor, and esophageal motor diagnoses could not differentiate AET-based or MNBI-based cohorts.

	Low MNBI (<2292 ohms)	Normal MNBI
Body mass index	46.5 ± 1.61	55.4 ± 3.37*
Ineffective esophageal motility	23%	25%
Number of reflux episodes	51.8 ± 6.01	53.0 ± 4.6
Total AET	4.93 ± 0.91	2.27 ± 0.47*
Supine AET	4.22 ± 1.09	0.64 ± 0.32*
AET > 6%	45.5%	0%
PSPW index	17.4 ± 2.3%	30.1 ± 3.1%*

[$p < 0.05$ compared to normal MNBI]*
Conclusion: Symptom questionnaires, HRM EGJ findings, and esophageal body motor function are unable to identify abnormal reflux metrics in obese patients, implying that ambulatory reflux monitoring is necessary to define reflux burden in this population. MNBI recorded 5 cm above the LES is able to segregate patients with abnormal AET from those with borderline and physiologic AET.
Disclosure: Nothing to disclose

P1780 HIGH PREVALENCE OF GERD IN PATIENTS SYMPTOMATIC ON PPI: RESULTS OF THE BRAZILIAN LOST PATIENT (LOPA) STUDY

C.T. Saad[1], J. Labenz[2], S. Attwood[3]
[1]*Hospital Regional – State University of Ponta Grossa, Endoscopy, Ponta Grossa, Brazil*
[2]*Diakonie Klinikum Jung-Stilling Hospital, Innere Medizin, Siegen, Germany*
[3]*Durham University, Health Services Research, North Tyneside, United Kingdom*

Contact E-Mail Address: caroline.saad@hotmail.com
Introduction: Randomized controlled trials report ~30% of GERD patients complain of bothersome residual symptoms (heartburn/regurgitation) despite PPI. Some patients' symptoms are caused by functional disease, however only a minority undergo anti-reflux surgery or formal evaluation. The LOPA (Lost Patients) studies of GERD patients in Germany revealed 46% of patients

experienced residual symptoms ≥2 days per week despite PPI but < 10% received specific GERD diagnostics or were recommended treatment alternatives.
Aims and Methods: The LOPA Brazil study is a prospective, multicenter, observational study conducted in 17 reflux specialty centers with 21 physicians (9 gastroenterologists, 12 surgeons). "Lost Patients" – with chronic GERD, on PPI therapy ≥1 year, and not satisfied with their treatment, were asked to complete a questionnaire. The physician was then asked to complete the patient's physiological information and treatment recommendation following the visit.
Results: Responses were collected from 511 patients (42% male, mean age 46.7). Mean duration of GERD was 7.2 years; patients were prescribed PPI therapy on average 5.2 years.
Overall, 77% (n = 393) experienced heartburn and/or regurgitation ≥2 days per week (39% 4–7 days). More than half (54%) of patients were dissatisfied with their GERD condition (score 1–2 on an Likert scale 1–5). Reasons for dissatisfaction included breakthrough symptoms (88%), fear of risks associated with long-term medication (49%), inconvenience of daily medication (48%), and side effects from medication (5%).
However, 62% of dissatisfied patients (166/265) and 66% overall (331/499) had never visited a surgeon for their GERD; 49% of patients said their doctor advised them against surgery.
pH or pH-impedance results were available for 56% (n = 288) of patients. In the GI and surgeon groups, 51% (46/84) and 56% (113/206) had pathological 24-h pH (time pH < 4.0 > 6.0%), respectively, and 65% (54/84) and 69% (143/206) with pathological DeMeester score (> 14.7), respectively.
Despite similar patient-reported symptoms and physiological results, differences were seen in how patients were consulted. GIs recommended 18% of patients to surgical consult, 79% to continue PPI therapy, 8% to try different reflux medication, and 7% to seek treatment for a non-GERD condition. Surgeons recommended 63% for surgical consult, 20% to continue PPI therapy, 1% to try different reflux medication, and 9% to seek treatment for a non-GERD condition.
Conclusion: "Lost Patients" with bothersome GERD symptoms are frequently seen in practice in Brazil. A screening tool could help identify and consult these patients, and raise awareness in general practice of patients who could benefit from additional investigation and specialized treatment.
Disclosure: All authors have worked as medical consultants for Endostim.

P1781 GERD PATIENTS ACROSS CULTURES HAVE SIMILAR CONCERNS: A COMPARISON OF "LOST" GERD PATIENTS IN GERMANY AND BRAZIL

C.T. Saad[1], J. Labenz[2]
[1]*Hospital Regional – State University of Ponta Grossa, Endoscopy, Ponta Grossa, Brazil*
[2]*Diakonie Klinikum Jung-Stilling Hospital, Innere Medizin, Siegen, Germany*

Contact E-Mail Address: caroline.saad@hotmail.com
Introduction: The LOPA (Lost Patients) I Study in Germany revealed 46% of patients experienced heartburn and/or regurgitation symptoms at least twice per week despite PPI; 20% were dissatisfied with their treatment. Few patients had received specific GERD diagnostics or recommended treatment alternatives (< 10%) despite breakthrough symptoms.
Aims and Methods: Follow-up studies to explore the perceptions of these GERD "Lost Patients" were conducted in Germany and Brazil. Patients with chronic GERD, taking PPI therapy for at least 1 year, and not satisfied with their treatment were asked to complete a questionnaire including satisfaction with their current condition, reasons for dissatisfaction, and perceptions about anti-reflux interventions. In Germany, the study was conducted in 17 general practice clinics; in Brazil, the study was conducted in 17 reflux specialty centers (21 physicians).
Results: Responses were collected from 641 patients in Germany and 511 patients in Brazil. The German patients suffered from GERD on average 9.4 years and were on PPI therapy for an average of 7.8 years; 72% were dissatisfied with their current treatment (score 1–2 on a Likert scale 1–5). The Brazilian patients suffered from GERD on average 7.2 years and were on PPI therapy for an average of 5.2 years; 54% were dissatisfied. In the German group, 82% reported heartburn or regurgitation symptoms at least 2 days in the prior week (50% 4–7 days). In the Brazilian group, 77% reported symptoms at least 2 days in the prior week (39% 4–7 days). 51% of the German group vs. 32% of the Brazil group reported using additional medication other than their prescribed PPI at least 2 days per week (35% vs. 14% 4–7 days).
Reasons for dissatisfaction included breakthrough symptoms (87% Germany; 88% Brazil), fear of risks associated with long-term medication (33% Germany; 49% Brazil), burden of daily medication (29% Germany; 48% Brazil), and side effects from medication (7% Germany; 5% Brazil).
Reasons why dissatisfied patients had not undergone anti-reflux surgery included being unaware of surgical options for reflux (47% Germany; 18% Brazil), concern about possible complications (26% Germany; 31% Brazil), feeling their condition was not serious enough (17% Germany; 49% Brazil); and a recommendation against anti-reflux surgery from their doctor (6% Germany; 38% Brazil).
Conclusion: Despite different healthcare systems, chronic GERD patients dissatisfied with long-term PPI therapy are frequently seen in routine care in both Germany and Brazil. Most patients experience breakthrough symptoms despite PPI, but also share concerns about the long-term risk of medications and burden of taking daily medication. Specialized reflux centers and new less invasive anti-reflux interventions could benefit these patients.
Disclosure: All authors have worked as medical consultants for Endostim.

P1782 ENDOSCOPIC TRANSORAL FUNDOPLICATION WITH MUSE FOR GASTROESOPHAGEAL REFLUX DISEASE: RESULTS OF A SINGLE-CENTER STUDY

F. D'Aversa[1], P. Familiari[1], R. Landi[1], F. Mangiola[1], I. Boskoski[1], V. Bove[1], A. Tringali[1], V. Perri[1], F. Attili[1], A. Gasbarrini[2], G. Costamagna[1]

Introduction: Proton pump inhibitors (PPI) are the treatment of choice of gastroesophageal reflux disease (GERD), but adverse events associated with long-term therapy are emerging. Anti-reflux surgery can control GERD symptoms, however patients are usually reluctant to undergo surgery. Endoscopic Transoral Fundoplication with MUSE system (Medigus Ultrasonic Surgical Endostapler) can offer an effective therapy for GERD, less invasive than surgery.
Aims and Methods: This retrospective, chart review of prospectively collected data evaluates the clinical outcomes of patients who were treated with MUSE in a single center.
All patients who underwent MUSE at our endoscopy center between May 2015 and December 2017 were retrospectively identified from a prospective database, collected and analyzed. The procedure was offered to patients with GERD, diagnosed by EGD and pH-monitoring study, who required and responded to pharmacological therapy. Symptoms were evaluated with a validated clinical score – GERD Health-Related Quality of Life (HRQL) score – and by monitoring the use and dosage of PPI. Objective parameters including findings at esophagogastroduodenoscopy (EGD) and esophageal pH-monitoring study were assessed before the procedure, after 6 months and every year. Clinical success was defined by ≥50% reduction of the dosage of PPI and by the GERD HRQL score (≥50% reduction compared to baseline or normalization [< 10] of the score).
Results: A total of 20 patients underwent MUSE during the study period (mean age 50.4 [± SD14.6], 65% males). The last 5 patients did not complete the minimum 6-month follow-up and were excluded from this analysis. One patient was lost to follow-up immediately after treatment. Mean symptoms duration before MUSE was 63 months (30–240). A median follow-up of 14.1 (6–36) months was available for 14 patients. At the date of the last visit, clinical success was achieved in 78.6% of patients (9 patients [64%] discontinued PPI and 2 patients [14%] take < 50% of the initial dosage). Three patients (21.4%) did not change the dosage of PPI after the procedure, because of enduring symptoms. All the clinical failures were diagnosed at the 6-month follow-up visit.
GERD-HRQL score was normalized or improved by ≥50% compared to baseline in 11 patients (78.6%) (table 1). The post-operative DeMeester score was significantly reduced compared to baseline ($p < 0.05$). De Meester score was normal in 6/10 patients (60%) with post-operative pH-monitoring study, and considerably reduced in an additional 10% of patients.

14 patients	Baseline 14 patients with f/u	Last follow-up (mean 14 months) 14 patients	p value
GERD-HQRL (mean, SD)	30.4 (±7.4)	13.3 (±10.8)	< 0.005
%TRT (mean, SD)	13.8% (±10.5)	3.75% (±16.6)	0.0677
DeMeester Score (mean, SD)	48 (±47.7)	48 (±47.7)	< 0.005
Esophagitis (%)	35.7	21	0.065

[Table 1]
Postoperative EGD revealed grade A esophagitis in 3 patients, and normal findings in 11 patients.
No adverse events occurred during the procedure and follow-up.
Conclusion: Our study confirms the safety and efficacy of the MUSE procedure for the treatment of GERD. Studies on large cohorts of patients, and with a longer follow-up, are needed to consolidate the role of MUSE in the treatment of GERD.

Introduction: Chronic reflux patients with long-term PPI therapy frequently have persistent symptoms. At least 20% of the patients are unhappy with their therapy. Therapy options are limited. A critical source of the persistent acid reflux is the *acid pocket*, which can be treated effectively by the non-systemic reflux suppressing action of alginates.
Aims and Methods: Chronic GERD patients with at least one year of PPI long-term therapy, who were dissatisfied with their therapy, were treated over a period of 14 days with alginate as add-on and when required (up to 4 times daily) in a prospective, multi-centre observational study in GP practices. The frequency of symptoms in the week before treatment was recorded, as well as in the second week of the study phase and the consumption of alginate. The validated GERD Q score was also applied. The patients assessed satisfaction with the therapy on a five-point Likert scale (very unhappy – happy) before the beginning and at the end of the study. The primary endpoint of the study was improvement in satisfaction with the therapy by ≥ 1 point.
Results: 155 patients (53% women, median age 57 (18–85) years) entered the study. Six patients had to be excluded from the final efficacy analysis (no intake of study drug, lost to follow-up). The median duration of GORD was 8 (1–50) years and the median time on PPI therapy was 6 years. On average the patients took 3 sachets of alginate per day. The alginate therapy led to an improvement by at least 1 point on the Likert scale in 72% of patients (1 step $n=45$, 2 steps $n=41$, 3 steps $n=16$, 4 steps $n=5$). Patients with a Gerd Q score > 8 had a higher response rate at 81%. There was improvement in all typical reflux symptoms and sleep disorders. The treatment was generally well-tolerated.
Conclusion: In chronic GORD patients on long-term PPI therapy who are dissatisfied because of remaining troublesome symptoms an alginate as add-on and taken on demand is a new and effective option to improve patients satisfaction. Typical reflux symptoms are a valuable predictor of treatment success.

Introduction: Gastroesophageal reflux disease (GERD) is a prevalent disease worldwide. The prevalence of GERD was found to be 22.8% in Turkey. The treatment of GERD is still based on acid suppression therapy and accordingly proton pump inhibitors (PPIs) are the most frequently preferred agents. Complications related to long-term PPI consumption are always worrying.
Aims and Methods: To evaluate efficacy and safety of dexrabeprazole 10 mg on intragastric and intraesophageal acidity in gastroesophageal reflux disease (GERD) patients.
This open-label, single-arm efficacy and safety study included patients aged between 18 and 65 years who were diagnosed with GERD. During the screening visit, the symptoms of the patients were recorded. The patients were prescribed to receive dexrabeprazole 10 mg tablet daily for 7 days. Physical examination, laboratory analysis for safety, upper gastrointestinal endoscopy and 24-hour intragastric and intraesophageal impedance-pH measurements were performed. In addition, the Reflux Symptom Score was calculated by applying a validated questionnaire both before and after the treatment.
Results: Among 14 patients included, 2 were unable to complete the study (one due to biliary colic and the other due to missing visits). The analyses were performed in 12 patients (7 males, 5 females). After one-week treatment period, significant decreases were observed in the percentage of time for 24-hour intragastric $pH<4$ (from 84.15 ± 26.51 to 50.59 ± 18.32; $p=0.0269$) and $pH<2$ (from 35.03 ± 41.48 to 11.68 ± 14.88; $p=0.0125$) and in the area under the curve (from 18714 ± 25739 to 6078 ± 12898, $p=0.0236$ for $pH\leq4$ and from 1562.4 ± 2777.1 to 23.550 ± 46.191, $p=0.0156$ for $pH\leq2$). The percentage of time for 24-hour intraesophageal $pH<4$ decreased after treatment (4.48 ± 3.08) as compared with the pre-treatment value (24.68 ± 28.38; $p=0.0253$). A significant change was also observed in the nocturnal measurement (from 45.24 ± 24.41 to 54.49 ± 17.63; $p=0.0001$). Significant decreases were observed after treatment in DeMeester score (from 44.74 ± 25.92 to 16.36 ± 10.45; $p=0.0036$) and acid reflux (from 70.3 ± 21.7 to 19.1 ± 14.2; $p < 0.0001$). The heartburn and regurgitation scores significantly decreased from the first day of treatment. No serious safety event was determined.
Conclusion: Dexrabeprazole evaluated in this study is the R(+) enantiomer of rabeprazole. The standard dose of rabeprazole is 20 mg; however, R enantiomer is recommended to be used at a dose of 10 mg. It has been demonstrated that R(+) rabeprazole is more effective than racemic rabeprazole and S(-) rabeprazole in preventing acid-induced gastric lesions. In conclusion, dexrabeprazole 10 mg was considered an effective and safe option for GERD treatment.

Introduction: Both long-term proton pump inhibitor (PPI) use and surgical fundoplication have potential drawbacks as treatments for chronic gastroesophageal reflux disease (GERD).
Aims and Methods: Our aim was to investigate the safe and efficacy of anti-reflux mucosectomy (ARMS) in porcine and determine the optimal circumference of resection in relation to gastroesophageal junction (GEJ). Nine swine were allocated into the following 3 groups by computerized randomization: Group A: control, Group B: 1/3 circumference of esophagus, Group C: 2/3 circumference of esophagus. We performed mucosectomy with a crescentic mucosal resection at 3cm above GEJ and 1cm below GEJ. The animals were kept on a liquid diet for 24 h prior to endoscopy. At 6 weeks, animals underwent esophagoscopy, X-ray barium meal, gastric yield pressure (GYP) and gastric yield volume (GYV) determination, and sacrifice for histopathologic to evaluate the cardia wall thickness and collagen deposition.
Results: The weight of swine were no significant difference, and swine had maintained their weight in three groups after the procedure. We both found scar formation at the GEJ in group B and C. Acute inflammatory cells and fibrous tissue were found in study groups. Compared with group A and group B, group C produced significantly higher GYP (24.23 ± 3.42mmHg, $p=0.009$) and significantly smaller GYV (2200.0 mL ± 238.96, $p=0.039$) after 6 weeks. Barium meal X-ray showed that the width of cardia was narrower (13.06 ± 2.10mm, $p=0.018$) and the time of wave was longer (2.88 ± 0.28s, $p=0.032$) in group C after the procedure, compared group A and B.
Conclusion: Our study demonstrated the potential anti-reflux effect and safety of ARMS. We also recommend the 2/3 circumference resection of esophagus at 3 cm distance from the GEJ.

Introduction: Dietary measures such as avoiding high-fat meals, sweets, alcoholic and carbonated beverages, are often advised to patients with gastro-esophageal reflux disease (GERD). Fermentable Oligo-, Di-, Mono-saccharides and Polyols (FODMAPs) induce lower gastrointestinal symptoms through their effects on intestinal function. However, the effect of FODMAPs on upper gastrointestinal physiology, including the occurrence of transient lower esophageal sphincter relaxations (TLESRs), reflux events and GERD symptom induction is unknown.
Aims and Methods: We aimed to investigate the effect of acute administration of two key FODMAPs, fructose and fructans, on the number of TLESRS, reflux episodes and symptom perception in healthy volunteers (HV). After an overnight fast, 20 HV (10 males, 30 y [21–56]) underwent a high-resolution impedance manometry. The number of TLESRs and reflux episodes were quantified 5 hours after consumption of a high-caloric meal (mashed potatoes and meatloaf; 740 kcal) enriched with 40g of either fructose, fructans or glucose (placebo). The HV undertook all 3 challenges in a single-blind randomized fashion with at least 1 week washout. Results were analyzed using mixed models.
Results: Overall, there was a significant difference in the number of TLESRs between the three conditions ($p=0.006$, Table 1). Post hoc analysis showed a significantly higher number of TLESRs in the fructan condition compared to placebo (corrected p-value, $p=0.005$) and a trend for fructose versus placebo ($p=0.05$, Table 1), which did not survive Bonferroni correction. The total number of reflux events was not affected by either FODMAP condition. The number of gas and mixed reflux events tended to be higher in the fructan condition, but this did not reach statistical significance (Table 1). LES pressures dropped significantly in the first postprandial hour in all 3 conditions to recover slowly back to baseline values ($p < 0.0001$), without any difference in LES pressure between the three conditions.
Conclusion: Ingestion of fructans increased the number of TLESRs compared to placebo. This increase was not seen after ingestion of fructose. Fructans are rich in FODMAPs, however fructose is only a FODMAP when present in excess of glucose. The absorption of fructose is probably enhanced because of the presence of other sugars including glucose in the meal. Ingestion of either FODMAP did not alter the number of reflux episodes in the HVs, but GERD patients have a higher incidence of reflux during TLESRs. Therefore, the effect of FODMAPs such as fructans or a low FODMAP diet on reflux parameters in GERD patients remains to be investigated.

	Glucose (placebo)	Fructose	Fructans	p-value of the main effect
TLESRs	25.2 ± 6.7	27.0 ± 8.7	28.4 ± 7.4	**0.006**
Reflux	16.6 ± 8.0	15.9 ± 9.6	18.7 ± 8.3	0.16
Mixed + Gas	6.7 ± 5.9	7.1 ± 5.7	8.8 ± 7.1	0.12

[The number of TLESRs and reflux episodes in the three different conditions (mean ± SD).]

Introduction: Several studies have reported changes of the pathologic analysis before and after endoscopic resection (ER) for esophageal intraepithelial neoplasia. We aimed to explore the risk factors for pathological upgrading after ER for lesions diagnosed as low-grade intraepithelial neoplasia (LGIN) with preoperative biopsy.

Aims and Methods: A total of 70 lesions which were initially diagnosed as esophageal LGIN by forceps biopsy and later underwent ER from November 2013 to July 2017 were included. They were divided into two groups according to pathological grading after ER. The risk factors for post-operation pathological upgrading were analyzed.

Results: The study enrolled 70 patients. The change of post–operation pathological diagnosis occurred in 30 (42.9%) patients (upgrade 28 (40.0%); downgrade 2 (2.9%)). In the upgrading group, ER upstaged it to high-grade intraepithelial neoplasia (HGIN) for 20 (28.6%) lesions and to early esophageal cancer for 8(11.4%) lesions. Univariate analysis showed that lesions≥1/2 esophageal circumference (P = 0.006), maximal longitudinal-diameter≥3cm (P = 0.005), submucosal infiltration in endoscopic ultrasonography (P = 0.037), lesions based on depressed type (0-IIa+IIc, 0-IIc, 0-IIc+IIa)(P = 0.005) and reddish surface (P = 0.019) were factors for pathological upgrading compared with preoperative biopsy. Multi-factor analysis indicated maximal longitudinal-diameter≥3cm (P = 0.008) and reddish surface (P = 0.013) were independent factors for pathological upgrading compared with preoperative biopsy.

Conclusion: Pathological upgrading of LGIN after ER was common, especially in large lesions with reddish surface. Endoscopic resection may be recommended for these lesions instead of follow-up observation.

Introduction: Although endoscopic submucosal dissection, which makes it possible to perform *en bloc* resection with tumor-free lateral and vertical margins, has been accepted as the standard treatment of superficial esophageal cancer, the incidence of stricture formation caused by ESD for widespread lesions is high. Some studies have reported that the use of oral steroids and local steroid injection are useful for preventing such stricture formation. We perform "planned ESD" to prevent severe stricture at our institution. When we resect widespread lesions that involve three-quarters or more of the circumference of the esophageal lumen, semi-circular ESD is performed. Small portions of the intraepithelial neoplasm are left. After reviewing the histopathological findings, we attempt a second endoscopic treatment (ESD, endoscopic mucosal resection, or argon plasma coagulation) to manage the remaining parts.

Aims and Methods: The aim of this study was to evaluate the usefulness of planned ESD for widespread superficial esophageal cancer in controlling post-procedural esophageal stricture. Between September 2005 and April 2015, 204 superficial esophageal neoplasms were treated with ESD in 192 patients. We evaluated clinical outcomes of ESD for the tumors in 22 patients (males: 20, females: 2, mean age: 68.5 years old) that involved three-quarters or more of the circumference of the esophageal lumen.

Results: The involved esophageal circumference was three-quarters in 13, four-fifths in 4, and whole in 5. Seventeen lesions were resected with positive tumor-lateral margins, and five had unknown margins, Twenty lesions underwent semi-circular resection, and two circular resection. Six patients received local steroid injection, 6 received systemic steroid treatment, and 10 received systemic steroid treatment combined with local steroid injection. The median number of endoscopic balloon dilatations was 1 session, 9 patients (41%) did not require any endoscopic balloon dilatation, but 4 (18%) required more than 20 sessions. The major complications were two cases of perforation. The median postoperative hospital stay was 5 days (range 3∼29 days). The depth of invasion was as follows, mucosal in 18 lesions, and submucosal invasion in 4 lesions. The mean tumor size was 51mm (range 42–90mm), and microvascular permeation was observed in two cases. Five cases of remnants were retreated endoscopically, and two required esophagectomy. Three patients developed local recurrence, and all cases were able to be retreated endoscopically. During the median follow-up period of 60 months (range 36-148), all the cases are still alive.

Conclusion: Planned semi-circular ESD for widespread superficial esophageal neoplasm may be an efficient strategy for preventing severe stricture formation.

Introduction: Cervical esophageal cancer (CEC) is a less common form of cancer. The survival rates of CEC patients remain poor because it is often locally advanced at the time of its diagnosis. With advances in endoscopy, more cases of superficial CEC are being found.

Aims and Methods: Endoscopic treatment was performed for 72 lesions of superficial CEC in 61 patients (male, n = 49; female, n = 19; median age, 68 years; range, 40–88 years) from April 2005 to December 2016. We divided the patients into 3 groups according to the location within the cervical esophagus: Group A (with invasion to the hypopharynx), Group B (proximal margin within 2 cm from the orifice of the esophagus), and Group C (proximal margin >2 cm from the orifice of the esophagus). Multiple esophageal cancers were observed in 50 patients (81.9%). CEC coexisted with primary head and neck cancer in 42 patients (68.8%). The aim of this retrospective study was to clarify the clinical outcomes of endoscopic treatment in patients with superficial CEC.

Results: Nineteen lesions (hypopharynx-dominant, 14 lesions; cervical esophagus-dominant, 5 lesions) were enrolled as Group A, 21 lesions were classified into Group B, and 32 lesions as were classified into C. Five lesions of Group A and One lesion of Group B were treated by neoadjuvant chemotherapy with the aim of preserving the larynx. Endoscopic treatment was performed under general anesthesia in Groups A and B, while 20 lesions (62.5%) in Group C were treated under intravenous anesthesia.

The procedures performed in Group A included transoral surgery (TOS) with endoscopic submucosal dissection (ESD; 12 lesions), TOS (3 lesions), endoscopic mucosal resection (EMR; 3 lesions), and ESD (1 lesion). The procedures performed in Group B included ESD (15 lesions), and EMR (6 lesions). The procedures performed in Group C included EMR (24 lesions), and ESD (8 lesions). Regarding the depth of tumor invasion, 5 lesions in Group A (cervical esophagus-dominant) were carcinoma *in situ* or showed micro-invasion, while 14 lesions (hypopharynx-dominant) showed subepithelial invasion.

The median size of the tumors was 29 mm (range, 8–52 mm), 3 lesions showed vascular invasion, all lesions were followed with no additional therapy.

Nineteen lesions in Group B were diagnosed as mucosal cancer, and 2 lesions invaded the submucosa. The median tumor size was 18 mm (range, 6–50mm), 2 lesions showed vascular invasion, and one lesion was treated with additional chemoradiotherapy.

Twenty-seven lesions in Group C were diagnosed as mucosal cancer; 5 lesions invaded the submucosa. The median tumor size was 11 mm (range, 2–25 mm), 3 lesions showed vascular invasion, and one lesion was treated with additional chemoradiotherapy.

Regarding complications, 4 patients experienced laryngeal edema and 4 developed esophageal stricture; however, there were no severe complications. The median hospital stay was 4 days (range, 2–10 days). There was one case of local recurrence in Group B; endoscopic retreatment was successful in this case. Lymphadenectomy were performed for three patients with lymph node metastasis occurred in Group A. During the median follow-up period of 48 months (range, 16–153 months), 6 patients died from other cancer and 2 died from other disease. There were no esophageal cancer-related deaths. Laryngectomy was performed in one case due to another hypopharyngeal cancer; the larynx was preserved in the other cases (98.3%). The cause-specific survival rate at 3 years was 100%.

Conclusion: Endoscopic treatment is less invasive and effective for improving the prognosis of patients with CEC.

Introduction: High-risk (hr)-human papillomavirus (HPV) has been associated with Barrett's dysplasia and oesophageal adenocarcinoma (OAC). Nevertheless, the prognostic significance of oesophageal tumour HPV status is unknown.
Aims and Methods: We hypothesized that HPV associated oesophageal tumours would show a favourable prognosis (as in viral positive head and neck cancers). Thus, we studied the association between HPV and related biomarkers of high-grade dysplasia (HGD)/OAC and survival. Pre-treatment biopsies were used for HPV DNA determination via PCR, in-situ hybridization for E6/E7mRNA and immunohistochemistry for p16INK4A and p53. Sequencing of TP53 was also undertaken.
Results: Amongst 142 HGD/OAC patients [M:F, 126 (88.7%): 16 (11.3%)] with a mean age of 66.0, SD+/− 12.1, 37 were HPV+ and 105 HPV-. HPV+ patients were mostly p16ink4a$_{high}$, p53$_{low}$ and wild-type TP53. There were more Tis/T1/T2 tumours in HPV+ subjects as compared with HPV- patients (75.7% versus 54.3%, p = 0.02). Mean disease-free survival was superior in the HPV+ group (40.3 months versus 24.1 months, p = 0.003) as was overall survival [43.7 months versus 29.8 months, p = 0.009]. Recurrence/progression was much reduced in the HPV+ cohort (24.3% vs 58.1%, p = 0.0004) as was distant metastasis (8.1% vs 27.6%, p = 0.015) and death from EAC (13.5% versus 36.2%, p = 0.01). HPV and transcriptionally active virus positivity were both associated with a superior DFS (HR = 0.33; 95%CI: 0.16–0.67, p = 0.002) and (HR = 0.44; 95%CI: 0.22–0.88, p = 0.02) respectively (log-rank test). E6/E7 mRNA positivity had borderline significance for improved DFS (HR = 0.50; 95%CI: 0.24–1.05, p = 0.069) but not p16INK4A$_{high}$ or p53$_{low}$. On multivariate analysis, superior DFS was demonstrated for HPV (HR = 0.39, 95%CI; 0.18–0.85, p = 0.02) biologically active virus (HR = 0.36, 95%CI: 0.15–0.86, p = 0.02), E6/E7mRNA (HR = 0.36, 95%CI: 0.14–0.96, p = 0.04) and p16$_{high}$ (HR = 0.49, 95%CI: 0.27–0.89, p = 0.02).
Conclusion: HPV+ HGD/OAC is a distinct biological entity with a favourable prognosis as compared with viral negative oesophageal tumours. If these findings are confirmed in larger cohorts with more advanced disease, it presents an opportunity for treatment de-escalation in the hope of reducing toxicity without deleteriously affecting survival.

P1791 THE MODIFIED GLASGOW PROGNOSTIC SCORE (MGPS) HAVE A PROGNOSTIC ROLE IN ESOPHAGEAL CANCER. (COMPARISON WITH PLASMA FIBRINOGEN AND SERUM ALBUMIN LEVELS (FA SCORE) AND NEUTROPHIL TO LYMPHOCYTE RATIO (NLR))

Contact E-Mail Address: rnsfk040@gmail.com
Introduction: Although the outcome of treatment of esophageal cancer has been improved, esophageal cancer still has poor prognosis. More accurate and convenient prognostic predictions are desired. It is reported that modified Glasgow Prognostic Score (mGPS) using albumin and CRP levels reflects long-term prognosis of solid cancer. We investigated the reliability of mGPS for prediction of long-term recurrence and survival.
Aims and Methods: One hundred and twenty-seven patients who underwent curative esophagectomy for esophageal cancer between February 2011 and January 2016 were enrolled. We investigated the reliability of mGPS for the prediction of OS and DFS. Furthermore, the comparison with FA score and NLR was conducted.
Results: The patients were105 males and 22 females. The average age was 63.9 ± 8.7 years old (35–81 years old). 57, 24, 37 and 9 patients were diagnosed with clinical stage I, II, III and IV. 64 patients received chemotherapy and 6 patients received chemoradiotherapy as a preoperative treatment. Thoracoscopic esophagectomy was performed in 108 patients and transthoratic esophagectomy was performed in 19 patients. Overall survival (OS) for 3 years was 71.0% and disease-free survival for 3 years (DFS) was 58.0%. This analysis included 104 patients with mGPS 0 (low-mGPS group) and 23 patients with mGPS 1 or 2 (high-mGPS group). OS and DFS in the high-mGPS group were significantly shorter (OS; p = 0.00008, DFS; p = 0.0002). In multivariate analysis, high levels of mGPS were independent risk factors on OS and DFS, such as ages and clinical stages (OS; HR 2.70, 95% CI: 1.08–6.76, p = 0.034. DFS; HR 2.16, 95% CI: 1.01–4.63, p = 0.046). The FA score and the NLR were not significant risk factors in multivariate analysis.
Conclusion: High levels of mGPS were significantly prognostic factors in patients who had undergone esophagectomy for esophageal cancer. More patients for analysis are needed.

Introduction: ESGE guidelines advise surgery in case of non-curative endoscopic resection in the esophagus considering the risk of lymph node metastasis. To our knowledge, no study had examined the outcomes of this surgery.
Aims and Methods: A retrospective review from 2012 to 2017 was performed in the department of digestive endoscopy of four French tertiary referral center. All patients had a non-curative endoscopic resection, defined by deep mural invasion, vertical positive margins, or poor histopronostic features, followed by esophagectomy after a multidisciplinary meeting decision. Outcomes measurements were the histological outcomes of surgical resection vs endoscopic resection, the rate of postoperative complications, overall, disease-free, and cancer specific survival and the evaluation of the post-operative complications.
Results: Twenty-one patients (10 with squamous cell carcinoma and 11 with Barrett's carcinoma) with a median age of 66 years were included. Tumors are localized in the mid and the lower esophagus for 11 and 10 patients respectively. The reasons of non-curative resection were: positive vertical margins (n = 6), SCC invading the muscularis mucosae (n = 5) and lesion invading the submucosal layer (n = 13), poorly differentiated cancers (n = 11) and presence of lymphovascular invasion (n = 5). Surgical techniques were Ivor-Lewis and transhiatal esohagectomies. Only two patients, with deep submucosal infiltration (500 for a squamous cell carcinoma, and 1200 µm for a Barrett's carcinoma) and poor differentiation had a lymph node involvement on the surgical specimen. We diagnosed 2 relapses (mediastinal lymph nodes, lung metastases) during a median follow-up of 16 months. The patient with lung metastases only had lymph node involvement on the surgical specimen. There were 4 deaths during the follow-up: one postoperative mortality (90-day), one death related to

aspiration pneumonia due to post-operative esophageal stricture, and two non-cancer related deaths. Forty-two percent of the patients (9/21) had a severe post-operative morbidity according to the Clavien-Dindo classification: IIIa (n = 2), IIIb (n = 3), IVa (n = 3) and V (n = 1). At the end of the follow-up, overall, disease-free and cancer specific-survival were 81%, 91%, and 91% respectively.
Conclusion: Esophagectomy after non-curative endoscopic resection of esophageal cancers allowed to resect lymph node metastases in two out 21, at the cost of 42% severe morbidity and 5% perioperative morbidity. Esophagectomy in this setting has comparable morbidity and mortality to that of esophagectomy for larger tumors, and the risk of lymph node involvement of early esophageal cancer, as well as the possibility of chemoradiation therapy or close follow-up need to be assessed in multidisciplinary meetings before indicating esophagectomy after endoscopic resection.

Introduction: Even though the accurate prediction of tumor depth (T staging) for superficial esophageal squamous carcinoma (SESC) is essential for making the proper decision on treatment strategy, there are not enough studies about standard endoscopic criteria. In this study, we tried to know the diagnostic accuracy of conventional endoscopy for T staging in SESC and to make the conventional endoscopic criteria for classifying mucosal and submucosal esophageal cancer.
Aims and Methods: For first step, new endoscopic criteria of mucosal (T1m) and submucosal cancer (T1sm) were created by 2 experienced endoscopists with 60 randomly selected cases of pathologically proven SESC. For second step, endoscopic findings of total 292 cases, which were treated by surgical or endoscopic resection for SESCs between 1991 and 2010, were reviewed according to the new endoscopic criteria to predict the tumor depth.
Results: The overall accuracy of new endoscopic criteria was 79.5% (232/292). The sensitivity, specificity, and positive and negative predictive values of mucosal cancers were 78.4%, 81.0%, 85.4%, and 72.6%, and those for submucosal cancers were 81.0%, 78.4%, 72.6%, and 85.4%. The prediction rate of mucosal cancers was high (95.9%) when the lesions were shown as flat or slightly elevated/depressed with smooth/even surface regardless of size. And those of submucosal cancers were high (85.6%) when the lesions were irregular/nodular protrusion regardless of size. In multivariate analysis, tumor size less than 3cm (odd ratio 0.450, p = 0.014) was found as independent affect for the accuracy of endoscopic criteria.
Conclusion: The accuracy of endoscopic prediction for estimating T staging is acceptable in SESC. Careful endoscopic examination with new endoscopic criteria in SESC can provide more information and help to decided treatment methods between surgery and endoscopic resection.

Introduction: Intrapapillary capillary loop (IPCL) patterns provide an endoscopically visible marker of early squamous cell neoplasia (ESCN). Narrow-band imaging with magnification endoscopy (ME-NBI) allows detailed assessment of these microvascular patterns. The Japanese Endoscopy Society (JES) **AB** classification describes ESCN and predicts invasion depth based on the intrapapillary capillary loop (IPCL) pattern. Early lesions are amenable to endoscopic therapy (EET) so the prompt characterisation and identification of mucosal lesions is vital. Endoscopists, particularly those in areas with low ESCN prevalence, may not be familiar with the characterisation of ESCN. We have designed a novel deep convolutional network (CNN) able to classify IPCL patterns as normal (A) or abnormal (B1/B2/B3), in order to alert endoscopists to abnormal areas in ESCN during lesion assessment.
Aims and Methods: 17 patients were recruited at a referral centre in Taiwan. Endoscopies were performed using ME-NBI (Olympus). IPCLs were classified for each video by 2 experts as normal (type A), or abnormal (type B1/B2/ B3), using the JES classification. Matched tissue was obtained by ESD for histologic evaluation of invasion depth. Images were quality controlled to remove uninformative (blurred) images. Our dataset consisted of 7046 images. A CNN was developed with five-fold cross validation. On average, each fold used 3962 images for training, and 1637 unseen images (846 normal and 791 abnormal) for testing. Class activation maps were generated to provide a clinically interpretable network output. Accuracy, F1 scores, sensitivity and specificity for abnormal IPCL detection were calculated.
Results: 17 patients were included (10 had early neoplasia [1 high-grade intraepithelial neoplasia (HGIN) 4 carcinoma in situ (CIS) invading to the lamina propria, 4 to the muscularis mucosa and 1 to the submucosa] and 7 were normal). Our algorithm operates at video rate and had an accuracy for differentiating abnormal IPCL patterns (type B1, B2, B3) from normal (type A) of 93.69%. The average F1 score for identifying abnormal areas of ESCN based on IPCL classification was similarly high at 92.2%. Our network also achieved a sensitivity and specificity for abnormal IPCL detection of 89.3% and 98% respectively.
Conclusion: We introduce a novel application of deep learning by developing a real-time CNN, with promising results in classifying squamous mucosa as normal or neoplastic based on the JES IPCL classification. Our system demonstrates a high accuracy, sensitivity and specificity for differentiating type A from type B1/2/3 IPCLs. Importantly for potential clinical applications our CNN operates in real-time. eCAMs demonstrate a novel and clinically interpretable network output – allowing clinicians to visualise which areas of IPCL patterns were classified as abnormal by the CNN. Further work is underway to develop a multiclass classifier, using a larger dataset, to distinguish between the subtypes of IPCL patterns. Such a validated system could be used in vivo to alert endoscopists to the presence of ESCN and direct planning of appropriate EET.

Introduction: Since endoscopic submucosal dissection (ESD) has been accepted as the treatment of choice for early gastric cancer (EGC) without lymph node metastasis, synchronous gastric epithelial neoplasia is no longer rare in the clinical practice. Knowledge about the characteristics associated with synchronous gastric epithelial neoplasia is of great importance to prevent delayed diagnosis.
Aims and Methods: Between November 2008 and December 2014, a retrospective study was conducted in a single tertiary referral hospital. Patients who underwent ESD due to EGC or high-grade dysplasia were analyzed to evaluate the incidence of synchronous gastric epithelial neoplasia and the factors associated to synchronous and overlooked synchronous lesions.
Results: A total of 488 patients were analyzed in this study. Synchronous lesions were found in 59 patients (12.1%) during the mean 37.7 months of follow-up. Among 77 synchronous lesions, 25 lesions (32.4%) were overlooked at the time of initial ESD. Age of $\geq$ 65 years, moderate to severe endoscopic atrophic gastritis, and elevated morphology of primary lesions were associated with synchronous gastric epithelial neoplasia. An important factor associated with overlooked lesions is the non-elevated morphology of lesions.
Conclusion: Careful endoscopic examination of the whole stomach is necessary in patients who are older and who have moderate to severe atrophic gastritis and elevated morphology of lesions to prevent delayed diagnosis of synchronous gastric epithelial neoplasia, especially non-elevated lesions. These factors may be considered as to selecting candidates for ESD.

Introduction: Gastric neuroendocrine neoplasms (gNENs) are classified into three categories: type I associated with atrophic body gastritis, type II related to multi-endocrine neoplasia type I, and type III when no background pathology is

identified. Type I gNENs are indolent diseases, mostly with low proliferative index (Ki67 ≤ 2%), and extremely low metastatic risk (<5%). Tumors > 1 cm are usually considered at higher risk of malignancy deserving more aggressive management, although data supporting this recommendation are scanty. Conversely, type III are malignant diseases with extremely high risk of dissemination and mortality. However, beyond the above-mentioned clinical classification, little is known on additional factors potentially related with poor clinical outcome in gNENs.

Aims and Methods: Retrospective analysis of type I and type III gNENs collected in four referral centers. Risk factor analysis was performed by logistic regression model. A composite negative endpoint was defined to identify patients with poor clinical outcome, and was considered to have occurred if tumor-related death, presence of metastases, or presence of angioinvasion at histology was observed. ROC curve analysis was used to identify the cutoff level variables as predictors of presence of negative endpoint. Survival probabilities were calculated by the Kaplan-Meier method. The distribution of continuous variables was reported as median and interquartile range (IQR; 25th to 75th percentiles). Mann-Whitney U test was used to compare the continuous variables.

Results: 161 patients included, with a total of 195 tumors: 171 type I (87.7%), and 24 type III (12.3%). Compared with type III, type I gNENs were smaller (median size 5 mm and 15 mm, respectively. $P < 0.0001$) and with lower Ki67 (2% and 5.5%, respectively. $P < 0.0001$). Negative endpoint occurred in 16 pts (9.9%), specifically in 14 type III (58.3%) and 2 type I (1.1%). In this subgroup, median Ki67 was 10% (3% – 41%), and median size was 20 mm (14 mm – 25 mm). Among patients with type I gNENs without features supporting negative endpoint (no tumor related death, no metastases, no angioinvasion), 20.3% had Ki67> 2%. When ROC analysis was performed to detect tumor size cut-off level able to predict negative endpoint, the value > 11 mm was identified (AUC 0.921, $p < 0.001$). Overall, 12.3% type I and 70.8% type III gNENS were > 11 mm, respectively ($p < 0.0001$). Regarding proliferative activity, 21.6% type I and 62.5% type III had Ki67 > 2%. When multivariate logistic regression was performed, tumor type and size were associated with negative poor clinical outcome (type III vs type I: OR = 9.2, $p = 0.005$; size: OR 1.12 for each increasing mm, $p = 0.0006$), whereas Ki67 did not maintain statistical significance (OR 1.03 for each increasing unit, $p = 0.149$). Overall, 5-yr survival probability was 100% and 60.5% in type I and type III gNENs, respectively ($p < 0.0001$).

Conclusion: In addition to tumor type, size was the strongest negative prognostic factor, which independently predicted negative outcome in gNENs. Ki67 > 2% was observed in a relevant proportion (20.3%) of type I gNENs with indolent clinical course. Compared with NENs rising from other digestive sites, Ki67 seems to have a minor prognostic role in these tumors. When facing patients with gNENs, tumor type and size should be considered as major factors affecting clinical outcome.

Contact E-Mail Address: nobue@nms.ac.jp

Introduction: In the 5th edition of gastric cancer treatment guidelines published by Japanese Gastric Cancer Association, the curability of endoscopic resection is classified by two factors: the degree of local resection and the possibility of lymph node metastasis. We examined cases diagnosed as non-curative endoscopic resection; endoscopic curability C (eCuraC).

Aims and Methods: Of 759 patients who underwent ESD for gastric tumors at our hospital from September 2005 to December 2017, 74 patients with eCuraC were retrospectively analyzed. They were classified into two groups, 30 patients who were adapted the expanded criteria for ESD but pathologically diagnosed only positive horizontal margin after ESD (eCuraC-1 group) and 44 patients didn't meet the curative criteria except for eCuraC-1(eCuraC-2 group). Patients who underwent additional surgical resection were examined pathologically for risk factors of lymph node metastasis.

Results: The sex (male / female) was 23/7, 36/8, average age was 71.1/72.2 years old, respectively. The pathological type (differentiated/undifferentiated) was 30/0, 36/8 ($p = 0.0134$), respectively. The operation time was 167.8 ± 112.6 minutes, 131.8 ± 98.1 minutes, the post-bleeding was 13.3%, 15.9%, the perforation was 3.3%, 11.4%, respectively, there were no differences. In eCuraC-1 group, 3 patients underwent additional ESD, 1 patient did argon-plasma coagulation, and 1 patient accepted surgical resection one year after ESD (no lymph node metastasis). 25 patients were followed without additional treatment (no recurrence). In eCuraC-2 group, 23 patients underwent surgical resection and 21 patients didn't receive treatment. The patients who underwent surgical resection were significantly younger than those who didn't receive treatment (67.0 ± 9.1 vs 77.8 ± 7.1 years; $p < 0.0001$). Among 21 patients, tumor was located in the upper third of the stomach more than those who underwent surgical resection (47.6% vs 8.7%; $p = 0.0128$). There was no gastric cancer death and 2 patients died of other cancers (cholangiocarcinoma, lung cancer). In surgical cases, risk factor for lymph node metastasis was histological lymph infiltration ($p = 0.0431$). There was no gastric cancer death and one patient died of lung cancer.

Conclusion: In eCuraC-1 group, risk of lymph node metastasis was low. In eCuraC-2 group, risk of lymph node metastasis was pathological lymph infiltration. Because elderly patients tend not to undergo surgical resection, it is necessary to observe them diagnosed with pathological lymph infiltration closely.

Contact E-Mail Address: dai06241114@gmail.com

Introduction: It had been shown that while gastric cancer (GC) was decreasing, signet ring cell carcinoma (SRC) had increased. However, the majority of the studies were performed more than 10 years ago. Recent trends of the tumor occurrence was not fully elucidated. In Japan, nation-wide registry started in 2006 in major cancer institutes and hospitals by the government support. In our institution, this registry enrolled 20,231 cancers for the most recent 10 years from 2007 to 2017 including 2,344 gastric cancers. It is particular interest to see SRC is still showing a tendency to increase in the era of *H. pylori* eradication.

Aims and Methods: Since January 2007 to December, 2017, there were 205 patients (8.7%) of SRC in 2,346 patients with gastric cancer registered in our hospital. We compared the period of earlier 6 years (2007–2012) and recent 5 years (2013–2017) and compared the characteristics and trends of SRC. Age, gender, clinical data of patients were obtained from the databases of in-hospital cancer registry.

Results: There was little difference between the characteristics of SRC and Non SRC (NSRC). The number of all GC in earlier 6 years was 1,354 (average 225.7/year, range 204–263), whereas in recent 5 years 992 (average 198,4, range 183–220).

We then compared the relative occurrence of SRC in GC. It was shown that in earlier 6 years (2007 to 2012), the range varied from 9.1 to13.8%, whereas the range was 4.6 to 9.6% in recent 5 years (2013 to 2017). The difference is statistically significant ($p = 0.0086$)

Conclusion: Reduction of SRC seems more rapid than that of all GC. Speculation could even be expanded the direct relation between *H. pylori* eradication and occurrence of SRC.

Disclosure: Nothing to disclose

P1800 DIAGNOSIS OF EARLY GASTRIC CANCER: A 17 YEARS SURVEY BASED ON SURGICAL SPECIMEN IN PARMA AREA

Introduction: In 2012 the reported incidence of gastric cancer (GC) in both sexes was 12.3/100,000 but the mortality was still high (8.7/100,000), early detection being strictly related to a better survival. Parma is considered a medium-low incidence area for GC. For early diagnosis, the detection of a precancerous condition like chronic atrophic gastritis (CAG) seems crucial, but the majority of such patients is asymptomatic and the diagnosis by means of non-invasive tests (serum Pepsinogens and Gastrin 17), as suggested in Kyoto and Maastricht V Guidelines, is up to now limited in clinical practice.

Aims and Methods: The aim of the study was to establish the burden of incidence of GC in a 17 years survey, focusing on the detection of Early GC. A 17-years interval (from January 2000 to December 2017) was considered in order to state the incidence of GC as reported in the archives of the Pathology Department of Parma University. Gastric cancers were classified as Early, following the Kodama classification, and Advanced. Furthermore the incidence per year throughout the considered interval was analyzed. Only the surgically removed cases were taken into account. A picture of CAG nearby the neoplasia was assessed according to O.L.G.A staging system. In both Early and Advanced cancers the node status was investigated.

Results: Overall, 1,674 (M = 969, F = 705) cases of GC were detected in the 17 years considered interval, representing 2 cases/week and 98 cases/year. Only 1,214 out of 1,674 (M = 707, F = 506, mean age: 82yrs, range: 26–108yrs) were surgical specimens, therefore analyzed. The diagnosis of Early gastric cancer was made in 128/1214 (10.54%) (M = 81, F = 79 mean age: 80yrs, range: 49–104yrs). The diagnosis of Advanced gastric cancer was established in 1086 pts (89.46%)

(M = 641, F = 445, mean age: 82.5yrs, range: 36–108yrs). A picture of CAG was found in more than 95% of the cases, both in Early and Advanced ones. Early cancers showed node metastasis in 20% of the cases compared with 80% in Advanced ones. Concerning the number of involved nodes, in early presentation of neoplasia pN1 staging was assessed in 30.76% (M = 21.21%; F = 40.32%) of the cases whereas in the advanced one the pN1 cases were only 14.73%, being N3 the most reported node status.
Conclusion: Early gastric cancer diagnosis is confirmed to be a very infrequent finding and this could account for the high mortality rate of the gastric neoplasia. The search for precancerous conditions like chronic atrophic gastritis is therefore mandatory. The incidence of GC in the Parma area is higher in male patients and seems to be permanent through the considered interval.

Introduction: Gastrointestinal malignant lymphoma has diverse endoscopic findings; therefore, it is difficult to diagnose in many cases. Since a long time, multiple erosions and cobblestone-like mucosa have been considered as characteristic endoscopic findings of MALT lymphoma. However, tumour advancement-induced submucosal vascular changes that show an irregular, tortuous microvasculature [tree-like appearance (TLA)] have been recently reported. In this study, we retrospectively investigated the characteristic endoscopic findings of gastrointestinal lymphomas, including MALT lymphoma.
Aims and Methods: Fifty patients who were histopathologically diagnosed with gastrointestinal malignant lymphoma (MALT lymphoma, 20; non-MALT lymphoma, 30) at our institute after 2010 were included in the study. The sensitivity and specificity of TLA using magnifying narrow-band imaging (NBI) and general endoscopy (based on Sano's classification and the findings of Akamatsu et al.) were determined. Patients with treatment-resistant MALT lymphoma were followed up for these findings.
Results: Among patients who were observed using magnifying NBI, TLA frequency in patients with MALT lymphomas was 72.7% (8/11), which was significantly higher than that in patients with non-MALT lymphoma (1/10, P = 0.008). Using a conventional light microscope, the frequencies of flat depression (11/20; 55%) and cobblestone-like mucosa (12/20; 60%) in the MALT lymphoma group were also observed to be significantly higher than those in the non-MALT lymphoma group (P = 0.005, 0.002); however, the sensitivity and specificity were lesser than those of TLA. No significant difference was noted in the presence or absence of colour change, white coat or multiple lesions. A correlation between the treatment effect and TLA finding was noted in treatment-resistant MALT lymphoma cases.
Conclusion: For MALT lymphoma with low epithelial invasiveness, morphological diagnosis using endoscopy is crucial to accurately determine the biopsy site. This study clarified that TLA is a specific finding of MALT lymphoma compared with all other gastrointestinal lymphomas showing a diverse morphology. In addition to a detailed observation using magnifying NBI, the presence of flat depression and cobblestone-like mucosa following conventional observation may facilitate an efficient endoscopic diagnosis of MALT lymphoma.

Introduction: Neuroendocrine tumors (NETs) are defined as epithelial neoplasms with predominant neuroendocrine differentiation. Depending on the point of origin, gastrointestinal neuroendocrine tumors (NETs) can be classified as a tumor of the foregut (esophagus, stomach and duodenum), midgut (distal duodenum to proximal colon), or hindgut (distal colon and rectum). Foregut NETs are considered rare, and the reported incidence is 10%-30% of all gastrointestinal NETs, but their incidence has been increasing in most countries over last 50 years[1]. The treatment of choice for NET is usually surgery. Early foregut NETs limited to mucosa/submucosa demonstrate low frequency of lymph node and distant metastasis, and thus have been managed with local excision (including endoscopic treatment) which offers improved quality of life compared with surgery[2]. We report our single-center experience of endoscopic resection (ER) for early foregut NET.
Aims and Methods: Patients with NET confirmed on histology were identified from a prospectively maintained endoscopic database over 5 years (2013–2017). All patients underwent pre-procedure radial endosonography (EUS) and abdominal CT scan. EMR, ESD or EFTR was performed in all patients under general anesthesia. High-definition gastroscope (GIF-HQ-190, Olympus Corporation, Japan) with distal transparent attachment was used. EMR was performed using diathermy snare. ESD and EFTR was performed using either Dualknife™ (Olympus) or Hybrid knife™ (ERBE GmBH, Germany). Hemostasis was achieved using Coagrasper™ (Olympus). For EFTR, closure was achieved using hemoclips (Olympus), PadlockTM clip (Aponos Medical, USA) or Overstitch™ (Apollo Endosurgicals, USA). Foregut NETs were graded as G1, G2, or G3 on basis of proliferative activity by mitotic count. All patients underwent regular follow-up to evaluate for any local recurrence or distant metastasis.
Results: Foregut NET managed by ER include 23 patients (25 lesions). Location – Stomach – 1, duodenal bulb – 17, descending duodenum – 7. Males-16. Mean age- 60.7 years. All lesions found incidentally during routine EGD for other indications; no patients reported symptoms of carcinoid syndrome. All tumors resected en bloc. Mean cross sectional area – 18.3 mm (range: 5–50); mean procedure time – 98.6 min (range: 20–135). EMR in 7 (30%), ESD in 13 (57%) & EFTR in 3 (13%). EFTR defect closed using omental patch & hemoclips in 1; full-thickness clip in two patients. According to WHO 2010 classification, histology – NET-G1–19; NET-G2–4. No intra procedural adverse events noted. Two delayed adverse events (11%) – delayed hemorrhage – 1, delayed perforation – 1. No mortality. Histology – clear margins in all. Follow up EGD at 4–6 weeks - complete healing in all. Median follow up was 12 months (3–72). No recurrence noted. One patient developed new lesion during follow up; ESD performed.
Conclusion: Endoscopic resection of foregut NET's is safe and effective. ER is safe and effective to provide high histologically complete resection rate, accurate histopathological evaluation, and a low complication rate.
Disclosure: Nothing to disclose

Contact E-Mail Address: mfkarakaya@yahoo.com
Introduction: Positron emission tomography/computed tomography (PET-CT) is an important imaging modality in the diagnosis, staging and monitoring the treatment response in oncology departments. As a result of the increased availability of PET-CT imaging, unexpected FDG uptake has been identified in a variety of sites in the gastrointestinal (GI) tract. Although incidental lesions of the GI tract on PET-CT scans are found only in about 3% cases, they are associated with a substantial risk of an underlying cancerous or precancerous lesion.
Aims and Methods: The aim of this study was to investigate whether incidental FDG uptake and has any clinical and histopathological importance detected in patients with non-GI malignancies. We particularly sought a suv-max value in predicting malign lesions of the GI tract. Between February 2011 and November 2016, 12530 patients had undergone PET/CT scan. Patients with GI malignancies, patients without Suv-max value on PET/CT and patients without endoscopic and histopathological examinations were excluded from the study. Patients with FDG uptake were stratified as follows: according to localization (esophageal, gastric and colonic) and histopathological findings (benign and malign). Receiver operating characteristic (ROC) curves were used and optimal cut-off points were calculated to describe the ability of suv-max value to predict the presence of a malign process.
Results: 157 out of 12530 patients with GI tract FDG uptake and endoscopic/histopathological results were included into the study. 40 patients had abnormal esophageal FDG uptake, 66 patients had gastric and 51 patients had incidental focal colorectal uptake. One patient had malign mesenchymal tumor and 39 patients had benign conditions (37.5% esophagitis) at esophagus. 12 patients had lymphoma, 1 plasmocytoma involvement and 2 patients had a newly diagnosed carcinoma of the stomach at gastroscopy. As for benign conditions, 37 had gastritis, 6 had benign ulcers, 5 had submucosal lesions and 2 patients had hyperplastic polyps of the stomach. A total of 27 patients had premalign/malign conditions of the colon. The histological results are as follows: adenomatous polyps (n = 15), colon cancer (n = 5), dysplasia (n = 4), insitu cancer (n = 2) and malign melanoma involvement (n = 1). The results of the benign condition of the colon are as follows: infectious colitis (n =), diverticular disease (n =), anastomotic line (n = 1), non-specific ulcer (n = 1) and no finding (n = 12). The cut-off values of Suv-Max for discriminating benign and malign conditions of the stomach and colon were 15.9 [AUROC;89.2, sensitivity% (95%CI) 78(52–92), specificity% (95%CI) 92(81–96)] and 9.7 [AUROC;71.6, sensitivity% (95%CI) 81(63–91), specificity% (95%CI) 62(42–78)].
Conclusion: Incidental focal gastric and colorectal FDG uptake is associated with a substantial risk of underlying premalign/malign conditions but not for esophagus. Gastroscopy and colonoscopy should be recommended due to incidental

focal FDG uptake, early identification of these lesions may change management of these patients.

Introduction: In oesogastric cancer (OGC), recent studies have shown a prevalence of mismatch repair deficiency (dMMR) from 8 to 23% with heterogeneous data between European and Asian studies. Questions have been raised about the prognostic impact of dMMR.
The aim of our study was to determine dMMR prevalence in a cohort of OGC, to determinate associated BRAF mutation and to evaluate the prognostic value of dMMR.
Aims and Methods: We have performed a retrospective multicenter study that has enrolled all consecutive patients from 2010 to 2015 with junction or gastric adenocarcinoma for which tumor sample (biopsies or surgical samples) and clinical data with follow up were available.
dMMR was determined by genotyping with PCR of 5 monomorphic mononucleotide repeats. In case of dMMR tumor, BRAF V600E mutation screening and immunohistochemistry (IHC) of MMR proteins were performed.
Overall survival (OS) was estimated by Kaplan Meier method and compared between groups by log rank test. Recurrence cumulative incidence were estimated and compared according to MMR status by Gray test.
Results: Two hundred and twenty-three tumors were analyzed, among them 180 (80%) were mismatch repair proficient (pMMR), 31 (14%) were dMMR and 12 tumors were undetermined. Patients with dMMR tumors were older than patients with pMMR tumors (median age 70.5 versus 60.8 years, $p = 0.003$). dMMR prevalence was 26% in patients ≥ 70 versus 12% in patients < 70 years. dMMR tumors were located in junction, fundus and antrum in 7.1%/25%/67.9% respectively versus 33.6%/27%/33.6% and 5.8% unknown for pMMR tumors ($p = 0.02$). There was no significant difference regarding gender (male 53.6% in dMMR versus 67.2% in pMMR), localized or metastatic stage (85.7%/14.3% in dMMR versus 81.6/18.4% in pMMR), histologic type (diffuse/intestinal/indeterminate type respectively 22.7%/ 45.5%/22.7% in dMMR and 29.7%/42.3%/18% in pMMR), tumor with signet-ring cells (47% of dMMR tumor versus 52% of pMMR tumor) or HER2 surexpression (11.1% in dMMR versus 9% in pMMR). We observed a trend for less lymph node metastasis (LNM) in dMMR tumor (N0: 60.9% in dMMR versus 32.1% in pMMR, $p = 0.056$). R0 surgery was obtained in 82% of cases in both groups. A trend for less neoadjuvant chemotherapy was observed in dMMR compare to pMMR (39.1% versus 58.4%, $p = 0.11$).
All the tumors that were determined dMMR by PCR presented a loss of expression of one of the MMR proteins (all MLH1 except 1 MSH6). For 12 tumors with equivocal status by PCR, none presented MMR proteins loss of expression. None of the 22 dMMR tumors had the V600E mutation of *BRAF*.
The median OS for all stages was 32.8 months in dMMR versus 25.2 months in pMMR ($p = 0,94$). In the subgroup of 136 patients who had surgery for localized cancer, cumulative incidence of recurrence at 3 years was 21% in dMMR versus 52% in pMMR group ($p = 0.03$).
Conclusion: In this cohort, dMMR prevalence in OGC was 14%, mostly associated with antral localization and aged patients. dMMR was associated with a lower risk of LNM and a lower cumulative incidence of recurrence. dMMR status determined by PCR was confirmed by IHC in all cases, with loss of MLH1 in nearly all cases. None of the dMMR tumor presented a *BRAF* mutation.

[5]*University Hospital of Santiago de Compostela, Clinical Analysis, Santiago de Compostela, Spain*

Contact E-Mail Address: fmacgar@yahoo.es
Introduction: Atrophic gastritis (AG) is the most important known risk factor for the development of non-cardial gastric cancer (GC), mainly in cases of extensive or advanced (moderate-severe) atrophy. Serological biomarkers (pepsinogen-I (PG-I), pepsinogen-II (PG-II), gastrin-17 (G-17), anti-H. pylori antibodies - HpAb-), provide non-invasive information about the morphological and functional integrity of the stomach, and they could be an useful tool for selecting patients at risk.
Aims and Methods: The aim of this study is to assess the diagnostic accuracy of a serological biomarker panel, GastroPanel® (GP) to predict the presence of moderate-severe AG in the corpus (CAG2+) and/or antrum (AAG2+) in patients with uninvestigated dyspepsia.
Methods: A prospective observational study was conducted. Inclusion criteria: patients > 50 years, with univestigated dispepsia, submitted to our Endoscopic Unit for upper GI endoscopy. PPIs were discontinued 4 weeks before fasting levels of PG-I, PG-II, G-17 and HpAb were determined by ELISA method. Five gastric biopsies were obtained (2 antrum, 2 body and 1 incisura) during endoscopy, that were independently evaluated by two pathologists blinded to the GP result. In case of discrepancy, histologic slides were reviewed by a third external pathologist. Updated Sydney System (USS) was used to graduate the presence of AG: 0 (absent), 1 (mild), 2 (moderate) or 3 (severe). Concordance between GP and histology was assessed using the kappa index. The accuracy and area under the ROC curve (CI95%) of PG-I < 30 µg/l and PG-I/PG-II ratio < 3 for the diagnosis of CAG2+ and of G-17 < 1 pmol/l for the diagnosis of AAG2+ were calculated.
Results: 131 consecutive patients were included (median 63 years (range 48–86), 60.3% women, 49.6% *H.pylori* positive). According to GP results, 16 patients (12.2%) presented AG: 13 CAG and 3 AAG, while AG was observed in histological analysis in 34 cases (25.9%): 16 CAG (8 CAG2+), 12 AAG (8 AAG2+) and 6 multifocal AG (4 CAG2+, 1 AAG2+). The overall agreement between histology and GP was 75.6% (99/131), kappa index: 0.63. For the diagnosis of CAG2+, the overall efficacy of PG-I < 30 µg/l and PG-I/PG-II ratio < 3 was respectively 96.2% (CI95%: 91.4–98.4) and 95.4% (CI95%: 90.4–97.9), with AUC-ROC 0.963 (CI95%: 0.923–1) for PG-I and 0.967 (CI95%: 0.928–0.997) for PG-I/PG-II ratio. For the diagnosis of AAG2+, the overall efficacy of G-17 < 1 pmol/l was 81.7% (CI95%: 74.2–87.4) with AUC-ROC 0.745 (CI95%: 0.611–0.878).
Conclusion: The serological biomarker panel GastroPanel® is an effective tool for the non-invasive screening of patients with uninvestigated dyspepsia, that allows detecting those patients at the highest risk of developing GC (basically, moderate-severe CAG).
Disclosure: Nothing to disclose

P1806 USEFULNESS OF UNDERWATER EMR FOR NON-AMPULLARY DUODENAL TUMOR

A. Takahashi, T. Oyama
Saku Central Hospital Advanced Care Center, Endoscopy, Nagano, Japan

Contact E-Mail Address: aurevoireurope@yahoo.co.jp
Introduction: Complication rate of endoscopic submucosal dissection (ESD) for superficial non-ampullary duodenal epithelial tumors (SNADET) is higher than that of other organ, because of thin muscle layer. Recently a new method, underwater EMR (UWEMR) has reported. However, the usefulness is not well known.
Aims and Methods: The aim of this study is to investigate the outcome of UWEMR for SNADET.
One hundred seven lesions of SNADET were treated from Feb. 2016 to Feb. 2018. Lesions less than 15mm in size were indicated for UWEMR. Large lesions were indicated for ESD or laparoscopy endoscopy collaboration surgery (LECS). Two, thirty-one and eight lesions were treated by EMR with injection, ESD and LECS, respectively. And the residual sixty six lesions undergone to UWEMR.
The procedure was changed from UWEMR to EMR or ESD, when the snaring was impossible. Four and 4 lesions were treated by EMR and ESD, respectively. Finally, fifty-eight lesions were treated by UWEMR. UWEMR was performed with a 10-mm or 15-mm snare (SnareMaster; SD-210L-10, SD-210L-15, Olympus, Tokyo).
Median age was 66 (43–87) years old. Macroscopic type; 0-I, 0-IIa and 0-IIc were 8, 26 and 24, respectively. Location; bulbs, 2nd portion and 3rd portion were 4, 42 and 12, respectively.
Artificial ulcer was closed by endo clips (EZ clip; HX-610-090L, Olympus, Tokyo) to prevent delayed perforation and bleeding. Intravenous PPI were used from just before UWEMR for two days, and followed by per-oral PPI

for one month. The patients were allowed to eat loose meal from two days after UWEMR.
Results: 1. The median diameter of tumor and specimen was 7 (2–25) and 12 (4–25) mm, respectively.
2. En-bloc resection rate was 91% (53/58). R0 and Rx rate was 69% (40/58) and 31% (18/58), respectively. When the final section contains neoplasia, lateral margin (LM) was diagnosed as LMx (N = 13). And, piecemeal resected cases were diagnosed as LMx (N = 5), too. The median diameter of tumor in R0 was 6 (3–18) mm. In contrast, that in LMx was 11 (2–25) mm. There was significant difference between diameter of tumor of R0 and that of RX (p = 0.0032). The rate of R0 was 87% (13/15) in 1–5mm, 77% (20/26) in 6–10mm, 60% (6/10) in 11–15mm, 20% (1/5) in 16–20mm and 0% (0/2) in 21–25mm. There was significant difference (p = 0.0095). The R0 rate for SNADET 10mm or less was excellent. However, it wasn't satisfactory for large lesion 16mm or bigger.
3. The rate of local recurrence was 0%.
4. Closing method; The mean number of clips was 5 (1–8). A second look EGD was performed 2 day after UWEMR. And some clips were dropped in 4 of 58 cases. However, the artificial ulcer was closed by the remaining clips. All of the clips were remained in 93% (54/58). Therefore, second look EGD to check closure of ESD is unnecessary.
5. Complications; Perforation during UWEMR was 0% (0/58). The rate of delayed perforation and bleeding was 0% and 0%, respectively.
Conclusion: UWEMR is a safe treatment for SNADET. And, R0 rate in 10 mm or less was excellent.
Clip closure after UWEMR was effective to prevent delayed bleeding and perforation.
Second look EGD is unnecessary to check the closure of artificial ulcer.

P1807 OUTCOME OF ESD FOR ESOPHAGO-GASTRIC JUNCTIONAL ADENOCARCINOMA

A. Takahashi, T. Oyama
Saku Central Hospital Advanced Care Center, Endoscopy, Nagano, Japan

Contact E-Mail Address: aurevoireurope@yahoo.co.jp
Introduction: The incidence of Esophago-gastric junctional adenocarcinoma (EGJAC) is lower than that of esophageal or gastric cancer. Therefore, the outcome of ESD for EGJAC is still unknown.
Aims and Methods: The aim of this study is to investigate the outcome of ESD for EGJAC.
One hundred eight patients (90 males and 18 females) with one hundred eleven EGJAC treated by ESD from Jan. 2000 to Mar. 2015 were enrolled to this retrospective study. EGJAC was defined as adenocarcinoma located between 1cm oral and 2cm anal from EGJ.
The median age was 74 (32–91). Follow-up period was 82 (1–211) months. Protuberant, flat and depressed type were 52, 3 and 56 lesions, respectively. T1b was sub-classified into T1bSM1 (500 micrometer or less) and T1bSM2 (501 micrometer or deeper). T1aM, T1bSM1 and T1bSM2 were 82, 15 and 14, respectively. Differentiated (DA) and poorly differentiated adenocarcinoma (PDA), were 106 and 5 lesions, respectively.
T1aM and T1bSM1 were followed up without an additional therapy (AT). And, AT was recommended for T1bSM2, and when lymph vascular involvement was positive.
Results: 1. The median diameter of tumor and specimen were 18 (2–61) and 40 (22–82) mm, respectively.
2. Complete resection and R0 rate was 100% and 99% (110/111), respectively.
3. Local recurrence rate was 0%.
4. Complications: The bleeding during ESD and delayed bleeding required blood transfusion was 0% and 0.9% (1/111). The perforation during ESD and delayed perforation was 0.9% (1/92) and 0%.
5. Prognosis
a) T1a-M (N = 82) and T1b-SM1 (N = 15)
All patients were followed up. No patients had metastasis, and died of EAC.
b) T1b-SM2 (N = 14)
Surgery was performed for eight patients (57%). No patient had lymph node metastasis (LNM). Five patients are alive without metastasis 3 patients were died of other disease without metastasis.
One was treated by radiation, and died of EGJAC 16 months after ESD.
Five patients were followed up without additional therapy. Three patients are alive without recurrence. One patient was died of EGJAC 70 months after ESD. One patient was died of other disease.
6. The risk factors of LNM (Univariate analysis)
a. Invasion depth; The rate of LNM in T1aM, T1bSM1 and T1bSM2 were 0% (0/82), 0% (0/15) and 7% (1/14), respectively (p = 0.0303).
b. Histological type; The rate of LNM in DA and PDA were 0% (0/106) and 20% (1/5), respectively (p = 0.0450).
c. Lymphatic involvement (LI); The rate of LNM of LI(+) and (-) were 33% (1/3) and 0% (0/108), respectively (p = 0.027).
7. The risk factors of LNM (Multivariate analysis)
Lymphatic involvement was the independent risk factor of LNM (p = 0.0339).
8. Prediction value of eCura system[1] for EGJAC
Twenty two patients were diagnosed as out of indication. Sixteen, four and 2 patients were classified to low, intermediate and high-risk groups. And the LNM rate were 0% (0/16), 0% (0/4) and 50% (1/2). The eCura system was compatible for not only gastric adenocarcinoma but also EGJAC.
Conclusion: ESD was a safe and useful treatment for superficial EGJAC.
The eCura system is an useful method to predict prognosis, for out of indication cases of EGJAC.
Disclosure: Nothing to disclose

Introduction: Treatment of locally recurrent gastric neoplasms after endoscopic resection remains challenging. We investigated the efficacy and safety of treatment options for recurrent gastric neoplasms localized to the scar of previous endoscopic submucosal dissection (ESD).
Aims and Methods: The clinicopathological characteristics and treatment outcomes of patients who underwent endoscopic treatment or surgery for recurrent gastric neoplasms between June 2010 and May 2017 were retrospectively reviewed.
Results: Of the 92 patients included, 74 underwent endoscopic treatment (54 redo ESD, 23 argon plasma coagulation [APC] ablation) and 18 underwent surgery. The redo ESD procedure time was significantly longer than that of the primary ESD (31.0 versus 22.0 minutes, $p = 0.018$). Overall, adverse events occurred in 11 patients (12.0%), with the incidence being significantly higher in the surgery group (27.8% versus 8.1% in the endoscopic treatment group, $p = 0.036$). Local recurrence-free survival rates were 81.1% for the endoscopic treatment group (86.3% and 69.6% for redo ESD and APC groups, respectively) and 100% for the surgery group (log rank $p = 0.033$). Logistic regression analysis showed that tumor size > 15 mm (odds ratio [OR]: 7.52, 95% confidence interval [CI]: 1.65–45.3, $p = 0.014$) and tumors located in the upper two thirds of the stomach (OR: 6.10, 95% CI: 1.32–37.1, $p = 0.029$) were associated with non-curative resection after redo ESD.
Conclusion: Endoscopic treatment could be an effective and safe alternative to surgery for selected patients with gastric neoplasms recurring at the site of previous ESD.

P1809 EVALUATION OF GASTRIC POLYPS DETECTED BY ENDOSCOPY: WHAT IS THE CLINICAL SIGNIFICANCE?

M. Garrido, R. Marcos-Pinto, T. Araújo, I. Pedroto
Centro Hospitalar do Porto, Gastroenterology, Porto, Portugal

Contact E-Mail Address: monicasofiagarrido@gmail.com
Introduction: Found in 6% of upper endoscopies, gastric polyps are a heterogeneous group of lesions that can vary in histology, neoplastic potential, and management. Currently, there are no clear guidelines for the management of these lesions.
Aims and Methods: The aim of this study was to evaluate gastric polyps, detected by upper endoscopy in our institution, with respect to their frequency, size, anatomic location, presence of dysplasia, histopathologic features and clinical outcomes. Clinical records from patients who underwent upper endoscopy with polypectomy between January 2012 and December 2017 were reviewed retrospectively.
Results: A total of 405 patients with a median age of 66 years (interquartile range 55–74 years) were included; 66.2% were female; 26.9% had *Helicobacter pylori* infection; 62.2% were taking proton pump inhibitors; 8.9% were diagnosed with hereditary polyposis or non-polyposis syndromes; 4.3% had a positive family history for gastric cancer. A total of 463 upper endoscopies with polypectomy were performed. Most polyps detected by endoscopy were solitary (56.8%). Of all gastric polyps, 40.2% measured between 0–5mm, 27.0% between 6–9mm and 32.8% ≥ 10mm. Gastric polyps were found most commonly in the corpus/fundus (58.8%), followed by antrum (33.5%), cardia (5.6%) and a minority (2.2%) in the antrum-body transitional zone or anastomotic site. Histopathologically, the most common polyp type was hyperplastic (60.5%), followed by fundic gland (14.5%), nonspecific/foveolar polypoid hyperplasia (14.3%), inflammatory fibroid (4.5%), adenomatous (3.9%), neuroendocrine (1.5%) and hamartomatous (0.9%). Among adenomatous polyps, 11 were low-grade dysplasia, 6 high-grade dysplasia and 1 had features of adenocarcinoma. Additionally, 3 hyperplastic polyps had dysplastic foci; all of these were ≥ 10mm. Dysplasia was shown to be significantly associated with polyp size ≥ 10mm (p = 0.018), and Familial Adenomatous Polyposis (FAP) (p = 0.009). During a median follow-up period of 12 months (data available in 96 cases), 45.3% of gastric polyps recurred, the large majority (78.9%) with the same histological type.
Conclusion: Most polyps detected by endoscopy were solitary, smaller than 1 cm, and found in the corpus/fundus. The most common type was hyperplastic polyp. Dysplasia was shown to be significantly associated with polyp size ≥ 10mm and

Familial Adenomatous Polyposis (FAP), which underlines the importance of endoscopic excision in these situations.

P1810 IMPACT OF PRE-NEOPLASTIC LESIONS AND TUMORS OF GI TRACT IN AFRICAN POPULATION IN PARMA AREA BASED ON PATHOLOGY RECORDS: RELATIONSHIP WITH RISK FACTORS AND HELICOBACTER PYLORI STATUS

J.P. Njike Yowoum[1], P. Crafa[1], **M. Capasso**[1], A. Barchi[1], G. Masciangelo[1], P. Caruana[2], C. Mancini[2], L. Franzoni[1], A. Nouvenne[1], C. Miraglia[1], O. Cavatorta[1], F. Di Mario[1]
[1]*University of Parma, Department of Medicine and Surgery, Parma, Italy*
[2]*University Hospital of Parma, Unit of Pathology, Parma, Italy*

Contact E-Mail Address: mario.capasso@studenti.unipr.it
Introduction: In Italy, in recent years African population is increasing, in particular in some regions like Emilia-Romagna where in 2017 Africans were 11.9% out of resident population. The life style of African immigrants is different from the Italian population, in particular as regards the consumption of meat, use of spices, alcohol consumption and smoking habit. The distribution of GI lesions both in Upper and in Lower tract is matter of interest for the public health in order to investigate risk factors, epidemiological data and burden of expenses in particular related with neoplastic diseases.
Aims and Methods: The aim of this study was to investigate the distribution of GI lesions in this two populations and to establish possible relationship with life style and epidemiological data. Based on records from Parma's Department of Anatomo-Pathology a Database was performed collecting biopsies coming from Upper and Lower GI endoscopy from 01/01/2007 to 30/12/2017. In particular, 25,763 biopsies have been examined from Upper GI endoscopy and divided in 24,683 diagnosis of Chronic Atrophic Gastritis (CAG) and 1,080 of Gastric Cancer (GC); while 40,673 biopsies from Lower GI endoscopy have been analysed and were divided in 36,988 polyps and 3,685 diagnosis of Colo-Rectal Cancer (CRC).
The records of Database allowed to set apart two different groups: Group A standing for non-African population inhabiting in Parma and Group B for African population resident in Parma.
Moreover, 321 consecutive African subjects resident in Parma (M/F 186/135), were enrolled to fill out a structured questionnaire about their feeding and life habits.
Results: Respectively 23,559 out of 24,683 CAG diagnosis (95.4%) and 1,076 out of 1,080 GC diagnosis (99.6%) were from Group A against 1,124 (4.5%) and 4 (0.4%) in Group B. However, *Helicobacter pylori* status was investigated in these pts and the data obtained showed 39% H.p.+ in Group A and 68% in Group B. In Group A, 41% of CAG diagnosis (mean age 63.5 yrs) were associated with intestinal metaplasia (IM), about 3 times higher than in Group B (95 pts, m.a. 52 yrs); within African population IM was more common in people coming from Sub-Saharan Africa (59 pts, 14%) than people from North Africa (36 pts, 10%). Concerning Lower GI biopsies, 36,899 out of 36,988 (99.8%) colonic polyps diagnosis were observed in 19,356 pts (M/F 12,368/6,988) from Group A, showing an higher rate than in Group B in which colonic polyps were detected in just 89 biopsies (0.2%) from 78 pts (M/F 36/42). Furthermore no CCR was diagnosed in Group B.
Records obtained by the questionnaire showed that 60% of sample eat foods from their country, less refined and fiber richer, with a lower consumption of red meat; 88% use spices, 65% don't drink alcohol and 92% don't smoke. In addition, 49.6% don't rely on conventional drugs, only 50.4% admit to follow medical prescriptions and, 27% try as first approach drugs coming from their country.
Conclusion: The results obtained in the study show discrepancy between diagnosis of CAG and GC in non-African Parma population in comparison with African one. This data is opposite to the trend of H.p. status in the two populations, as well as for the distribution of intestinal metaplasia. As regards Lower GI features, African people is affected by very little number of lesions (both colonic polyps and CCR). The results from questionnaire also demonstrated peculiar pattern of eating, smoking and drinking from African subjects, searching for original country products.
Disclosure: Nothing to disclose

P1811 ACCURACY OF LINEAR-ARRAY EUS FOR PREOPERATIVE STAGING OF GASTRIC CANCER

V.G. Mirante[1], G. De Nucci[2], T. Gabbani[1], P. Soriani[1], S. Deiana[1], G. Manes[2], M. Vecchi[3], M. Manno[1]

Contact E-Mail Address: v.mirante@ausl.mo.it
Introduction: The incidence of gastric cancer is declining worldwide. However, it still remains the second most common cause of cancer-related death in the world. Endoscopic ultrasound (EUS) is used for preoperative staging of gastric cancer due to its potential ability to assess both depth of local tumor infiltration and regional lymph node involvement. The indication and accuracy of linear EUS, however, are still controversial.
The aim of this retrospective multicenter trial was to determine the accuracy of linear EUS compared with the contrast enhanced computed tomography (CECT) and with final pathologic specimen with regard to tumor depth and nodal status.
Aims and Methods: We retrospectively enrolled 132 cases of gastric cancer who underwent surgical resection between 2015 and April 2018 from two hospitals of Northen Italy, preoperatively evaluated for depth of invasion of tumor and lymph nodes stations involvement with linear EUS and classified according with TNM classification (UICC).
Results: Of 132 patients, 56 were localized in corpus, 45 in antrum, 20 in the gastric angulus, 8 in fundus, 2 in cardia and in one case the tumor was in the pylorus. Mean age of patients was 65 (+/−10) and mean tumor size was 45 mm (+/−15) ranging from 15 to 80 mm maximum. The overall diagnostic accuracy of EUS in preoperative determination of cancer depth of invasion was 66.7% (4/6) and 62% (18/29), 65% (41/63), 76% (26/34), for T1 (T1b), T2, T3, and T4, respectively. The diagnostic accuracy of metastatic lymph node involvement or N staging of EUS was 68% (46/67) for N0 and 67% (50/65) for N+.
The performance of T staging with CT scanners was not high: 66.7% for T1, 62% for T2, 61% for T3, 8% for T4. For lymph node involvement, the sensitivity value for CECT was significantly lower than that for EUS: 47% for N1, 0% for N2.
Conclusion: Our data indicates that EUS may be superior to CECT in preoperative locally N staging. Additionally, EUS accuracy in T staging is still suboptimal and probably more than one single diagnostic procedure should be used.

Introduction: Diagnosis of autoimmune diseases warrants exclusion of concomitant autoimmune disorders, as the coexistence in the single individual is frequent. The diagnosis of autoimmune gastritis (AG), a condition in which auto-antibodies targeted against components of the oxyntic epithelium progressively destroy the mucosa of gastric body (C) and fundus, is established histologically, with the presence of mucosal atrophy. Although the Operative Link on Gastritis Assessment (O.L.G.A.) is a widespread staging system for gastric atrophy, it does not provide information on the severity of disease in terms of the degree of gastric function impairment.
Aims and Methods: The aim of the present study was to establish the usefulness of pepsinogen I (PGI) and gastrin-17 (G-17) in the evaluation of gastric atrophy severity, assessed by the O.L.G.A. staging system.
Patients with autoimmune gastritis, diagnosed by APCA positivity and histological assessment, according with O.L.G.A. staging, were consecutively enrolled in the study. Serological determination of PGI and G-17 was performed in all. Patients on therapy with acid suppressants were excluded, as these drugs cause an alteration in serum levels of PGI and G-17. Accordingly to literature, patients were considered affected by gastric atrophy when PGI < 30 μg/l and G-17 > 7 pmol/l.

Abstract No: P1812
Table 1: Concordance between PGI, G-17 and O.L.G.A. staging

	STAGE 0	STAGE I		STAGE II		STAGE III	
	A0C0 *(n = 33)*	A0C1 *(n = 7)*	A1C1 *(n = 3)*	A0C2 *(n = 12)*	A1C2 *(n = 8)*	A0C3 *(n = 35)*	A1C3 *(n = 25)*
PG I: Medium value ± SD	110.0 ± 85.7	25.6 ± 25.3	23.20 ± 31.3	16.42 ± 16.6	13.5 ± 11.5	7.87 ± 4.56	10.8 ± 9.74
G-17: Medium value ± SD	8.09 ± 17.8	24.6 ± 29.6	44.2 ± 34.9	118.6 ± 136.4	144.1 ± 92.8	122.8 ± 133.4	108.3 ± 78.4

Results: A total of 144 patients (124 F, mean age 58.3 ± 13.6) were included in the study; 21 patients with antral (A) atrophy only were excluded from the analysis. PGI levels showed a progressive reduction that paralleled the increasing O.L.G.A. stage, shown in the table below. The concordance between the mean values of PGI and atrophy severity was statistically significant ($p < 0.0001$). A similar, but opposite, statistically significant ($p < 0.0001$) result was observed for G-17, which levels show a progressive increase with worsening of gastric atrophy.
Conclusion: In our study, the concordance between PGI, G-17 and the prognostic O.L.G.A. staging permits to consider the non-invasive test as a first level cost-effective exam for the evaluation of gastric function. Furthermore, G-17 levels showed a significant increase moving from stage I to stage II, a stage that corresponds to a different risk of developing gastric adenocarcinoma, so the serological markers resulted able to correlate to the severity of lesions, assessed by O.L.G.A. staging.

P1813 HYPERTHERMIA REGULATES BOTH SLC22A16 EXPRESSION AND ABCG2 EXPRESSION VIA ROS PRODUCTION TO ENHANCE THE CYTOTOXICITY OF DOXORUBICIN

H. Matsui, H. Kurokawa
University of Tsukuba, Faculty of Medicine, Tsukuba, Japan

Contact E-Mail Address: hmatsui@md.tsukuba.ac.jp
Introduction: Hyperthermia (HT) is a non-invasive cancer therapy. Treatment temperature between 41 to 44°C has no cytotoxic damage in normal cells, while the temperature does in cancer cells because of the underdeveloped vascular system. HT often used with other cancer therapy such as radiation-therapy and chemotherapy. However mechanisms of synergistic effects among these therapies remains unclear. The 42°C environment is a cellular mild heat stress generating O_2^- from mitochondrial electron transport chain. We have previously reported that the expression of ATP-binding cassette sub-family G member 2 (ABCG2), which is known as breast cancer resistant protein (BCRP), was suppressed by increasing mitochondrial ROS to induce cancer specific porphyrin accumulations.
Aims and Methods: Since ABCG2 is a transporter of doxorubicin (DOX), we hypothesized that synergistic effect of HT and chemotherapy may be induced by down-regulation of ABCG2 expression via intracellular ROS increase. In this study, we elucidated whether HT with intracellular ROS increase by HT can enhance the cytotoxic effect of DOX for gastric epithelial cells. The gastric epithelial cellular cancerous mutant, RGK1 was incubated at 37 or 42°C for 1h. Intracellular ROS generation was detected by electron spin resonance (ESR). Cytotoxicity of DOX was measured using the Cell Counting Kit 8. ABCG2 expression was analyzed by Western blotting.
Results: ESR signal peak with HT treatment became high as compared to without HT treatment, indicating intracellular ROS level was increased by HT treatment. Cell viability and ABCG2 expression were decreased by DOX exposure and by HT treatment.
Conclusion: Thus we conclude that the enhancement of HT treatment effect by DOX is considered to be result of down-regulation of BCRP expression by ROS.

Introduction: Homeobox (HOX) genes encode a family of homeodomain-containing transcription factors that bind with specific DNA strands. HOXB9 is a member of the HOX family and is classified into B cluster. The function of HOXB9 has been extensively investigated in lung and breast carcinomas. However, knowledge about its function and regulation mechanism in gastric cancer (GC) is still quite limited.
Aims and Methods: This study aims to comprehensively investigate the expression and functional role of HOXB9 and elucidate its regulatory mechanisms in gastric carcinogenesis. HOXB9 were screened out by expression microarray of GC cell lines. The clinical relevance of HOXB9 in GC was analyzed from both online datasets and immunohistochemistry of tissue microarray. siRNA-mediated HOXB9 knockdown were applied in the functional assays such as cell proliferation, monolayer colony formation, cell invasion, cell-cycle distribution analysis, and anti-tumor drug sensitivity test. The miRNA that potentially binds to the 3'UTR of HOXB9 was predicted by miRDB and TargetScan. The regulation of HOXB9 by putative miRNA was confirmed by qRT-PCR, Western blot, and dual luciferase activity assays. The *in vivo* functional roles of HOXB9 and miRNA were revealed by xenograft formation assay.
Results: HOXB9 showed higher mRNA expression compared with other HOX members in GC cell lines. The relative mRNA expression of HOXB9 was upregulated in GC cells compared with immortalized gastric epithelium cell GES-1. Its overexpression was associated with poorer outcome in GC patients. Knocking down HOXB9 led to suppression of cell proliferation, monolayer colony formation, and cell invasion ability. In addition, siHOXB9 induced G1 phase cell cycle arrest and increased anti-cancer drug such as Fluorouracil and Cisplatin sensitivity. HOXB9 was further confirmed to be a direct target of tumor suppressor miRNA, miR-28-5p. Their expressions exhibited negative correlation in primary GC samples. Re-overexpression of HOXB9 partly reversed the tumor-suppressive effect of miR-28-5p.
Conclusion: HOXB9 is over-expressed and plays oncogenic role in gastric carcinogenesis. The activation of HOXB9 in GC is partly due to the silence of a tumor-suppressive miRNA, miR-28-5p. These findings not only elucidated a novel oncogenic transcription factor HOXB9 in gastric carcinogenesis but also enriched its regulatory mechanism by miRNA.

Introduction: There is an increasing evidence that microbiota may substantially contribute to carcinogenesis. *Fusobacterium* species (*Fusobacterium* spp.), in particular *Fusobacteria nucleatum* (*F. nucleatum*), are frequently found in colorectal cancer (CRC), and prognostic role in CRC has been suggested. Gastric cancer (GC) is strongly related to *H. pylori* infection; however, the data on microbiota and in particular *F. nucleatum* are limited to microbiome profiling studies and clinical relevance not elucidated.
Aims and Methods: The aim of the study was to evaluate the presence of *Fusobacterium spp.* and *F. nucleatum* in GC, chronic gastritis with or without atrophy/intestinal metaplasia, and to correlate the positivity to clinicopathological characteristics and prognosis of GC patients. For this purpose, *Fusobacterium* spp. and *F. nucleatum* were measured in several biopsies, including CRC tissues (n = 27, T-CRC), matching non-tumoral colon tissues (n = 26, N-CRC), GC tissues (n = 81, T-GC), matching non-tumoral gastric tissues (n = 78, N-GC), gastritis (n = 26) and controls (n = 18). Probe-based qPCR with internal normalization to PGT was used for quantification. Expression data were further analyzed for clinicopathological characteristics and survival (up to 2500 days) and correlated with global (LINE-1) and gene-specific miR-137 methylation.
Results: *Fusobacterium spp.* and *F. nucleatum* were present more frequently in T-CRC with 92.6% and 74.0% in comparison to N-CRC with 80.8% and 53.9%, respectively. In comparison, *Fusobacterium* spp. were detected in N-GC in 65.4% and in T-GC in 77.8%, while *F. nucleatum* was present in N-GC in 23.1% and in T-GC in 28.8% of the gastric samples. The comparison of normalized Ct-values of T-GC and T-CRC revealed a significantly higher bacterial content in CRC for both *Fusobacterium* spp. ($p = 0.0003$) and *F. nucleatum* ($p = 0.007$). Overall, there was a significant correlation between *Fusobacterium* spp. and *F. nucleatum* in T-GC ($p < 0.0001$) as well as of *F. nucleatum* between N-GC and T-GC ($p < 0.0001$). Furthermore, we observed no significant difference between controls, chronic gastritis with and without atrophy/intestinal metaplasia, N-GC and T-GC. Clinicopathological analysis between *F. nucleatum*-positive and -negative subgroups revealed no difference in regard to gender, *H. pylori*-status, tumor stage and tumor localization. There was a positive correlation between *F.nucleatum* and age. Overall survival analysis of GC patients revealed a trend towards the worse survival in *F. nucleatum* positive subjects ($p = 0.13$). However, we observed a significantly worse overall survival only in Lauren's diffuse (positive 244.5 day vs. negative 1229.5 days, $p = 0.009$), but not in intestinal type (median 1406.5 days vs. 1323 days, $p = 0.64$) GC. *F. nucleatum* showed no correlation to global DNA methylation marker LINE-1 or miR-137 methylation.
Conclusion: *F. nucleatum* is frequently present in GC tumoral and non-tumoral tissues although less frequently as in CRC. *F. nucleatum* positivity showed strong association with overall survival in Laurenńs diffuse, but not in intestinal type of GC. Further data are needed to explore the possible functional role of *F. nucleatum* in diffuse type GC patients and interaction with gastric microbiota.

Introduction: Although gastric cancer is considered as a disease of middle-aged and elderly, 2%-15% of patients with gastric cancer are young. Only a few studies with small samples have been conducted. The purpose of our study is to review the epidemiological characteristics, evaluate the survival and prognostic factors of gastric cancer in young subjects.
Aims and Methods: This is a retrospective study including patients admitted in our department for gastric adenocarcinoma between January 2007 and June 2017. Our study included a descriptive component of the epidemiological and clinical characteristics of gastric cancer in patients under 45 and a univariate analytical component of clinical differences with older subjects, survival analysis (Kaplan Meier) and prognostic factors in multivariate.
Results: 265 patients were included during this period. Patients under 45 accounted for 30.6% (n = 81). The average age of our patients was 36 ± 6.10. We observed a male predominance with a sex ratio H / F of 1.25. The familial forms remain infrequent (1.2%) The distal site of the tumor represented 27.2%. Histologically, the linitic form (24.7%, $p = 0.009$) and the poorly differentiated ADK were significantly more frequent. 93.9% of patients had a significantly advanced or metastatic disease (p 0.002). Survival at 5 years in young subjects was 7%, in multivariate analysis only vascular invasion, advanced stage and linitic or poorly differentiated forms were prognostic factors.
Conclusion: In our study, gastric cancer remains frequent and aggressive in young subjects compared to western series. Survival remains low in the literature values.

Contact E-Mail Address: wh8609@gmail.com
Introduction: Cytotoxin associated gene A protein *(CagA)* of *Helicobacter pylori (HP)* is a major virulence factor that plays a crucial role in gastroduodenal pathologies [1]. *CagA* gene contains the Glu-Pro-Ile-Tyr-Ala *(EPIYA)* segments in its variable region. Polymorphisms of *EPIYA* motifs results in variations of behavior and aggressiveness between *HP* strains [2]. According to *EPIYA* motifs, *HP CagA* gene is subcategorized as East Asian (more aggressive) or Western (less aggressive) types. Western strains contain only *EPIYA motifs A, B and C*. On the other side, East Asian strains contain *EPIYA motifs A, B and D* without *EPIYA-C*. The *EPIYA* pattern and its correlation with the various gastroduodenal disorders differ geographically. Understanding the role of *EPIYA* pattern could be used regionally as individual risk stratification tool for *PUD* and gastric cancer [3].
Aims and Methods: The aim of our work is to define the *EPIYA* pattern of the *HP* isolates in Egyptian patients and to evaluate any possible correlation with *PUD* and gastric cancer. One hundred and twenty-one patients were recruited in Cairo university Endscopy unit. After signature of the informed consent, multiple biopsies were taken endoscopically from antrum and body of the stomach for molecular detection of *HP* and histopathological assessment. Fifty-eight *HP* isolates were detected by PCR. Out of them, 33 isolates contain *CagA* gene. After endoscopic and histopathological assessment, patients were divided to 3 groups (chronic non atrophic gastritis, PUD and gastric cancer). After that, the *EPIYA* motif genotyping was determined then patients were sub-grouped to 2 groups (No more than *EPIYA-C* motif and multiple *EPIYA-C* motifs). Finally, statistical analysis was done to determine any possible correlations with *PUD* or gastric cancer.
Results: Out of the 33 *CagA* positive strains, *EPIYA-ABC* was the most presented pattern in 23 isolates (69.7%) and the least common pattern was *EPIYA-ABCCC*, which was positive only in two cases (6.1%). Both *EPIYA-AB* and *EPIYA-ABCC* were presented in 4 strains for each (12.1% for each). There were significant statistical correlations between presence of *CagA* gene and *PUD*, beside the correlation between no more than one *EPIYA-C* motif group and chronic non-atrophic gastritis. No significant correlation was found between the increase in *EPIYA-C* motifs number and *PUD* or gastric cancer despite the fact that all patients with gastric cancer (4 isolates) had multiple *EPIYA-C* motifs.
Conclusion: In Egypt, the *CagA* gene is Western type with a variable number of *EPIYA-C* and no *EPIYA-D* motifs. Furthermore, a significant statistical association is confirmed between the *CagA* gene and *PUD*. Regarding *EPIYA* pattern, a significant relation is found between the decrease in *EPIYA -C* motifs and chronic non atrophic gastritis (less aggressive behavior). But, no significant association is confirmed between the increase in number of *EPIYA-C* motifs and *PUD* or gastric cancer.

Introduction: Therapies for *H. pylori* are based on antimicrobial agents also used for other infectious diseases. Since antibiotic resistance develops continuously, it is mandatory to perform periodic prevalence assessment to guide clinicians in selecting the most appropriate therapy in their setting.
Aims and Methods: The aim of this study was to evaluate trends in the prevalence of primary resistance to clarithromycin, metronidazole and levofloxacin over a 5-year period. Consecutive 1325 naïve *H. pylori*-positive patients were studied between 2010 and 2015, and resistances assessed by E-test using the MICs clinical breakpoints recommended by the EUCAST- (>0.5 mg/L, >8 mg/L and >1 mg/L for clarithromycin, metronidazole and levofloxacin, respectively). A univariate and multivariate logistic regression analysis was conducted to examine whether age, sex, BMI, smoking, alcohol consumption, familiarity for gastric cancer, education, country of birth, endoscopic findings, and year of enrolment in the study were potentially involved in bacterial resistance.
Results: When all the 3 antimicrobial agents were considered together, only 39.1% (95% CI: 36.4 to 41.7) of patients were susceptible to all the drugs tested. In the remaining 60.9% (95% CI: 58.3 to 63.5), resistance to one, two or all three agents was present. However, 12.5% (95% CI: 10.9 to 14.4) of patients were resistant to all the antimicrobial agents. When clarithromycin and metronidazole were considered, 45.0% (95% CI: 42.3 to 47.7) of strains were susceptible to both agents. In the remaining 55% (95% CI: 52.3 to 57.7), resistance to one or two agents was present. However, 22.6% (95% CI: 20.5 to 25.0) of patients were resistant to both antimicrobials. Considering clarithromycin, 59.2% (95% CI: 56.6 to 61.9) of the strains were susceptible, and 36.1% (95%CI: 30.4 to 41.9) were resistant. Considering metronidazole, 61.4% (95% CI: 58.7 to 63.9) of the strains were susceptible, and 38.6% (95%CI: 36.1 to 41.3) were resistant. Finally, considering levofloxacin, 61.4% (95% CI: 58.7 to 63.9) of the strains were susceptible, and 38.6% (95%CI: 36.1 to 41.3) were resistant. The multivariate analysis showed that the risk of carrying resistant strains increased significantly and independently over the years (OR: 1.15; 95% CI: 1.08 to 1.23; $p < 0.0001$; OR: 1.11; 95% CI: 1.04 to 1.19; $p = 0.002$; OR: 1.16; 95% CI: 1.08 to 1.25; $p < 0.0001$, for clarithromycin, metronidazole, and levofloxacin respectively).
Conclusion: The prevalence of primary resistances to the antimicrobial agents tested in our region was high and increased significantly between 2010 and 2015. Regional health authorities should consider to set up regular monitoring of primary resistance for *H. pylori*. If strategies to reduce and to improve the use of antibiotics are nor put in place, it will be increasingly difficult to eradicate *H. pylori* infection in future years.

Introduction: Antibacterial resistance is the major cause of failed eradication attempts in the management of *Helicobacter pylori*.
Aims and Methods: Our aim was to evaluate the *H. pylori* resistance rates encountered by European Gastroenterologists in their routine clinical practice. A Local Coordinator was selected from each country with more than 10 *H. pylori* references in PubMed. Each Coordinator selected a representative group of recruiting investigators from his/her country. An e-CRF was created on AEG-REDCap to systematically register all adult patients infected with *H. pylori*. Variables included: *H. pylori* diagnostic test used, use of culture and susceptibility testing, or molecular tests for the evaluation of antibiotic resistance.
Results: Data regarding resistance to antibiotics was available in 12% (2,684) of cases (21,300 patients). In naïve patients, there was no resistance in 44% of strains. Resistance to the most common antibiotics in naïve patients was: 22% to clarithromycin, 31% to nitroimidazoles, and 18% to quinolones; and dual resistance to clarithromycin and nitroimidazole in 13% of the cases. Resistance rates increased after each failed eradication attempt. Table shows antibiotic resistance per line.
Conclusion: The mean rate of *H. pylori* clarithromycin resistance (22%) in European treatment-naïve patients discourages the empirical use of standard triple therapy. Furthermore, concomitant treatment may be soon limited by the increasing dual resistance to clarithromycin and metronidazole (13%). There is a strong acquisition of antibiotic resistance after failed treatments.

Resistance	Line of treatment					
	Overall	First (naïve)	Second	Third	Fourth	Fifth
No resistance	35%	44% (40–48)	13% (4–25)	9% (0–23)	9% (0–37)	16% (0–63)
Clarithromycin	35%	22% (18–27)	60% (54–67)	73% (67–79	78% (64–92)	79% (54–100)
Metronidazole	39%	31% (27–35)	52% (44–59)	65% (58–73)	64% (48–80)	64% (33–96)
Levofloxacin	24%	18% (14–23)	29% (21–40)	46% (40–52)	47% (27–67)	32% (0–76)
Dual (C+M)	23%	13% (8–18)	41% (32–50)	56% (47–65)	55% (37–73)	58% (24–92)

C – clarithromycin, M – metronidazole; the parenthesis includes the 95% confidence interval

Introduction: Virulence factors of *Helicobacter pylori* (*H.pylori*) affect the immunopathological gastritis pattern. The serine protease HtrA is a newly identified virulence factor that disrupts intercellular adhesion and contributes to the intercellular entry of *H.pylori in vitro*.
Aims and Methods: Aim of the study was to evaluate the phenotype of gastritis and HtrA expression of *H.pylori* isolates in relation to CagA and VacA virulence factors. In a prospective study with focus on the relationship of *H. pylori* virulence and gastritis phenotypes, we cultivated 157 *H.pylori* strains from antrum and corpus from 89 patients with chronic gastritis (CNAG), atrophic gastritis (AG), peptic ulcer diseases (PUD) and gastric cancer (GC). *H.pylori cagA*, *vacA* s/m genotype and HtrA and GlmM mRNA expression were determined by PCR. Anti-*H.pylori* and anti-CagA-IgG status was evaluated using commercially available ELISA. Histological gastritis phenotype was characterized based on the updated Sydney score.
Results: All *H.pylori* isolates expressed HtrA, which was similar between isolates from antrum and corpus within each individual patient. HtrA expression was independent from *cagA* positivity or *vacA* s/m genotypes. There was no association between HtrA expression and anti-*H.pylori*-IgG or anti-CagA-IgG systemic immune response. Histopathological analysis revealed similar HtrA expression between patients with CNAG, AG, PUD or GC, which was not correlated with gastritis activity and chronicity scores. No correlation was found between HtrA expression and intestinal metaplasia or degree of atrophy. PPI intake had no effect on the HtrA expression.
Conclusion: HtrA is constantly expressed in all *H. pylori* strains. However, HtrA expression showed no association with gastritis phenotypes nor with *cagA*, *vacA* status or *H.pylori*-serology. The functional role of HtrA remains uncertain.

Introduction: Culture methods have been traditionally used to evaluate the efficacy of *Helicobacter pylori* eradication assays. Nevertheless, they are material and time consuming so a quicker and easier methods are needed.

Aims and Methods: We aimed to design a protocol to assess *H. pylori* viability using flow cytometry (FC). Strain TIGR-26695 was cultured in Columbia Agar medium supplemented with blood (COS). Growing bacteria were suspended in 0.9% NaCl (3 McFarland of turbidity). Colony counting was performed by 1:10 dilution, plating 10µl in COS and 5-days incubation in a CO_2 incubator. Aliquots of bacterial suspension were killed by heat, 70% isopropanol, or 0.5% bleach. Live-dead mixed suspensions were performed, ranging from 0–100% in intervals of 10% of live. Live/Dead BacLight™ Kit was used to stain bacteria for FC analyses using FACS-CantoII cytometer. The%live bacteria added to each mix was compared to the % live estimated by FC. Counting beads (CB) were used to estimate the microbial density using FC.
Results: The optimized protocol involved addition of 1.5µl Syto9 and 0.2µl propidium-iodide to a 1:100 dilution of the bacteria in 979µl NaCl (15 minutes, dark); 10µl CB were added immediately before FC acquisition. A good correlation between the % live and the FC-estimations were obtained for the heat-killed ($R^2 > 0.99$) and the isopropanol models ($R^2 > 0.97$). Bleach treatment caused the fragmentation of bacteria, and could not be properly detected using FC. Bacterial density estimations were comparable between FC and culture.
Conclusion: FC is a fast, accurate and reproducible method to assess *H. pylori* density and viability.

Introduction: Due to the high rates of resistance to clarithromycin, triple therapy with PPI, amoxicillin, and clarithromycin is inadequate when the local clarithromycin resistance rates exceed 20%. Quadruple therapy with bismuth subcitrate, metronidazole and tetracycline administered in conjunction with a PPI has shown eradication rates greater than 80–90% in randomized controlled trials as primary therapy and appears to be highly effective even in strains that are resistant to metronidazole.
Aims and Methods: The purpose of this study is to evaluate the efficacy of quadruple therapy with a combination formula containing in a capsule 140 mg of bismuth potassium subcitrate (equivalent to 40 mg of bismuth oxide), 125 mg of metronidazole and 125 mg of hydrochloride of tetracycline (Pylera®, Aptalis Pharma, Bridgewater, NJ, USA) administered four times a day, associated with omeprazole twice daily compared to classical first-line therapy based on clarithromycin 500 mg, amoxicillin 1 g and esomeprazole 40 mg administered twice daily, who have never received treatment prior to eradicating *H. pylori* infection. We did a retrospective unicentric observational study in conditions of usual clinical practice, comparing the efficacy of 10 days of quadruple therapy with omeprazole plus a single three-in-one capsule containing bismuth subcitrate potassium, metronidazole, and tetracycline (quadruple therapy) versus 10 days of esomeprazole, amoxicillin, and clarithromycin (standard therapy) in adults with recorded *H. pylori* infection. The eradication rates of both groups were identified as intention-to-treat (ITT) and per-protocol (PP) analyses. *H. pylori* eradication was confirmed by a 13C-urea breath test at least 4 weeks after the completion of eradication therapy.
Results: A total of 221 patients (114 and 107 patients in the standard therapy and quadruple therapy, respectively) were analyzed. There were 82 male and 139 female patients. ITT eradication rates were 86.92% (93/107; 95% confidence interval (CI), 84.4%-93.3%) in the 10-day bismuth-based quadruple therapy group and 78.07% (89/114; 95% CI, 70.3%-85.7%) in the 10-day standard therapy group ($P = 0.08$). And, PP eradication rates were 91.18% (93/102; 95% CI, 85.6%-96.7%) in the 10-day bismuth-based quadruple therapy group and 82.41% (89/108; 95% CI: 75.1%-89.6%) in the 10-day standard therapy group ($P = 0.06$). There were no significant differences in both treatment groups according to both ITT and PP analyses.
Conclusion: Despite there being no significant differences between the two groups, the eradication rate 10-day bismuth-based quadruple therapy is more higher for treatment of *H. pylori* infection than 10-day standard therapy with esomeprazole.

Introduction: Little is known about the long impact of *Helicobacter pylori (H. pylori)* eradication therapies on the gut microbiota and metabolic parameters.
Aims and Methods: We aimed to assess the changes in the gut microbiota and metabolic parameters before and 2 weeks, 2 month, and 1 year after first-line treatment of *H. pylori* infection. Adult patients with documented *H. pylori* infection ($n = 1620$) were randomized in this multicenter, open-label trial to receive concomitant therapy for 10 days (CT10) or bismuth quadruple therapy for 10 days (BQ10) or triple therapy for 14 days (TT14). The long-term outcomes included the reinfection rate, the changes in the gut microbiota, body weight, glucose, insulin resistance, and lipid profiles. Fecal samples were collected before and 2 weeks, 2 months, and at least 1 year after eradication therapy in a subgroup of patients (National Taiwan University Hospital and its Yun-Lin Branch). Amplification of the V3 and V4 hypervariable regions of the 16S rRNA was done followed by high throughput sequencing (Illumina miseq). Weighted-unifrac method was used to analyze the β-diversity.
Results: Of the 1155 successfully treated patients, reinfection/recrudescence was observed in 3.3% (13/390), 2.6% (10/388), and 3.4% (13/377) of patients treated with TT14, CT10, and BQ10 after 1.55 years, respectively ($p = 0.751$) in our preliminary results. 16S rRNA was sequenced and analyzed in a total of 782 fecal DNA samples. Compared to baseline ($N = 83$), the species-richness (α-diversity) was significantly reduced at 2 weeks ($N = 57$, $p = 0.000078$), but the richness gradually returned at 2 month ($N = 70$, $p = 0.11$) and 1 year ($N = 79$, $p = 0.83$) after TT14 treatment. Compared to baseline ($N = 76$), α-diversity was significantly reduced at 2 weeks ($N = 40$, $p = 6.3 \times 10^{-15}$), at 2 month ($N = 62$, $p = 0.00015$), and 1 year ($N = 65$, $p = 0.017$) after CT10 treatment. Compared to baseline ($N = 83$), the α-diversity was significantly reduced at 2 weeks ($N = 32$, $p = 9.1 \times 10^{-13}$), at 2 month ($N = 72$, $p = 3.3 \times 10^{-8}$), and 1 year ($N = 63$, $p = 0.0024$) after BQ10 treatment. Compared to baseline, there was significant

differences in the fecal microbiota structure (β-diversity) at 2 weeks ($p = 0.0005$) and at 2 month ($p = 0.0427$) after TT14, but the difference was not significant at 1 year ($p = 0.085$). There was significant difference in the β-diversity at 2 weeks ($p = 0.0001$) and at 1 year ($p = 0.038$) after CT10. There was significant differences in the β-diversity at 2 weeks ($p = 0.0001$), 2 month ($p = 0.0002$), and 1 year ($p = 0.0074$) after BQ10. We observed mild increase in the body weight (64.3 vs. 65 kg, $p < 0.001$), body mass index (24.38 vs. 24.59, $p < 0.001$), high-density lipoprotein (54.9 vs. 58.4 mg/dL, $p < 0.001$), and total cholesterol (194.6 vs. 197.8 mg/dL, $p = 0.009$) 1.55 year after eradication therapy. However, there were no significant changes in the insulin resistance (HOMA-IR) and low-density lipoprotein levels.
Conclusion: The abundance and diversity of gut microbiota changed significantly immediately after *H. pylori* eradication therapy. The microbiota appeared to be restored with time but the speed and extent of restoration varied according to the eradication regimens. (Funded by National Taiwan University Hospital and Ministry of Science and Technology of Taiwan; ClinicalTrials.gov, NCT01906879)

Introduction: Pylera associated with a proton pump inhibitor (PPI) for 10 days is, according to actual statements, a therapeutic option as first line eradication therapy, after proving a satisfactory efficacy (more than 90%). Our working group recommends that *H.pylori* eradication treatments should be validated in each geographical area before they can be recommended as a first-line therapy.
Aims and Methods: Unicenter, observational, prospective, non-controlled study. A total of 125 consecutive patients with *Helicobacter pylori* infection were included from 2016–2018. The average age is 54-year-old (18–81), 57% women, 41.6% with non-investigated dyspepsia, 25.6% with functional dyspepsia, 19.2% peptic ulcer disease and 13.6% with other diagnoses. All patients received a first-line therapy with Pylera for 10 days, 3 capsules four times a day with a PPI (68% omeprazole 40 mg) at breakfast and dinner. In each patient was studied the compliance, adverse effects by telephone contact as well as and the efficacy. The treatment was considered effective when the urea breath test (UBT) was negative 4 weeks after finishing treatment. All cases are included in *H.pylori* European Register (HP-EuReg) and monitored through AEG-REDCap platform.
Results: 119 patients (95.2%) completed the treatment (>90% of the dose). 5 of the 6 patients that discontinued treatment were due to adverse events. 35% of patients (28%) reported some side effect, being serious adverse event in only just 1 patient (*C.difficile* colitis). *H.pylori* eradication rates were 94.9% (IC 95% 90.9–98.9) of patients (113/119) per protocol analysis; and 92% (IC 95% 87.1–96.8) of patients (115/125) for the intention to treat analysis.
Conclusion: Therapy with Pylera for 10 days has, according to our experience, high efficacy, high compliance (>90%) and acceptable security, being a recommended therapeutic option as first-line eradication therapy.

Introduction: N-acetyl cysteine (NAC) has mucolytic, antioxidant, and antimicrobial effects which has been suggested recently as an adjuvant to the eradication of *Helicobacter pylori (H. pylori)* infection. This study was aimed to determine the effectiveness of NAC in addition to standard quadruple therapy on Eradication of *Helicobacter Pylori.*
Aims and Methods: In this double-blinded controlled clinical trial (IRCT201605201155N24), 92 patients with the diagnosis of *H. pylori* infection in gastric biopsies were randomly allocated into intervention and control groups. Both groups received a 14-day regimen of quadruple therapy comprising amoxicillin, clarithromycin, pantoprazole and bismuth subcitrate. In addition to quadruple therapy regimen with similar timing, the intervention and control groups received NAC and placebo, respectively. The urea breath test (UBT) was performed to confirm the eradication of *H. pylori* eight weeks after the end of treatment.
Results: The percentage of *H. pylori* eradication in the intervention and control groups was 78.3% (CI 95%: 66.38–90.21) and 71.7% (CI 95%: 59.57–84.49%), respectively ($p = 0.804$) which were not statistically significant. Eradication rate was significantly higher in smokers who were treated with NAC.
Conclusion: Although the *H. pylori* eradication rate was higher in patients who received NAC as an adjunctive drug, it was not statistically significant. This study showed that the rate of *H. pylori* eradication significantly increased in smokers who received NAC.

P1826 EFFECTS OF PROBIOTICS OR BROCCOLI SUPPLEMENTATION ON *HELICOBACTER PYLORI* ERADICATION WITH STANDARD CLARITHROMYCIN-BASED TRIPLE THERAPY

Y.-W. Chang, **S.K. Lee**
Kyung Hee University Hospital, Dept. of Inernal Medicine, Gastroenterology, Seoul, Korea (Republic of)

Contact E-Mail Address: ryo7@naver.com
Introduction: The eradication failure of standard triple therapy (proton pump inhibitor, clarithromycin and amoxicillin) for *Helicobacter pylori* infection has increased due to antibiotics resistance in Korea. Supplementation of some probiotics improved *H. pylori* eradication rates and reduced the adverse events of the triple therapy. Sulforaphane extracted from broccoli is a potent bacteriostatic agent against *H. pylori* strains, and also exhibits bactericidal effects in a human epithelial cell line.
Aims and Methods: We aimed to determine whether *Saccharomyces boulardii* probiotics or sulforaphane supplementation can increase the *H. pylori* eradication rate and/or reduce antibiotics-associated adverse events in a Korean population. A total of 217 patients with *H. pylori*-positive chronic gastritis or peptic ulcer disease were recruited. All participants were diagnosed with *H. pylori* infection using rapid urease or C^{13}-urea breath test. Clarithromycin resistance test was performed for all patients by detecting A2142G and A2143G point mutations in *H. pylori* 23S rRNA using a dual-priming oligonucleotide PCR. Thirty-four patients were clarithromycin resistant and hence excluded from the study. Finally, 183 patients not resistant to clarithromycin were randomly assigned to three groups using a computer program: triple therapy only (group A, $n = 61$), triple therapy plus probiotics (group B, $n = 61$), and triple therapy plus sulforaphane (group C, $n = 61$). Group A received pantoprazole, amoxicillin, and clarithromycin for 7 days. Groups B and C received the same PPI-based triple therapy for 7 days. Additionally, one capsule with either probiotics or sulforaphane was given for 4 weeks. Eradication of *H. pylori* was assessed using a ^{13}C-urea breath test 4 weeks after treatment. We collected information of drug compliance and adverse events such as, taste disturbance, diarrhoea, headache, epigastric pain, nausea, and urticaria.
Results: The eradication rates according to ITT and PP analyses were 85.2% and 88.1% in group A, respectively. ITT and PP analyses showed 81.6% and 90.9% eradication rates in group B and 87% and 94.6% in group C, respectively. The eradication rates between the three groups according to ITT and PP analyses were insignificantly different based on multiple group comparison test ($p = 0.744$, $p = 0.313$, respectively). The frequency of overall adverse events in the three groups was not different ($p = 0.847$). The frequency of gastrointestinal disturbances, such as diarrhoea, epigastric pain, and nausea, were lower in group B than group A, but insignificantly different ($p = 0.262$)
Conclusion: Probiotics or sulforaphane supplementation with triple therapy on *H. pylori* infection neither increased the eradication rate nor reduced the adverse events in a Korean population.
Disclosure: Nothing to disclose

Introduction: Italian guideline suggests 10-day sequential or bismuth-based quadruple therapies for first-line *H. pylori* treatment. Comparison between these regimens is lacking. We assessed the efficacy of these therapies in clinical practice, and evaluated the role of primary bacterial resistance towards clarithromycin and metronidazole.
Aims and Methods: Consecutive patients with *H. pylori* infection were enrolled. Bacterial culture with antibiotics susceptibility testing was attempted in all cases. Patients received either a sequential therapy with esomeprazole 40 mg for 10-day

plus amoxicillin 1000 mg for the first 5 days followed by clarithromycin 500 mg and tinidazole 500 mg (all b.i.d) for the remaining 5 days, or bismuth-based therapy with esomeprazole 20 mg b.i.d and Pylera® 3 tablets q.i.d. for 10 days. *H. pylori* eradication was assessed by using ^{13}C-urea breath test.
Results: A total of 495 patients were enrolled. Following sequential (250 patients) and quadruple (245 patients) therapies, respectively, the eradication rate were 92% and 91% at intention-to-treat and 96% and 97% at per protocol analyses. Overall, the pattern of bacterial resistance did not significantly affect the cure rate, but the presence of clarithromycin and metronidazole dual resistance tended to reduce the success rate of both sequential (84.8% *vs* 90.1%; $P = 0.4$) and quadruple (85% *vs* 94.1%; $P = 0.06$) therapies. Adverse events occurred more frequently with the quadruple than with sequential therapy (56.9% *vs* 25.8%; $P < 0.001$).
Conclusion: In our country, sequential and bismuth-based quadruple therapies achieved similarly high eradication rates as first-line treatments for *H. pylori* infection in clinical practice.

Introduction: Antimicrobial agents have a significant impact on gut microbiota and its functions. Negative effects of antibiotics can be associated with depletion of beneficial microbiota and increasing amount of antibiotic resistance genes in potentially pathogenic bacteria.
Aims and Methods: The aim of our study was to evaluate the effect of *H. pylori* eradication therapy on the distribution of antimicrobial resistance genes especially in cases of beneficial microbiota survival. Stool samples from 35 *H. pylori*-positive patients before and after eradication therapy according to the standard protocol of Maastricht IV were analysed. Shotgun sequencing was performed on the SOLiD 5500xl W platform according to the manufacturer's recommendations. Reads were aligned to the CARD database (version 1.1.7) with bowtie 1.2.0 software.
Results: Significant changes in ratio and number of microorganisms including beneficial microbiota were detected in the intestinal microbiome of all patients after eradication therapy. Thus, 28 (80%) patients showed a decrease in the *Bifidobacterium* proportion and 12 (34.3%) patients had a decreased *Lactobacillus* ratio after therapy. An increase in *Bifidobacterium* and *Lactobacillus* genera was detected in 2 (5.7%) and 6 (17.1%) cases, correspondingly. These genera were absent in gut microbiota of 2 (5.7%) and 7 (20%) patients. Significant quantitative changes have been identified in genes that determine resistance to 8 out of 28 antibiotic groups (according to CARD): determinants of aminoglycoside, beta-lactam, macrolide, sulfonamide, macrolide/streptogramin/MLSb resistance, resistance to glycopeptide antibiotics, peptide antibiotics, efflux pump complex or subunit conferring antibiotic resistance. The changes were also associated with the variability of antibiotic resistance genes abundance in *Bifidobacterium* and *Lactobacillus*, including *ileS*, *tetW*, *cat*-TC, specifying mupirocin, tetracycline and chloramphenicol resistance in those bacteria.
Conclusion: The data indicates that *H. pylori* eradication therapy associated with the use of β-lactams and macrolides induces significant changes in the pattern of resistance genes to antimicrobial drugs of different groups in beneficial representatives of gut microbiota. Metabolic pathways and resistance of the corresponding organisms remain to be studied in pure cultures.
Disclosure: The work is performed according to the Russian Government Program of Competitive Growth of Kazan Federal University. The research was performed using the equipment of Interdisciplinary Centre for Shared Use of Kazan Federal University

P1829 IS THE INTERVAL BETWEEN THE FIRST AND THE SECOND H.P. ERADICATION THERAPY RELEVANT FOR THE SUCCESS OF THE CURE? A COMPARISON BETWEEN ONE WEEK, ONE MONTH AND ONE YEAR

Introduction: The success of *Helicobacter pylori* (H.p.) eradication therapy is based on the effectiveness of the therapeutical schedule as well as on the resistance of H.p. strains to the antibiotics in different areas.
Aims and Methods: Aim of this study was to compare different intervals between the first H.p. eradication therapy and the second attempt, by using for both, the same schedule.
Two hundred and fifty nine consecutive H.p. positive patients (Male 135, Mean Age 52 years range 27–81) were enrolled in the study, after failure of first line treatment based on triple one week therapy (Omeprazole 20 mg/b.i.d., Amoxicillin 1 g/b.i.d., Tinidazole 500 mg/b.i.d.). All patients underwent a rescue therapy based on the same schedule at different intervals from the end of the first line therapy: 35 pts (Male 22 Mean age 51 range 27–72) after 7–10 days (Group 1); 44 pts (Male 24 mean age 53 range 28–75) after 1 month (Group 2); 82 pts (Male 43 mean age 49 range 29–78) after three months (Group 3); 98 pts (Male 46 mean age 53 range 28–81) after six-twelve months (Group 4). The H.p. eradication was established by means of U.B.T., performed at least one month after the end of rescue therapy.
Results: The success of the therapy in the four groups is summarized in the table. In Group 1 we experienced 4 drop outs, 5 in Group 2, 8 in Group 3 and 9 in Group 4.
Conclusion: The interval between the first and the second attempt of H.p. eradication therapy seems in our study crucial in determining the success of the cure, at least a six-months interval being the critical time to influence the results.

Group	Cured patients	Intention to treat	Per protocol	p
1	9/35	27.5	29.0	n.s.
2	14/44	31.8	35.8	n.s.
3	31/82	37.8	41.8	n.s.
4	69.88	70.4	77.5	0.01

Introduction: According to all current available data, there is so far no universally effective regimen for *Helicobacter pylori* (*H. pylori*) eradication therapy. The Toronto Consensus for the treatment of *H. pylori* infection recommends that both the concomitant non-bismuth quadruple therapy (proton pump inhibitor [PPI] + amoxicillin + metronidazole + clarithromycin [PAMC]) and the traditional bismuth-containing quadruple therapy (PPI + bismuth + metronidazole + tetracycline [PBMT]) should play a more prominent role in eradication of *H. pylori* infection, and should be prescribed for 14 days. The Maastricht V consensus also recommends as first-line treatment in areas of high (>15%) clarithromycin resistance, a 14-days course of either the bismuth or the non-bismuth quadruple, concomitant therapies, unless a 10-days regimen is proven equally effective locally. Moreover, the American College of Gastroenterology (ACG) Clinical Guideline for the treatment of *H. pylori* infection clearly state that prior antibiotic exposure should be incorporated into the decision-making process and that most patients would be better served by first-line treatment with non-bismuth concomitant therapy for a period of 10–14 days, although the quality of evidence regarding duration is still very low. The objective of this study is to compare the efficacy rates of the 10-day versus the 14-day PAMC therapy in Greece, a country with an antibiotic-resistance pattern similar to the USA and most central and southern European countries (high clarithromycin resistance >20% and intermediate metronidazole resistance <40%).
Aims and Methods: Our prospective randomized study included 384 patients with newly diagnosed *H. pylori* infection, randomized to receive a 10-day or a 14-day concomitant PAMC therapy. Treatment outcome was assessed by C^{13}-urea breath test at least 4 weeks after therapy. Intention to treat (ITT) and per protocol (PP) analysis of the eradication rates were performed. Secondary end points included patient compliance, safety and eradication rates related to previous antibiotic exposure (ClinicalTrials.gov Identifier: NCT02959255).
Results: The two groups achieved almost equal eradication rates, both in the ITT and in the PP analysis (85.1% for the 10-day versus 85.9% for the 14-day, $p > 0.05$, and 93.6% for the 10-day versus 94.4% for the 14-day, $p > 0.05$, respectively), after adjusting for age, gender, smoking status, prior exposure to antibiotics, peptic ulcer disease and/or non-ulcer dyspepsia. Patient compliance was excellent for both groups (99.5% for the 10-day and 98.7% for the 14-day concomitant PAMC therapy group, $p > 0.05$). Major adverse events that led to discontinuation of the treatment were not statistically significant between groups ($p > 0.05$). Regarding minor adverse events, a trend towards more episodes of diarrhea was recorded in the 14-day (group A) versus the 10-day therapy group (25.4/% and 34.7%, respectively, $p > 0.05$).

Conclusion: Both the 10- and the 14-day concomitant PAMC therapy exhibited almost equally high eradication rates, with excellent compliance and an acceptable safety profile. Thus, according to our data, in Greece, there is no necessity for *H. pylori* eradication treatment extension to 14 days.

Introduction: Quadruple therapy with bismuth subcitrate, metronidazole and tetracycline administered in conjunction with a PPI has shown eradication rates greater than 80–90% in randomized controlled trials as primary therapy and appears to be highly effective even in strains that are resistant to metronidazole.
Aims and Methods: The purpose of this study is to evaluate the efficacy and safety of quadruple therapy with a combination formula containing in a capsule 140 mg of bismuth potassium subcitrate (equivalent to 40 mg of bismuth oxide), 125 mg of metronidazole and 125 mg mg of tetracycline hydrochloride administered four times a day, associated with omeprazole twice daily compared to quadruple therapy without bismuth in patients who have never received eradicating treatment for *H. pylori* infection.
Between January 2017 and December 2017, we performed an observational, retrospective and multicenter study under conditions of usual clinical practice, comparing the efficacy and safety of 10 days of quadruple therapy with omeprazole plus a three-in-one capsule containing bismuth potassium subcitrate, metronidazole and tetracycline (Pylera) versus 14 days of amoxicillin 1gr, metronidazole 500mg, clarithromycin 500mg twice a day plus omeprazole 40mg day (quadruple without bismuth) in adults with *H. pylori* infection. The eradication rates of both groups were identified in intention-to-treat (IT) and protocol (PP) analyzes. *H. pylori* eradication was confirmed by a 13C-urea breath test at least 4 weeks after the completion of eradication therapy.
Results: A total of 196 patients (81 and 115 patients on quadruple therapy with bismuth (Pylera) and quadruple therapy without bismuth, respectively) were analyzed. 62 male and 134 female patients with a mean age of 53 ± 14.39. ITT eradication rates were 85.19% (69/81, confidence interval (CI) 95%, 77.3%-93.0%) in the 10-day bismuth-based quadruple therapy group and 77.39% (89/115, 95% CI, 69.6%-85.1%) in the 14-day bismuth quadruple therapy group ($P = 0.17$). And, PP eradication rates were 93.24% (69/74, 95% CI, 87.4%-99.0%) in the bismuth-based quadruple therapy group and 83.96% (89/106, CI 95%, 76.8% -91.0%) in the quadruple therapy group without bismuth ($P = 0.06$). There were no significant differences in both treatment groups according to both ITT and PP analysis. Adverse event rates were 10.39% (8/77) in the 10-day bismuth-based quadruple therapy group and 23.30% (24/103) in the 14-day bismuth quadruple therapy group ($p = 0.07$).
Conclusion: Despite there being no significant differences between the two groups, the eradication rate 10-day bismuth-based quadruple therapy is higher for the treatment of *H. pylori* infection than quadruple therapy without bismuth. Regarding treatment safety, there were no significant differences between the two groups.

P1832 PREDICTIVE FACTORS FOR REGRESSION OF LOW-GRADE GASTRIC MALT LYMPHOMA AFTER ANTI-*HELICOBACTER PYLORI* TREATMENT

A. Hammami, A. Ben Slama, A. Hassine, N. Elleuch, H. Jaziri, S. Ajmi, A. Brahem, M. Ksiaa, A. Jmaa
university Hospial Of Sahloul, Sousse, Tunisia

Contact E-Mail Address: aya_med@hotmail.fr

Introduction: Eradication of *Helicobacter pylori* (*H. pylori*) is accepted as initial treatment of low-grade gastric mucosa-associated lymphoid tissue (MALT) lymphoma. However, 10–20% of gastric low grade MALT lymphomas are unresponsive to *H. pylori* eradication treatment. The aim of this study was to find out the predictive factors of complete remission of gastric MALT lymphoma after *H. pylori* eradication.
Aims and Methods: From 2006 to 2016, consecutive 64 patients with modified Ann Arbor stage IE and II1E gastric MALT lymphoma were enrolled, and their medical records were reviewed. The patients were initially treated by *H. pylori* eradication. The complete remission was determined by endoscopic and histologic finding.
Results: 48 patients (75%) achieved complete remission after *H. pylori* eradication therapy. Mean follow up time for these patients was 38.8 months [6- 72 months]. Eight patients (12.5%) failed to achieve complete remission. Eight patients were lost of sight. There was no significant difference in the age, sex, endoscopic appearance, and large cell component between the remission group and failure group. Among 12 patients with proximal tumor, 8 patients (66.6%) achieved complete remission. On the other hand, among 52 patient with distal tumor, 40 patients (76.9%) achieved complete remission. The odds ratio of proximal tumor for *H. pylori* eradication failure was 28.9 (95% CI = 2.9–288.0).
Conclusion: The discovery of the etiologic role of *H. pylori* infection in gastric lymphoma has radically changed its therapeutic approach. The proximally location of MALT lymphoma is a risk factor of the *H. pylori* eradication treatment failure.

Introduction: CagA is a defined virulence factor of *H. pylori* whose infection is associated with an increased risk of gastric cancer. However, it is unclear what its role is in oncogenic YAP pathway and epithelial-mesenchymal transition (EMT) during gastric tumorigenesis.
Aims and Methods: YAP and E-cadherin proteins in human gastric biopsies were assessed. PMSS1 *DcagA* mutants were generated and then co-cultured with AGS cells compared with *H. pylori* wild-type strains. Immunofluorescence, Western blot and qRT-PCR analyses were performed for the alteration of YAP pathway. Moreover, EMT and cell invasion were investigated after inhibition of YAP in response to *H. pylori* infection.
Results: Increased YAP in concert with decreased E-cadherin were identified in the human gastric tumorigenesis cascade; further YAP expression is enhanced in *H. pylori*+ chronic non-atrophic gastritis tissues (CNAG) compared with *H. pylori*- CNAG. In AGS cells, CagA+ *H. pylori* strains elevated expression and nuclear translocation of YAP, upregulated its downstream genes, and promoted EMT, which was abolished by inactivation of CagA. These *H. pylori*-triggered EMT and cell invasion were significantly suppressed by treatment of YAP inhibitor.
Conclusion: Our findings indicated that *H. pylori* CagA plays a crucial role in promoting gastric tumorigenesis via activation of the oncogenic YAP pathway and subsequent enhancement of EMT.

Introduction: Genetic polymorphisms of Toll-like receptors (TLRs) play important roles in gastric carcinogenesis. The -196 to -174del polymorphism affects the TLR2 gene and alters its promoter activity.
Aims and Methods: The aim of this study is to determine whether this polymorphism is associated with susceptibility to gastric carcinoma and its prognosis. This study consisted of 260 patients with gastric cancer and 260 healthy controls. All subjects were unrelated ethnic Han Chinese and residents in Jiangsu Province, People's Republic of China. The polymorphism was assessed using polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) analysis. The infection status of *H. pylori* was determined using a validated serological test. Survival was analyzed by Kaplan-Meier survival curves.
Results: Multiple logistic regression analyses revealed that the -196 to -174 del/del genotype (adjusted OR = 2.59, 95% CI = 1.33–5.07) but not ins/del genotype (adjusted OR = 1.36, 95% CI = 0.95–1.96) had significantly higher gastric

cancer risks, compared with the ins/ins genotype. Further stratification analyses revealed that an increased risk of gastric cancer associated with del/del genotype was evident among male (adjusted OR = 2.35, 95%CI = 1.03–5.34), and in younger subjects aged less than 60 years old (adjusted OR = 3.19, 95%CI = 1.20–8.50). When stratified by the histologic subtype, the del/del genotype was found to be positively associated with intestinal gastric cancer (adjusted OR = 2.62, 95%CI = 1.34–5.14). In addition, we demonstrated that the del/del genotype and *H. pylori* infection may have a synergistic effect and conferred an OR of 3.04 for developing gastric cancer. High TNM stage including III (HR = 4.77, CI = 2.02–11.23) and IV (HR = 15.48, CI = 6.53–36.67) showed a strong association of poor overall survival, compared with stage I. Cox proportional hazards analysis showed that ins/del genotype (HR = 1.23, CI = 0.82–1.87) and del/del genotype (HR = 1.60, CI = 0.76–3.40) were not associated with poor survival, compared with the ins/ins genotype.
Conclusion: Our data suggested that the – 196 to – 174 del/del genotype of TLR2 may increase the risk of gastric cancer in the Chinese population and there were significant joint effects of this polymorphism and *H. pylori* infection. Our results also revealed that del/del genotype was not associated with poor prognosis of gastric carcinoma in the Chinese population.
Disclosure: Nothing to disclose

P1835 A MULTI-INSTITUTIONAL PROSPECTIVE, OBSERVATIONAL STUDY ON THE RISK FACTORS FOR GASTRIC CANCER AFTER SUCCESSFUL *H.PYLORI* ERADICATION

S. Takayama[1], O. Handa[1], R. Mukai[1], A. Majima[1], K. Inoue[1], O. Dohi[1], N. Yoshida[1], K. Kamada[1], K. Katada[1], K. Uchiyama[1], T. Ishikawa[1], T. Takagi[1], H. Konishi[1], Y. Naito[1], Y. Ito[1]

Contact E-Mail Address: shunt02@koto.kpu-m.ac.jp
Introduction: It has been reported that *Helicobacter pylori* (*H. pylori*) eradication therapy reduced the risk of gastric cancer (GC), and as a country with high incidence of GC, the prevention of GC by *H. pylori* eradication is an important issue. In Japan, the eradication therapy for *H. pylori*-infected gastritis was approved as an insurance indication since 2013, and the eradication treatment has been widely performed. On the other hand, GC is discovered after successful *H. pylori* eradication and its incidence rate and the risk factors are still unknown.
Aims and Methods: The aim of this study is to investigate the incidence rate and the risk factors contributing to the development of GC in patients after successful *H. pylori* eradication prospectively.
A prospective, multi-institutional observational study was conducted. We enrolled patients who received *H. pylori* eradication therapy from June 2008 to April 2017. After successful eradication, enrolled patients underwent an annual endoscopic observation for screening of GC. The difference in the incidence rate of GC by background (gender, age at the eradication therapy, the past history of GC, familial history of GC), lifestyle (smoking, drinking), comorbidities (hypertension, hyperlipidemia, diabetes) and endoscopic mucosal atrophy was analyzed.
Results: A total of 498 patients, including 262 men (54%) and 236 women (46%), were analyzed. The average age at eradication therapy was 63.1 years. The mean follow-up period was 1108 days (188–3354days). GC was discovered in 23 patients (1.52%/year). Kaplan-Meier analysis (log-rank test) showed that the incidence rate of GC was significantly higher in men (2.24%/year, P = 0.015), over 65 years old at the eradication (2.28%/year, P = 0.013), presence of the past history of GC (3.11%/year, P = 0.001), hypertension (2.91%/year, P = 0.009), smoking (3.81%/year, P = 0.013), and severe mucosal atrophy (2.22%/year, P = 0.041). Multivariate analysis using cox hazards model showed that the past history of GC and smoking were independent risk factors for GC after successful eradication: the past history of GC, HR 2.58(95%CI 1.05–6.35), P = 0.039; smoking, HR 2.85(95%CI 1.09–7.46), P = 0.033.
Conclusion: The past history of GC and smoking were independent risk factors of GC after successful *H. pylori* eradication.

P1836 THE MANAGEMENT OF GASTRIC MALT LYMPHOMA

B.S. Park, **S.H. Lee**, J.H. Cho, S.B. Kim, K.O. Kim, K.H. Kim, B.I. Jang, T.N. Kim
Yeungnam University College of Medicine, Department of Internal Medicine, Daegu, Korea (Republic of)

Contact E-Mail Address: dr9696@nate.com
Introduction: Gastric mucosa-associated lymphoid tissue (MALT) lymphoma is a rare extranodal marginal zone B cell lymphoma, accounting 1% to 6% of all gastric malignancies. The association between gastric MALT lymphoma and *Helocibacter pylori* (*H. pylori*) infection has been well known and *H. pylori* eradication is an effective treatment in *H. pylori*-positive MALT lymphoma. However, the complete remission (CR) rates after *H. pylori* eradication in *H. pylori*-negative MALT lymphoma is very low and the treatment strategy remains controversial. We investigated the effectiveness of each treatment option for *H. pylori*-negative MALT lymphoma and *H. pylori*-positive MALT lymphoma with treatment failure after *H. pylori* eradication.
Aims and Methods: We conducted retrospective single-center study using medical records of patients who were diagnosed with gastric MALT lymphoma in Yeungnam University Medical Center between January 2005 and December 2016. Response to each treatment options and relapse after CR were evaluated by pathologic base using endoscopic biopsy.
Results: Of the 68 patients, 50 patients were enrolled. Mean ages were 55.4 ± 11.7 years and mean follow-up periods were 42.5 ± 31.0 months (range : 3–133.6). *H. pylori* infection was detected in 42 patients (84.0%). Of these *H. pylori*-positive MALT lymphoma, 36 patients (81.7%) were treated with *H. pylori* eradication as primary treatment and the CR rates after *H. pylori* eradication was 72.2% (n = 26). Patients without CR after *H. pylori* eradication (n = 10, 27.8%) were received radiotherapy as secondary treatment. All of them were shown CR and no one had relapse after radiotherapy. 2 patients (4.8%) of *H. pylori*-positive MALT lymphoma were treated with radiotherapy as primary manner and all reached CR. 1 of them (50%) had relapse after treatment, but another CR had been achieved after secondary radiotherapy. All patients with *H. pylori*-negative MALT lymphoma (n = 8, 16.0%) were treated with radiotherapy as primary treatment. The CR rates after radiotherapy was 100% and no one had had relapse after radiotherapy.
Conclusion: . Although *H. pylori* eradication is effective treatment in *H. pylori*-positive MALT lymphoma, radiotherapy may be worthwhile treatment option in *H. pylori*-negative MALT lymphoma and *H. pylori*-positive MALT lymphoma as 2ndary treatment after *H. pylori* eradication

Introduction: Gastric cancer (GC) is one of the most fatal forms of malignant cancers. Recently discovered microRNAs (miRNAs) post-transcriptionally regulate gene expression and play important role in a variety of processes. The aim of a study was to examine hsa-miR-20b-5p (miR-20b) function in gastric carcinogenesis by experimentally determining miRNA target-genes and impact to physiological cell processes *in vitro* and *in vivo*.
Aims and Methods: GC cell lines (AGS, MKN28) and normal gastric tissue were analyzed for expression of miR-20b. After bioinformatics analysis five potential target genes were selected for miR-20b (*EREG*, *FAT4*, *IRF1*, *TXNIP*, *PTEN*) and analyzed for expression changes in mRNA and protein levels after transfection with miR-20b inhibitor. Cell viability was assessed using a MTT assay, colony formation and proliferation was evaluated using clonogenic assay, and cell migration was determined using wound healing assay. INS-GAS mice model was used to evaluate the miR-20b alterations *in vivo* following *H. pylori*infection with follow up to 50 weeks.
Results: miR-20b expression was up-regulated in GC cell lines ($p = 0.008$, $p = 0.003$; AGS and MKN28 respectively) compared to controls. Inhibition of miR-20b expression significantly increased *IRF1*, *PTEN*, *TXNIP* genes expression level in AGS ($p = 0.008$, $p = 0.021$, $p = 0.046$, respectively) and MKN28 cell line ($p = 0.003$, $p = 0.005$, $p = 0.0004$, respectively) 24 h after transfection. *IRF1*, *TXNIP* genes expression remained increased 48 h post-transfection in AGS cell line ($p = 0.001$, $p = 0.006$, respectively), while only *TXNIP* - in MKN28 cell line ($p = 0.001$). Expression levels of *EREG* and *FAT4* was undetermined in both GC cell lines. Secondly, miRNA target-genes were analyzed for protein expression changes. Analysis revealed that PTEN protein expression in AGS cell culture increased statistically significantly 72 h after transfection ($p = 0.020$). TXNIP protein expression increased in MKN28 72 h after transfection ($p = 0.036$). Finally, miR-20b inhibition reduced cell viability in AGS ce ll line ($p = 0.029$). Furthermore, number of colonies reduced dramatically in both cell lines ($p = 0.0002$, $p = 0.021$; AGS and MKN28 respectively) compared to cells transfected with control miRNA. INS-GAS mice showed gender specific miR-20b expression pattern following *H. pylori* infection. Only male mice showed significantly higher miR-20b expression for all time points ($p = 0.029$). There was a stepwise increase in miR-20b expression during the different time points from 12 to 50 weeks with highest difference at 50 weeks ($p = 0.003$).
Conclusion: Our data shows that miR-20b may target *PTEN* and *TXNIP* and play an important role in gastric carcinogenesis by mediating cell viability and colony formation in GC-derived AGS and MKN28 cell cultures. The data from INS-GAS mice experiments support the role of miR-20b in GC *in vivo*.

P1838 *HELICOBACTER PYLORI* INFECTION AND THE INTERLEUKIN 8 -251 T > A POLYMORPHISM MIGHT BE A RISK FACTOR OF GASTRIC CANCER

Y.-W. Chang, S.K. Lee
Kyung Hee University Hospital, Dept. of Inernal Medicine, Gastroenterology, Seoul, Korea (Republic of)

Contact E-Mail Address: cywgi@chol.com

Introduction: IL-8 is a major neutrophil-activating cytokine and plays a central role in the immuno-pathogenesis of *H. pylori*-induced gastric mucosal injury. The IL-8 -251 T > A polymorphism has been reported to be associated with increased production of IL-8 protein, and higher risks of atrophic gastritis (AG), peptic ulcer disease (PUD), and gastric cancer (GC). However, many other reports are inconsistent with these findings.

Aims and Methods: We aimed to investigate 1) whether polymorphisms in IL-8 influence susceptibility to *H. pylori* infection, and the associations of the polymorphisms with the risk of gastroduodenal diseases in a Korean population, and 2) to analyze our and other investigators' large-scale data regarding the IL-8 -251 T > A polymorphism and GC risk in Korean, Japanese, Chinese, and Caucasian populations.

We consecutively enrolled 176 *H. pylori*-negative control subjects, 221 subjects with *H. pylori*-positive non-atrophic gastritis, 52 mild AG, 61 severe AG, 175 PUD, and 283 GC. Allele-specific PCR-RFLP was conducted for polymorphisms in IL-8 -251 T > A. IL-8 levels in gastric mucosal tissues were measured by enzyme-linked immunosorbent assay. We collected large-scale raw data of GC patients (n = 3,217) and controls (n = 3,810) from Asian (Korea, Japan, and China), and Caucasian (Poland, Finland, and Portugal) populations, and analyzed GC risk according to IL-8 -251 T > A genotype.

Results: IL-8 levels were significantly different between *T*/*T* wild type, *T*/*A* heterozygote, and A/A mutant genotypes. IL-8 -251 A allele carriers (*A*/*A* + *T*/*A*) showed increased IL-8 levels, and were significantly associated with the risk of severe AG and GC. Global data of IL-8 polymorphism and the risk of GC development showed that Japanese population was similar to Korean population. The combined Korean and Japanese populations had significantly increased GC risk for the IL-8 -251 *T*/*A* and *A*/*A* genotypes compared to the *T*/*T* genotype, and for A allele carriers compared to non-carriers.

Conclusion: We suggest that a combination of *H. pylori* infection and the IL-8 -251 T > A polymorphism might increase the risk of severe AG and GC in a Korean population

Disclosure: Nothing to disclose

Introduction: *Helicobacter pylori* (HP) infection is commonly responsible of multifocal atrophic gastritis without intestinal metaplasia, intestinal metaplasia and dysplasia, which is the most relevant premalignant gastric condition (PGC). HP-eradication is mandatory to stop the chronic gastric inflammation, but the long-term risk of gastric premalignant/malignant lesions progresses even after HP-eradication. Several studies showed that high-resolution endoscopy with narrow-band imaging (HRE-NBI) could be more accurate than white-light endoscopy (WLE) alone in diagnosing PGC. Nevertheless, no study focused on the diagnostic performance of endoscopy in detecting PGC after HP eradication on an interim follow-up.

Aims and Methods: In the present study, we aimed to assess the efficacy of HRE-NBI in the diagnosis of PGC, before and after HP eradication. A prospective study was performed in our institution involving the regular use of high-resolution gastroscopes with and without NBI. From June 2016 to June 2017, all patients that received an endoscopic diagnosis of HP-related gastritis by an expert endoscopist, were reassessed by WLE and HRE-NBI, including biopsy samples according to the Sydney system, within six months after the proved HP eradication. Kimura-Takemoto modified classification and endoscopic grading of gastric intestinal metaplasia (EGGIM), proposed by Pimentel-Nunes *et al.* were used to evaluate the degree of atrophy and IM. Histologic result was considered the diagnostic gold standard. Operative Link on Gastritis Assessment (OLGA) and Operative Link on Gastric Intestinal Metaplasia (OLGIM) were assessed by an expert gastrointestinal pathologist.

Results: Of 83 screened patients, 36 were enrolled and a total of 72 HRE-NBI were performed before and after the proved HP eradication. The major indications for endoscopy were gastroesophageal reflux (60%), abdominal pain (30%), dyspepsia (5%), or anemia (5%). The median age of the all patients was 58 years (range 32–72), and they were prevalently female (86.1%). Among them, 17 patients (47.2%) were current drinkers, 4 (11.1%) were active smokers and 2 (5.5%) had a familiar history for gastric cancer. The proportion of patients with degree 3–4 of EGGIM scale, significantly decreased after HP eradication (33.3% vs. 11.1%, $p = 0.04$), whereas the proportion of patients with more advanced degree of EGGIM scale (5–6) showed a trend of increase (16.7% vs. 36.1%, $p = 0.06$). In the latter group, the majority of patients (69.2%) had a lower degree of EGGIM scale (3–4) before anti-HP therapy, whereas the minority (15.4%) had the same degree ($p < 0.05$). Moreover, the proportion of OLGA and OLGIM stages did not change after HP-eradication. Interestingly, the proportion of patients with histological diagnosis of dysplasia on random biopsies did not change significantly after HP eradication (36.1% vs. 16.7%; $p = 0.06$), whereas the proportion of patients with histological dysplasia on "de novo-appeared" superficial lesions, significantly increased after HP disappearance (0% vs. 38.9%; $p < 0.001$).

Conclusion: HRE-NBI could be more precise in diagnosing dysplasia after HP-eradication, presumably as the gastric mucosal aspect is less corroborated by the inflammatory changes induced by the HP chronic infection, which could lead to an underestimation of the premalignant lesions. These findings suggest that a non-invasive test for HP identification should be performed in at risk patients as a first step, and only after achieving HP eradication they should undergo a gastroesophageal endoscopy to identify more correctly PGC.

P1840 THE ROLE OF CAPSULE ENTEROSCOPY IN COELIAC DISEASE: RESULTS OF A PROSPECTIVE STUDY IN A TERTIARY REFERRAL CENTER

F. Ferretti[1,2], S. Orlando[1], L. Roncoroni[1], M. Vecchi[1,2], L. Elli[1]
[1]*Fondazione IRCCS Ca Granda Ospedale Maggiore Policlinico, Center for the Prevention and Diagnosis of Celiac Disease, Gastroenterology and Endoscopy Unit, Milan, Italy*

Contact E-Mail Address: francesca.ferretti01@gmail.com

Introduction: Coeliac disease (CD) is a chronic enteropathy that usually improves after the withdrawal of gluten with clinical and histological remission. In rare cases, the course of CD can be complicated by the development of refractory disease (RCD type 1 and type 2) and malignancies of the gastrointestinal tract, like small bowel (SB) lymphoma and adenocarcinoma. Although uncommon, this evolution is burdened with an extremely severe prognosis. In the last years, several diagnostic strategies have been proposed for early identification of CD complications. In particular, capsule enteroscopy (CE) has been proposed as a useful tool to evaluate patients with persistence or recurrence of symptoms despite an ongoing gluten-free diet. The aim of this study was to evaluate the diagnostic performance of CE in high-risk coeliac patients, especially in the detection of CD-related complications.

Aims and Methods: Between November 2014 and November 2017 we prospectively enrolled coeliac patients who underwent CE for suspected complicated CD, non-adherence to gluten-free diet (GFD) or in the follow-up of known RCD. CE was defined positive for CD-related findings in case of atrophy, erosions, ulcers or mass lesions throughout the SB. Enrolled patients underwent also gastroscopy, complete blood tests and, when clinically indicated, radiologic examinations. We evaluated the diagnostic performance of CE in the identification of SB lesions and complications. Patients with a final diagnosis of RCD or malignancy were defined as complicated CD.

Results: Overall, 121 consecutive CD patients were enrolled. A total of 143 capsule examinations was performed (18 patients repeated CE). The majority of patients (61%) underwent CE for suspected complicated CD, 25% for non-adherence to GFD and 14% for RCD follow-up. The mean follow-up time after CE was 13 ± 9 months. After the complete diagnostic work-up, the final diagnosis was: uncomplicated CD (83% of patients) and complicated CD (17%, 11 RCD type 1, 8 RCD type 2 and 2 lymphoma). CE was positive for CD-related findings in 55% of patients (67/121). CE sensitivity for the detection of mucosal atrophy was 62%, specificity was 81%. The incidence of complications in patients with suspected complicated CD and non-adherence to GFD was 5.7%. In the group of patients with already known RCD at enrollment, two patients (1.6%) developed enteropathy-associated T cell lymphoma and they both had positive CE. A significant correlation between age and CE findings was found: patients with positive CE had a significantly more advanced age at CD diagnosis compared to patients with negative CE ($p = 0.005$). Moreover, in patients ^{3} 50 years old at the CE execution CD-related findings were more frequent compared to younger patients ($p = 0.01$). Any statistical correlation was found with positive CD serology and incorrect GFD ($p > 0.05$).
Conclusion: Capsule enteroscopy plays a pivotal role in the clinical follow-up in order to detect the persistence of atrophy, the extent of the lesions throughout the SB and to early identify CD-related complications. According to our results, complicated CD is an uncommon condition; in this setting, patients aged > 50 years and with a diagnosis of CD in older age should be considered at higher risk of complications and accurately investigated with CE. On the contrary, neither a persistent positive serology nor an incorrect GFD seem to be related to the onset of complicated CD.

Contact E-Mail Address: aciccone.md@gmail.com
Introduction: Several studies have shown that weight changes are common in patients with coeliac disease (CD) after starting a gluten-free diet (GFD), but data on the prevalence of metabolic syndrome (MS) are still scarse.
Aims and Methods: The aim of the study is to evaluate the prevalence of Metabolic Syndrome (MS) and Hepatic Steatosis (HS) in patients with CD, before and after GFD.
185 adult patients with CD were enrolled. In all patients the presence of the following risk factors were evaluated: increased waist circumference (WC), body mass index (BMI), hypertension, hypercholesterolemia, reduction of HDL cholesterol, hypertriglyceridemia, hyperglycemia. Diagnosis of MS was made according to International Diabetes Federation (IDF) criteria. HS was assessed by ultrasonography (US).
Results: At the time of the CD diagnosis 6 patients (3.24%) fulfilled the diagnostic criteria for MS, 27 (14.59%) after GDF ($p < 0.0001$). Rates of MS subcategories, before and after GFD were respectively: increase in WC, 24 (13%) vs 43 (23.24%) ($p < 0.0001$); hypertension, 8 (4.3%) vs 22 (12%) ($p < 0.0001$); reduction of HDL cholesterol, 41 (22.2%) vs 86 (46.5%) ($p < 0.0001$); hypertriglyceridemia, 22 (11.9%) vs 26 (14%) ($p = 0.3339$); hyperglycemia, 20 (10.8%) vs 36 (19.46%) ($p = 0.0088$); total hypercholesterolemia, 43 (23.2%) vs 88 (47.56%) ($p < 0.0001$); BMI >25, 45 (24.3%) vs 78 (42.16%) ($p < 0.0001$). Furthermore, HS was found in only 3 (1.7%) patients at the time of diagnosis, and in 20 (11.1%) after GFD ($p < 0.0001$).
Conclusion: Therefore, the prevalence of overall metabolic alterations and hepatic steatosis increased in patients with CD after a gluten-free diet.
Disclosure: Nothing to disclose

Introduction: Refractory celiac disease (RCD) is defined by persistent or recurrent symptoms and villous atrophy despite strict adherence to a gluten-free diet for at least 6 to12 months. RCD is classified as type 1 (normal intraepithelial lymphocyte phenotype on immunohistochemistry and flow cytometry analysis), and type 2 (clonal intraepithelial lymphocyte population with aberrant phenotype). Budesonide is an effective treatment to induce clinical remission in RCD type 1 and 2. However, histologic response is less frequent.
Aims and Methods: The aim of this study is to evaluate the clinical and histologic response to budesonide in patients with RCD type 1 and 2, as well as the effect of budesonide on the aberrant intraepithelial lymphocytes (IEL) assessed by flow cytometry in the subgroup of type 2 RCD patients. We conducted a monocentric retrospective study. Patients with a diagnostic of RCD type 1 and type 2 who were treated with budesonide alone were included. Treatment consisted of open capsule budesonide. Complete histologic response was defined by normalization of the architecture of the small intestinal mucosa (Marsh 0 or I score). Partial histologic response was defined as an improvement of the Marsh classification.
Results: 10 patients with RCD I and 8 patients with RCD II were included. The mean duration of treatment with budesonide was 23.5 months [4–108]. Overall, a complete clinical response was observed in 17 out of 18 patients treated with budesonide (94.4%). A complete histologic response was seen in 4 patients (22.2%) and a partial histologic response was seen in 5 patients (27.8%). Half of the patients had no change in the architecture of the small intestinal mucosa. Patients who had complete or partial histologic response had been on budesonide for a mean period of time of 30 months, while patients with no response had a mean duration of treatment of 15 months ($p = 0.4$). In patients with type 2 RCD, there was no significant change on the percentage of aberrant IELs assessed by flow cytometry with treatment ($p = 0.16$), as well as no effect on clonal rearrangement of T-cell receptor gene.
Conclusion: Budesonide is associated with a high clinical response but lower histologic response in refractory celiac disease. There was no impact on the percentage of aberrant IELs assessed by flow cytometry in RCD type 2.

Introduction: Refractory coeliac disease (RCD) is defined by the persistence of malabsorption and intestinal villous atrophy after one year of strict gluten-free diet. It's a rare condition with a prevalence of 2–5% among coeliac patients. RCD can be classified into two subtypes: type 1 RCD (RCD I) is characterized by a polyclonal pattern of intraepithelial T cells receptor and a normal phenotype of intraepithelial lymphocytes (IEL) with surface CD3 and CD8 expression; type II (RCD II) is characterized by a clonal expansion of abnormal IEL lacking surface markers CD3, CD8 and T-cell receptor and a preserved intracellular CD3 expression. RCD II is an aggressive disease with a high risk to develop enteropathy-associated T-cell lymphoma (EALT) and a poor response to steroids and immunosuppressive therapy. Considering the poor prognosis of RCD II, a treatment with chemotherapeutic agents should be considered. Cladribine is a purine analogue that may induce clinical and histological response in RCDII.
Aims and Methods: The aim of this study was to evaluate the clinical and histological response to cladribine therapy in RCD II.
From January 2015 to October 2017 we retrospectively enrolled RCD II patients treated with cladribine in the cohort of celiac disease patients afferent to the Celiac Disease Center of our unit. All enrolled patients underwent small bowel assessment to early detection of complications by computed tomography (CT), magnetic resonance enterography or capsule endoscopy. Patients were treated with subcutaneous (SC) cladribine in our haematology unit. We collected clinical, histological and follow-up data.
Results: 12 patients were affected by RCD II. Of them, 2 patients were candidate for cladibrine therapy. The first patient was a 63-year-old man diagnosed with CD since 2007. In 2012, after esophagogastroduodenoscopy (EGD) for persistent symptoms, RCDI was diagnosed. A steroid therapy was started with transient clinical benefit. In 2015, a new EGD was performed for recurrence of symptoms with evidence of a 60% T-IEL infiltrate with aberrant phenotype and a monoclonal TCR on a polyclonal basis. Capsule endoscopy (CE) demonstrated widespread atrophy in more than half of the small intestine, while CT and PET resulted negative. Because of steroid refractoriness, a treatment with SC cladribine was started. He underwent 3 cycles every 6 months, with a 30% dose reduction for the first 2 cycles. Treatment was well tolerated, without hematological toxicity. After III cycles he had weight gain and resolution of diarrhea and a macroscopic improvement of ileal atrophy and ulcers, without significant reduction of T cell infiltration. The second patient was a 62-year-old woman diagnosed with CD in January 2016. A EGD revealed a 60% T-IEL infiltrate with aberrant phenotype and monoclonal TCR on a polyclonal basis. CE demonstrated

widespread signs of jejunal atrophy and erosions, while CT and PET were negative. Since steroids were ineffective, she underwent 3 cycles of SC cladribine. Treatment was well tolerated. There was an improvement of clinical symptoms and of ileal atrophy and ulcers, with a 50% reduction T IEL infiltrate.
Conclusion: Both patients showed a clinical and histological response to SC cladribine without hematologic toxicity or infectious complications suggesting that this treatment could be a safe and effective option in elderly patients affected by RCD II. Furthermore, the outpatient administration of the treatment lead to a reduction of patient's discomfort and costs related to hospitalization.

Introduction: Celiac disease (CD) is a chronic immune-mediated disease with a strong genetic background, stimulated by gluten ingestion (1). It is known that small bowel epithelial barrier function is altered in CD patients. In the small bowel mucosa, immune cells are activated after contact with antigen-presenting cells exposing gliadin-derived peptides, which leads to a multifaceted inflammatory cascade ultimately leading to villous atrophy and disruption of the epithelial barrier (2). However, the underlying mechanism for the disrupted barrier function in CD is still unclear. It has been hypothesized that activated monocytes could exert a direct effect on epithelial cells, causing impairment of the epithelial barrier even at earlier phases of the disease and/or after removal of the trigger of the immune reaction (i.e. gluten/gliadin).
Aims and Methods: To model the role of celiac monocytes in the dysregulation of barrier function in CD we isolated peripheral blood mononuclear cells (PBMCs) from blood samples of HLA-DQ2-positive CD patients who were on a gluten-free diet. Intestinal epithelial cells (Caco-2) were treated with either PBMCs or CD14+ PBMCs (representing monocytes) in the presence or absence of interleukin-15 and trypsin-digested gliadin (IL-15/Tglia) in order to verify the role of active gliadin stimulation. As a control untreated Caco-2 or Caco-2 only treated with IL-15/Tglia were included to rule out direct toxic effects of gliadin/IL-15 on the epithelium. The integrity of the Caco-2 barrier was monitored by serial measurements of transepithelial resistance (TER). Intracellular localization of proteins with a key role in epithelial barrier function (occludin, JAM-A and ZO-1 for apical junctional complex and CD71 for epithelial transcytosis of gliadin) were investigated using confocal microscopy after immunostaining
Results: A decreased TER was observed in Caco-2 cells after treatment with celiac CD14+ PBMCs as compared to untreated cells. PBMCs that were activated by IL-15/Tglia revealed a more pronounced TER decrease. In control Caco-2 cells that were treated with IL-15/Tglia alone, TER did not decrease as found in completely untreated control cells. Exposure of Caco-2 cells to celiac monocytes resulted in a decreased expression of junctional proteins JAM-A and occludin and to a less stringent junctional or membrane association. ZO-1 localization and expression remained unchanged. With regard to the transcytosis protein CD71, confocal microscopy revealed an altered localization after treatment with PBMCs and CD14+ PBMCs, with evidence of a diffuse intracellular localization as compared to CD71 clusters in untreated cells.
Conclusion: Celiac PBMCs have an effect on epithelial barrier function of Caco-2 cells. Specifically, PBMCs as well as CD14+ monocytes appear to impair the epithelial barrier function. This is associated with an altered expression pattern of key proteins for tight junction assembly. These data suggest that in CD, monocytes play a role in transducing the gliadin-dependent epithelial barrier defect.

Introduction: The definition "gluten-related disorders" gathers multiple pathologies with overlapping symptoms including the celiac disease (CD) and the newly reported non-celiac gluten sensitivity (NCGS). To date, the diagnosis of NCGS is proposed for patients that have distress from gluten ingestion, have a negative CD serology and have a preserved intestinal architecture. Biomarkers for NCGS are not yet available, therefore the NCGS diagnosis remains based on symptoms, exclusion criteria and eventually gluten challenge. The availability of specific and objective diagnostic tests that identify a pathology is a crucial problem common to different diseases. Gene expression profiles have shown to have the necessary qualification to carry on this endeavour.
Aims and Methods: The present study aims to define a gene expression signature that might be helpful in the diagnosis of NCGS. Patients with positive CD serology (anti-tTG IgA and/or anti-EMA autoantibodies) and strong positive histology (Marsh grade $\geq$3) were enrolled as celiac. Symptomatic patients with negative CD serology and histology nevertheless responsive to gluten exclusion were enrolled as NCGS. Patients with gluten-independent dyspeptic symptoms who required gastrointestinal endoscopic examination were enrolled as controls. Total RNA extracted from duodenal biopsies was used for microarray analysis.
Results: The genome-wide expression analysis was carried on RNA extracted from intestinal mucosa of 8 female patients affected by NCGS (mean age 33.2 ± 5.8 years) and 6 age-matched female controls. Gene expression data were subjected to quantile normalization and log2 transformation before statistical analysis. Differentially expressed transcripts were identified by using a moderated T-test and Benjamini-Hochberg correction (adjusted $p < 0.05$; FC > 2). This approach revealed the presence of 37 differentially expressed transcripts. About 40% of these transcripts were long non-coding RNA (LncRNA) or Long intergenic noncoding RNAs (LincRNA). A subgroup of 5 patients affected by NCGS (mean age 33.4 ± 4.7 years) was also examined by microarray against 5 celiac disease patients. Statistical analysis revealed 26 differential transcripts, 40% of which also belonged to the Lnc-RNA and Linc-RNAs.
Conclusion: The results of this study confirm that patients affected by NCGS, however similar when compared to controls and to patients affected by celiac disease, show a sufficiently distinct genomic expression signature. RNA expression levels of NCGS do not completely overlap to that of controls and CD indicating that NCGS is a discrete disease. Finally, these results suggest that targeted expression profiling of specific sets of genes may be helpful in both positive diagnosis and/or exclusion of NCGS in symptomatic subjects.

Introduction: Microvesicles (MVs) have been recently implicated in cellular cross-talk both in health and disease, carrying surface receptors traceable to their cells of origin and shuttling molecules potentially controlling systemic processes. Recent studies have demonstrated an increased number of circulating MVs in a variety of conditions, including active celiac disease (CD)[1]. Non Celiac Gluten Sensitivity (NCGS) is a poorly defined syndrome primarily characterized by abdominal symptoms elicited by the ingestion of gluten in individuals not affected by celiac disease or wheat allergy. However, its underlying pathophysiology is scarcely understood.
Aims and Methods: To assess and characterize circulating MVs in a cohort of NCGS patients, we enrolled symptomatic NCGS patients, confirmed after gluten challenge and age/sex-matched healthy controls. All subjects performed serology testing and intestinal biopsy. CD exclusion required negative anti-tTG titers and absence of villous atrophy at histology. Circulating MVs were identified on whole blood samples by a no-lyse/no-wash method, combined with volumetric count (FACSVerse, BD), based on a novel 6-colour flow cytometry panel, in order to identify and enumerate the whole MV compartment and its subpopulations. Data are expressed as mean $\pm$ SD. Statistical differences were evaluated by T-test.
Results: We evaluated 14 NCGS patients (mean age $= 39.3 \pm 12.9$, F/M = 4:1) and 28 age/sex-matched healthy controls. Mean total circulating MVs were significantly higher in NCGS (respectively 47533.5 ± 16219.2 vs 14203.7 ± 7402.8 MV/μL, $p < 0.001$). Subgroup analysis showed that CD31+ and CD45+ MVs, of endothelial and leucocyte origin respectively, were not significantly different. However, EpCAM+ MVs, of epithelial origin, and CD41a+ platelet-derived MVs were significantly higher in NCGS patients (respectively 661.3 ± 236.8 vs 233.1 ± 190 MV/μL and 5513.2 ± 5957.7 vs 1200.3 ± 1395.9 MV/μL, $p < 0.005$). Mean total annexin V+ MVs showed a similar pattern (respectively 12050.4 ± 5818.5 vs 2639.4 ± 1675.8 MV/μL, $p < 0.001$), bearing increases in all subpopulations, with a 6-fold increase in CD31+ annexin+ and a 4-fold increase in EpCAM+ annexin+ MVs.
Conclusion: NCGS patients show higher numbers of total circulating MVs than age- and sex-matched controls. Phenotypical assessment suggests that this increase is driven in part by the epithelial- and platelet-derived compartments, potentially implying increased peripheral signaling from the intestinal mucosa. Annexin V identifies a compartment of MVs that express phosphatidylserine on the cellular membrane, an event found in apoptosis and activation of the cell of

origin. Differences in expression of this activated compartment could provide insights on the pathophysiology of NCGS and the possible signaling pathways that may mediate symptom onset.

Contact E-Mail Address: efkn78@gmail.com
Introduction: Circulating microvesicles (MVs) are potential mediators of cellular cross-talk in physiological and pathological systemic processes. Increased numbers of total MVs have been demonstrated in a variety of conditions, including celiac disease (CD)[1]. Non celiac gluten sensitivity (NCGS) diagnosis is based on the exclusion of CD, wheat allergy and other inflammatory conditions and on the demonstration of a strict correlation between symptoms and gluten consumption. However, markers for a positive diagnosis are lacking.
Aims and Methods: The aim of this study was to assess the potential diagnostic value of circulating MVs as a serological marker for NCGS diagnosis. To this end, we enrolled symptomatic NCGS patients confirmed after gluten challenge, age- and sex-matched newly diagnosed CD patients and asymptomatic controls. All subjects performed serology testing and intestinal biopsy. CD diagnosis required positive anti-tTG titers and presence of villous atrophy. MVs were identified on whole blood samples by a no-lyse/no-wash method, combined with volumetric count (FACSVerse, BD), based on a novel 6-colour flow cytometry panel. Data are expressed as mean ± SD. Statistical differences were evaluated by ANOVA-Welch with post-hoc Bonferroni or Dunnet's T3 test; diagnostic accuracy was assessed by ROC curves.
Results: We evaluated 14 NCGS patients (mean age = 39.3 ± 12.9, F/M = 4:1) against 22 CD subjects and 28 healthy controls. Anti-tTG levels were positive only in CD vs NCGS and controls (respectively 102.4 ± 63.1 vs 4.2 ± 3.3 and 3.9 ± 2.8 U/ml, $p < 0.001$). Villous atrophy was present only in CD patients; however, infiltrative lesions were present in 35% of NCGS and 28% of controls (p n.s.). Mean total MVs were significantly higher both in NCGS and CD compared to controls (respectively 47533.5 ± 16219.2 and 39283.1 ± 17828.6 vs 14203.7 ± 7402.8 MV/μL, $p < 0.02$ vs controls). Mean total annexin V+ MVs were significantly increased only in NCGS subjects (respectively 12050.4 ± 5818.5 vs 4044.8 ± 4769.8 and 2639.4 ± 1675.8 MV/μL, $p < 0.03$ vs CD and controls). ROC curve analysis of total and annexin V+ MV counts, when predicting NCGS, showed an AUC of respectively 0.780 and 0.839 ($p < 0.02$), whereas for CD AUCs were not predictive. Each parameter (total MV counts and annexin V+ MV counts), when combined with tTG negativity and absence of villous atrophy, yielded a further increase in AUC, respectively 0.882 and 0.905 ($p < 0.001$).
Conclusion: Total MV counts are increased in CD and NCGS patients when compared to age- and sex-matched controls. However, NCGS patients seem to express characteristically higher levels of annexin V+ MVs, suggesting parent cell activation. This parameter, combined to serological and histological exclusion of CD, seems to have a high diagnostic accuracy in NCGS and may represent a candidate marker for positive diagnosis of this syndrome.

Contact E-Mail Address: efkn78@gmail.com
Introduction: Non celiac gluten sensitivity (NCGS) diagnosis is principally based on the exclusion of CD and on the demonstration of a strict correlation between symptoms and gluten consumption. However, markers for a positive diagnosis are lacking. MicroRNA (miRNA) molecules, implicated in immune response, modulate post-transcriptional gene expression, showing distinct expression patterns in a number of diseases, including Celiac Disease (CD).
Aims and Methods: The aim of this study was to characterize miRNA patterns in NCGS and CD and assess their potential diagnostic value for NCGS diagnosis. We enrolled symptomatic NCGS patients confirmed after gluten challenge, age- and sex-matched newly diagnosed CD patients and dyspeptic controls. All subjects performed serology testing and intestinal biopsy. CD diagnosis required positive anti-tTG titers and presence of villous atrophy. Differentially expressed miRNAs in circulating leucocytes and duodenal mucosa were assessed by real-time PCR. Statistical differences were evaluated by a linear model with False Discovery Rate correction. Unsupervised Principal Component Analysis (PCA) was used to assess the discriminatory capability of miRNA patterns; principal component diagnostic accuracy was assessed by ROC curves.
Results: We evaluated 27 NCGS patients (mean age = 39.8 ± 11.3) against age- and sex-matched CD subjects and dyspeptic controls. Anti-tTG levels were positive only in CD vs NCGS and controls (respectively 99.4 ± 56.3 vs 4.5 ± 2.6 and 3.9 ± 1.8 U/ml, $p < 0.001$). Six miRNAs were differentially expressed in NCGS mucosal samples, while another 6 were identified in peripheral blood; notably, 2 of those miRNAs were expressed differentially only in mucosal biopsies or blood samples. At PCA, the first principal component showed an OR = 3.71 (95%CI: 1.57–8.75, $p = 0.003$) for NCGS status vs CD and an OR = 0.35 (95%CI: 0.16–0.78, $p = 0.011$) for NCGS status when compared to dyspeptic controls. ROC curve analysis of this component showed respectively an AUC of 0.743 (95%CI: 0.612–0.874, $p = 0.002$) and of 0.832 (95%CI: 0.706–0.958, $p < 0.001$).
Conclusion: The present study shows that patients selected according to established criteria are well definable with the use of miRNA profiling methods. Resulting miRNA signatures of NCGS patients are unique and absent in CD, further supporting non celiac gluten sensitivity as a distinct clinical entity even at the gene expression level. Differentially expressed miRNA patterns discriminate between patient groups with a high degree of accuracy and are strongly predictive of a NCGS status after exclusion of CD, both on mucosal and peripheral blood samples. As such, miRNA profiling, combined with serological and histological exclusion of CD, may represent a future marker for positive diagnosis of this syndrome.

Contact E-Mail Address: m.zwolinska-wcislo@uj.edu.pl
Introduction: Celiac disease (CeD) is an autoimmune, complex disorder of the gastrointestinal tract with wide range of clinical manifestation. The inflammatory process in CeD may cause changes in visceral perception increase of visceral sensitivity. Water load test is a standardized test used to induce gastric distension and to evoke gastric motility without the enterohormonal response.
Aims and Methods: The aim of the study was to investigate the effect of water ingestion on autonomic nervous system (HRV- heart rate variability) and gastric motility (EGG- electrogastrography) in patients with CeD compared to healthy subjects.
53 neurologically asymptomatic patients with CeD (13 males, 40 females, mean age 43.4 ± 14.8 years) and 50 healthy subjects (12 males, 38 females, mean age 44.1 ± 9.2 years) were studied. The simultaneous 30 minutes recording of ECG with HRV analysis and EGG were performed before and after water intake (500 ml per 5 minutes).
Results: ANS. At rest the spectral domain HRV analysis parameters were significant lower in patients than in control (LF – 291.9 vs. 836.0, p = 0.00004; HF – 348.5 vs. 965.5, p = 0.001). Water test induced the increase of LF (536.2 vs. 1163.4; p = 0.0003) and HF (543.7 vs 1224.9; p = 0.006) indices, similarly as a control, but not reached normal value.
EGG. Fasting CeD patients showed decreased% time of normogastria (51.8 ± 18 vs. 86 ± 12.3, p = 0.02) and mean slow wave coupling (SWC) (62.1 ± 18 vs. 67 ± 18%, p = 0.01) with increased dominant power (log DP) (12.5 ± 1.2 vs. 11.1 ± 1.1, p = 0.0001) in comparison to control group.
After water load test in CeD group decreased% time of tachygastria in EGG (7.08 ± 5.5 vs. 5.75 ± 1.7; p = 0.04) was noted.
Conclusion: In CeD the activation of autonomic system especial parasympathetic component after water load test was lower than in control group. Diminished responsiveness of ANS in CeD may contribute to disturbances of gastric myoelectric activity.
Disclosure: Nothing to disclose.

P1850 NON-CLASSICAL CLINICAL PRESENTATION OF CELIAC DISEASE IS MORE PREVALENT IN THE 21ST CENTURY: A SINGLE-CENTER EXPERIENCE

Introduction: Celiac disease is a gluten-triggered systemic autoimmune disease which can strike at any age. Presenting symptoms can be manifold, clinical phenotype may range from severe malabsorption syndrome to silent celiac disease.
Aims and Methods: We aimed to investigate whether celiac clinical phenotype changed in the past decades by performing a retrospective data collection from patients' files in our academic centre. Variables of interest included age at diagnosis, year at diagnosis (before or after the year 2000), diagnostic histology (graded by Marsh-Oberhuber classification), clinical presentation (divided into classical and non-classical celiac disease per Oslo criteria), extraintestinal symptoms (i.e., anemia and dermatitis herpetiformis), and concomitant diseases (i.e., metabolic bone disease and autoimmune diseases including thyroid disease). Independent sample t-test and chi-square test were used in statistical analysis.
Results: Altogether, 265 patients were diagnosed in our unit (60 males and 205 females) between 1971 and 2018. Mean age at diagnosis was 13.7 ± 17.4 years and 33.6 ± 15.0 years in patients diagnosed before and after the year 2000, respectively, with a significant difference between groups ($p < 0.001$). Classical clinical presentation was more common in patients diagnosed before the year of 2000, as compared to those diagnosed earlier (86.0% vs. 42.6%, respectively; $p < 0.001$). Distribution of intestinal damage was, as follows: Marsh 1: 0.6%, Marsh 2: 2.3%, Marsh 3a: 15.1%, Marsh 3b: 36.0%, Marsh 3c: 45.9%. Dermatitis herpetiformis, anemia, and metabolic bone disease were present in 12.8%, 44.4%, and 60.4% of the cases, respectively. Almost one-third (32.0%) of our patients were affected by concomitant autoimmune diseases, 18.5% of the population suffered from autoimmune thyroid disease. Diagnostic histology, frequency of dermatitis herpetiformis, anemia, metabolic bone disease, and autoimmune diseases were not different between patients diagnosed before and after the year 2000. Refractory celiac disease did not occur in our study population.
Conclusion: Our data suggest a significant shift in clinical phenotype of celiac disease: non-classical clinical presentation is more prevalent in the 21st century without significant difference in the complications and concomitant diseases.

P1851 DIFFERENCES IN SYMPTOMS AND GAS PRODUCTION FOLLOWING FRUCTOSE AND LACTOSE INGESTION IN PATIENTS WITH FUNCTIONAL GASTROINTESTINAL DISORDERS

C. Wilder-Smith[1], S.S. Olesen[2], A. Materna[3], A. Drewes[2]

Introduction: Patients with functional gastrointestinal disorders (FGID) often experience symptoms on ingestion of rapidly fermentable sugars, collectively referred to as FODMAPs (1). While it is clinically apparent that the reactions to individual FODMAPs differ, there is currently limited supportive evidence that the human or microbiome metabolism varies between sugars (2,3). Differences in fermentation and downstream effects of individual FODMAPs could be expected, based on the wide variability in intestinal microbiome function and composition.
Aims and Methods: We compared the induction of symptoms and the production of exhaled gases following ingestion of fructose and lactose in patients with FGID. Fructose and lactose breath tests were performed in a single centre in 2042 successive referred patients with FGID defined by Rome III criteria. Breath hydrogen and methane gas concentrations, and gastrointestinal (GI: abdominal bloating, flatulence, fullness, nausea, diarrhoea, abdominal cramps or pain, borborygmi, gastro-oesophageal reflux symptoms) and central nervous system (CNS: tiredness, difficulty concentrating, headache) symptom intensities were scored on a 3-point Likert scale for 5 hours after sugar ingestion. The time profiles of symptoms and of breath gas concentrations were analysed over time and compared between the two sugars. Treelet Transforms were used to derive data-driven symptom clusters for comparison between fructose and lactose.
Results: Eleven symptom profiles and the hydrogen and methane breath concentrations showed significant dynamics over time following sugar ingestions (all $p < 0.0001$). The time profiles of all symptoms, except reflux, and of breath concentrations differed significantly between fructose and lactose tests (all $p < 0.0001$). The onsets of GI and CNS symptoms and of peak hydrogen and methane gas concentrations were markedly delayed and the durations of symptoms prolonged following lactose compared with fructose ingestion. Two distinct symptom clusters were identified by Treelet Transform analysis, comprising a GI and a CNS cluster. These were identical following fructose and lactose, except that diarrhoea was not part of the GI cluster for fructose.
Conclusion: The time profiles of symptom generation and of gas production clearly differ following fructose and lactose in patients with FGID, suggesting different handling of these common FODMAPs. The most obvious and as yet unexplored explanations are differential effects on GI transit, or divergent distribution or functional capacity of the microbiome metabolizing fructose and lactose. Differential effects of individual sugars in FGID are likely to be of clinical consequence and need to be examined further.
Disclosure: Nothing to disclose

Introduction: Non-celiac gluten sensitivity (NCGS) is a gluten-related disorder characterized by the absence of allergic or autoimmune etiopathogenetic mechanisms. In the absence of sensitive and specific biomarkers for its diagnosis, the "Salerno Experts' Criteria" represent the only diagnostic tool currently available: it is based on in-vivo gluten challenge with periodical clinical evaluation. On the other hand, oral mucosa patch tests supported by Laser Doppler Perfusion Imaging (LDPI) have been recently proposed for the diagnosis of adverse reactions to foods, such as NCGS and nickel allergic contact mucositis.
Aims and Methods: Our aim was to compare the two methods for the diagnosis of NCGS: the oral gluten challenge according to "Salerno Experts' Criteria" and the Gluten Oral Mucosa Test Patch (GOMPT) supported by LDPI.
We enrolled a total of 30 subjects. 15 patients (Group A) presented with gluten-related symptoms and were on a free diet (FD) for at least 6 weeks. 15 healthy volunteers (Group B) were enrolled as control group. We excluded patients suffering from: celiac disease; allergy to gluten, wheat and other cereals; inflammatory bowel diseases; infectious diseases; autoimmune diseases; malignancies.
At the entrance of the study, patients and controls completed the modified version of the Gastrointestinal Symptom Rating Scale (GSRS) questionnaire: symptoms were quantitatively assessed using a scale from 1 to 10. They also underwent GOMPT, which consists of a gluten-containing stimulation test applied on the oral mucosa. LDPI, which produces quantitative data about oral mucosa vascularization before and after GOMPT, was also performed. Then, all patients followed a gluten-free diet (GFD) for 6 weeks with a second questionnaire completed. Afterwards, they started a double-blind placebo controlled trial, according to "Salerno Experts' Criteria". Capsules containing gluten (Product A) or rice flour (placebo, Product B) 6 gr/day have been consumed for one week respectively, with an intermediate wash-out week. A symptom questionnaire was repeated every week.
Results: There was no significant difference in symptoms' intensity between GFD period and Product A (gluten) period, as well as between Product A (gluten) and B (placebo) period. On the other hand, intensity significantly varied in 15/22 symptoms between FD and GFD period; in 12/22 symptoms between FD and washout (GFD) period; in 4/22 symptoms between FD and Product B (placebo) period. However, 7/22 symptoms do not show any significant difference. Questionnaires from control patients did not show any statistically significant difference.
14 out of 15 patients (93%) belonging to Group A showed GOMPT-positive results. 78.6% of them reported both local lesions and systemic symptoms during and after GOMPT, whereas the remaining 21.4% only presented systemic symptoms. Control patients from Group B showed GOMPT negative results, with only 13.3% reporting headache and drowsiness.
LDPI showed a statistically significant difference in mucosal perfusion after GOMPT in patients from Group A (p value < 0.003), while there was no significant alteration after simulation with vaseline (negative control). Control patients from Group B showed no significant difference in LDPI.
Conclusion: According to our data, the modified GSRS questionnaire alone seems to be not enough for NCGS diagnosis. In fact, it was not possible to observe statistically significant differences in symptoms' intensity during gluten and placebo intake. On the other hand, GOMPT supported by LDPI could be extremely useful for a fast and effective NCGS diagnosis.

Introduction: The Gaxilose test (GT) is a non-invasive method for the diagnosis of hypolactasia. Its efficacy and safety have already been proved in three clinical trials (1, 2). However, the impact on diagnostic thinking and on patient management had to be evaluated to confirm its clinical benefit.

Aims and Methods: The objective was to demonstrate the non-inferiority of the GT, compared to the Hydrogen Breath Test (HBT) on the impact on diagnostic thinking and on patient management for the diagnosis of hypolactasia. Patients with clinical symptoms of lactose intolerance were recruited in a multicentric clinical trial and randomly assigned to perform the GT or the HBT. The gastroenterologists had to complete for each patient a pre-test and a post-test visual analogue scale (VAS) questionnaire indicating their expected probability of diagnosing hypolactasia. The impact on diagnostic thinking was evaluated through the mean of the absolute values of the differences between the pre-test and post-test VAS scores and compared between the GT and the HBT. To assess the impact on patient management, the physicians completed a pre-test and a post-test management questionnaire. The percentage of patients who passed from '*No intervention*', '*Prescription of additional diagnostic tests*' or '*Referral to another specialist*' at pre-test to '*Diet adjustment and follow-up*' at post-test was compared for both diagnostic tests. The limit of non-inferiority was defined in both cases as -10%.

Results: 147 patients (115 females and 32 males, age range: 19–70 years, mean age: 38.41 years) were included in the analyzed population. Among them, 74 performed the HBT and 73 performed the GT. The impact on diagnostic thinking was $31.74 \pm 23.30\%$ for the GT and $24.28 \pm 19.87\%$ for the HBT. The difference between both was 7.46%, with lower 95% confidence limit (CL) of 1.55%, higher than the limit of non-inferiority ($p < 0.001$). The percentage of patients who passed from '*No intervention*', '*Prescription of additional diagnostic tests*' or '*Referral to another specialist*' at pre-test to '*Diet adjustment and follow-up*' at post-test was 6.85% for the GT and 5.41% for the HBT. Therefore, the difference between the GT and the HBT was 1.44% (95% CL: -6.31, 9.20). The lower 95% CL of the difference was also higher than the non-inferiority limit ($p = 0.007$). No serious adverse events were reported during the study.

Conclusion: The results demonstrate the non-inferiority of the GT compared to the HBT on the impact on diagnostic thinking and patient management for the diagnosis of hypolactasia.

P1854 SYSTEMATIC REVIEW WITH META-ANALYSIS: THE PREVALENCE OF BILE ACID MALABSORPTION AND THE RESPONSE TO CHOLESTYRAMINE IN PATIENTS WITH CHRONIC WATERY DIARRHOEA AND PRIOR CHOLECYSTECTOMY

L. Ruiz Campos[1], F. Fernández-Bañares[2]

Introduction: Post-cholecystectomy diarrhoea has a prevalence of 9.1% according to a systematic review published in 2012. The frequency of bile acid malabsorption (BAM) in these patients ranges between 57 and 100%, and some authors have suggested that they could be treated with cholestyramine without a prior testing of the presence of BAM. However, in most studies, the sample size is small and the response to cholestyramine has been scarcely evaluated.

Aims and Methods: To perform a systematic review and meta-analysis to assess the prevalence of BAM in patients with chronic watery diarrhoea and previous cholecystectomy and the response to cholestyramine.

MEDLINE was searched up to January 2018. Selected studies included cholecystectomized patients with chronic watery diarrhoea who were tested by 23-seleno-25-homotaurocholic acid (SeHCAT) test for the assessment of BAM. BAM was defined as 7 day SeHCAT retention of $< 10\%$ or $< 15\%$, depending on the study. We calculated the pooled rate of BAM and 95%CI using a random effects model and the inverse variance method. I^2 was calculated to asses heterogeneity across studies (0–39%, not important; 40–75%, moderate; and 76–100%, important).

Results: The search strategy identified 9 relevant studies comprising 361 individuals. The rate of BAM ranged from 57% to 100%. The pooled rate in the $< 10\%$ subgroup (G10; 8 studies) was 68% (95%CI: 53–83%) and 70% (95%CI: 59–81%) in the $< 15\%$ subgroup (G15; 5 studies). There was significant heterogeneity in effect sizes in the two groups (G10: $I^2 = 91\%$; G15: $I^2 = 73\%$). Five studies comprising 166 patients evaluated the effect of cholestyramine in patients with BAM. The pooled cholestyramine response rate was 77% (95%CI: 64–90%) with significant heterogeneity ($I^2 = 72\%$). After excluding the only study of G15, the pooled rate was 82% (95%CI: 72–93%) with moderate non-significant heterogeneity ($I^2 = 56\%$).

Conclusion: These data provide evidence that two thirds of patients with chronic watery diarrhoea and prior cholecystectomy have BAM. Response to cholestyramine in these patients is excellent. These findings have implications for the routine clinical practice and future guideline development.

P1855 DIAGNOSTIC YIELD OF ENDOSCOPY IN CF-LVAD PATIENTS WITH GASTROINTESTINAL BLEEDING

A. Ali[1], H. Tran[1], O. Rizvi[2], M. Adhaduk[1], Y. Assouline Dayan[1]

Introduction: Patients with continuous flow left ventricular assisted devices (CF-LVADs) carry an increased risk of gastrointestinal bleeding (GIB) up to 30%. In these patients, GIB lesions can be found anywhere in the GI tract, making optimal diagnostic and treatment approach difficult. With increasing use of CF-LVADs, an efficient approach for diagnosis and treatment of LVAD-related GIB is important.

Aims and Methods: We aimed to examine the diagnostic yield of endoscopies in Left Ventricular Assist Device-associated gastrointestinal bleeding in a tertiary medical center.

This is a retrospective study on patients who were implanted with continuous flow – Left Ventricular Assist Device (CF-LVAD) at the University of Iowa in 2010–2015, followed for a maximum of 2 years from the time of CF-LVAD implantation, or until death or heart transplant. All patients with gastrointestinal bleeding (GIB) were admitted, monitored and underwent endoscopic workup for diagnosis and management of the source of bleeding. Patient's demographics, clinical parameters and diagnostic yield of endoscopic procedures were recorded. Recurrent rate of GIB, subsequent endoscopic procedures and mortality rate were also collected.

Results: Out of 104 patients implanted with Heartmate II CF-LVADs, 37 developed GIB, with mean age of 57.7 ± 12.4 years, and 86.5% were males. Time from CF-LVAD placement to GIB was 122.9 ± 166 (range 10–715 days), with a rate of 88.9/100 patient-years. Majority of patients (43.2%) presented with melena, whereas 18.9% presented with occult GIB. At initial GIB episode, EGD as an index procedure was performed in 21.6%, colonoscopy in 13.5% and both EGD and colonoscopy in 64.9%. Bleeding lesions in the upper GI tract were found in 51% of the patients, followed by 29% lesions in small bowel and 8% lesions in the colon. Diagnostic yields of EGD and colonoscopy were 62.5% (20/32) and 17.2%, (5/29) respectively, Video capsule endoscopy (VCE) had a diagnostic yield of 23.8% (5/21). Eleven enteroscopies either push or double balloon identified 6 bleeding lesions in the small bowel.

The most common lesions found by EGD were erosions (40%) and angiodysplasia (35%), whereas ischemic changes were the most common lesion found on colonoscopy in 4 of 5 (80%) patients [Table 1]. Majority of the bleeding lesions were found in the upper GI tract (62.5%), within the reach of EGD, and 8/37 (23.8%) bleeding lesions were detectable by VCE. The combined diagnostic yield of EGD and VCE was 67.5%.

Location	Lesions
Upper GI tract (n) EGD(32)	Esophagus: ulcer (1), esophagitis (1) Stomach :ulcer (1), erosion (6), angiodysplasia (4), GAVE (2), ischemia (1) Doudenum:angiodysplasia (3)
Small bowel (n) VCE(21) Enteroscopy (11)	jejunum and ileum: VCE: erosion (2), angiodysplasia (3) Enteroscopy:Angiodysplasia (4), oozing blood (2)
Colon (n) Colonoscopy (29)	Colon and terminal ileum: ulcer (1), ischemic changes (4)

[Lesions of GIB identified in GI tract with each type of endoscopy]

During the 2-year follow-up, 73% of patients had recurrent GIB; and 32.4% of them experienced more than 2 episodes with a mean of 3.14 bleeding episodes/patient. During the 2 years follow-up, 18 patients (48.6%) died; among these, 4 (22.2%) deaths were related to GIB.
Conclusion: In a cohort of 104 CF-LVAD patients followed up for 2 years, 35.6% of them developed GIB, mostly in the first 6 months, with a high recurrence rate. Most GIB bleed lesions were found in upper GI tract or small bowel. EGD showed the highest diagnostic yield, followed by VCE. We suggest that evaluation of GIB in CF-LVAD patients should be initiated with EGD and a VCE, to optimize diagnostic yield and successful intervention.

Introduction: The use of anticoagulants is associated with an increased risk of upper and lower gastrointestinal (GI) bleeding.
Aims and Methods: The aim of this study was to evaluate whether different anticoagulant groups increase the yield of small bowel (SB) findings in patients who undergo small bowel capsule endoscopy (SBCE) for iron deficiency anaemia (IDA) or overt SB bleeding following negative bidirectional endoscopies.
The SBCE findings of 2 groups of patients presenting with IDA or overt SB bleeding after negative bidirectional endoscopy were compared: Group 1: patients were on antiplatelets / newer anticoagulants / warfarin / aspirin, Group 2: patients were not on any anticoagulants.
Results: 139 patients in group 1 were compared to 119 patients in group 2 (mean age 71.3 ± SD8.7). Both groups were gender and age matched. Indications in the 2 groups were anaemia and overt SB bleeding ($p = 0.145$). Patients in group 1 were on: aspirin (58; 42.4%), warfarin (5; 3.6%), newer oral anticoagulants (61; 43.9%), thienopyridines and ticagrelor (23; 16.5%), NSAIDs and anticoagulants (5; 3.6%). 16 patients (11.5%) were on 2 and 1 patient (0.719%) was on 3 anticoagulants.
There was no statistical difference in the upper GI ($p = 0.609$) and SB yield ($p = 0.499$). There was also no statistical difference in findings according to SB location (proximal / mid / distal / diffuse / terminal ileum) within the 2 groups.
Comparing subcategories in group 1:
There were no statistical difference in upper GI yield ($p = 0.796$) and SB yield ($p = 0.479$) across subcategories in group 1 but patients on aspirin had the highest SB yield (73.2%). Patients on dual anticoagulants (64.3%) and those on thienopyridines and ticagrelor (63.6%) were more likely to have proximal positive findings ($p = 0.014$). Patients on NSAIDs and anticoagulants (60%) were most likely to have white tipped villi ($p = 0.014$) and denuded villi (40%) ($p = 0.011$).
Comparing each anticoagulant separately to controls:
Patients on aspirin ($p = 0.050$) and warfarin ($p = 0.004$) were more likely to have white-tipped villi when compared to controls. Patients on warfarin were more likely to have denuded villi ($p = 0.004$). Patients on thienopyridines or ticagrelor were more likely to have proximal SB involvement ($p = 0.038$).
Conclusion: Being on anticoagulants does not increase the prevalence of SB findings on SBCE in patients with SB bleeding. A bigger prospective study is needed to confirm the lack of relationship between SB bleeding and anticoagulants.
Disclosure: Nothing to disclose

P1857 RHEMITT SCORE: THE BEGINNING OF A NEW ERA IN THE PREDICTION OF REBLEEDING!

Introduction: Mid gastrointestinal bleeding (MGIB) accounts for 5–10% of gastrointestinal hemorrhages, and small bowel capsule endoscopy (SBCE) is the gold-standard for investigational approach. In spite of the acknowledgement of some risk factors, no score can currently predict the individual risk of small bowel rebleeding after SBCE.
Aims and Methods: We aimed to create a predictive score of small bowel rebleeding risk, in patients that underwent SBCE for MGIB.
Retrospective, unicentric study, including patients that underwent SBCE for MGIB, from June 2006, to October 2016. Every patient had a 12 months minimum follow-up.
Statistical variables were chosen according to clinical relevance and previous evidence in the literature, and their correlation with the occurrence of small bowel rebleeding after SBCE was assessed. Univariate analysis allowed us to select covariables with marginal association ($p < 0.15$) with the outcome variable, which were then included in a Cox regression hazard multivariate model. Finally, we attributed points to each variable category in order to create a score with clinical applicability.
Results: Out of 357 patients submitted to SBCE for MGIB, 230 (64.3%) were female and the mean age was 64 years old. The main indication to SBCE was iron-deficiency anemia (72.8%) and 88 patients (24.6%) presented with rebleeding during the follow-up.
The significantly different variables allowed us to create a new measure for the prediction of the individual risk of gastrointestinal rebleeding, the RHEMITT score, that presented a good accuracy to the outcome variable (area under curve 0.843, CI 95%0.801–0.885). From the regression coefficients obtained, we designed a score, from 0 to 18 points, (**R**enal disease, 3 points [$p < 0.001$]; **H**eart Failure, 1 point [$p = 0.044$]; **E**ndoscopic capsule lesions P1, 2 points [$p = 0.021$]; P2, 3 points [$p = 0.002$]; **M**ajor bleeding, 5 points [$p < 0.001$]; **I**ncomplete capsule, 2 points [$p = 0.031$]; **T**obacco, 2 points [$p = 0.006$]; Endoscopic **T**reatment, 2 points [$p = 0.002$]), establishing 3 risk groups for rebleeding: 0–3 points (0%); 4–10 points (25.4%);> 11 points: (63.8%).
Conclusion: We present a new score for patients with MGIB, named RHEMITT, which accurately anticipates the individual risk of small bowel rebleeding after initial SBCE.
Disclosure: Nothing to disclose

P1858 IMPACT OF THE TIMING OF CAPSULE ENDOSCOPY IN OVERT OBSCURE GASTROINTESTINAL BLEEDING ON YIELD AND REBLEEDING RATE – IS SOONER THAN 14 D ADVISABLE?

Introduction: An early diagnosis with capsule endoscopy (CE) in overt-obscure gastrointestinal bleeding (OGIB) patients can lead to an appropriate specific intervention, better long term-outcomes and reduce unnecessary medical costs. ESGE recommends performing CE as soon as possible after the bleeding episode, optimally within 14 days.
Aims and Methods: Evaluate the impact of the timing of capsule endoscopy (CE) in overt-obscure gastrointestinal bleeding (OGIB), mainly when it is performed within 48 hours.
Retrospective, single-center study, including patients submitted to CE in the setting of overt-OGIB between January 2005 and August 2017. Patients were divided into 3 groups according to the timing of CE (≤ 48 h; 48 h-14 d; ≥ 14 d). The diagnostic and therapeutic yield (DY and TY), the rebleeding rate and the time to rebleed were calculated and compared between groups. The outcomes of patients in whom CE was performed before (≤ 48 h) and after 48 h (> 48 h), and before (< 14 d) and after 14 d (≥ 14 d), were also compared.
Results: One hundred and fifteen patients underwent CE for overt-OGIB. The DY was 80%, TY-46.1% and rebleeding rate – 32.2%. At 1 year 17.8% of the patients had rebled. 33.9% of the patients performed CE in the first 48 h, 30.4% between 48h-14d and 35.7% after 14 d. The DY was similar between the 3 groups ($P = 0.37$). In the ≤ 48 h group, the TY was the highest (66.7% vs 40% vs 31.7%, $P = 0.005$) and the rebleeding rate was the lowest (15.4% vs 34.3% vs 46.3% $P = 0.007$). The time to rebleed was longer in the ≤ 48 h group when compared to the > 48 h groups ($P = 0.03$).
Conclusion: Performing CE within 48 h from overt-OGIB is associated to a higher TY and a lower rebleeding rate and longer time to rebleed.

Introduction: Small bowel varices (SBV) are a rare consequence of portal hypertension and could lead to life-threatening mid-gut bleeding. Radiological intervention (RI) is usually considered first line management (e.g. Trans-jugular intrahepatic portosystemic shunting (TIPS), stenting of occluded mesenteric veins +/– embolisation of culprit varices). In cases where RI is impossible, management options become very limited.

Aims and Methods: This multicentre case series evaluated the usefulness of DBE assisted cyanoacrylate injection of SBV. Retrospective review of DBE facilitated cyanoacrylate injection of SBV (December 2015 to October 2016). Demographic, clinical, endoscopic and radiological findings, interventions and follow-up data were analysed.

Results: Ten DBEs were performed in 6 patients (4 women, median age: 68.5-years). All patients had at least one previous surgery (colectomy (n = 1); hemihepatectomy (n = 2); small bowel resection (n = 2); appendicitis with peritonitis (n = 1); splenectomy (n = 1)); one patient had a history of intra-abdominal sepsis in childhood causing portal vein thrombosis and one had cryptogenic thrombosis of the portal and the mesenteric vein. No radiological or surgical options were deemed feasible in any case. SBV were diagnosed at capsule endoscopy and triple phase computed tomography mesenteric angiography. At DBE, a total of 13 nests of SBV were identified and injected with cyanoacrylate glue. There were no haemorrhagic or embolic complications but 1 patient developed an infection of a congenital urachal cyst, which was treated successfully with antibiotics. All patients underwent DBEs via the anterograde route, 2 patients required bi-directional DBE for treatment of both proximal and distal SBV and in total 2 patients required a repeat DBE for further treatment of SBV. At 30-day follow-up post-therapy, only 1 patient had experienced a mild recurrence of mid-gut bleeding treated conservatively. One patient presented with acute gastrointestinal bleeding 7 months later and a repeat DBE with cyanoacrylate injection therapy was successfully performed. One patient was lost to follow-up. The remaining patients had 12 months of follow-up without any recurrent gastrointestinal bleeding.

Conclusion: Cyanoacrylate injection therapy of SBV at DBE appears to be a safe and effective management strategy for this condition when other first-line options are not feasible.

Introduction: Video capsule endoscopy (VCE) is effective in the detection of small bowel lesions in patients with overt obscure gastrointestinal bleeding (OGIB). However, there is little evidence of its impact on long-term clinical outcomes and survival.

Aims and Methods: The objective of this study was to evaluate the long-term clinical impact of a positive finding in VCE after a first episode of overt OGIB. Retrospective, single-center study that analyzed patients with OGIB who underwent VCE between October 2008 and October 2017. The findings in VCE were considered positive if active bleeding and/or hemorrhagic lesions were detected. Bleeding recurrence (BR) was defined as the need for transfusions, hemoglobin drop ≥2 g/dl, or evidence of overt gastrointestinal bleeding.

Results: A total of 108 patients underwent VCE after a first episode of OGIB, 55% men, with a median age of 70 years (IQR 56–80). The median follow-up was 23 months (IQR 11–51). The VCE revealed positive findings in 66% of the patients, with angiodysplasias (37%) and ulcers (15%) being the most frequent. After VCE, targeted therapy was performed in 26%. In the follow-up, BR occurred in 28% after a median period of 8 months (IQR 3–15). Bleeding recurrence was more frequent after a positive VCE (40% vs. 11%, p = 0.002). Targeted therapy after a positive VCE was not associated with a lower occurrence of BR (42% vs. 38%, p = 0.8). In the multivariate logistic regression, a positive VCE (OR 6.6, 95% CI 1.7–25.6; p = 0.006) and valvular heart disease (OR 3.9, 95% CI 1.4–11.1; p = 0.01) were independent risk factors for BR. In the follow-up, a positive VCE was associated with a higher number of emergency episodes (β = 1.1, 95% CI 0.2–2.0; p = 0.018), number of days of hospitalization (β = 10.0, 95% CI 1.4–18.7; p = 0.023) and endoscopic procedures (β = 2.6, 95% CI 1.4–3.9; p < 0.001). The mortality rate at 12 and 36 months was 22% and 46%, respectively. Patients with a positive VCE had a lower survival, compared to those with a negative VCE (mean 51 vs. 82 months, p = 0.013). In the multivariate analysis, a positive VCE was independently associated with the survival estimate (HR 2.7, 95% CI 1.2–6.1; p = 0.017).

Conclusion: After a first episode of OGIB, patients with a positive VCE have a greater risk of long-term BR, with a consequent negative impact on survival. In our study, targeted therapy for the source of bleeding didn't affect the risk of BR. A high degree of suspicion with regular clinical surveillance, etiologic investigation and timely intervention may be important. Further observations are necessary in order to evaluate the impact of targeted therapy in the long-term follow-up of these patients.

Introduction: Balloon Enteroscopy and Capsule Endoscopy have facilitated the diagnosis of pathologic findings in patients with suspected small bowel bleeding with similar accuracy (1,2). However, therapeutic potential of Balloon-Assisted Enteroscopy combined with its high diagnostic yield in patients that present with overt small bowel bleeding may favor its indication as a first-line endoscopic approach in this group of patients (3).

Aims and Methods: The aim of this study was to determine the impact of the clinical presentation of small bowel bleeding on the diagnostic and therapeutic yield of Single Balloon Enteroscopy (SBE) at a tertiary referral center in Sao Paulo, Brazil.

We retrospectively reviewed consecutive patients that have undergone SBE for the diagnosis and treatment of potential small bowel bleeding, after negative esofagogastroduodenoscopy and colonoscopy. This study was undertaken from November 2011 until March 2017 at a referral tertiary hospital in Sao Paulo, Brazil. All procedures were performed with CO2 insufflation. Sedation of patients was managed by the team's anesthesiologist accordingly. Enteroscopies of patients that presented with active bleeding and/or clinically important comorbidities were performed under general anesthesia at the surgical room. Diagnostic yield was described as the total number of cases diagnosed among the total number of patients that underwent SBE. Therapeutic yield was defined as the total number of successfully treated patients among the total number of patients that were performed SBE. Diagnostic and therapeutic yield of SBE were analyzed according to bleeding presentation and endoscopic findings were described.

Results: A total of 122 SBEs were performed in 84 patients (48 male/36 female, mean age 59 years old SD 21.34). The route of insertion was antegrade in 89 cases (72.95%) and retrograde in 33 (27.05%). 28 patients underwent antegrade and rectal SBE sequentially at a single time. The mean procedural time for antegrade and retrograde approaches was 62 minutes.

Main findings in occult bleeding at SBE were 37 cases of angioectasias, 7 ulcers, 5 polyps and tumors and 5 cases of hemorrhagic gastritis of excluded stomach. Endoscopic lesions in patients that presented clinically with overt bleeding were 6 angioectasias, 2 dieulafoy's, 3 ulcers, 10 cases of polyps and tumors, 2 varices and 2 hemorrhagic gastritis of excluded stomach. There were no complications in this series of patients. Diagnostic and therapeutic yield of SBE according to bleeding presentation (occult VS overt bleeding) is described in table 1.

Conclusion: SBE was an effective diagnostic and therapeutic tool in overt small bowel bleeding, suggesting that this enteroscopy modality may be an appropriate first line diagnostic and therapeutic endoscopic approach for the management of overt bleeding cases.

	n of successful cases/n of total cases	Yield%	p
Diagnostic			0.019
Occult	36/48	75	
Overt	34/36	94.4	
Therapeutic			0.0027
Occult	22/48	45.9	
Overt	29/36	80.5	

[Diagnostic and therapeutic yield of single balloon enteroscopy according to bleeding presentation]

Introduction: Chronic stenosing enteritis (CSE) is a novel ulcerative and stenosing disease of the small bowel that is distinct from Crohn's disease, celiac disease, and NSAID-induced small bowel injury. Similar conditions have been described in Japan and Korea as cryptogenic multifocal ulcerating stenosing enteritis, chronic nonspecific stenosing ulceration, and most recently chronic enteropathy associated with mutations in the *SLCO2A1* gene (CEAS), a prostaglandin transporter gene. There are currently no studies examining the outcomes to medical and surgical therapies in patients with CSE. We report our experience with treating CSE.

Aims and Methods: 16 patients diagnosed with CSE were identified between 2007 and 2017 at UMass Medical Center. Patient epidemiology, laboratory studies, endoscopic procedures, radiographic studies, pathology reports, medical treatment, surgical interventions, and disease course were collected retrospectively. All patients underwent video capsule endoscopy as part of their initial work-up. Complete remission was defined as resolution of iron deficiency and clinical symptoms including abdominal pain, bleeding, and anemia. Partial remission was defined as persistent iron deficiency with resolution of clinical symptoms. Iron deficiency was determined using standard ferritin and transferrin saturation thresholds.

Results: The median duration of follow-up was 48 (4.5–85.3) months. 75.0% of patients presented with bleeding or iron deficiency anemia. 80.0% of patients were found to be iron deficient (see Table 1). 43.8% of patients required intravenous iron therapy. A total of 62.5% of patients underwent surgical resection for CSE and 31.3% received biologic therapy with infliximab or adalimumab. Only 3 patients received steroids, none of whom achieved remission with this therapy. The overall rates of full remission, partial remission, and no remission were 20.0%, 26.7%, and 26.7% respectively. 26.7% of patients had resolution of clinical symptoms but no available follow-up iron studies to evaluate for full remission. 1 patient was lost to follow-up after initial diagnosis.

	Gender	Age at Onset (Years)	Iron Deficiency	Surgery	Biologic Therapy	Outcome
1	M	70	+	–	–	F
2	M	55	–	+	–	P*
3	F	61	+	–	+	P
4	M	62	–	+	–	N
5	M	56	+	–	–	N/A
6	M	63	+	–	–	F
7	M	57	+	+	–	N
8	M	53	+	+	+	P
9	M	72	–	+	–	P*
10	M	75	+	–	–	N
11	M	53	+	+	+	P
12	M	37	+	+	–	F
13	F	43	N/A	+	+	N
14	M	58	+	+	+	P
15	M	30	+	+	–	P*
16	F	74	+	–	–	P*

[Table 1: Patient Characteristics, Treatment, and Outcomes in Chronic Stenosing Enteritis]

Biologic therapies included infliximab and adalimumab.
F = full remission; P = partial remission; P* = clinical remission without available follow-up iron studies; N = no remission; N/A = data not available

Conclusion: Patients with CSE can be successfully treated with iron supplementation, surgery, and biologic therapy. Iron studies may have a role in monitoring disease activity, particularly when clinical symptoms are resolved. Further studies are needed to determine the long-term implications of these interventions.

Introduction: Small bowel angioectasias (SBAs) commonly occur in patients with hereditary haemorrhagic telangiectasia (HHT). Patients with small bowel (SB) involvement and those with severe gastrointestinal (GI) bleeding are significantly older

Aims and Methods: Patients with known HHT were included in this study. Data on GI investigations was recorded. The impact of SB capsule endoscopy (CE) and double balloon enteroscopy (DBE) was evaluated.

Results: 10 patients (60% males) with genetically confirmed HHT were included. Mean age at first SB endoscopy was 62.6 ± SD14.4 years.

Patients had the following co-morbidities: chronic thromboembolic pulmonary hypertension (1), chronic kidney disease (2), respiratory (2), cardiac (4), superior mesenteric vein thrombosis (SMVT) (1), malignancies (2). 1 patient was on warfarin. Another patient was on deltaparin.

Some patients had evidence of extra-GI arterio-venous malformations (AVMs): pulmonary (2), cerebral (2), nasal mucosa (3), hepatic (1).

Patients had a total of 39 gastroscopies, 16 colonoscopies and 6 push enteroscopies. 7 patients underwent SBCE: 6 (85.7%) had proximal, 1 (11.1%) had mid and 3 (33.3%) patients had distal SBAs. 2 patients had a colon capsule which showed angioectasias.

6 patients had several DBEs (median 4; SD ± 6) with a mean 130.5 ± SD133.3 between DBEs. All were antegrade DBEs except for 1. 57 SBAs were treated with argon plasma coagulation (APC) on average at each DBE. There was a mean improvement in haemoglobin in patients who underwent regular DBEs (93.8 vs 102.1 g/dL; p = 0.102). 6 patients were transfusion dependent initially but 4 improved following intervention.

Need for transfusion resolved in 1 patient when started on lanreotide, regular endoscopy and APC and in 2 patients on starting DBEs and APC. 1 patient passed away from pneumonia. Another patient was switched unsuccessfully from octreotide to lanroetide. She stopped being transfusion dependent with regular OGDs and APC. Another patient was unwilling to undergo further endoscopies due to multiple co-morbidities. He improved on lanreotide. In 2 patients anaemia remains persistently problematic. 1 of them is also on deltaparin for SMVT. The other patient has recurrent epistaxis which makes it harder for him to have further endoscopies.

In comparison, 40 (29%vs 85.7%) from a total of 138 patients referred due to anaemia for SBCE between 2014 and 2015 had SBAs. (p = 0.004).

Conclusion: SBCE is a useful screening tool in patients with HHT to assess for SBAs which occur more commonly than in patients with anaemia but no underlying HHT. Most patients had proximal SBAs which were amenable to regular DBEs and APC. A small number required additional pharmacotherapy to improve transfusion requirements.

Introduction: A diet low in fermentable carbohydrates, FODMAPs (Fermentable Oligo-, Di-, Monosaccharides And Polyols) seems to be a promising treatment option for patients with IBS. However, the pattern of FODMAP consumption among patients with IBS, e.g. the types, amounts and the variability in FODMAPs consumed, is still unclear. This information is necessary when planning surveys, to be able to obtain data that are sufficiently accurate for the study objectives.

Aims and Methods: The aim of this study was to characterize the variation in FODMAP intake among patients with IBS, and to calculate the number of days needed to capture the FODMAP intake at the individual level with a certain precision, as well as how many days are required for ranking individuals within a group. Food intake was recorded during four consecutive days (Wednesday-Saturday) in patients with IBS, and intake of energy and nutrients, including FODMAPs, were calculated in a special version of the software Dietist XP 3.1 (Kostdata.se, Stockholm, Sweden) linked to a FODMAP database. Calculation of the coefficient of variation within subjects (CV_w), coefficient of variation between subjects (CV_b), the number of replicate days required per subject to estimate an individuals nutrient intake, and the number of observations required to correctly rank individuals into quartiles of consumption, were calculated.

Results: Diet records were provided from 151 women and 46 men with IBS. The reported mean energy intake was 2039 ± 502 kcal among women and 2385 ± 573 kcal among men, and the median FODMAP intakes were 18.7g (range 3.7–73.4) and 22.8g (range 3.6–165.7), respectively. Lactose contributed to >53% of the total intake in FODMAPs, excess fructose with 27%, fructans with 12%, polyols

with 5%, and galacto-ologosaccharides contributed with the least amount, 3%. There were no significant gender differences in the proportion of energy adjusted FODMAP intake. The ratio of CV_w / CV_b for total FODMAP intake was 0.83 for women and 0.67 for men, and below 1 for all FODMAPs. This indicates that there is larger variation between subjects than within subjects with respect to FODMAP intake. To capture the intake of FODMAPs at the individual level with a precision of +/−20%, 19 days of replicate observations are required (as seen in the table). Ranking individuals within a group according to FODMAP intake would require between 2–6 days of replicate observations.
Conclusion: Our results show that there is more variation between subjects than within subjects regarding FODMAP intake. Dietary data with good precision at the individual level would not be obtainable using a reasonable number of days of food records. However, if the study objective is to rank individuals into quartiles of FODMAP consumption, this can be achieved with a good level of precision by using food records.

	Number of days to capture true mean intake at the individual level (95% CI)		*Number of days required for ranking individuals into quartiles of consumption*	
	+/−20%	+/−30%	r = 0.90	r = 0.95

Introduction: Restricting intake of fermentable carbohydrates, FODMAPs (Fermentable Oligo, Di-, Monosaccharides And Polyols) is increasingly recommended in the management of IBS. However, it is still unclear if the habitual FODMAP consumption correlates to IBS symptom severity, and if this relationship differ among IBS subgroups. The aim of this study was to define the habitual FODMAP intake among patients with IBS, and to evaluate the relationship between FODMAP intake and symptom severity and pattern in IBS.
Aims and Methods: The aim of this study was to define the habitual FODMAP intake among patients with IBS, and to evaluate the relationship between FODMAP intake and symptom severity and pattern in IBS. Patients with IBS recorded food intake during four consecutive days and they were instructed to maintain their regular diet. Intake of energy, nutrients and FODMAPs were calculated in the software Dietist XP 3.1 (Kostdata.se, Stockholm, Sweden), linked to an in-house FODMAP database. IBS symptom severity was measured with the IBS severity scoring system (IBS-SSS), and IBS subgroups were defined according to the Rome III criteria.
Results: Diet records were provided from 151 women and 46 men with IBS; IBS with constipation (IBS-C) n = 44 (22.3%), IBS with diarrhea (IBS-D) n = 54 (27.4%), mixed IBS (IBS-M) n = 46 (23.4%) and unsubtyped IBS (IBS-U) n = 46 (23.4%). Mean intake of total FODMAPs was similar across the different subtypes, with a mean intake of 20.7 ± 11.9 g/day (median 19.4 g). Neither age, anxiety, depression nor somatic symptoms were associated to FODMAP intake. For individual FODMAPs we noted a higher lactose intake among IBS-M compared to IBS-D, 12.9 ± 8.7 g vs. 8.1 ± 7.1 g, $p = 0.02$. When including all patients, we did not see any difference in the symptom severity (IBS-SSS) across the four quartiles of FODMAP intake: Q1, 296 ± 97; Q2, 303 ± 63; Q3, 292 ± 92; Q4, 316 ± 85 ($r_s = 0.073$, $p = 0.53$). However, when stratifying on IBS subgroups, there was a significant correlation between FODMAP intake and increased overall IBS symptom severity among IBS-U patients, $r_s = 0.401$, $p = 0.006$, and for the IBS-SSS subscales pain frequency and bowel habit dissatisfaction (table 1).
Conclusion: This study shows no major differences in FODMAP intake among IBS patients with different bowel habits or severity of symptoms, except for an association between IBS symptoms and FODMAP intake in unsubtyped IBS. However, it seems likely that patients who are intolerant to certain FODMAPs have already reduced their FODMAP intake, which was not investigated in this study.

	FODMAP intake among different IBS subtypes			
	IBS-C	IBS-D	IBS-M	IBS-U
IBS-SSS total	0.009	0.000	−0.002	0.401**
Pain intensity	0.041	−0.137	0.197	0.129
Pain frequency	0.145	0.062	−0.058	0.385**
Bloating severity	−0.027	−0.003	−0.064	0.091

P1866 ASSESSING THE EFFECTS OF TWO PROBIOTIC FORMULATIONS ON CACO-2 CELL EPITHELIUM BARRIER MODEL

P. Palumbo, F. Lombardi, B. Cinque, S. Giuseppe, A. Kapaj, M.G. Cifone
University of L'Aquila, Department of Life, Health and Environmental Sciences, L'Aquila, Italy

Contact E-Mail Address: paola.palumbo@univaq.it
Introduction: It is largely known the beneficial effect of probiotics to improve human health through reestablishing the composition of the gut microbiota and contributing to the maintenance of gastrointestinal tract function. Probiotics protect the host from pathogens by competitive exclusion, preserve barrier integrity, affect the host immune system and remove heavy metals and environmental toxins. Since changes in manufacturing affect the functional properties of probiotic formulations [1–4], we have compared the *in vitro* effects of two 450 billion multi-strain high concentration formulations, identified by us as USA-made and Italy-made, on human colon adenocarcinoma cell line, CaCo-2, a model widely used as an optimum for studies on intestinal barrier functions [5].
Aims and Methods: The aim of this research was to identify if two 450 billion commercial probiotic preparations sourced from different production sites (USA and Italy) could affect the integrity of intestinal barrier in vitro as well as protect from heat-induced dysfunction of the epithelial monostrate. CaCo-2 monolayers were seeded in Transwell chambers where they close up shaping a model of intestinal barrier. The effects of both probiotic formulations, at 10^8 CFU/ml final concentration, were analyzed on both transepithelial electrical resistance (TEER) and 4 kDa fluorescein isothiocyanate-dextran (FD4) flux in CaCo-2 cells before and after exposition to heat stress. TEER and dextran flux are considered as a reliable tool to evaluate the physiological state and integrity of epithelial or endothelial barrier and can also be used to predict paracellular permeability following several stimuli [6]. Considering that tight junctions are thought to be exceptionally effective structures operative in several main functions of the intestinal epithelium under both physiological and pathological circumstances, the effects of probiotic treatment before heat-induced damage on the levels of tight junction proteins i.e. zonulin-1 and occludin were also analyzed by western blotting and densitometry of relative bands.
Results: Treatment with both products did not significantly affect basal levels of TEER and FD4 flux values. On the other hand, a 4 h pre-treatment with USA-made probiotic was able to totally prevent the heat-induced damage as shown by TEER and dextran flux analyses. Instead, the Italy-made product did not exert significant effects on both TERR values and dextran flow altered by heat damage. The basal levels of zonulin were not modulated by a 3 hr-treatment with both probiotic formulations while USA-made product was able to upregulate occludin expression. Of note, Italy-made product, at the same experimental conditions, induced a significant decrease of occludin levels compared with both untreated cells and USA-made product treatment. Also in this context, just pre-treatment with USA-made formulation was able to totally prevent both zonulin and occludin level reduction induced in heat-stressed monolayers.
Conclusion: The results confirm that the production conditions of this 450 billion formulation are crucial for its efficacy and safety, as previously reported [1–4]. A careful selection of the probiotic agent, standardization of the dose and detailed characterization of the beneficial effects are essential when considering use of a probiotic for the dietary management of serious diseases. As a general rule, there is the need to reconfirm safety and/or efficacy for any probiotic product made at a different factory even if contains the same species.

Introduction: The heterogeneous character of functional gastrointestinal disorders makes it challenging to find effective treatment options. Compared to synthetic drugs, phytotherapeutic medicines can have broader pharmacological effects and are often better tolerated.

Aims and Methods: The current study aimed to investigate the effect of a combination of peppermint oil (41.5 mg l-menthol) and caraway oil (50 mg) (POCO) on gastric motility, gastric emptying, nutrient volume tolerance, postprandial symptom levels and gastrointestinal peptide hormones in 32 healthy subjects in a single-blinded, placebo-controlled, randomized, parallel design. On study day 1, a ^{13}C breath test was performed after an overnight fast to assess gastric emptying rate 30 minutes after study medication administration (POCO or placebo). This was followed by an intragastric pressure (IGP) measurement using high-resolution manometry, during which 350 mL of a nutrient drink was intragastrically infused at 60 ml/min 30 minutes after a second dose of study medication. IGP was measured until 2 hours after infusion. On study day 2, IGP was measured for 4 hours in the fasted state after intake of study medication, followed by a second dose of study medication and 30 minutes later intragastric infusion of a nutrient drink until the participant was fully satiated (0–5 likert scale). IGP was measured until 2 hours after the infusion. Gastrointestinal symptom intensity (bloating, fullness, nausea, belching, epigastric burning, cramps and pain) was rated during IGP measurements on a 100 mm VAS. Blood samples were collected during IGP measurements in fasted and fed state to assess glucagon-like peptide 1 (GLP-1) levels. Data were analysed using linear mixed models.

Results: POCO had no significant effect on intragastric pressure in fasted ($p = 0.08$) or fed state (infusion of 350 mL or until full satiation) ($p = 0.98$ and $p = 0.12$ respectively). Further, no significant differences in nutrient volume tolerance and gastric emptying rate were observed between POCO and placebo ($p = 0.55$ and $p = 0.39$, respectively). However, in the fasted state, hunger levels were higher and satiation levels were lower following POCO administration compared to placebo (average change in hunger after POCO: 11.73, average change in hunger after placebo: -7.74, average change in satiation after POCO: -11.13, average change in satiation after placebo: 3.98, $p < 0.001$ for both). In the fed state, hunger and satiation scores did not differ between placebo and POCO ($p > 0.66$ for all). In addition, gastrointestinal symptoms were not affected by POCO administration ($p > 0.23$ for all). No significant differences were found in active GLP-1 levels between POCO and placebo ($p = 0.29$).

Conclusion: An acute dose of POCO did not affect gastric function in healthy subjects, but increased hunger ratings in the fasting state. The effects of POCO on gastric function and hunger sensations in patients with functional gastrointestinal disorders, as well as their contribution to symptom improvement, needs to be elucidated in future studies.

P1868 DIETARY FODMAPS CAN LEAD TO MICROBIAL PRODUCTION OF GLYCATION AGENTS, INCREASING MUCOSAL MASTOCYTES AND IMPACTING COLONIC MUCUS BARRIER FUNCTION

J.B.J. Kamphuis, S. Yvon, V. Tondereau, H. Eutamène, V. Theodorou
INRA TOXALIM UMR 1331, Neurogastroenterology & Nutrition, Toulouse, France

Contact E-Mail Address: jbj.kamphuis@gmail.com

Introduction: Irritable Bowel Syndrome (IBS) is characterized by abdominal pain, often associated with diet. Limiting the consumption of FODMAPs (fermentable oligos-, di-, mono-saccharides, and polyols), unabsorbed in the small intestine and fermented by the gut microbiota, improves symptoms in 70% of IBS patients. However, the mechanisms behind this effect remain unclear. Our hypothesis is that bacterial metabolites resulting from fermentation of FODMAPs, such as aldehydes (glycation agents), can cause symptoms via the formation of advanced glycation end-products (AGEs). A low-grade inflammation caused by AGE-RAGE interaction, supported by mast cell activation, could also have negative effects on the epithelial barrier function. Mast cells can induce mucin release from goblet cells in immobilization stress in rats. Alternatively, FOS supplementation in rats can impair cecal epithelial mucus barrier function, and inulin supplementation to rats after weaning modifies mucin gene expression, colonic crypt depth and goblet cell numbers. In humans, IBS patients often report passage of mucus *per rectum*. We used a mouse model to investigate whether an increased intake of dietary FODMAPs is implicated in mucus barrier particularities, to study the mechanisms of effect of a low-FODMAP diet.

Aims and Methods: Three groups of mice (C57BL/6 ♂) were treated daily for 21 days with an oral gavage of saline or saline solution containing 5 mg of lactose and/or 5 mg of anti-glycation agent pyridoxamine for lactose experiments, additionally, three groups of mice (C57BL/6 ♂) followed diets for 21 days; control (AIN-93M), 10% FOS (AIN-93M; part of starch replaced by FOS), and 10% FOS + 1mg/ml pyridoxamine in drinking water. Mucosal mast cell (MMC) numbers were analysed by immunofluorescence. Goblet cell numbers in empty colon, and mucus barrier thickness in colon containing faeces in paraffin embedded colon were analysed by classical histology.

Results: Lactose and FOS treatments significantly ($P < 0.01$) increased the number of mucosal mast cells in both groups (Lactose: 0.74 v 0.54 mast cell/crypt; FOS: 1.27 vs 0.67 mast cells/crypt), which was prevented by co-administration with pyridoxamine. Mucus production indicated by emptying goblet cells was increased significantly in both groups (Lactose: 1.71 v 1.08 active goblet cells/crypt; FOS: 1.89 v 1.01 active goblet cells/crypt), which was prevented by co-administration with pyridoxamine for lactose, and attenuated but not completely prevented for FOS. The mucus layer separating epithelium and colonic contents showed significantly ($P < 0.0001$) reduced thickness in FODMAP-treated groups (Lactose: 10.7μm v 18.4μm; FOS: 8.6μm v 16.0μm), which, again, was prevented by co-administration of anti-glycation agent pyridoxamine.

Conclusion: Our results show that increased FODMAP intake can induce an increase in the number of mucosal mast cells in mice, impacting the normal functioning of the colonic mucus barrier. The prevention of these effects by anti-glycation agent pyridoxamine implies a role of glycation processes in the origin of these effects. The aberrant production of mucus in empty colon in the absence of contents might explain the reduced formation of the faecal mucus layer. Given the similar results obtained with both FODMAP representatives, this work suggests a common mechanism responsible for the adverse effects observed, namely, the generation of glycation agents derived from FODMAP fermentation by the gut microbiota.

Introduction: Bladder pain syndrome/interstitial cystitis (BPS/IC) is a debilitating chronic, inflammatory disorder of the bladder and urinary tract characterized by variable degree of bladder pain, frequency and urinary urgency. BPS patients are often affected by several gastrointestinal symptoms, such as abdominal pain, dyspeptic symptoms, alternance of constipation and diarrhea, sometimes referring to IBS, GERD, food allergy or intolerance. Our patients' diet is influenced by lots of restrictions introduced by themselves in order to improve these symptoms. This study aimed to better understand how a weight control strategy can influence IBS/BPS patients' psychological state.

Aims and Methods: The study was conducted in the Multicentric Interstitial Cystitis Referral Center of the Catholic University in Rome, in a population of 37 female, aged 25–57, affected by BPS according to the "European Society for the Study of Interstitial Cystitis (ESSIC)" criteria plus IBS. Patients were categorized into two groups, a normal BMI group, between 19–24.9, and a pathological weight group, whom 14 female with BMI less than 18.9 and 23 patients with BMI more than 25. All subjects were asked to fill our Psycho-Gastroenterological Questionnaire (PGQ), which takes into account the following parameters: number of medical examinations due to gastrointestinal symptoms, sensation of pain scored the Visual Analogue Scale (EQ-VAS); form of the feces established with the Bristol Stool Chart (BSC); gastrointestinal symptoms assessed with the Gastrointestinal Symptoms Rating Scale (GSRS); anxiety with the State-trait anxiety inventory (STAI Y-1 and STAI Y-2); a self-perceived evaluation of psychological well-being expressed by the Psychological General Well-Being Index (PGWBI); levels of anxiety and depression with the Hospital Anxiety and Depression Scale (HADS); perceived Self-efficacy in the management of negative emotions and expression of positive emotions with General Self-Efficacy Scale (GSE); levels of resilience with the Connor-Davidson Resilience Scale (CD-RISC). Differences between the two groups were evaluated by Student's t test and considered significant for $p < 0.05$.

Results: Compared to pathologic BMI group, normal BMI group has a higher EQ-VAS score (45 ± 18 vs 35 ± 19) and a lower GSRS score (15 ± 7 vs 17 ± 6), but these differences were not statistically significant. On the other hand, scores of STAI Y-1 (47.5 ± 10.7 vs 58.5 ± 13.4, $p < 0.05$), STAI Y-2 (39.3 ± 10.6 vs 52.4 ± 10.1, $p < 0.05$), PGWBI (62.9 ± 15.8 vs 45.4 ± 18.7, $p < 0.05$), HADS (7.5 ± 3.8 vs 10.7 ± 5.3 for anxiety, 5.6 ± 2.5 vs 9.3 ± 3.6 for depression, $p < 0.05$), GSE (30.2 ± 3.5 vs 22 ± 9.3, $p < 0.05$); CD-RISC (71.1 ± 10.2 vs 55.7 ± 12.6, $p < 0.05$) are all significantly better among normal BMI group.

Conclusion: Our study demonstrate that weight control can strongly improve IBS/BPS patients' QoL. Further studies about the most fitting diet for patients with such gastrointestinal distress are required.

P1870 NO EVIDENCE FOR INCREASED RISK FOR CANDIDAEMIA IN THE PRESENCE OF POLYMORPHISMS IN THE CD58, LCE4A-CLORF68 AND TAGAP LOCI IN HOME PARENTERAL NUTRITION PATIENTS

Y. Wouters, H. Roelofs, G. Wanten
Radboudumc, Gastroenterology and Hepatology, Nijmegen, Netherlands

Contact E-Mail Address: yannick.wouters@radboudumc.nl

Introduction: Home parenteral nutrition (HPN) patients have an increased risk of catheter-related bloodstream infections, including candidaemia. In a large hospital cohort, three single-nucleotide polymorphisms (SNPs) in CD58, LCE4A-Clorf68 and TAGAP loci have recently been associated with an increased risk for candidaemia.[1]

Aims and Methods: We hypothesized that HPN patients with one or more SNPs have an increased risk for candidaemia. We analyzed blood samples of adult HPN patients who started HPN between 1976 and 2017 at our referral center for intestinal failure (IF). Patient characteristics were retrospectively collected, such as sex, age at start HPN, pathological mechanism of intestinal failure, diabetes, and the time on HPN. A Poisson regression analysis was performed to correct for confounders. Primary outcome was the risk for candidaemia of patients with and without a SNP in CD58, LCE4A-Clorf68 or TAGAP loci.

Results: In total, 342 patients were included in the analysis. The median follow-up time was 3.6 years (IQR 1.5–7.2). In 41 (12%) patients, at least one episode of candidaemia (range 1–6) occurred. When comparing candidaemia-positive and -negative patients, 0 (0%) and 7 (2.3%) had a SNP in the CD58 locus, 1 (2.4%) and 7 (2.3%) in the LCE4A-Clorf68 locus, and 1 (2.4%) and 4 (1.3%) in the TAGAP locus, respectively. There was no increased risk for candidaemia for any of these three SNPs (rate ratio, 0.65; 95%CI, 0.08–5.51; $P = 0.70$).

Conclusion: In this study, known SNPs in CD58, LCE4A-Clorf68 or TAGAP loci were not associated with an increased risk for candidaemia in HPN patients. An explanation for these results may be that having a venous access device itself is a more predominant risk-factor than a genetic predisposition for candidaemia.

Disclosure: Nothing to disclose

Introduction: Collagen synthesis is essential in wound healing processes for conferring strength. We designed a large-animal experimental model to investigate the strength of wound healing and collagen deposition at the site of intestinal anastomosis following administration of a formula diet, which contains HMB, arginine and glutamine.

Aims and Methods: Pigs ($n = 6$) were laparotomized under general anesthesia and the small intestines were divided at 3 sites in each pig. End-to-end anastomosis was performed by continuous suture. The pigs were divided into 2 groups: one fed the experimental formula (EX group) and the other not fed the experimental formula (control group). In the EX group, normal diet mixed with the formula (HMB 1500 mg/day, arginine 1700 mg/day, glutamine 1700 mg/day) was fed from the day after the operation. At one week after the anastomosis, relaparotomy was performed and the operated small intestine was extirpated. Then, the anastomotic segments were evaluated by the burst test (BT), tension strength test (TST) and pathologic examination.

Results: All of the pigs survived without loss of appetite and weight until they were sacrificed for evaluation. The BT was 49.4 ± 12.2 mmHg in the EX group and 35.9 ± 13.1 mmHg in the control group. The TST at the first sign of rupture was 6.07 ± 1.43 N in the EX group and 4.07 ± 1.70 N in the control group. The TST at complete division was 10.2 ± 2.07 N in the EX group and 7.54 ± 1.71 N in the control group. The amount of collagen deposition was 4627 ± 1368 N in the EX group and 2834 ± 1099 N in the control group. The TST and amount of collagen deposition in the EX group were significantly larger than the corresponding values in the control group ($P < 0.05$).

Conclusion: The formula diet may promote wound healing by stimulating collagen deposition at sites of intestinal anastomosis site and thereby strengthen the anastomoses.

Introduction: Decreased concentration of TGF-β in inflammatory bowel disease (IBD) leads to worsening of digestive system inflammation. Nutritional support with a polymeric diet rich in TGF- β (Modulen IBD) has been used as the first line treatment for pediatric Crohn's Disease. However, there are few studies concerning the effect of this kind of diet in adults

Aims and Methods: The aim of this study was to present our initial experience on the use of Modulen IBD and to evaluate nutritionnal status of patients with IBD four weeks after receiving it.

A prospective descriptive study conducted in the department of hepato-gastro-enterology of our university hospital, including 15 patients who received Modulen IBD as a supplementation oral diet 50 g per day diluted in 210ml of water for 4 weeks. Patients continued to be on their regular conservative treatment. Different anthropometric parameters and serum estimations including CRP, albumin, creatinine and folic acid were measured at the beginning and 4 weeks later. Activity of the disease was assessed by the use of Harvey Bradshaw's score (CD) and mayo clinic's score (UC). For statistical analysis a paired t-test was used. Results were considered significant if P was less than 0.05.

Results: A total of 15 patients were included. The average age was 35.9 years [23–61] with a male predominance of 60%. 13.3% of Patients were followed for ulcerative colitis (UC) type pancolitis, 13.3% patients for indeterminate colitis (IC) and 73.3% patients for Crohn's disease (CD) with a predominance of ileo-caecal involvement in 63.6%, 81.8% of patients received a combotherapy by anti -TNF (Infliximab in 66.6%, Adalimumab in 33.3%) and a immunosuppressant (MTX in 55.5%, Azathioprine in 22.2%, 6-Mercaptopurine in 22.2%) and 26.6% of patients had an ileo-caecal resection. Anthropometric parameters measured at baseline and 4 weeks after receiving Modulen IBD were significantly improved: Weight 54.38 ± 13.09 vs 56.46 ± 13.28 (p.0.001), BMI 18.62 ± 3.96 vs 19.46 ± 4.09 (P.0.01), mid-arm circumference 23.22 ± 3.53 vs 23.68 ± 3.57 (P.0.024). The Crohn's disease activity score was significantly improved 2.1 ± 1.28 vs 1.1 ± 1.19 (P.0.02). The biological assessment showed a significant decrease in CRP 17.3 ± 11.1 vs 5.2 ± 4.2 (P.0.005), and a increase rate of albumin 35.6 ± 7.6 vs 38.5 ± 6.3 (P.0.003) with a significant improvement of Nutritional Risk Index (NRI) 90.26 ± 14.6 vs 93.86 ± 14.9 (P.0.042). There was no significant improvement in rate of creatinine 7.1 ± 1.3 vs 7.7 ± 1.8 (P.0.12) and folic acid 5.2 ± 2.6vs 5.6 ± 2, 8 (P.0.32). minor symptoms (nausea and diarrhea) were reported in one case. Otherwise the food was well tolerated by all patients.

Conclusion: Polymeric diet rich in TGF- β could be a wise tool not only to improve nutritional status of patients with IBD especially Crohn's disease but also to contribute of obtaining a longer clinical remission and thus a better quality of life.

P1873 AGE, ALBUMIN AND C-REACTIVE PROTEIN ARE USEFUL PREDICTORS OF 30-DAY MORTALITY IN PERCUTAENOUS ENDOSCOPIC GASTROSTOMY TUBE INSERTION

C. Lane[1], A. Corp[1], V. Subramanian[2], H. Rafferty[1]

[2]*Leeds Teaching Hospitals NHS Trust Dept. of Gastroenterology St. James University Hospital, Dept. of Molecular Gastroenterology, Leeds, United Kingdom*

Contact E-Mail Address: carllane@gmail.com

Introduction: Percutaneous endoscopic gastrostomy (PEG) tube insertion is an accepted method for providing medium to long-term enteral nutrition. There is significant morbidity and mortality associated with PEG tube insertion with a variable 30-day mortality. Multiple risk factors have been suggested to identify poorer outcomes. Age and albumin have been independently associated with 30-day mortality with the Sheffield Gastrostomy Score (SGS) being devised to help estimate 30-day mortality[1]. Low albumin and elevated C-reactive protein (CRP) have been shown to be associated with high short-term mortality[2].

Aims and Methods: We aimed to identify risk factors associated with 30-day mortality in our cohort, to compare our outcomes with the SGS, and to establish whether a composite of CRP and SGS is useful if stratifying risk.

A retrospective cohort study of all PEG tube insertions between 2007–2014 was conducted. Data was collected for patient age, sex, indication, albumin and CRP. This was analysed to identify statistically significant predictors for 30-day mortality. 30-day mortality in our cohort was compared to the SGS, including the effect of adding CRP to the score.

Results: 900 patients had a PEG inserted (median age 67, 516 males). The main indications were stroke (42%), progressive neurological disorder (24.2%) and neurosurgical conditions (10.7%). 692 (77%) cases were available for full analysis after exclusion of incomplete data or albumin/CRP levels obtained over 7 days prior to PEG insertion. 30-day mortality was comparable to the Sheffield cohorts (70/692 vs 51/403, $p = 0.2$ [reference cohort]; vs 24/153, $p = 0.56$ [internal cohort]; vs 81/616, $p = 0.13$ [external cohort]). Univariate analysis predictors of 30-day mortality were increasing age, decreasing albumin and increasing CRP. PEG insertion by indication was not associated with 30-day mortality (all $p > 0.05$). Age ($p = 0.029$) and albumin ($p = 0.031$) remained independently associated with 30-day mortality after multivariate analysis. Application of the SGS revealed no significant difference in 30-day mortality between our cohort to the rate predicted

($p > 0.05$). For each increasing SGS gradation mortality rose, with 2.3% scoring zero compared to 40% scoring three. Albumin < 30 with CRP ≥10 was significantly associated with increased 30-day mortality (OR 3.25, 95% CI 1.68–6.33, $p < 0.001$). When CRP ≥10 was given a score of one and incorporated into the SGS, analysis of survival by using the log rank test still showed significantly reduced survival with increasing score ($p = 0.001$).

Conclusion: Overall 30-day mortality was similar in our cohort to other studies. PEG insertion by indication had no significant effect on 30-day mortality, but age and albumin remained independently significant. The SGS showed good predictive ability in our external cohort. Addition of CRP may be a useful predictor of 30-day mortality in combination with albumin or SGS.

Introduction: Exclusive Enteral Nutrition (EEN) induces clinical remission in ~70% of children and adolescents with active Crohn's disease (CD), and is comparable to steroids

Aims and Methods: We aimed to evaluate the impact of EEN in adults with active CD.

Patients with active CD referred for nutritional intervention in a tertiary inflammatory bowel disease (IBD) center, were enrolled. Baseline weight and nutritional needs were recorded. EEN recommended for induction of remission by an IBD nutritionist was administered by oral polymeric formula with no other food items allowed. Patients were treated for at least three weeks. Physician's Global assessment (PGA), Harvey Bradshaw Index (HBI), biomarkers (blood count, C-reactive protein [CRP], and albumin), weight, and body mass index (BMI) were recorded at baseline and at the end of the EEN course.

Results: A total of 37/50 patients (74%) with active CD completed a full EEN course. Sixteen patients (32%) had newly diagnosed CD (<1.5 years); male/female 31/19; mean age: 33.2 ± 9.9 years; median disease duration 10.4 ± 9.8 years (range 0–36 years). Montreal classification: L1–17 (34%), L2- 4 (8%), L3 -29 (58%); B1-22 (43%), B2 -16 (32%), B3 -7 (14%); P- 11 (22%). Disease severity by PGA at baseline was: 9-mild, 28-moderate, 13-severe disease. Mean EEN duration was 5.4 weeks (range 3–16). Significant improvement in activity indices was observed after EEN: HBI 7.17 ± 4.7 vs 2.46 ± 2.7 ($p < 0.001$); median CRP 4.4 ± 5.2 (IQR 1.23–5.5) mg/dl vs 1.01 ± 1.4 (IQR 0.39–1.01) mg/dl ($p < 0.001$); mean albumin 3.78 ± 0.6 mg/l vs 4.24 ± 0.45 mg/l ($p = 0.002$) WBC 9.73 ± 4.07 vs 7.9 ± 3.07 ($p = 0.047$). There was no change in weight or BMI during EEN course.

Patients with long-standing CD ($n = 25$) also experienced significant improvement in activity indices after EEN: HBI decreased from 5.64 ± 5.1 to 2.89 ± 3.24 ($p < 0.001$); CRP from 4.43 ± 5.51 (IQR 1.28–5.63) mg/dl to 1.06 ± 1.45 (IQR 0.5–1.2) mg/dl ($p = 0.004$), and albumin increased from 3.75 ± 0.54 to 4.28 ± 0.37 ($p = 0.004$). A trend for improvement in disease activity was apparent also in the 20 patients who received EEN as an *add- on* therapy to stable doses of their baseline therapy: HBI decreased from 7.54 ± 5.5 to 2.56 ± 3.0 ($p < 0.001$) and CRP decreased from 4.44 ± 6 (IQR 1.07–5.35) mg/dl to 0.96 ± 1.4 (IQR 0.45–0.64) mg/dl ($p = 0.009$). Albumin increased from 3.72 ± 0.68 to 4.1 ± 0.43 ($p = 0.021$), and hemoglobin increased from 12.6 ± 2.0 gr/dl to 13.4 ± 1.4 gr/dl ($p = 0.033$).

Conclusion: EEN is an effective nutritional intervention in adults with active CD. EEN is associated with decreased clinical and biologic inflammatory activity, and may be beneficial in patients with newly diagnosed, as well as long-standing CD. EEN may may be a bridge or an *add-on* induction treatment in patients who flare on stable treatments.

Introduction: Subjects with learning disability (LD) have a high incidence of aspiration pneumonia and respiratory mortality. This contributes to the high incidence of chronic lung disease[1] and disproportionately high mortality from respiratory conditions[2] in this cohort. Subjects with LD sometimes undergo Percutaneous Endoscopic Gastrostomy (PEG) insertion to reduce aspiration, usually as part of a multifactorial indication including the need for nutritional support. However, subjects who receive nutrition through a PEG are still at risk of aspiration of their feed[3]. There is no current evidence describing the outcomes from PEG insertion in subjects with LD with respect to respiratory tract infections.

Aims and Methods: The aim of this study is to examine subjects with LD who undergo PEG placement, for subsequent respiratory tract infections and mortality in The Health Improvement Network (THIN) primary care database. The Health Improvement Network (THIN) represents a group of General Practices (primary care) covering 6% of the UK population, which is representative of the UK population structure. The present study is a retrospective, population-based cohort study of subjects with learning disability undergoing PEG placement within this dataset. Subjects undergoing PEG placement with LD were sought using Read codes previously developed by an expert panel. Subjects were segregated by those with coded lower respiratory tract infection including specific aspiration pneumonia codes within 1 year prior to PEG placement (exposed) and those without (unexposed). The rate of respiratory tract infections in the year prior to and the year following PEG placement were assessed in the exposed and unexposed cohort. Incidence rates were calculated for respiratory tract infections and mortality, at any time point following PEG placement for both populations. A multivariable logistic regression model was constructed for factors associated with LRTI up to 1 year after of PEG placement. Covariates included age, gender, deprivation, Charlson score category (0 or 1+) epilepsy and exposure group.

Results: 214 subjects with LD had a PEG inserted. 53.7% were male and the median age was 27.6(IQR 19.6–38.6) years. 73.0% and 27.0% had Charlson comorbidity scores of 0, and 1+ respectively. 27.1%(58/214) of this population met the criteria to be included in the exposed cohort. The rate of LRTI in the year following PEG was 22.4% when corrected for length of follow-up. 37.9%(22/58) exposed and 11.5%(18/156) unexposed subjects developed LRTI less than 1 year after PEG($p < 0.001$). In logistic regression analysis female gender (OR 0.41(95%CI:0.18–0.95), $p = 0.038$) and the exposed cohort (4.6(2.1–10.1), $p < 0.001$) were associated with LRTI within 1 year of PEG placement.

27.1%(58/214) subjects died whilst under follow-up. Incidence rate of death was 80 and 45 per 1000 person year for exposed and unexposed subjects respectively (IRR 1.76(1.00–3.11), $p = 0.047$).

Conclusion: In this study of LD subjects, no significant reduction in LRTI incidence was seen following PEG placement compared to the year before. Mortality was also higher in subjects with at least 1 LRTI in the year prior to PEG placement compared to the unexposed cohort. In light of these findings, a careful risk-benefit assessment must be made in potential PEG candidates with a particular focus on the intended benefit of PEG insertion.

Introduction: Patients with chronic intestinal failure (CIF) often develop cholestatic liver injury (*viz*. intestinal failure-associated liver disease, IFALD) which

may lead to liver failure, and need for organ transplantation. The aim of this study was i) to investigate whether citrulline (CIT), an enterocyte function marker, and the enterokine FGF19 were associated with chronic cholestasis (CC) and survival, and ii) to develop and validate a risk score to predict 5-year survival of CIF patients.

Aims and Methods: This is a cohort study of 135 consecutive adult CIF patients on intravenous supplementation (IVS) (> 3 months). Plasma CIT and FGF19 were assessed. CC and survival were studied by univariable and multivariable logistic regressions and Cox modeling, respectively. A predictive risk score was developed, C-statistics were calculated and validated internally

Results: Patients (mean age 50 years, 100 females) with CC (n = 23, 17%) had a poor 5-year survival (38% vs 62% P = 0.009). Terminal ileum resection (OR 3.3, P = 0.02), (remnant) small bowel length (P = 0.02), low FGF19 levels (≤107 pg/mL) (OR 3.9, P = 0.03) and low CIT levels (≤20 μM) (OR 4.7, P = 0.003) independently predicted CC. In multivariable analysis, low CIT (OR 6.0, P = 0.002) and low FGF19 levels (OR 3.8, P = 0.049) were significantly associated with CC after adjustment for gender (OR 6.6, P = 0.021). Patients with low CIT levels or low FGF19 levels had a poor 5-year survival (20% vs 69%, P < 0.001), (54% vs 66%, P = 0.060), respectively. Independent predictors of overall survival were frequency of HPN infusions per week (HR 1.2, P = 0.097), low CIT levels (HR 3.2, P < 0.001) and low FGF19 levels (HR 2.6, P = 0.056). These three variables were incorporated in a risk model, Model for End-Stage Intestinal Failure (MESIF), using the estimates of the regression coefficients in the multivariable analysis. The C-statistic was 0.79 (95% CI 0.65 to 0.92) and 0.76 after internal validation. The 5-year survival rates for patients with a MESIF score ranging from 0 to 20, 20 to 40 and above 40 were 80%, 58% and 14%, respectively.

Conclusion: The MESIF score is associated with long-term survival of CIF patients. The MESIF score might be useful to identify CIF patients who need closer clinical monitoring or early consultation at transplantation centres. Further external validation and confirmation is required.
