Results: Were included in the first group of IBD 28 patients vs. 15 in the second group of controls. The middle age was 46 years vs. 48 years in the second group. The sex ratio [H/F] was 1.33 vs. 1.14. The IBD group were divided in 15 cases of Crohn disease and 13 cases of Ulcerative colitis (UC) disease. The activity of the disease was variable from minimal to severe. Proteolytic activity was greater in patients vs. healthy controls (294.3 U/ml vs. 22.9U/ml, $p < 0.05$). Particularly high activity has been observed in the severe forms of both UC and Crohn's disease. We found a significant decrease in protease activity in the presence of both inhibitors: PMSF (1mM) (294.3 ml/l vs 63.60 U/ml $p < 0.01$) and SBTI (1mM) (294.3 U/ml vs 79.6 U/ml $p < 0.05$). Using the serpin ES (14 μg/μml) non-significant decrease in the proteolytic activity was found (294.3U/ml vs 242.2 U/ml, $p > 0.05$). In reverse zymography only one band was found in the first group vs. three bands in the healthy groups.
Conclusion: Our study demonstrated a higher proteolytic activity of fecal water in IBD group comparing to healthy people and this activity was concordant to the severity of the thrust. Serine inhibitors were able to decrease the proteolysis. Thus, majority were serine proteases. The lower concentration of serpin ES may explain the lesser inhibition. Finally, in IBD patients there is a natural deficiency in serpins therefore an imbalance in the homeostasis can be suggested as hypothesis to the pathophysiology of the IBD disease. Restoring this balance proteases-inhibitors can lead to new therapeutic perspectives especially by manipulating the microbiota using genetically modified probiotics.

P0589 FREQUENCY OF SERONEGATIVE VILLOUS ATROPHY IN FUNCTION OF THE DEFINITION USED: DIAGNOSTIC UTILITY OF TRANSGLUTAMINASE DEPOSITS AND GAMMADELTA+ CELL COUNTING

B Arau[1], E Tristán[1], C Ferrer[2], R Garcia-Puig[3], A Carrasco[4], L Ruiz Campos[1], P Ruiz[1], M Esteve[1,5], F Fernández-Bañares[1,5]

Introduction: Seronegative villous atrophy (SNVA) can be caused by coeliac or non-coeliac causes. Despite several international consensus on coeliac disease (CD), there is no agreement on how to approach the diagnosis of subjects with SNVA.
Aims and Methods: Evaluate 1) The diagnostic accuracy for CD of different tTG cut-offs with or without EmA and 2) The frequency of SNVA of coeliac cause in our geographical area.
Between April 2010 and November 2017 all consecutive patients with villous atrophy (VA) were prospectively registered. Coeliac serology (tTG and EmA), tTG subepithelial deposits, and gammadelta+ intraepithelial cells (by flow cytometry) were measured. CD was diagnosed based on the Catassi criteria (rule 4 of 5). Three definitions of positive serology were used: 1. Definition based on NICE guidelines: tTG> 8 U/ml (recommended by the manufacturer: Elia Celikey, Phadia) *plus* EmA+ for titres of tTG between 8 and 20 U/ml; 2. Given that >98% of the individuals in the general population of our health area have serum tTG < 2 U/mL, titres of tTG between 2 and 8 U/mL with EmA+ were considered positive; 3. tTG+ >2 U/mL (even with negative EmA). For each cut-off definition, sensitivity (S) and specificity (E) for the diagnosis of CD were calculated.
Results: 238 VA were diagnosed (225 CD, 13 non-CD) (age, 18±1.2 years, limits 0 to 84, 70% women). 24 of the 225 (11%) patients with CD presented serum tTG < 8 U/ml or between 8 and 20 U/ml with negative EmA (< 17 years, 5% *vs.* ≥17 years, 21%; $p < 0.001$). All had positive tTG deposits (19/24) or gammadelta+ cells (22/24) and clinical response to a gluten-free diet, confirming the diagnosis of CD. Using the NICE definition as a cut-off point, 37/238 patients had SNVA (24 CD, 13 non-CD) (S, 89%; E, 100%). Considering also as tTG+ titres between 2–8 U/mL with EmA+, 26/238 had SNVA (13 CD, 13 non-CD) (S, 94%; E, 100%) (S, $p < 0.001$ vs. NICE). Finally, considering tTG+ >2 U/mL, 17/238 had SNVA (5 CD and 12 non-CD) (S, 98%; E, 92%) (S, $p < 0.001$ vs. NICE).
Conclusion: CD is the most frequent cause of SNVA in our area. Based on the definition of negative serology used, the frequency of seronegative CD varies from 2 to 11%. Both the tTG deposits and the gammadelta+ cells analysed by flow cytometry are complementary diagnostic tools of great value in these patients. The serum tTG cut-off in clinical practice should be reconsidered.

Introduction: Recently, we have described a diagnosis scoring system (Score 'Coeliac-lite') that allows diagnosing the forms of coeliac disease (CD) without atrophy. The Score is based on the assessment of the intraepithelial lymphocyte count, the gammadelta+ cell count, coeliac serology, and HLA-DQ2.5/8 (UEG 2017), and has a good accuracy to predict GFD response (AUC, 0.83). The ESPGHAN 2012 CD diagnostic criteria support the use of tTG mucosal deposits in doubtful cases.
Aims and Methods: To assess whether the determination of tTG deposits in the duodenal mucosa can improve the diagnostic accuracy of the Score 'coeliac-lite'. 119 patients with symptoms of the CD spectrum without villous atrophy were included (age, 39.6±1.5 years; 71% women), who were treated with a gluten-free diet (GFD) based on positive serology and/or compatible histology (lymphocytic enteritis) and/or a positive coeliac genetics and/or CD IEL cytometry pattern. In all of them, the Score coeliac-lite (cut-off ≥10) and the presence of subepithelial tTG IgA deposits (confocal immunofluorescence) were analysed. 28 patients (15%) with inconclusive results of the tTG deposits assay were excluded. Response to GFD was defined as clinical *plus* histological (or serological when positive) remission. The diagnosis of CD was based on the rule of '4 of 5' by Catassi. The relationship between presence of deposits and Score positivity and GFD response was analysed using a binary logistic regression analysis.
Results: The response to a GFD was 86% in patients with a Score≥10 and 29% for a Score<10 ($p < 0.001$). The tTG deposits were positive in 55% of patients, being more frequently positive in patients with a Score≥10 ([<10], 38%; [10–16], 74%; [≥17], 87.5%; $p < 0.001$). There was a non-significant trend to a higher response rate to GFD in patients with a Score≥10 and positive tTG deposits (Score<10: tTG+ 23% vs. tTG- 33%, $p = 0.39$; and Score≥10, tTG+, 91% vs. tTG- 67%, $p = 0.06$). This trend was likely due to that tTG deposits were positive in 87% of patients with positive serology (serum tTG >2 U/mL in 30% of patients, being those with a Score ≥17). The logistic regression analysis showed that only the Score 'coeliac-lite' (OR, 14; $p < 0.001$) had an independent predictive value for GFD response (tTG deposits: OR, 1.08, $p = 0.9$).
Conclusion: The assay technique of tTG deposits was inconclusive in 15% of the patients, which limits its routine use. As well, a positive result does not seem to provide important additional information with respect to the Score 'coeliac-lite'.

P0591 COELIAC DISEASE IN SELECTIVE IGA DEFICIENCY. SAME PATHOLOGY, DIFFERENT APPROACH TO DIAGNOSIS AND SURVEILLANCE

S Farrais, **D Fresneda**, J Blas, A Romero, L Blas, S Rodríguez, A Varela, J Porres, J Martínez-Becerra
Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain

Contact E-Mail Address: diana.fresneda.cuesta@gmail.com
Introduction: Selective IgA deficiency (sIgAd) is the most common primary humoral immunodeficiency in the Caucasian population.
Patients with sIgAd have a 10- to 20-fold increased risk of developing coeliac disease (CD), especially silent forms.
CD in patients with sIgAd must be tested with Immunoglobulin G (IgG) antibodies (Ab).
There is a paucity of literature on this topic and international clinical guidelines do not establish which Ab, IgG tissue transglutaminase (tTG) or IgG deaminated gliadin peptide (DGP), should be used for the screening and surveillance of sIgAd-CD patients.
Aims and Methods: The 3 main objectives of our study were to identify which IgG-Ab in sIgAd-CD patients should be preferably chosen for the screening, to study their clearance once a gluten free diet (GFD) has been established and to show if a correlation does exist between Ab levels and villous atrophy grading. For this purpose, individuals tested in order to dismiss CD between December 2012 and December 2017, were revised retrospectively.
All sIgAd patients with positive results for one or more IgG-Ab were included. A group of CD patients without sIgAd with same characteristics as those above were randomly selected as a control group.
Results: 29 patients were included. 26/29 CD (17/26 group A: CD newly-diagnosed. 9/26 group B: CD follow-up). 3/29 had isolated IgG DGP and were not CD (false positive). In group A at diagnosis 25% were IgG DGP negative (false negative). The totality of confirmed CD (26/26) had IgG tTG and IgG endomysial positive. It was observed that the more severe the atrophy was, the higher the Ab levels were. After 5 months, (±3) of GFD, no reduction of IgG tTG was proved. However, among controls, IgA tTG showed 60% reduction by this time. In GFD-adherent at long-term follow-up (26 months) IgG tTG remained positive in >70% despite villous recovery.
Conclusion: Our results suggest the importance of a screening strategy based on IgG tTG in sIgAd patients.
This study demonstrates the lower rate of Ab clearance with the long-term persistent Ab in spite of GFD.
In line with EPSGHAN recommendations, levels associated to villous atrophy are assay-dependant also among sIgAd-CD patients.

P0593 PREDICTIVITY OF AUTOIMMUNE STIGMATA FOR GLUTEN SENSITIVITY IN SUBJECTS WITH MICROSCOPIC ENTERITIS: A RETROSPECTIVE STUDY

G Losurdo, M Principi, A Giangaspero, A Iannone, A Amoruso, M Barone, E Ierardi, A Di Leo
University of Bari, Emergency and Organ Transplantation, Bari, Italy

Contact E-Mail Address: giuseppelos@alice.it

Introduction: Non celiac gluten sensitivity (NCGS) is an emerging gluten-related disorder most likely characterized by a selective involvement of innate immune system. Some reports suggested a possible association with other autoimmune diseases. We aimed to investigate whether the presence of autoimmune stigmata in a group of patients with both clinical suspicion of NCGS and histological picture of microscopic enteritis could be predictive factors of NCGS.

Aims and Methods: Patients with microscopic enteritis were followed up by means of periodical laboratory and clinical examinations. At baseline, we collected data about previous clinical history, including existence of autoimmune diseases, and patients were tested for autoantibody assay. NCGS was diagnosed according to Salerno criteria, while other causes of microscopic enteritis were diagnosed according to well-established protocols. Patients with celiac disease were excluded from the final analysis. Student's t and chi-square test were applied in univariate analysis for continuous and binary variables, respectively. Kaplan-Meier curves were drawn and Cox regression was used to estimate hazard ratios (HR).

Results: 63 patients were included in our final analysis. 22 had a final diagnosis of NCGS, while the remaining 41 had non gluten-related causes of microscopic enteritis (irritable bowel syndrome was found in 34). The prevalence of autoimmune thyroiditis was higher among NCGS (40.1%) than in other microscopic enteritis (14.6%, $p = 0.03$). Furthermore, we found in NCGS a higher positivity rate for IgG anti-gliadin antibodies (AGA) (27.3% versus 2.5%, $p = 0.006$) and anti-nucleus autoantibodies (ANA) (45.4% versus 12.2%, $p = 0.005$). Autoimmune thyroiditis was associated to an increased risk of NCGS diagnosis (HR = 2.4), but with a not significant trend ($p = 0.06$). Both ANA (HR = 2.4, $p = 0.04$) and AGA (HR = 2.7, $p = 0.04$) were directly associated to NCGS diagnosis.

Conclusion: NCGS may have a cohort of autoimmune stigmata that can precede its diagnosis and may have a predictive value.

Introduction: Patients with coeliac disease commonly report symptoms of 'brain fog'. The mechanisms are poorly understood, but disease-related cognitive deficits and psychological problems have been suggested.

Aims and Methods: The aim of the study was to register self-reported symptoms of inattention and concentration impairment in coeliac disease before and after treatment with gluten-free diet, compared to a healthy control group.

Patients with newly diagnosed coeliac disease were included consecutively from 2 out-patient clinics (Oslo University Hospital and Lovisenberg Diaconal Hospital). The patients completed the questionnaires Adult ADHD Self-Report Scale v1.1 Symptoms Checklist (ASRS) and Hospital Anxiety and Depression Scale (HADS) prior to start of a gluten-free diet and after at least 12 months on the diet. Health care personnel at Oslo University Hospital served as healthy controls.

Results: A total of 33 newly diagnosed coeliac patients (median age 38, range 19–72, 24 women, 9 men) were included in the study. Of these, 27 patients met for follow up after minimum 12 months and repeated the questionnaires. 60 healthy controls (median age 45, range 24–69, 41 women, 19 men) completed the same questionnaires.

Coeliac patients had significantly higher scores than healthy controls on ASRS (median 27.0, IQR 20.0–35.5 vs. median 22.5, IQR 19.0–26.0, $p = 0.007$) and HADS (median 8.0, IQR 5.0–13.0 vs. median 5.0, IQR 2.0–8.0, $p = 0.0008$). After minimum 12 months on a gluten-free diet, coeliac patients improved their results on both ASRS (median 23.0, IQR 17.0–28.0, $p = 0{,}013$) and HADS (median 6.0, IQR 2.0–10.0, $p = 0{,}003$). There was no difference between coeliac patients on a gluten-free diet and healthy controls.

Conclusion: Coeliac patients reported significantly more symptoms than healthy controls on ASRS and HADS. The difference in regard to healthy controls disappeared after introduction of a gluten-free diet.

Introduction: Small bowel capsule endoscopy (SBCE) has a useful role in detecting macroscopic changes and identifying complications of coeliac disease (CD).

Aims and Methods: In this study, we aimed to identify the relationship between clinical parameters to SBCE findings in patients with CD in comparison to a control group.

Patients with a history of histology confirmed CD (Marsh 3 grade) who underwent a SBCE were included in this study. A group of age matched patients undergoing SBCE for other indications were selected as a control group. Demographic data, clinical symptoms, serology and SBCE findings were collected.

Results: 86 patients (mean age 53.8 years; SD±14.8) with CD who underwent a SBCE were included. These were compared to 85 healthy, age (52.8 years; SD±1.17; $p = 0.630$) and gender-matched controls with a normal SBCE. Indications for SBCE in the CD group included: anaemia (16.3%), ongoing clinical symptoms (100%). Indications for controls included: anaemia (3.5%), gastrointestinal symptoms (100%), raised faecal calprotectin (17.6%).

Patients with CD had a mean duration of disease of 9.75 years SD±14.4. Histology at time of SBCE was Marsh: 0 (16.0%), 1 (12.0%), 2 (2.0%), 3a (24.0%), 3b (18.0%), 3c (28.0%). Areas of small bowel (SB) affected on SBCE were: proximal (55.8%), mid SB (1.2%), distal (3.5%), diffuse (4.7%), proximal and mid SB (5.8%), proximal and distal SB (1.2%). 14% of patients had a normal SBCE.

There was a significant correlation between small bowel transit (SBT) and length of abnormal SB ($p = 0.004$) in patients with CD. There was a significant longer SBT in CD patients than in controls (271.1 SD±13.1 vs 220 SD±97.6 minutes, $p = 0.006$).

There was a significant correlation between anti-gliadin IgA ($p = 0.001$), anti-gliadin IgG ($p = 0.0001$) and SBT and anti-gliadin IgA ($p = 0.038$), anti-gliadin IgG ($p = 0.001$) and length of abnormal SB. There was a significant correlation between anti-gliadin IgG and percentage of SB affected ($p = 0.017$).

There was no significance in mean SBT ($p = 0.462$), length of abnormal SB ($p = 0.194$) and percentage of affected SB ($p = 0.285$) across Marsh classifications. Those with scalloping on SBCE were more likely to be of Marsh 3B (30.0%) and 3C (45.0%) ($p = 0.020$). Patients with villous blunting were also more likely to be of Marsh 3B (28.6%) and 3C (57.1%) ($p = 0.013$).

There was no significance in SBT, abnormal length and percentage SB affected across presenting symptoms.

Conclusion: SBCE findings in CD correlate with serology (anti-gliadin IgA, anti-gliadin IgG). We have shown that SBT correlates with length of abnormal SB, thus confirming that SBT is affected by abnormal SB. This is the first study confirming a longer SBT in CD patients by SBCE.

Disclosure: Nothing to disclose

P0596 WHAT IS THE ROLE OF CAPSULE ENDOSCOPY IN EVALUATING PATIENTS WITH REFRACTORY COELIAC DISEASE?

S Chetcuti Zammit[1], D.S Sanders[2], R Sidhu[1]
[1]*Royal Hallamshire Hospital, Gastroenterology, Sheffield, United Kingdom*
[2]*Royal Hallamshire Hospital - NHS Trust, Royal Hallamshire Hospital; Sheffield/GB, Gastroenterology, Sheffield, United Kingdom*

Contact E-Mail Address: stf_che@yahoo.com

Introduction: Small bowel capsule endoscopy (SBCE) is used in refractory coeliac disease (RCD) to assess the extent of disease and ensure there are no complications (lymphoma or ulcerative jejunitis). However there are no published reports on SBCE in RCD following immunosuppressive therapy.

Aims and Methods: Patients with histologically confirmed refractory coeliac disease (RCD) who underwent a SBCE at baseline and after treatment were enrolled in this study. These were compared to a group of control CD patients with no underlying RCD.

Results: 19 patients (median 53 years) with RCD (12 patients; 63.2% - type 1) were compared to 28 patients with control CD (median 48 years). There was no statistically significant difference in duration of disease, gender, age at SBCE and serology between the 2 groups.

Patients with RCD were more likely to have worse histology (Marsh 3a-c) than SBCE control CD who had a higher percentage of normal histology at the time of SBCE ($p = 0.002$) Those with RCD had a longer abnormal small bowel (SB) mucosa (185 SD±167.6 vs 29.5 SD±73 minutes $p = 0.0001$) and longer percentage of abnormal SB (53.9 SD±38.0 vs 6.9 SD±15.2 minutes $p = 0.0001$) when compared to those with control CD.

A repeat SBCE was carried out after a mean of 9.63 SD±6.6 months in patients with RCD following treatment. There was no statistical significant difference in histology and serology at the time of the first and second SBCE. Patients received the following treatment: 36.8% steroids, 26.3% immunosuppressants, 36.1% combination of mycophenolate / azathioprine and steroids. However, there was an improvement in the length of abnormal SB mucosa (185 vs 116 minutes; $p = 0.035$) and the percentage of abnormal SB (50.8 vs 32.9%; $p = 0.027$). 7 patients (36.8%) had diffuse mucosal involvement on the first SBCE but only 4 (21.1%) had diffuse disease on repeat SBCE ($p = 0.007$). There was no statistical correlation between coeliac serology and small bowel passage time, length of mucosal abnormality and percentage of affected SB at first and second SBCE. The same findings were also true for histology.

Conclusion: More severe SB involvement on SBCE can be found in patients with RCD. This is the first study that shows an improvement in SB abnormality on SBCE following treatment of RCD patients. Histology is useful in distinguishing RCD from non-RCD but not for assessing improvement in patients with RCD following treatment. SBCE might potentially be regarded as a less invasive, more accurate way of following up these patients.

[3]*Hospital Universitario San Pedro de Alcántara, Department of Inmunology, Cáceres, Spain*

Contact E-Mail Address: xavi_molina@hotmail.com
Introduction: Ultrashort celiac disease (USCD) is a novel CD subtype limited to the duodenal bulb (D1), with recently conflicting frequency rates (0.1% to 10%). Compared to conventional CD (CCD), a mild clinic and histologic phenotype with minimal laboratory abnormalities has been reported. However, we currently lack data on flow cytometry findings in these patients.
Aims and Methods: Unicenter prospective study conducted from February 2015 to February 2018, including patients with a new diagnosis of CD. A systematic biopsy protocol (separate biopsies for flow cytometry and histologic study from D1 (1–2) and D2 (2–4)) was performed in all patients undergoing duodenal biopsies to rule out CD. CD diagnosis was defined by Catassi and Fasano criteria plus compatible duodenal flow cytometry (CD103+ > 90, TCR gammadelta > 16, and NK-CD3 < 8), either in D1 or both D1+D2. Baseline characteristics were compared between CCD and USCD patients.
Results: A total of 66 patients (54% pediatric) with a new diagnosis of CD were included, of whom 7 (10%) showed USCD. No significant differences were observed between CCD and USCD regarding demographic, clinic, laboratory or CD serology parameters. Of note, 71% of USCD showed intermittent positive CD serology titres within a 5-yr period before diagnosis, and CD had been previously ruled out in 54% of them by means of normal D2 biopsies. Marsh I-II lesions on D1 histology were significantly higher in USCD compares to CCD patients (60 % vs. 15%, p 0.04). As for flow cytometry, no relevant differences in D1 were observed regarding IELs or TCR gammadelta between groups, whereas typical NK-CD3 count was significantly less diminished in USCD patients (CCD 1.2 ± 0.9 vs. USCD 7.57 ± 5.52, $p < 0.001$).
Conclusion: Up to 10% of pediatric and adult CD patients in our series showed USCD. No villous atrophy was documented in up to 57% of patients with USCD and flow cytometry was instrumental for an adequate diagnosis. A immunophenotype with a minimal decrease in NK-CD3 cells, mimicking that of CD patients on a gluten-free diet, was observed in USCD patients.
Disclosure: Nothing to disclose

Introduction: Peripheral T-cell lymphomas (PTCL) are considered orphan diseases and develop in the setting of chronic inflammation as celiac disease (CD). A small proportion of CD patients develops refractory celiac disease (RCD), associated with an increased risk of enteropathy associated T cell lymphoma (EATL), In this context our group has focused on EATL in CD patients with the aim to profile microRNA contents in CD, RCD and EATL patients to obtain molecular biomarkers useful to classify and stratify CD patients according to their 'neoplastic risk'.
Aims and Methods: Clinical series were composed by 7 RCD, 24 EATL, 10 AITL, 10 ALCL, 21 PTCL-NOS. EATL and lymphocytic infiltrate of RCD II (RCD-TIL), were obtained by Laser MicroDissection (LMD6000, Leica) from FFPE blocks. The expression profile of 301 miRNA was determined using TaqMan Array Microfluidic Cards (Thermo Fisher Scientific). Statistical analysis was performed using BRBArray Tools, GenePattern and R Software Packages.
Results: Our data show that miRNA profiling distinguished EATLs from other PTCLs. Specifically, EATL are characterized by a subset of miRNAs significantly up-or down-modulated compared to PTCLs. When RCD patients were considered in the analysis, our data showed that RCD II TILs are more similar to EATLs than to other PTCLs (by PCA analysis). Therefore these results suggest that unique miRNA signatures are conserved by RCD and EATL. On the other hand, our results show that specific oncosuppressor miRNA families are lost in EATL compared to RCD patients, such as the miR-200, let-7 and miR-192-215 families.
Conclusion: These data suggest that the identification of such signatures could trace the evolution of the inflammatory response of CD into a carcinogenetic process. The availability of accurate biomarkers could implement surveillance and early EATL diagnosis. CD patients' stratification according to their neoplastic risk could address follow-up and screening program, pursuing a 'personalized medicine' approach for CD patients.

Introduction: Primary gastrointestinal follicular lymphomas (PGFL) represent a rare entity whose clinical characteristics, management and prognosis after a long term follow-up, have not been well described.
Aims and Methods: Our aim was to prospectively analyse the clinical, biological, endoscopic and pathological features, as well as treatment outcome, of a series of consecutive patients with PGFL. All adult patients with PGFL, consecutively enrolled into the multicenter French national study between 1990 and 2014, were evaluated and followed up prospectively. Diagnosis was based on histomorphological criteria according to the WHO classification (confirmed by a reference pathologist). Follow-up comprised at least annual clinical, biological and endoscopic evaluation for all patients.
Results: Among 27 patients with PGFL included in the study, there were 13 men and 14 women, median age at diagnosis was 61 years (extremes: 33–79). The median follow-up was 88 months (6–190). The most frequent circumstances of diagnosis were fortuitous diagnosis (n = 11), followed by abdominal pain (n = 6), rectal bleeding (n = 5), and dyspepsia (n = 4). The duodenum was the most common site of involvement (n = 13) and multifocal localizations were observed in 7 patients (26%). Endoscopic aspect was the most frequently micronodular or polyposis type or mixture of both. Surveillance was the most frequently adopted attitude (low tumour mass) (n = 18, 66%), followed by chemotherapy (n = 7, 26%). The overall 5-year survival rate was 93%. Out of 16 patients receiving only surveillance, 6 (22%) reached a spontaneous complete remission. On the other hand, in 3 patients a transformation into high-grade lymphoma was observed. Moreover, in 3 patients secondary tumours were observed.
Conclusion: This study is the biggest series of PGFL including clinical and endoscopic results with a long term follow-up, published so far. It shows that PGFL are frequently fortuitously diagnosed by gastroenterologist during endoscopy, most frequently localized in the duodenum, and usually of an indolent course and good prognosis. However, in rare cases, their transformation into more aggressive high-grade lymphoma may be observed. An appropriate characterization and follow-up of these lymphomas is mandatory.

P0600 NEUROENDOCRINE TUMORS OF THE GASTROINTESTINAL TRACT ARISING IN INFLAMMATORY BOWEL DISEASES: MORE THAN A COINCIDENCE?

S Rizza[1], G Canavese[2], D Ribaldone[1], P Cassoni[2], M Astegiano[1], L Venezia[1], P Cortegoso Valdivia[1], C.G De Angelis[1]

Introduction: The risk to develop gastro-intestinal malignancies is higher in patients affected by inflammatory bowel diseases (IBD). Apart from colorectal cancer, associated with grade and duration of the active inflammation, there is a growing evidence of neuroendocrine tumors (NETs) development in these patients and a correlation between these two diseases has been postulated. Enteroendocrine cells seem to be involved in the innate immune system machinery that is damaged in IBD: studies performed in IBD patients and experimental murine models proved that subtypes of interleukin-17 and Toll-like receptors (TLR) are expressed in neuroendocrine cells. In addition, defects of density, differentiation and hormonal production in enteroendocrine cells have been described in an experimental study and microcarcinoids have been detected in up to 10% of patients affected by long standing ulcerative colitis.
Aims and Methods: We report a series of 5 NETs developed in 4 IBD-affected patients. Histological parameters and immunophenotype of the neoplastic lesions were reviewed by an expert pathologist. The neoplastic lesion immunophenotype was assessed using A-chromogranin (CgA), synaptophysin (Syn), serotonin and somatostatin receptor type 2A (SSTR2A).
Results: We evaluated 4 patients (3 M, 1 F), aged between 32 and 63 years, affected by Crohn's disease (3 cases) and ulcerative colitis (1 case) with a diagnosis of gastro-intestinal NET. In 3 cases diagnosis was incidental after surgery for severe IBD relapse (1 was located in the appendix, 2 in the ileum), whereas in 1 case NET was discovered in the duodenum during an endoscopic examination. 4 G1 (ki67 < 3%, well differentiated, WHO 2017) NETs and a mixed epithelial - neuroendocrine tumor (MANEC) were detected in the resection specimens of the

four cases (Table 1). In 3 cases active IBD was found in specimens, with focal, slight increase of neuroendocrine cells, but no evidence of nodular hyperplasia. None of our patients showed evidence of loco-regional or at distance metastatic disease and no one experienced neoplastic relapse over the years of follow-up.
Conclusion: Although it was suggested that well recognized modulators of inflammatory response in IBD, such as interleukins, could modify the growth and functions of neuroendocrine cells, our results did not confirm these data, at least from a quantitative standpoint. In 3 of our cases, in fact, only a moderate increase of endocrine cells with no evidence of pre-neoplastic lesions was detected in the bowel mucosa with active disease, suggesting that IBD-induced inflammatory response may not be able to activate, via local or systemic signals, the carcinogenetic pathways of neuroendocrine lesions. NETs were incidentally diagnosed during surgery in 3 of the 4 cases. Considering that these lesions are often undetectable at endoscopy because of the submucosal - parietal location, a follow up including more specific imaging tests, such as Computed Tomography/ Magnetic Resonance Imaging (CT/MRI) and endoscopic ultrasonography (EUS), could improve early detection of these neoplasms. Larger studies are needed to confirm this hypothesis.
Disclosure: Nothing to disclose

Introduction: Primary small intestinal lymphoma usually has a good prognosis, and is treated with chemotherapy alone. However, some patients with primary small intestinal lymphoma need surgery because of strictures before or after chemotherapy. Endoscopic balloon dilation (EBD) is a safe alternative in some patients with benign small intestinal strictures. However, there is no evidence of the efficacy or safety of EBD for small intestinal strictures secondary to primary small intestinal lymphoma. We retrospectively analyzed the clinical features of primary small intestinal lymphoma in patients treated with EBD to evaluate its efficacy and safety.
Aims and Methods: A total of 2081 patients underwent double-balloon enteroscopy (DBE) from April 2005 to January 2017 at Jichi Medical University Hospital. Five consecutive patients with small intestinal strictures secondary to primary small intestinal lymphoma treated with DBE-assisted EBD (four males, mean age 61±7.8 years) were retrospectively reviewed.
Results: All patients had a single stricture causing obstruction. Three of the five strictures formed before chemotherapy, including two follicular lymphomas and one marginal zone lymphoma, which were localized lesions, corresponding to Lugano classification stage I-II1. 2 of the 5 strictures occurred post-treatment, and included 1 follicular lymphoma and 1 diffuse large B-cell lymphoma, which were advanced lesions corresponding to Lugano classification stage IV. A total of 13 DBE-assisted EBD were performed for these 5 strictures. The diameter at the first dilation was limited to 10mm or less to avoid perforation before remission, and then gradually increased up to the largest possible size (12–18mm) to facilitate long-term patency. 4 of the 5 strictures required multiple DBE-assisted EBDs (2 lesions: 2 EBDs, 2 lesions: 4 EBDs). The median follow-up after the final DBE-assisted EBD was 22 months (9–94 months). 1 patient developed bowel obstruction during follow-up, due to adhesions (no recurrent stenosis). No adverse events associated with DBE-assisted EBD were observed.
Conclusion: DBE-assisted EBD provides favorable short-term outcomes in patients with small intestinal strictures secondary to primary small intestinal lymphoma. DBE-assisted EBD for the strictures associated with primary small intestinal lymphoma has the potential to be a safe and effective treatment to avoid surgery.
Disclosure: Hironori Yamamoto has patents for double-balloon endoscopy produced by Fujifilm Corporation. He also has a consultant relationship with the Fujifilm Corporation and has received honoraria, grants, and royalties from the company. Introduction: Small intestine GIST is regarded as roughly 20% of GIST on the whole, and while endoscopy is spreading and diagnostic opportunities are increasing. However, its clinical features are still unclear.
Aims and Methods: To clarify the clinical features of small intestinal GIST cases diagnosed by double balloon endoscopy (DBE), 32 consecutive cases, who were diagnosed as GIST from June 2003 until March 2018, were enrolled in this study. The clinical characteristics such as, sex, age, examination motive, endoscopic diagnosis, and other examination methods were analyzed, and the usefulness of biopsy diagnosis was evaluated retrospectively. Furthermore, the overall survival rate was also elucidated as a single-centre cohort study.
Results: There are 17 males and 15 females. Average age is 66 ± 14 (30–83) years old. Number of lesions is 27 cases (84.4%) with single occurrences and 5 cases with repeated occurrences.
Lesion sites is 4 cases of deep duodenum, 25 cases of jejunum and 3 cases of ileum.
Motives for examination is 27 cases of Gastrointestinal bleeding (16 cases of black feces, 7 cases of anemia, 4 cases of bloody stools), 2 cases of abdominal pain, 2 cases found while following up on other diseases, 1 case of positive PET scan.
Abdominal CTs were performed before DBE in 28 cases, and 4 cases (14.3%) of those unable to identify lesions via CT scan, but 2 of those 4 cases were identified via capsule endoscopy, and the remaining 2 cases identified only through DBE. On the other hand, in 3 cases (9.4%) where lesions were identified beforehand in the CT scan, the lesions could not be rendered in the DBE, but in 1 case where the scope could not be inserted into the lesion site, the lesion site was able to be identified through contrast radiography. Capsule endoscopy was performed in 15 cases, with 4 cases (26.7%) failing to identify the lesion, but in all 4 cases it was possible to identify the lesion via DBE. In 20 (69.0%) of the 29 cases where lesions were able to be observed via endoscopy, endoscopic observation revealed accompanying apex ulceration.
DBE biopsy diagnosis was performed in 18 (56.3%) cases, 12 (66.7%) of which histological diagnosis was possible. Post-biopsy bleeding was observed in 6 cases (33.3%). The overall 1-, 3-, and 5-year survival rates were 96.2% (95% CI, 89.0% to 100%), 96.2% (95% CI, 89.0% to 100%), and 77.5% (95% CI, 59.6% to 100%).
Conclusion: With small intestine GIST, there are rare cases where CT scan and capsule endoscopy are unable to identify lesions, and especially when bleeding is in doubt, it is suggested that balloon-assisted endoscopy should be performed with the possibility of GIST in mind. The diagnostic rate of biopsy by DBE cannot be said to be sufficient, and with a high frequency of post-biopsy bleeding, it goes without saying that safety can also be regarded as insufficient. In cases where biopsy diagnosis is commensurate with the risk of bleeding and diagnosis by endoscopic imaging is difficult, we think that this should be performed with caution.

P0603 TUMOUR DETECTION RATES AT CAPSULE ENDOSCOPY PERFORMED FOR THE INVESTIGATION OF IRON DEFICIENCY ANAEMIA

B Cooper, H Martin, M Macedo, M McStay
Colchester University Hospital, Gastroenterology, Colchester, United Kingdom

Contact E-Mail Address: benjamin.cooper@doctors.org.uk

Introduction: Iron deficiency anaemia (IDA) is a common problem seen by gastroenterologists and a key aim in its investigation is the diagnosis or exclusion of malignancy. Currently the BSG guidelines only suggest small bowel imaging if there is an inadequate response to iron therapy post non-diagnostic upper and lower gastrointestinal endoscopy1.
Aims and Methods: The aim of this study was to review the role of capsule endoscopy (CE) in the investigation of IDA, with a focus on the detection of neoplasms. All CEs were undertaken over a 5-year period at a medium sized district general hospital for recurrent IDA or obscure GI bleeding (208 of a total of 471) were reviewed. The results were divided into neoplastic findings, clinically significant but non neoplastic findings and insignificant or normal findings. For those cases that detected a potential neoplasm, electronic records were reviewed to ascertain the final diagnosis.
Results: 208 CEs were reviewed. The patients had an age range of 19 to 91 years with a median age of 68. 115 of the patients were women and 98 men. Of these 208, 10 (4.8%) were found to have a potential neoplasm, 148 (71.2%) were found to have clinically significant but non neoplastic findings, 50 (24%) were found to have insignificant or normal findings. Of the 10 that were found to have a suspected neoplasm; 1 was a tumour in the third part of the duodenum, 3 were Gastro Intestinal Stromal Tumours (GIST), 1 was a neurofibroma, 1 was a small bowel lymphoma, 1 an ileal neuroendocrine tumour, 1 was a caecal tumour and 2 had non-malignant findings (duplication cyst and small bowel Crohn's disease). The mean age of those with malignancy was 68 versus 64 in those without malignancy. The mean haemoglobin of those with malignancy was 79. Of the other significant pathology detected; Angioectasia was the primary diagnosis in

114 (54%), small bowel Crohns in 14 (6.7%), NSAID enteropathy in 11 (5.2%) and miscellaneous causes in 7 (3.4%). This series has a detection rate of 3.4% (7 out of 208) for neoplasia. The tumour detection rate of 3.4% in our series of 208 IDA patients with a mean age of 68 is compared with a rate 4.5% from a series of 220 IDA patients with a mean age of 40.5. 2

Conclusion: In our series the diagnostic yield of CE for IDA is 76.0%. 3.4% were diagnosed with malignancy. Patients with malignancy were older than those without. While small bowel tumours are rare, our experience suggests that they are more common than previous data suggests. CE is a beneficial tool in the investigation of IDA with negative bi-directional endoscopies, particularly in the investigation for malignancy

Introduction: Small bowel carcinomas (SBC) are rare neoplasms, often associated with poor prognosis and limited therapeutic challenges. Several predisposing conditions for SBC development are known, including immune-mediated intestinal disorders, such as coeliac disease (CD) and Crohn's disease (CrD). CD-associated SBC (CD-SBC) harbor much more frequently microsatellite instability (MSI) in comparison with both CrD-associated SBC (CrD-SBC) and sporadic SBC (spo-SBC).[1] In colorectal and gastric cancers MSI is associated with expression of programmed cell death ligand-1 (PD-L1),[2,3] a crucial immune checkpoint aimed at inhibiting and escaping immune system response, thus leading to responsiveness to PD-L1/programmed cell death protein-1 (PD-1) pathway blockade treatment.[4]

Aims and Methods: Aim of this study was to investigate PD-L1 expression in a large cohort of non-familiar SBC, either or not associated with CD or CrD, and correlated it with MSI status. We assessed PD-L1 by immunohistochemistry (clone E1L3N, Cell Signaling) in a total of 82 non-familial SBC, i.e. 32 CrD-SBC, 23 CD-SBC and 27 spo-SBC. We correlated PD-L1 expression with MSI, which was evaluated using a pentaplex panel of monomorphic mononucleotide repeats.

Results: PD-L1 positivity (>5% of tumour or immune cells) was seen in 22 (27%) cases, including 8 CrD-SBC (25%, 3 MSI and 3 non-MSI cases), 8 CD-SBC (35%, 7 MSI and one non-MSI) and 6 spo-SBC (22%, 3 MSI and 3 non-MSI). In all positive cases, PD-L1 was essentially expressed on stromal immune cells, which were predominantly macrophages restricted to the tumour invasive margin, while PD-L1 reactivity on tumour cells was found only in two, both MSI cases, i.e. one CrD-SBC (tumour cell membrane) and one CD-SBC (tumour cell cytoplasm). The frequency of PD-L1 expression did not differ significantly among the 3 groups. PD-L1 positivity was more frequently observed in MSI SBC (13/27, 48%) in comparison with non-MSI SBC (9/55,16%). The association between PD-L1 immunoreactivity and MSI status was statistically significant ($p = 0.0035$). The single CrD-SBC case with PD-L1-positive tumour cells had a lymphoepithelioma-like morphology and was positive for Epstein-Barr virus latent phase markers.

Conclusion: Our study showed an association between PD-L1 immunoreactivity and MSI status, similar to that reported in colorectal and gastric cancers. Interestingly, an Epstein-Barr virus positive case of CrD-SBC also expressed PD-L1 on tumour cells. These findings could be relevant in selecting patients affected by SBC in whom therapeutic PD-1/PD-L1 inhibition could be beneficial.

Introduction: The diversity of microbes living within us, a large proportion of which reside within our gut, has been increasingly appreciated. Recent evidence suggests that the gut microbiota (GM) plays a role in energy harvest, storage, and expenditure. E.g. GM transplantation from obese to germ-free mice had been shown to induce obesity [1]. The purpose of the present study was to evaluate the differences between GM composition in lean and obese subjects.

Aims and Methods: The study included untreated subjects aged 25 to 76 years carefully selected through exclusion of chronic diseases by means of clinical and laboratory evaluation, abdominal US, ECG, treadmill test, ECHOCG.

Microbiota composition was studied by sequencing of the V3-V4 variable regions of the 16S rRNA gene according to recommended protocol of 16S metagenomic sequencing Library Preparation. Diet - by quantitative assessment. Statistical analysis was performed using the R3.1.0., generalized linear models (FDR, age, and sex adjusted).
Results: 104 participants were included (38 men). BMI obesity (O) was determined in 26%, abdominal obesity (AO) in 55%. O and AO were associated with high abundance of gram-negative opportunistic genera Serratia (FDR 0.003; 0.004) and Prevotella (FDR < 0.001; < 0.001). Low Oscillospira abundance was strongly correlated with AO (FDR < 0.001). This genus is a 'central enigmatic component' of the gut microbiome, which reduce inflammation and associated with leanness and high physical activity level. The average caloric intake was 2156±545 kcal. Average daily intake of carbohydrates 210±91g; proteins 79±20 g; fat 107±32g. Bifidobacterium (FDR 0.008) representation was increased and Serratia decreased (FDR 0.008) in those who consumed more starch. High fat consumption was associated with high Serratia (FDR 0.014) and low Oscillospira (FDR 0.004) abundance. Thus, high representation of opportunistic bacteria was associated with O and AO. In addition, the bacteria were more presented among those who consumed smaller amounts of starch, and beneficial bacteria abundance was lower in those who consumed a lot of fat.
Conclusion: We concede that GM composition is strongly associated with obesity and GM modification by diet may be a relevant therapeutic avenue for obesity.

Introduction: Obesity is a major public health issue; it may have different impacts depending on its grade. Indeed, grade I/II obese subjects seem to be protected from irritable bowel syndrome (IBS) while IBS prevalence is increased by a factor of six in morbid obesity patients than to the general population.
Aims and Methods: The aim of the present study was to evaluate the response of obese mice to a stress model, the water avoidance stress (WAS), which is frequently used to study the pathophysiology of IBS.
Male C57Bl/6 mice fed a high fat diet (60% kcal as Fat; HFD) or not (standard diet; SD) for 12 weeks (W12). At W12, WAS (1h/day for 10 consecutive days) was performed (SD-WAS and HFD-WAS, $n = 15$) or not (SD-CC and HFD-CC, $n = 15$). Body composition was assessed by EchoMRI (at W0, W12 and after WAS). The intestinal permeability was evaluated *in vivo* by oral gavage with FITC-dextran. Colonic permeability was assessed *ex vivo* by using Ussing chambers. Expression of tight junction proteins and plasma corticosterone were evaluated by westernblot and ELISA, respectively.
Results: HFD mice had a higher body weight than SD mice, related to increased fat mass without altering lean mass. In response to WAS, only HFD mice lost weight. A strong increase in plasma corticosterone was observed among HFD-WAS mice compared to SD-CC and SD-WAS mice. HFD-WAS mice also showed an increase in intestinal permeability compared with the other groups. There was a positive correlation between intestinal permeability and corticosterone levels ($r = 0.51$, $p = 0.021$). Finally, *in vivo* colonic permeability was increased in SD-WAS, HFD-CC and HFD-WAS groups compared with SD-CC group but in more pronounced manner in HFD-CC and HFD-WAS groups. Occludin expression was reduced in SD-WAS, HFD-CC and HFD-WAS compared with SD-CC.
Conclusion: High-fat diet obesity modifies the response to stress in mice with an increased sensitivity and enhanced intestinal permeability. The involved mechanisms and the impact on the functional bowel disorders remain to be determined.

P0607 OVERNIGHT OR MORNING ONLY SPLIT DOSING WITH 1 L POLYETHYLENE GLYCOL NER1006 CAN DELIVER 92% OR HIGHER RATES OF SUCCESSFUL OVERALL COLON CLEANSING IN NORMAL WEIGHT AND OBESE PATIENTS

B Amlani[1], **J Halonen**[1], L Clayton[2]
[1]*Norgine Ltd, Medical Affairs, Harefield, United Kingdom*
[2]*Norgine Ltd, Clinical Development, Harefield, United Kingdom*

Contact E-Mail Address: jhalonen@norgine.com
Introduction: Adequate bowel cleansing is essential for effective colonoscopy, but may be hard to achieve in overweight or obese patients.[1] The ESGE minimum performance standard rate for adequate colon cleansing success is 90%, a measure which includes overweight or obese patients.[2] NER1006 is a novel 1 L polyethylene glycol (PEG)-based bowel preparation. It was evaluated in the two phase 3, randomized, treatment-blinded central reader-assessed trials MORA[3] and NOCT.[4] This post hoc analysis of MORA and NOCT assessed the cleansing efficacy of 2 split dosing regimens of NER1006 in patients according to body mass index ranges (BMI).
Aims and Methods: Patients aged 18–85 years were randomized to receive a split-dosing regimen of either evening/morning (PM/AM) NER1006, or same day morning only (AM/AM) NER1006. Overnight split dosing started at ~6:00 pm (± 2 h) with dose 2 at ~6:00 am (± 2 h). Morning only dosing started at ~5:00 am (± 2 h) with dose 2 at ~7:00 am (± 2 h). The percentage of patients with overall bowel cleansing success (Harefield Cleansing Scale (HCS) grades A and B) was analysed for normal weight patients (BMI 18.5–24.9), overweight patients (BMI 25.0–29.9) and obese patients (BMI ≥30.0), respectively. Data were analysed using the modified full analysis set 2 (mFAS2) population, which comprised all patients who received at least 1 dose of study drug and who had documented primary endpoint data from a central reader.
Results: The mFAS2 population had 787 patients. Data from 776 (227 normal weight, 310 overweight, 239 obese) were included in the analysis (Table 1). 11 patients were excluded for missing or low (< 18.5) BMI data (insufficient sample sizes). Among normal weight and obese patients, both dosing regimens NER1006 PM/AM and NER1006 AM/AM attained overall cleansing success rates of 92% or higher. For overweight patients, NER1006 PM/AM attained overall cleansing success rates of 90–98%.
Conclusion: Overnight or morning only split dosing with NER1006 delivered overall HCS cleansing success (e.g. adequate level cleansing) in at least 92% of normal weight or obese patients and for overweight patients, NER1006 overnight split dosing was successful in 90–98%. NER1006 therefore meets the ESGE minimum performance standard for colon cleansing in these weight groups.

P0608 DUODENO-JEJUNAL BYPASS LINER FOR THE TREATMENT OF DIABETES MELLITUS IN OBESE PATIENTS: COMPLETENESS OF DUODENAL BLINDING AS THE KEY FACTOR FOR EFFICACY

M Benes, P Drastich, T Hucl, J Spicak
Institute of Clinical And Experimental Medicine, Hepatology and Gastroenterology, Prague, Czech Republic

Introduction: The global increase in obesity incidence results in an increase of type 2 diabetes mellitus (T2DM). Surgical treatment has proven to be effective, however it carries a high risk of complications. The duodenal-jejunal bypass liner (EndoBarrier®, GI Dynamics, EB) is an endoscopic implant that mimics the intestinal bypass portion of the Roux-en-Y Gastric Bypass. It results in weight loss and improvements in glucose control in obese patients with T2 diabetes mellitus (T2DM).

Aims and Methods: This is a analysis of a prospective, controlled, multicentre study aimed to identify factors associated with an outcome of EB for T2DM. Seventy subjects (45 with an implant, 25 controls) were included in the study. The groups were comparable with respect to age, gender, BMI (mean 41.7 vs. 39.5 kg/m2), T2DM duration (7.8 vs. 8.3 years), HbA1c level (88 vs 86 mmol/mol) and T2DM treatment. In the EB group, all devices were successfully implanted. Only 6 devices had to be explanted prior to the end of the 10 months study period (bleeding, dislocation and need for ERCP because of choledocholithiasis). At 10 months there was significantly greater weight loss and %EWL (19% vs. 7% and 43 vs. 12) and significantly improved long term compensation of T2DM marker HbA1c (decreased by 25 vs. 10 mmol/mol) in the EB group. T2DM medicinal treatment could be reduced in more device subjects than controls. There was no serious adverse event. Deepness of anchor ingrow, lower initial BMI and lower body height were identified as positive factors for efficacy of EB for T2DM compensation.

Conclusion: The EB is safe when implanted for 10 months, and results in significant weight loss and HbA1c reduction. Deepness of anchor ingrow, lower initial BMI and lower body height could be positive factors for efficacy.

Introduction: Obesity is an important public health problem that has reached epidemic proportions in the world. The placement of intragastric balloon (IGB) is nowadays widely accepted as a main endoscopic procedure to lose weight. Other than the endoscopist, the dietician is the only professional considered essential in the multidisciplinary team for IGB patient management. He is considered to play an important educational role just before and after the endoscopic procedure, but his real role during the follow up when IGB is in site has not been investigated. The aim of this study is to evaluate the impact of dietician support and behavioural therapy in patients treated with IGB while the device is in site.

Aims and Methods: We retrospectively reviewed records of 170 obese patients subjected to IGB treatment in Gastroenterology Unit, University Hospital of Udine, Italy, from 2003 to 2015. Their epidemiological characteristics were also evaluated. Patients were treated with nonadjustable fluid-filled (700 ml average filling, mean residence time 204±23 days) IGB. During the follow-up patients were interviewed regarding their diet and calories intake and a weight check-up was conducted in order to calculate % total body weight loss (%TBW) and Δ Body Mass Index (ΔBMI). According to our protocol, during the frame of IGB in site, patients were invited to undergo a dietician check-up (DC) every 1.5 months accompanied by cognitive behavioural therapy in order to obtain a behaviour-change intervention. According to their adherence to DCs, patients were grouped in not adhering (0 DC), partially adhering (1–2 DCs) and totally adhering ($\geq$ 3 DCs) to the protocol. A comparison was made among the three groups regarding %TBW and ΔBMI at 180±15 days during IGB in site. To compare quantitative variables the Kruskal-Wallis test was used.

Results: Among the 170 patients (58 males, 112 females, mean age 44±12 years) included in the study, mean initial weight was 123.6±27.7 kg and mean baseline BMI was 44±9 kg/m.^{2} Body weight data at 180±15 days during IGB in site, as well as adherence to DCs were available for 146 out of 170 patients. There was no difference between the patients adhering, partially adhering and not adhering to DCs regarding %TBW at 180±15 days ($p = 0.17$). However not adhering patients had a higher ΔBMI at 180±15 days in comparison to those adhering or partially adhering to CDs ($p = 0.03$). Mean pre-procedural weight and BMI were lower in patients who were treated with psychotropic drugs prior to IGB treatment ($p = 0.002$ and $p = 0.025$, respectively); however no difference was observed in %TBW and ΔBMI at 180±15 days during IGB in site ($p = 0.20$; $p = 0.51$). Mean pre-procedural BMI was higher in patients with obese first degree relatives ($p = 0.03$) and a significant difference was observed in relation to %TBW and ΔBMI at 180±15 days during IGB in site ($p = 0.03$; $p = 0.048$).

Conclusion: Dietician support accompanied by behavioural therapy seems not to be effective in lowering weight as an addition to the obesity treatment using IGB when the device is in site. Prospective studies including a greater number of subjects are needed in order to further enlighten this issue.

Introduction: Over the past decade, several studies have demonstrated that bariatric surgery (BS) is the gold standard for the treatment of morbid obesity and weight-related comorbidities and is far more effective than nonsurgical interventions. However, it permanently alters the gastrointestinal anatomy and might induce long-term deficiencies and absorption issues. Adherence to treatment recommendations such as multivitamins, iron tablets, Vitamin B and D supplementations is a crucial aspect in the management of patients submitted to bariatric surgery.

Aims and Methods: The aim of this study was to evaluate the adherence to treatment recommendations in a large population of obese patients submitted to BS using a new validated web-based instrument.

An anonymous web survey by a new validated questionnaire consisting of 23 items evaluating: a. Bariatric procedures performed; b. Individual reasons underlying BS; c. Lapse of time since last BS, d. the frequency of follow-up (FU) visits post BS, e. Perception of well-being post BS; f. Adherence to recommendations post BS; g. Changes in lifestyles, was launched through e-methods. Participants have been invited among patients who underwent BS from 1996 to 2016. A single surgeon (L. A). performed all procedures.

Results: We received an automatic notification of delivery from 1100 out of 1600 obese subjects and 290 (81.4 % female, mean age 39.5 ± 10.1) filled in the questionnaire. 59% underwent Sleeve gastrectomy (SG), 31 % Roux-enY- gastric Bypass (RYGB), 7.2 % adjustable gastric banding (AGB), 2.8% other procedures such as mini gastric-one anastomisis gastric bypass (MGB-OAGB) and duodenal switch (DS), 6.2% had a revisional procedure and only one underwent three bariatric operations. The time interval from surgical procedures was < 1 yrs in 20.9%, 1 to 3 yrs in 25.1%, 4 to 6 yrs in 29.6% and 7 to 10 yrs in 24.4 %. The last FU visit was < 1 yrs in 51%, < 2 yrs in 18 %, < 3 yrs in 6.9%, < 4 yrs in 5.9%, < 5 yrs in 4.5 % and > 5 yrs in 11.7% obese subjects. Only 31.4% adhere to treatment recommendations. The risk of non-adherence to treatment recommendations was around two times higher in malabsorptive (RYGB, DS, MGB-OAGB) than restrictive procedures (AGB and SG) and decreases with age and strict follow-up. (OR = 1.96, 95%CI: 1.256–3.058). It is also independent of sex, the time interval from BS and basal BMI. Moreover, 72% of subjects showed an improvement of their quality of life (QoL) due to a significantly stronger self-identity.

Conclusion: Adherence to treatment recommendations in our obese patients is low especially after malabsorbtive bariatric procedures possibly since in Italy, vitamin supplementation and micronutrient blood tests are not reimbursed by the national health insurance. Conversely, QoL strongly improved.

P0611 THE EFFECTS OF OAT β-GLUCAN CONSUMPTION AT BREAKFAST ON APPETITE AND FOOD INTAKE, AS WELL AS BLOOD GLUCOSE, PLASMA INSULIN AND PLASMA GLP-1 CONCENTRATIONS IN HEALTHY SUBJECTS

S.M.M Zaremba[1], I.F Gow[1], S Drummond[1], J.T McCluskey[1], R.E Steinert[2]
[1]*Queen Margaret University, Dietetics, Nutrition & Biological Sciences, Musselburgh, United Kingdom*
[2]*DSM Nutritional Products Ltd., R&D Human Nutrition and Health, Basel, Switzerland*

Contact E-Mail Address: szaremba@qmu.ac.uk

Introduction: High fibre consumption is associated with lower body weight (1), and improved postprandial glycemia (2). There is evidence that oat β-glucan lowers appetite and exerts an inhibitory effect on eating; however, not all studies are consistent and the underpinning mechanisms are not entirely understood.

Aims and Methods: We investigated the effects of 4 g high molecular weight (MW; 2.213 x10^6 g mol^{-1}) oat β-glucan on *ad libitum* eating, subjective appetite, glycaemia, insulinaemia and plasma GLP-1 responses in 33 normal-weight subjects (22 female/11 male, mean age (years): 26.9 ± 1.0, BMI (kg/m^2): 23.5 ± 0.4). The study followed a double-blind, cross-over design with subjects fed two different test breakfasts with and without oat β-glucan on two different days in random order, followed by an *ad libitum* test meal. Blood samples and ratings for subjective appetite were collected postprandially at regular time intervals. Viscosity of test meals were measured using a constant shear rheometer, Bohin Rheometer C-VOR 150 (Malvern Bohin Instruments) at a shear rate of 50 s^{-1}, representative of gastric conditions.

Results: Oat β-glucan increased feelings of fullness ($p = 0.046$) and satiety ($p = 0.021$), but did not affect energy intake or amount eaten at the *ad libitum* test meal. There was a treatment by time interaction for plasma GLP-1, plasma

insulin and blood glucose. GLP-1 was significantly reduced at 90 min ($p = 0.021$), blood glucose at 30 min ($p = 0.008$) and plasma insulin at 30 and 60 min ($p = 0.002$ and 0.017, respectively) following the oat β-glucan breakfast when compared with the control breakfast. Viscosity of test breakfast containing oat β-glucan was significantly greater compared to control ($p < 0.05$).
Conclusion: Four grams of high MW oat β-glucan lowers appetite but not *ad libitum* eating and beneficially modulates postprandial glycaemia and insulinaemia, however, it does not increase plasma GLP-1 secretion.
Disclosure: Robert. E. Steinert is an employee of DSM Nutritional Products, Basel, Switzerland.

P0612 VARIABILITY IN THE NIGHT PROFILE OF TOTAL GHRELIN IN OBESE PATIENTS WITH OBSTRUCTIVE SLEEP APNEA

P Pardak[1], **R Filip**[1], M Krzaczek[2], J Woliński[3]
[1]*Clinical Hospital No. 2, Clinical Department od Gastroenterology, Rzeszów, Poland*
[2]*ZOZ GASTROMED, Lublin, Poland*
[3]*The Kielanowski Institute of Animal Physiology & Nutrition, Polish Academy of Sciences, Jabłonna, Poland*

Contact E-Mail Address: r.s.filip@wp.pl

Introduction: Ghrelin is a hormone produced in the gastrointestinal tract. The main functions of ghrelin are the initiation of food intake and the stimulation of gastrointestinal motility. Obstructive sleep apnea is the most common sleep breathing disorder in which occurs repetitive upper airway obstruction causing fragmentation of sleep and decreasing sleep quality. The most important cause of sleep apnea is overweight. In the literature, we find reports that both inefficient sleep and obesity affect ghrelin but the results concerning their impact, especially on the night ghrelin profile, still require research[1,2].
Aims and Methods: Patients evaluated for sleep breathing disorders were divided into the study group with diagnosed obstructive sleep apnea and into control group. During sleep, blood samples were collected at 23, 1, 3, 5, 7. Total serum ghrelin was measured with a radioimmunoassay test, according to the manufacturer's instructions. Statistical analyses were performed to find correlations between total ghrelin levels and score in Epworth sleepiness scale and selected sleep parameters from polysomnography- apnea hypopnea index (AHI) and % snoring time during sleep were chosen. Moreover, the correlations between total ghrelin levels and parameters of obesity (BMI, abdominal circumference) were assessed.
Results: The study included 59 patients (49 men and 10 women), 46 patients were diagnosed with sleep apnea (OSA group). Most of the patients included in the study were overweight (20.3%) or obese (74.6%). After analysis of results in both groups, we observed a tendency towards lower ghrelin values in OSA group. However, only for values measured at 5 am this correlation was statistically significant, the trend in the other assays were close to statistical significance. There was no substantial relationship between ghrelin values and sleep parameters (AHI, % snoring time) and severity of daytime sleepiness (ESS). After analysis between obesity parameters and total ghrelin concentrations we found a statistically significant negative correlation between obesity parameters (stronger for BMI) and ghrelin levels in the first hours of sleep- at 23 and 1, while at 3 this correlation was close to statistical significance [Table 1]

	OSA group		Control		
Ghrelin	BMI	Waist circumference	BMI	Waist circumference	Both BMI
23:00	**−0.41(0.0050**)**	**−0.36 (0.0135*)**	0.32 (0.2799)	0.41 (0,1618)	**−0.31 (0.0185*)**
1:00	**−0.40(0.0069**)**	**−0.37 (0.0125*)**	0.21 (0.4936)	0.24 (0.4371)	**−0.30 (0.0203*)**
3:00	**−0.26 (0.0869)**	**−0.25 (0.0959)**	0.21 (0.4821)	0.22 (0.4706)	**−0.24 (0.0710)**
5:00	−0.21 (0.1739)	−0.21 (0.1707)	0.14 (0.6545)	0.23 (0.4481)	−0.21 (0.1219)
7:00	−0.21 (0.1637)	−0.23 (0.1371)	0.23 (0.4481)	0.28 (0.3538)	−0.18 (0.1749)
Mean	**−0.32 (0.0312*)**	**−0.28 (0.0561)**	0.26 (0.3839)	0.30 (0.3156)	**−0.26 (0.0485*)**

[Table 1. Correlation between obesity parameters and total ghrelin values.]
Conclusion: During sleep, in group with obstructive sleep apnea, we observed a trend towards lower total ghrelin values. There was no significant relationship between total ghrelin values and sleep parameters and severity of daytime sleepiness. We found a statistically significant, negative correlation between obesity parameters (stronger for BMI) and total ghrelin levels in the first hours of sleep. These results indicate that lower values of total ghrelin at night are probably not the effect of inefficient sleep, but the result of being overweight. Further research should focus on understanding the clinical significance of these results.

P0613 EXCESSIVE BODY FATNESS AT YOUNG AGE INCREASES RISK OF COLORECTAL CANCER: META-ANALYSIS AND DOSE-RESPONSE ANALYSIS

X Lei, C Geng, X Li, C Wang
West China Hospital of Sichuan University, Department of Gastroenterology, Chengdu, China

Contact E-Mail Address: lxl_kylin@163.com

Introduction: Colorectal cancer (CRC) was thought to be associated with overweight and obesity, and the CRC development may be due to early life exposures. However, the relationship between BMI at young age (age ≤30 years) and CRC remains less defined. We hypothesized that overweight and obese at young age were independent risk factors for later-life CRC risk.
Aims and Methods: We conducted a meta-analysis and dose-response analysis to quantify the association betwen colorectal cancer risk and overweight and obesity.
We searched Pubmed, Embase, Medline and Cochrane Library biomedical literature databases before Nov 16, 2017. Fourteen articles with 2 455 416 participants were included. The WHO definition was used to classify the BMI categories: overweight (≥25.0–29.9 kg/m^2) and obesity (≥30.0 kg/m^2) compared with normal weight (≥18.5–24.9 kg/m^2) as the reference category. Where non-standard categories of BMI and reference category were used, Hamling method was used to generate the adjusted risk ratios according to standard BMI categories and same reference category (normal). Random effect models and a dose-response analysis were used in this meta-analysis.
Results: Compared with normal weight people, overweight and obese young adult had a significant 16% (95% CI: 1.06–1.26) and 32% (95% CI: 1.11–1.56) higher risk of CRC, respectively. However, the association between BMI at young age and CRC risk may not exist for obese women (RR: 1.22 (95%CI: 0.99, 1.51)); Overweight, but not obese, may not a risk factor for rectal cancer (RR 1.12 (95% CI: 0.97, 1.29)). In dose-response analysis, we observed a linear relationship between BMI at young age and CRC risk. Each 1 kg/m^2 increment was associated with a 2% increased risk. Moderate heterogeneity was observed.
Conclusion: In conclusion, our meta-analysis, included 14 original studies, reveals that a 16% and a 32% higher risk of CRC for overweight and obese people separately when compared with normal weight people at their young age. Dose-response analysis indicates a 2% increase in risk of CRC for each 1 kg/m^2 increase in BMI at young age. These results indicate that reducing body fat at young adulthood could help prevent later life CRC risk.

P0615 SAFETY AND EFFECTIVENESS OF PER-ORAL ENDOSCOPIC MYOTOMY IN CHILDREN WITH ACHALASIA: A COMPARISON OF THE RESULTS IN PAEDIATRIC AND ADULT PATIENTS

K Yamashita[1], H Shiwaku[1], T Ohmiya[1], H Okada[1], H Inoue[2], S Hasegawa[1]
[1]*Fukuoka University Faculty of Medicine, Department of Gastroenterological Surgery, Fukuoka, Japan*
[2]*Showa University Koto-Toyosu Hospital, Digestive Disease Center, Tokyo, Japan*

Introduction: Achalasia is a primary motility disorder characterized by incomplete lower oesophageal sphincter relaxation. It has a relatively low incidence among children. Endoscopic balloon dilation and laparoscopic myotomy were the available treatments for achalasia regardless of age until the introduction of per-oral endoscopic myotomy (POEM). POEM is demonstrated to be effective and safe for the treatment of adult patients with achalasia as a novel incision-free endoscopic surgery, however, it is rarely performed in children.
Aims and Methods: The objective of this study was to review the safety and effectiveness of POEM in paediatric patients by comparing the results of paediatric and adult patients. The data of 218 consecutive patients with achalasia who underwent POEM at our institution between September 2011 and June 2017 were retrospectively reviewed. The patients were classified into two groups: (A) paediatric patients, and (B) adult patients. Age, previous treatments for achalasia, duration of symptoms, pre- and post-POEM Eckardt scores, manometry findings, and treatment outcomes, including duration of hospitalization and occurrence of complications, were compared between the groups using the chi-square and Student's *t*-tests.
Results: There were 7 patients in group A and 211 in group B. The median age was 15.0 ± 3.1 years (range: 9–18 years) in group A and 52.0 ± 17.8 years (range: 19–93 years) in group B. The mean duration of symptoms was significantly longer for group B than for group A (122.9 months [range: 3–840 months] vs. 30.7 months [range: 1–84 months]; $p = 0.001$). The length of myotomy was statistically different between the groups (14.0 cm [range: 7–24] in group A and 15.0 cm [range: 5–28] in group B; $p = 0.046$) There were no statistically significant differences among the groups with respect to previous treatments for achalasia, median operation times, mean hospitalizations, or occurrence of complications. The median follow-up periods were 39.6 months [range: 18–54 months] for group A and 38.4 months [range: 10–79 months] for group B. Significant Eckardt scores

and integrated relaxation pressure reductions were achieved in both groups. No perioperative mortality or major postoperative complications occurred.
Conclusion: POEM is a minimally invasive, incisionless operation. POEM is a safe and effective operation for both paediatric and adult patients. POEM may be a useful treatment method for both paediatric and adult patients with achalasia. Long-term follow-up studies would be helpful to determine whether POEM could become an appropriate therapy for paediatric patients with achalasia in the near future.

P0616 CHANGES OF MORPHLOGICAL DISORDERS OF GASTRIC MUCOSA IN CHILDREN WITH CHRONIC GASTRITIS CO-INFECTED WITH HELICOBACTER PYLORI AND EPSTEIN-BARR VIRUS AFTER A COURCE OF ANTIHELICOBACTER THERAPY

E Spivak[1], R Levit[2], O Zaytseva[2]

Introduction: The persistence of Epstein-Barr virus in the gastric mucosa in Hp-associated chronic gastritis increases the prevalence, severity and activity of inflammation.
Aims and Methods: The aim of the work is to estimate the dynamics of morphological disorders of the gastric mucosa in children with chronic gastritis co-infected with *Helicobacter pylori* and Epstein-Barr virus after course of anti helicobacter therapy.
69 children aged 7–17 with chronic Hp-associated gastritis were observed. According to the study of gastrobiopsy there was a chronic inflammatory process in all cases. Via polymerase chain reaction Epstein-Barr virus (EBV) persistence in the gastric mucosa was detected in 46 out of 69 patients (66.7 %), highly pathogenic strains of *Helicobacter pylori* containing CagA gene were detected in 47 cases (68.1 %). In addition to the standard morphological study, morphometric analysis of the cellular composition of gastric glands was performed. Patients were examined twice: before and six months after the course of anti helicobacter therapy.
Results: Morphological study of gastrobiopsy materials conducted 6 months after the course of anti helicobacter therapy has allowed us to find out that none of the patients had eradication of *Helicobacter pylori*. In most cases, a decrease in severity of the process in the body of the stomach (62.5 %) and in the antral region (73.9 %) was recorded. However, every third patient was found to have no regression or progression of disorders of morphology of gastric mucosa. This dynamics of the pathological process in associated with co-infection with highly pathogenic strains of *Helicobacter pylori* and EBV (31.9 % against 13.6 % in patients with no co-infection, $p < 0,01$). The morphometric analysis of the cellular composition of fundum glands found that severe hyperplasia endocrinocytes remained in group of EBV- positive patients after 6 month, while the number of parietal cells increased by 56.3 %, in the pyloric glands. In EBV - negative patients their number did not change, there was a significant decrease in the number of endocrinocytes (39.0 % of the original figures, $p < 0,05$.
Conclusion: Co-infection of gastric mucosa of highly pathogenic strains of *Helicobacter pylori* and Epstein-Barr virus is a factor in the absence of eradication, regression of pathogenic changes and disorders of the cellular composition of gastric glands.
Disclosure: Nothing to disclose

P0617 SEVERITY OF HISTOLOGICAL DAMAGE IN COELIAC DISEASE: ASSOCIATED FACTORS AND LONG-TERM SIGNIFICANCE

Introduction: Recent paediatric guidelines allow non-invasive diagnosis of coeliac disease in selected patients. However, besides diagnostic purposes, there might be other reasons for the duodenal biopsy. For example, it is unclear whether patients with severe villous atrophy have higher risk to develop long-term complications and should therefore be followed up more closely. We investigated if the severity of intestinal lesion affects other disease features and long-term prognosis.
Aims and Methods: Comprehensive medical data of 835 children diagnosed with coeliac disease in 1966–2014 were collected. Furthermore, questionnaires evaluating overall health, coeliac disease-related symptoms (GSRS questionnaire), quality of life (PGWB questionnaire), lifestyle and gluten-free diet were sent to 559 currently adult patients. All study variables were compared between patients divided to three groups based on the severity of diagnostic histopathology.
Results: Altogether 284 (34%) patients had partial, 332 (40%) subtotal and 219 (26%) total villous atrophy. Those with more severe lesion were born (1996 vs 1996 vs 1991, $p < 0.001$) and diagnosed (2007 vs 2006 vs 1999, $p < 0.001$) during earlier years and had higher median endomysium antibody titers (1:200 vs 1:500 vs 1:500, $p < 0.001$), and lower haemoglobin (126 vs 124 vs 121, $p = 0.005$) and body mass index (16.6 vs 16.1 vs 16.1, $p = 0.005$). They were also less often screen-detected (33% vs 25% vs 17%, $p < 0.001$) and had more anaemia (16% vs 22% vs 35%, $p < 0.001$) and growth disturbances (20% vs 38% vs 54%, $p < 0.001$), whereas there was no difference in gender distribution or the overall frequency of symptoms at diagnosis. Differences between the groups at diagnosis persisted after adjustment with birth and diagnosis year. The groups had similar short-term (6–24 months) dietary adherence and treatment response. At total, 237 (42%) adults responded the questionnaires median of 18.5 years after the diagnosis. After adjustment of the groups, there were no differences in working full-time, presence of children or coeliac disease in the family, smoking or frequency of physical exercise, adherence to gluten-free diet, experience of dietary treatment, self-perceived health, presence of associated diseases, quality of life or gastrointestinal symptoms in adulthood.
Conclusion: Severe villous atrophy at childhood diagnosis was associated to more difficult clinical presentation. However, the degree of mucosal damage did not affect the long-term treatment outcomes in adulthood.

Introduction: Coeliac disease (CD) is a lifelong immune-mediated systemic disorder affecting about 1% of the population. The majority of adult and paediatric patients remain undiagnosed and diagnostic delays in many regions reach up to 10 years.
Aims and Methods: The aim of our study was to identify the diagnostic delays in children with CD in Central European region.
We retrospectively analysed medical records of children and adolescents diagnosed with CD in 2016 from five Central European countries as a part of a multicentre web-based survey, focusing on the age at the diagnosis and the duration between first CD related symptoms, first visit to paediatric gastroenterologist and confirmation of the diagnosis. Differences between preschool (< 6y) and school-age children were also studied. Statistical analysis was performed using SPSS for Windows.

Abstract No: P0618: Table 1. Diagnostic delays in children with Coeliac disease in Central Europe

	No of centres	No of patients	Age at diagnosis ($p < 0.05$)	Symptoms to visit at PaedGI (duration; median (range))	PaedGI to diagnosis ($p < 0,001$) (duration; median (range))	Symptoms to diagnosis (duration; median (range))
Croatia	6	43	10y	3m (0–4y)	2m (0–7y)	7m (0–8y)
Germany	5	39	6.5y	6m (0–5y)	0m (0–8m)	8m (0–5y)
Hungary	21	283	7y	6m (0–14y)	1m (0–8y)	8m (0–14y)
Italy	2	59	5y	6m (0–5.5y)	1m (0–8m)	7m (0–6y)
Slovenia	7	35	7.5y	6m (0–7y)	1m (0–5y)	7m (0–7y)
TOTAL	41	459	7y	6m (0–14y)	1m (0–8y)	8m (0–14y)

Abstract No: P0621: Table 1. Clinical presentation of CD in different regions of Central Europe.

SYMPTOM		TOTAL (N = 652)	CROATIA (N = 66)	GERMANY (N = 69)	HUNGARY (N = 381)	ITALY (N = 82)	SLOVENIA (N = 54)
Asymptomatic		20.2%	12.1%	23.2%	20.7%	24.4%	16.7%
Abdominal pain	As a leading sy. (as all symptoms)	33.1% (51.5%)	36.4% (47.0%)	36.2% (56.5%)	24.4% (41.2%)	14.6% (23.2%)	33.3% (40.7%)
Growth retardation		13.8% (21.9%)	9.1% (16.7%)	17.4% (18.8%)	10.5% (17.8%)	13.4% (19.5%)	5.6% (11.1%)
Diarrhoea		12.9% (30.6%)	15.2% (25.8%)	4.3% (27.5%)	10.2% (23.9%)	12.2% (24.4%)	9.3% (22.2%)
Iron deficiency		10.2% (24.0%)	7.6% (15.2%)	2.9% (4.3%)	9.4% (24.9%)	6.1% (11.0%)	9.3% (14.8%)
Abdominal distention		7.1% (32.1%)	3.0% (9.7%)	5.8% (20.3%)	6.6% (31.5%)	3.7% (11.0%)	5.6% (20.4%)
Constipation		5.4% (13.8%)	3.0% (9.1%)	1.4% (5.8%)	3.9% (9.4%)	7.3% (19.5%)	7,4% (18.5%)
Unexplained fatigue		3.3% (11.7%)	1.5% (9.1%)	4.3% (14.5%)	2.4% (6.8%)	4.9% (14.6%)	0.0% (13.0%)
Other symptoms		4.0% (4.2%)	0.0% (0.0%)	0.0% (0.0%)	4.7% (5.0%)	3.7% (3.7%)	0.0% (0.0%)

*Study was co-financed by Interreg CE programme (CE 111, Focus IN CD).

Results: Data from 459 children and adolescents (66% female, 41% preschool) from Croatia, Hungary, Germany, Italy and Slovenia, were available for further analysis.
Median age at the time of diagnosis was 7 years (range 7m–18.5y) and more than two thirds of children were diagnosed before the age of 10 years. There was significant difference between regions regarding the median age at the diagnosis, being the lowest in Italy, and the highest in Croatia ($p < 0.05$).
Median duration from first CD related symptoms to the first visit of paediatric gastroenterologist was 6 months (range 0–14y; preschool 5m (0–5y), school-age 6m (0–14y)), with no significant regional difference.
Median duration from the first visit of paediatric gastroenterologist to the confirmation of the diagnosis was 1 month (range 0–8y; preschool 1m (0–8m), school-age 1m (0–8y)) and significant difference was found between regions ($p < 0.001$), being the highest in Croatia and Slovenia.
Median delay from the first symptoms to diagnosis was 8 months (range 0–14y; preschool 6m (0–5y), school-age 9m (0–14y)) without regional differences.
Conclusion: Our data showed that diagnostic delays in children with CD in five Central European countries are lower in comparison with the available data from other regions. Within the Central Europe, we did not find important differences in delays between the onset of symptoms and final diagnosis. However, the delay between the first visit of paediatric gastroenterologist and the final diagnosis was significantly higher in Slovenia and Croatia. This could be attributed to regional differences in the availability of diagnostic methods and/or capacity of paediatric gastroenterology service, as well as to the older age at diagnosis in Slovenia and Croatia, which is correlated with longer diagnostic delays, however it also could be caused by lower number of patients from some countries.
Regardless of relatively short diagnostic delays that we found, there is still a room for further improvement. Undiagnosed and/or untreated CD is associated with severe complications; therefore, it is very important to raise the awareness about the disease prevalence, changes in clinical presentation, and the use of reliable diagnostic methods in order to further reduce delays and the unnecessary burden of undetected and thus untreated disease.

Introduction: Potential celiac disease (PCD) is still a controversial clinical condition: there is not yet agreement on prognosis and treatment.
Aims and Methods: Aim of our study was to investigate the natural history of the disease and to identify risk factors associated with possible development of villous atrophy.
We prospectively enrolled 340 PCD children (twice positive anti-tTG IgA and anti-endomisyum antibodies + duodenal mucosa Marsh 0 or 1): 67.1% females, most asymptomatic (86.7%). They were followed till 144 months (median 76.1) with serial clinical, serological and histological evaluations. 208 are still on gluten-containing diet, the remaining being on GFD because of symptoms or parental choice.
Results: During FU 88/340 (25.8%) became anti-tTG negative. 42 (20.2%) children developed villous atrophy: cumulative survival at 12 years was 42% and 61% for males and females, respectively. A cluster of events (children developing villous atrophy) was observed in the first 2 years of FU with no difference between sex. The best predictors of evolution to villous atrophy at the time of enrollment were: intraepithelial lymphocyte infiltration ($p = 0.001$), age >10 years ($p = 0.001$), HLA homozygosity ($p = 0.021$), intensity of anti-tTG2 intestinal deposits (p .049). Familiarity for CD and other autoimmune disease did not impact the natural history of this condition.
Conclusion: PCD is confirmed to be an heterogeneous condition, but it seems possible to identify risk factors at the time of diagnosis and in first years of follow-up to discriminate children who will develop eventually villous atrophy.

Introduction: Coeliac disease (CD) is a lifelong immune-mediated systemic disorder, affecting genetically susceptible individuals after ingestion of gluten. It occurs approximately in 1% of the population and has a diverse clinical presentation, ranging from classical gastrointestinal manifestation of malabsorption to subclinical and asymptomatic forms.
Aims and Methods: The aim of our study was to present clinical manifestations of CD among the children and adolescents in Central European (CE) region.
41 centres from five CE countries (Croatia (CRO) - 6, Germany (GER) - 5, Hungary (HUN) - 21, Italy (ITA) - 2 and Slovenia (SLO) - 7) provided data as a part of a multi-centre web-based survey. We retrospectively analysed medical records of children and adolescents diagnosed with CD in 2016, focusing on a single leading symptom indicative of CD and other associated symptoms. We compared clinical presentation at the time of diagnosis of preschool (< 6y) and school-age children and analysed regional differences in clinical picture. Statistical analysis was performed using SPSS for Windows.
Results: Data from 652 children and adolescents (64.0% female, 37.0% preschool) from CRO (N = 66), GER (N = 69), HUN (N = 381), ITA (N = 82) and SLO (N = 54) with the diagnosis of CD, confirmed in 2016, were available for further analysis.
Median age at the time of diagnosis was 7 years (range 7m–18.5y). 20.2% of children were asymptomatic, out of which 64.4% belonged to a known risk group (73% with positive family history of CD).
The most common leading symptom at the time of diagnosis was abdominal pain (33.1%), followed by growth retardation (13.8%) and diarrhoea (12.9%). We did not find any regional differences regarding the most common leading symptom. Abdominal pain was also found to be the most common leading symptom in both, preschool (20.9%) and school-age (41.1%) children. In preschool children, the second most common leading symptom was diarrhoea (17.0%), followed by growth retardation (16.0%) and in school-age children the opposite was found (growth retardation - 12.4%, diarrhoea - 10.2%).
Conclusion: Our data showed that clinical presentation of CD is diverse in children in CE. Although classical clinical presentation is not so frequent, gastrointestinal symptoms, especially abdominal pain, remain the leading symptom in all compared groups of children and adolescents. In school-age children, abdominal pain was twice as common in comparison to preschool children. In Germany it was a leading complaint in almost half of the included children.
Also becoming increasingly common is for CD to present as an asymptomatic disease. Our data showed that one fifth of included children had no symptoms before the diagnosis was confirmed with asymptomatic group being the largest in Italy and Germany compared to other regions.

It is very important to raise the awareness about the changes in clinical presentation of childhood CD shown by our data and by other studies in order to prevent diagnostic delays and negative consequences of undetected/untreated disease.

Introduction: ESPGHAN allowed in 2012 to confirm the diagnosis of coeliac disease (CeD) without biopsy in children with CeD-relevant symptoms (as defined in Husby, JPGN 2012) and serum anti-transglutaminase antibody levels exceeding 10 times the upper limit of normal (High TGA+) in whom endomysial antibodies (EMA) are positive and who carry HLA-DQ2 or DQ8. In this study we explored how these criteria are followed in clinical practice.
Aims and Methods: Paediatric gastroenterologists in Hungary were asked to upload medical data of their patients diagnosed with CeD between January 2016-April 2017 concerning disease presentation, antibody, histology and DQ results into an anonymised web database developed during the Interreg Central Europe 'Focus in CD' project and utilised before in Croatia, Germany, Italy and Slovenia. Here we present the results of the Hungarian subgroup.
Results: 27 gastroenterology services representing all counties in Hungary uploaded altogether 654 patients' data diagnosed in the last year with CeD, of whom 566 were children and adolescents below 18 years of age (median 8 years [range 1–18]). Biopsy was performed in 435 children (76.8%), which showed Marsh 2–3 lesions or villous atrophy by other grading in 413 (95%), Marsh 0–1 in 12 (2.7%), or the biopsy specimen was not evaluable in 10 (2.3%). In 26 children biopsy was not possible because of the parents' refusal or other medical reasons. In other 105 patients (18.5%) the no-biopsy approach was applied, in whom EMA was tested in 92/105 (87%) and HLA-DQ was determined in 94 (89.5%). The most frequent reasons for the lack of genetic testing were high costs not supported by insurance, and for replacement of EMA the use of DGP in 2 centers. Altogether 75% of children (79/105) had all the criteria required by the 2012 ESPGHAN guidance for the non-invasive diagnosis, while 84% (88/105) fulfilled the protocol of having CeD-relevant symptoms, High TGA+ and EMA+ result. In these cases, HLA-DQ testing did not add to the diagnosis, indicating a safe diagnosis even without genetic testing. Also in the group where biopsy was not possible because of parental refusal, 65% of children (17/26) fulfilled these criteria and the same was true for 43% of children (188/435) who eventually received endoscopy.
Conclusion: The majority of practising paediatric gastroenterologists in Hungary follow well ESPGHAN criteria in making the no-biopsy diagnosis of CeD. As omitting HLA-DQ testing does not compromise accuracy, this would make the no-biopsy approach more broadly available also in countries with less financial resources. Of note is that also 43% of children who currently undergo biopsy already do qualify for these less strict criteria even before the endoscopy, but a final diagnosis also must depend on collaboration and acceptance by parents.
Grant support: Interreg Central Europe CE111 Focus in CD, NKFI120392 and EFOP-3.6.1-16-2016-00022 projects.

Introduction: Anemia is a common finding in untreated celiac disease, but the mechanisms behind this association are obscure. Abnormal expression of small intestinal iron transport proteins could provide a possible explanation but the existing research is scarce and contradictory. We investigated whether aberrant expression of the transporter proteins is associated with anemia in pediatric celiac disease.
Aims and Methods: Duodenal cytochrome B (DcytB), divalent metal transporter 1 (DMT1), ferroportin, hephaestin and transferrin receptor 1 (TfR1) were stained immunohistochemically in duodenal biopsies of 27 celiac disease patients with villus atrophy and 16 children with normal mucosal morphology. Twenty of these 43 individuals had anemia. The expressions of the proteins were investigated as regards to intensity (negative/weak, strong) and the results were compared between the groups. Subgroup analyses were made between children with positive celiac serology but normal villi (potential celiac disease) and seronegative controls.
Results: In celiac disease patients, no differences in protein expressions between anemic and non-anemic patients were seen. The expressions of DcytB ($p = 0.036$) and hephaestin ($p = 0.040$) were significantly lower in celiac disease patients than individuals with normal mucosal morphology (Table 1), and there was a similar but non-significant trend in the expression of DMT1 ($p = 0.060$). In the subgroup analysis of the morphologically normal patients, there were no differences between seropositive or -negative patients.
Table 1. The intensity of the iron transporter proteins in duodenal biopsies 43 children.

	Celiac disease N = 27 %	No villous atrophy N = 16 %	P-value
DcytB			
Negative/Weak	82.5	56.3	0.036
Strong	14.8	43.8	
DMT1			
Negative/Weak	77.8	50.0	**0.060**
Strong	22.2	50.0	
Ferroportin			
Negative/Weak	74.1	75.0	0.946
Strong	25.9	25.0	
Hephaestin			
Negative/Weak	88.9	63.5	**0.040**
Strong	11.1	37.5	
TfR1			
Negative/Weak	70.4	50.0	0.182
Strong	29.6	50.0	

DcytB, duodenal cytochrome B; DMT1, divalent metal transporter 1, TfR1, transferrin receptor 1

[The intensity of the iron transporter proteins in duodenal biopsies 43 children.]
Conclusion: We conclude that anemia in celiac disease is not associated with abnormal expression of iron transporters. Instead, the expressions of DcytB and hephaestin, enzymes catalyzing the reduction and oxidation of iron, respectively, are decreased in patients with villous atrophy. These changes might lead to insufficient absorption of iron in the small intestine and thus predispose to the development of anemia in untreated celiac disease.
Disclosure: Nothing to disclose

P0624 THE RELATIONSHIP BETWEEN THE STATUS OF VITAMIN D AND P53 PROTEIN IN CHILDREN WITH CELIAC DISEASE

O Kamilova[1], N Alieva[2]

Introduction: The presence of antibodies reacting with the p53 tumor suppressor protein has been described in patients with some autoimmune disorders.
Aims and Methods: Our purpose was to explore the relationship between the level of vitamin D and the content of p53 proteins in the mucous membrane of the

duodenum in children with celiac disease (CD). In 42 children with CD at the age from 7 to 15 years in the biopsy samples of the duodenum was determined the level of p53 protein expression by monoclonal mouse antibodies to human proteins (clone DO-7) Dakopatts, (Denmark). Level of 25 D (OH) was determined in serum by ELISA (Elecsys-2010).
Results: Vitamin D deficiency was diagnosed in 33 children with CD (13.3 ± 3 ng / ml), 9 patients have vitamin D insufficiency (24 ± 4ng / ml). In the group of children with vitamin D deficiency, the amount of p53 protein in the mucous membrane of the duodenum was $6.5 \pm 0.3\%$, and in the case of vitamin D deficiency it was $3.1 \pm 0.3\%$. The number of interepithelial lymphocytes of the small intestinal mucosa was $83.3 \pm 5.4\%$ in cases of vitamin D deficiency, at vitamin D insufficiency it was $38.0 \pm 3.9\%$.
An inverse strong correlation was found between the values of vitamin D and the values of tissue protein p53 ($r = -0.759$, $p < 0.001$).
Conclusion: Immunohistochemical methods established a relationship between vitamin D deficiency and increase of the p53 protein in the mucosa of the small intestine in sites of atrophy of the epithelium in children with CD, which is an indirect confirmation of the delay in the regeneration of the small intestine at vitamin D deficiency.

Introduction: *Helicobacter pylori* (HP) infection is a primary cause of gastric and duodenal ulcers. Most HP uninfected gastroduodenal ulcers are caused by NSAIDs. Many capsule endoscopic studies of healthy volunteers revealed that concomitant administration of non-selective NSAIDs and PPI can induce small intestinal mucosal injuries in over 50% of subjects.
Aims and Methods: As HP infection is the main cause of duodenal ulcers, the impact on small intestinal mucosa is clear. Therefore, the aim of the study was to investigate any association between HP infection and small intestinal mucosal injury. Two RCTs evaluated small intestinal mucosal injury in healthy volunteers after NSAIDs treatment, all subjects were checked for HP infection by breath test or serum antibody before treatment to evenly distribute subjects with HP infection in both RCT groups. From the studies, 213 subjects (38 subjects treated with diclofenac plus PPI, 34 treated with diclofenac plus PPI and rebamipide, 72 treated with loxoprofen plus PPI, and 69 treated with celecoxib only), whose entire small intestine was evaluated before and after NSAIDs treatment by capsule endoscopy were included in the analysis. Numbers of small intestinal mucosal breaks were compared between subjects infected with HP and those without HP infection before and after NSAIDs treatment.
Results: In all subjects prior to NSAIDs treatment, there were more mucosal breaks in 46 subjects infected with HP than 167 subjects without HP infection; however, there were no significant differences (0.44 ± 1.9 vs 0.22 ± 1.0; $p = 0.30$). In all subjects following NSAIDs treatment, mucosal breaks were statistically greater in subjects infected with HP than subjects without HP infection (16.0 ± 68 vs 2.25 ± 8.6; $p = 0.011$). After treatment, there were more mucosal breaks in subjects infected with HP than those not infected in subgroups that were treated concomitantly with non-selective NSAIDs plus PPI. In the subgroup treated with celecoxib only, there was little difference in the number of mucosal breaks for HP infection.
Conclusion: There is a high possibility that *H. pylori* infection exacerbates small intestinal mucosal injury in concomitant non-selective NSAIDs treatment with PPI.
Disclosure: All authors have declared no conflicts of interest.

Introduction: 24% of chronic diarrheas in older children are of unknown etiology. Small bowel bacterial overgrowth syndrome (SBOS) is an underdiagnosed disorder in children usually suspected where no etiology has been ascertained after an extensive workup. Existing literature on SBOS in children have used study designs that are not full-proof. Most studies are based on breath test analyses and response to empirical antibiotics. Limited studies have used small bowel intubation and aspiration as the primary modality for diagnosis of SBOS in children which is considered gold standard.
Aims and Methods: This was a prospective longitudinal interventional study. We aimed to assess a) the prevalence of SBOS, b) the specific microbiological profile and antibiotic sensitivity in SBOS in the jejunal cultures, c) correlation of bacteriological confirmation with yield of breath tests, and d) response to antibiotics and outcome after stopping the therapy. Chronic diarrhea $\pm$ bloating patients of >3months with undetermined etiology underwent glucose and lactulose hydrogen breath tests on days 1 and 2. Jejunal aspirate by jejunoscopy for culture and sensitivity was performed on day 3. Those with bacterial confirmation on jejunal culture were subjected to 2 therapeutic phases (primary: day 1–14; secondary: day 28–42) of two sensitive oral antibiotics with a wash out phase of 2 weeks (day 14–28) in between. Co-trimoxazole was emperically chosen in primary antibiotic failure. SBOS was defined as all of the following: a) jejunal aspirate bacteriological count of $\geq 10^5$ CFU/mL, b) positive hydrogen breath test (glucose or lactulose) and c) response (clinical and breath test) within 2 weeks of completion of antibiotic therapy. Their long-term outcome over 6 months was noted.
Results: Of the 48 children aged 14.6 ± 3.3 y, 8 did not satisfy all the SBOS criteria. Another 5 were excluded as they had a specific disease later at follow-up (celiac disease, $n = 2$; giardiasis, $n = 2$; combined variable immunodeficiency, $n = 1$). SBOS as per the above criteria was present in 16/35 (46%) cases. The jejunal cultures ($n = 16$) yielded *Pseudomonas* ($n = 8$), *Eschericia coli* ($n = 7$) and *Klebsiella* ($n = 4$) and *Steptococcus* ($n = 3$). 7/16 cultures grew >1 organism. 2/4 *Klebsiella* were resistant to all antibiotics and treated with empirical choice of antibiotics. Of the positive glucose ($n = 12$) and lactulose ($n = 7$) hydrogen breath tests, dual positivity was seen in three. In the first therapy phase, primary antibiotics administered as per sensitivity pattern were cefixime ($n = 10$), norfloxacin ($n = 6$) and co-trimoxazole ($n = 2$). 5/10 of cefixime group did not show response after 2 weeks. In the second therapy phase after wash out period, secondary antibiotics administered were co-trimoxazole ($n = 8$), norfloxacin ($n = 4$), cefixime ($n = 2$) and nitrafurantoin ($n = 2$). Cefixime resistant organisms ($n = 5$) and multi-antibiotic resistant *Klebsiella* ($n = 2$) responded clinically to co-trimoxazole. All patients responded by hydrogen breath tests. Over a follow-up period of 3 (2–9) months, 5 patients (31%) had recurrence of symptoms. All 5 were primary antibiotic responsive and responded (clinical and breath test) to the same antibiotics during recurrence.
Conclusion: SBOS (jejunal culture and breath test positivity) is seen in 46% of chronic diarrhea with no discernable etiology. Gram negative organisms are the commonest flora in 80%; multibacterial in 43%. Primary antibiotic response is seen two-third. Co-trimoxazole is a favourable drug for primary antibiotic failure and antibiotic resistant groups. One-third have relapse of SBOS and are respond to primary antibiotics.

Introduction: The aim of this project was to assess the effectiveness of a method to adjust pancreatic enzyme replacement therapy (PERT) in Cystic Fibrosis (CF) based on the prediction of the optimal dose according to food properties, by means of modelling of results of *in vitro* digestion studies.
Aims and Methods: Prospective interventional study with 43 patients from 5 European centres. During 24h they followed a fixed diet (5 meals), along with the optimal dose of enzymes for each meal previously characterised or determined by *in vitro* digestion. Fat in stools was determined after samples collection, which was carried out using colorimetric markers for a precise identification of stools corresponding to the study meals. Beta regression models were applied to explain the relationship of study variables with coefficient of fat absorption (CFA).
Results: Median CFA was 90% (95% CI 84, 95%) with no differences among centres. Patients' compliance with protocol was 99% and median Bristol stool scale was 3–4. No association of CFA with age, mutation or BMI z-score, but a significant effect was found with transit time ($p < 0.05$). Findings suggest that these variables do not play as an important role as food characteristics do on lipids digestion (on the basis of which the study doses were established).
Conclusion: Applying the *in vitro* predicted recommended PERT dose for each meal, the clinical target of CFA is reached with low variability among patients. The proposed approach can be considered a first step towards an evidence-based method to adjust PERT in CF.

Introduction: CYP2R1 and CYP27A1 hydroxylases involve in the hydroxylation from vitamin D_3 to 25-hydroxyvitamin D_3 ($25[OH]D_3$), and CYP27B1 hydroxylase further catalyzes the conversion of $25(OH)D_3$ to $1,25(OH)_2D_3$, the most active vitamin D metabolite, which plays a role in the immune regulation and pathogenesis of hepatitis C virus (HCV) infection. The present study aims to investigate the relationship between the polymorphisms of vitamin D pathway genes (*CYP2R1*, *CYP27A1* and *CYP27B1*) and HCV infection outcomes in Chinese population.

Aims and Methods: Nine single nucleotide polymorphisms (SNPs) from *CYP2R1*, *CYP27A1* and *CYP27B1* were genotyped in a Chinese population with high risk of HCV infection. The distributions of these SNPs were compared among groups of different HCV infection outcomes, including 863 HCV persistent infection cases, 524 spontaneous clearance subjects and 1079 uninfected controls.

Results: Logistic regression analyses showed that *CYP2R1* rs12794714-G, rs10741657-A, rs1562902-C, and rs10766197-G alleles were significantly associated with increased susceptibility to establishment of HCV infection (all $p_{FDR} < 0.05$, in additive/dominant models), and the combined effect of the four unfavorable alleles was related to an elevated risk of HCV infection in a locus-dosage manner ($p_{trend} = 0.008$). The risk effects of the four unfavorable alleles were more distinct among drug user or subjects aged < 50 years. Moreover, haplotype analyses suggested that compared with the most frequent $A_{rs12794714}G_{rs10741657}T_{rs1562902}A_{rs10766197}$ haplotype, the haplotype containing the four unfavorable alleles GACG indicated a risk effect of HCV infection (adjusted odds ratio [OR] = 1.243, p = 0.006). However, no links were found between these SNPs and viral clearance, and also no associations of the other two genes with infection outcomes were found.

Conclusion: Our study implicated that genetic variants in *CYP2R1* may be marker SNPs for risk of HCV infection susceptibility in Chinses population.

Introduction: Splenomegaly is always observed in patients with liver cirrhosis. As an important immunological organ, the spleen plays a crucial role in regulating immunological response. Besides, spleen directly connected with the liver via the portal circulation. The immune cells and cytokines derived from spleen may affect the progression of liver cirrhosis. However, the abnormalities of splenic immune function with liver cirrhosis have not been fully characterized.

Aims and Methods: To fully assess the changes of immune cell subsets in the spleen of liver cirrhotic rats and explore whether cyclooxygenase-2 (COX-2) is involved as a potential modulator in these change. Twenty-four male Sprague-Dawley rats weighing 200–250g were randomly assigned into 3 groups with 8 rats in each group. The control group: received intraperitoneal injection of normal saline (1ml, twice a week); the TAA group: received intraperitoneal injection of thioacetamide (TAA, 200 mg/kg, twice a week for 16 weeks); the TAA+celecoxib group: received TAA intraperitoneally and celecoxib via gastric gavage (20 mg/kg/day). Sections from paraffin-embedded livers were stained with hematoxylin and eosin and Sirius Red. The expression of collagen III was tested by immunohistochemistry. Besides, Protein expression of a-SMA and COX-2 was evaluated by Western blot. Flow cytometry was used to detect the number of total T cell, CD4+ T-cell, CD8+ T-cell, Treg (CD4+CD25+FOXP3+), total B cell (B220+), follicular B cell (B220+CD21+CD23+), marginal B cell (B220+CD21+CD23-) and the activated B cell (B220+CD38+) in the spleen of each group. The enzyme-linked immunosorbent assay was performed to evaluate the expression of IgG and IgM both in the spleen and serum.

Results: A considerable amount of collagen was visualized in the liver of TAA group compared with that of the control group. While reduced fibrotic area was found in liver of the TAA+celecoxib group. The hepatic protein expression of a-SMA increased significantly by 2.3-fold compared with that in the control group. While the hepatic a-SMA protein expression decreased significantly in the TAA+celecoxib group. Elevated protein expression of COX-2 was detected in the spleen of the TAA group compared with that in the control group. But celecoxib significantly reduced the expression of COX-2 in spleen of the TAA+celecoxib group. Besides, compared with the control group, the protein expression of IgM and IgG in spleen and serum were found to be greatly increased in the TAA group. While they were significantly reduced in TAA+celecoxib group compared with that in TAA group. Moreover, the number of splenic total T cell, CD8+ T-cell, Treg, total B cell and the activated B cell (B220+CD38+) were all increased in TAA group compared with the control group, while dramatically reduced in TAA+celecoxib group. Interestingly, compared with the control group, the number of splenic marginal B cell (B220+CD21+CD23-) were decreased in TAA group, while increased in TAA+celecoxib group. And no obvious changes of splenic CD4+ T-cell and follicular B cell (B220+CD21+CD23+) were observed in each group.

Conclusion: The present study indicates that COX-2 may be involved in regulating the development and differentiation of immune cell subsets in spleen of liver cirrhosis. And the inhibition of COX-2 by celecoxib could attenuate the liver cirrhosis and the relevant immune dysfunction. Furthermore, the study shed light on the fact that Celecoxib may ameliorate liver cirrhosis partly through the targeting splenic abnormalities.

P0630 CELECOXIB ATTENUATES HEPATOCYTE APOPTOSIS THROUGH INHIBITION OF ENDOPLASMIC RETICULUM STRESS IN CIRRHOTIC RATS

W Su[1,2], Y Tai[1], S Tang[1], J Gao[1], C Tang[1]

Introduction: Endoplasmic Reticulum Stress (ERS) is an important mechanism in the process of liver disease and chronic progression. ERS is involved in the progression of liver fibrosis and its recovery. Excessive and prolonged ER stress triggers apoptosis to eliminate dysfunctional cells. Apoptosis induced by ER stress is is considered to be important way on the origin and development of liver fibrosis. Cox-2 induction is closely related to endoplasmic reticulum stress. Our previous studies have found that the Cox-2 inhibitor, Celecoxib, can improve hepatic fibrosis and portal hypertension. But the role of Celecoxib in alleviating liver fibrosis is related to alleviating ERS, and there is no research report.

Aims and Methods: To investigate whether celecoxib could alleviate the development of liver fibrosis by reducing hepatocyte apoptosis via inhibition of endoplasmic reticulum stress (ERS) response. Methods: Peritoneal injection of thioacetamide (TAA) was employed to induce liver cirrhosis for 16 weeks (200 mg/kg/3 days before 8 weeks, 100 mg/kg/3 days after 8 weeks). 45 male Sprague-Dawley rats were randomly assigned to the control, TAA, and TAA+celecoxib groups. TAA-cirrhotic rats received celecoxib (20 mg/kg/day) or its vehicle by gastric gavage for last 8 weeks. rats were put to death after 16 weeks, and serum AST, ALT and ALB content in rats were detected. The degree of fibrosis was assessed by visible hepatic fibrotic areas (Sirius red) and hydroxyproline contents. The stress level of endoplasmic reticulum was evaluated by detecting its marker protein GRP78 and CHOP. Apoptosis level is evaluated by the detection of Caspase-12 and Caspase-3, hepatic expression of PERK, IRE1 and ATF6 is related to ERS.

Results: Celecoxib administration significantly decreased serum AST and ALT levels in the liver, without significant changes in ALB. The degree of fibrosis in liver fibrosis and hydroxyproline was significantly reduced to celecoxib (−38% and −25.7%, $p < 0.01$). Compared with the TAA group, celecoxib ameliorated endoplasmic reticulum stress by lowering the level of GRP78 ($p < 0.05$). Consistently, the up-regulation of hepatic apoptosis-level (Caspase-12, Caspase-3) and CCAAT/enhancer binding protein homologous protein(CHOP)induced by TAA was significantly inhibited after celecoxib administration. Furthermore, the expressions of critical molecules in ERS (PERK,IRE1,ATF6) was reduced after celecoxib management ($p < 0.05$).

Conclusion: Therapeutic administration of celecoxib can efficiently reduce hepatic apoptosis in TAA-cirrhotic rats. These effects may be due to the suppression of CCAAT / enhancer binding protein homologous protein (CHOP) expression, which are subsequent to the inhibition of endoplasmic reticulum stress.

Disclosure: Nothing to disclose

P0631 THE PREDICTIVE ABILITY OF LABORATORY INDICES IN ASSESSING ADVANCED HEPATIC FIBROSIS AMONG CHRONIC HEPATITIS C PATIENTS WITH DIFFERENT STATUSES OF ANTI-VIRAL TREATMENT AND BODY MASS INDEX

Introduction: Histological staging is essential for prognostication and treatment decision among patients with chronic hepatitis C. Liver biopsy is the gold standard in assessing liver fibrosis but is invasive with potential complications. Therefore, many non-invasive methods to predict liver fibrosis have been reported. Aspartate aminotransferase (AST)/platelet ratio index (APRI) and fibrosis-4 (FIB-4) are well-known serum markers and have been widely used to predict histological results. However, in clinical settings, serum biomarkers might rapidly fluctuate over time and be influenced by many factors, such as anti-viral treatment, steatohepatitis status, and other comorbidities. It is not well established how these factors influence the diagnostic accuracy of APRI and FIB-4 in evaluating liver fibrosis. Therefore, this study aimed to investigate the predictive ability of two laboratory indices for liver fibrosis in patients with different statuses of anti-viral treatment, body mass index (BMI), and other comorbidities.

Aims and Methods: A total of 96 patients (men, 53.1%) with chronic hepatitis C infection who underwent liver biopsy between September 2015 and December 2017 at Tatung Mackay Memorial Hospital, Taiwan were retrospectively reviewed. The histological appearance of fibrosis was assessed using the Ishak scoring system (range, 0–6) and several laboratory values were evaluated. The APRI was calculated as AST [IU/L] / upper limit of normal AST [IU/L]) × 100 / platelet count [109/L]. The FIB-4 index was calculated as AST [IU/L] × age [years] / platelet count [109/L] × alanine aminotransferase (ALT) [IU/L]1/2. The predictive performance of two indices was assessed using receiver operating characteristic (ROC) analysis, and the area under the ROC curve (AUROC) was evaluated.

Results: The mean age was 59.3 (range, 35–83) years. The proportion of diabetes, hyperlipidemia, and hypertension was 27.1%, 69.8%, and 47.9%, respectively. A total of 29 (30.2%) patients were hepatitis C treatment naïve, 18 (18.8%) had virological breakthrough during interferon-based anti-viral treatment, and the remaining patients completed anti-viral treatment. The APRI and FIB-4 AUROCs were both higher in patients who completed the treatment than those who did not. Furthermore, patients with BMI $\leq$25 kg/m^2 had higher predictive ability of the two laboratory indices than those with BMI $>$25 kg/m^2 (Table).

Conclusion: The laboratory indices, APRI and FIB-4, can predict advanced fibrosis in the liver in patients with hepatitis C infection. The diagnostic accuracy seems better in patients who received anti-viral treatment and those with BMI $<$ 25 kg/m^2. These indices will be useful in estimating liver fibrosis.

	AUROC	Cut-off	Sensitivity	Specificity	PPV	NPV
Total 96 patients						
APRI	0.747	0.66	64.9%	71.2%	58.5%	76.4%
FIB-4	0.739	2.63	62.2%	78.0%	63.9%	76.7%
Treatment naïve or virological breakthrough (n = 47)						
APRI	0.691	1.26	60.0%	77.3%	75.0%	63.0%
FIB-4	0.635	4.18	48.0%	81.8%	75.0%	58.1%
Treatment completion (n = 49)						
APRI	0.757	0.52	58.3%	83.8%	53.9%	86.1%
FIB-4	0.784	1.91	75.0%	78.4%	53.0%	90.6%
BMI $\leq$ 25 (n = 43)						
APRI	0.890	1.11	83.3%	80.6%	62.4%	92.6%
FIB-4	0.796	2.69	75.0%	74.2%	53.0%	88.5%
BMI $>$ 25 (n = 53)						
APRI	0.699	0.44	76.0%	60.7%	42.8%	86.7%
FIB-4	0.740	1.78	80.0%	64.3%	46.5%	89.3%

APRI = aspartate aminotransferase / platelet ratio index; AUROC = area under the receiver operating characteristic curve; BMI = body mass index; FIB-4 = fibrosis-4; NPV = negative predictive value; PPV = positive predictive value.

[Analysis of two laboratory indices in identifying advanced (Ishak 4–6) liver fibrosis.]

P0632 DENDRITIC CELL CONTRIBUTES TO AUTOIMMUNE HEPATITIS VIA AUTOPHAGY INHIBITION

X Fan, R Men, T Wang, M Wen, T Ye, L Yang
West China Hospital of Sichuan University, Chengdu, China

Contact E-Mail Address: fxl0833@163.com

Introduction: Dendritic cells (DC) is a pivotal cell participating in various kinds of autoimmune diseases and plays an important role in autoimmune hepatitis (AIH). However, the mechanism used by DCs to take part in the development of AIH *in vivo and vitro* remains unclear.

Aims and Methods: The study was aimed to investigate the functions of DCs and mechanisms of DCs alteration in AIH. Peripheral blood samples were collected from 12 patients with biopsy-proven AIH and 6 healthy controls (HC). Mature DCs (CD11C+HLA-DR+) and activated T lymphocytes (CD4+CD3+ and CD8+CD3+, respectively) were detected by flow cytometry (FCM). In concanavalin A (Con A, 20mg/kg for 12h) induced AIH mice, the percentage of mature DCs (CD11C+CD80+) and activated T lymphocytes (CD4+CD69+ and CD8+CD69+, respectively) in the blood, spleen and liver were detected by FCM. Circulating TNF-α, IFN-γ, and IL-6 were assessed by ELISA. *In vitro*, immature DCs were generated from mice bone marrow (BMDC) cultured with GM-CSF (10ng/ml) and IL-4 (10ng/ml). We then treated the immature BMDCs with Con A (10, 20, 40μg/mL) and LPS (1μg/ml) for 24 hours respectively. The expression of major histocompatibility complex II (MHC-II), CD80 and CD86 was determined by FCM. The expression of autophagic related proteins were determined by western blot.

Results: The percentage of mature DCs in the peripheral blood of AIH patients was obviously higher than that in HCs, accompanied by the elevation of activated T lymphocytes. Similarly, the percentage of mature DCs and activated T lymphocytes in blood, spleen and liver were also increased in the Con A-induced hepatitis mice. Moreover, the inflammatory cytokines, such as TNF-α, IFN-γ, and IL-6 were significantly up-regulated in the Con A-treated group. Further study showed that the percentage of LPS-induced mature BMDCs from AIH mice was increased than that from control mice. *In vitro*, Con A stimulation promoted the maturation of BMDCs as evidenced by higher levels of MHC-II, CD80 and CD86 as compared with control cells. Interestingly, Con A markedly decreased autophagy level (decreased LC3 protein expression) in BMDCs.

Conclusion: We provided a strong evidence that abnormal maturation of DCs mediated the progression of AIH. Furthermore, the impaired autophagy activity could be an important mechanism for DCs to promote the development of AIH.

Introduction: NASH diagnosis and the need for reliable noninvasive methods to distinguish it from simple steatosis and allow for grading and staging of disease are of high necessity. Adipocyte fatty acid binding protein (AFABP) is adipokine involved in the inflammation and insulin resistance.

Aims and Methods: We aimed to evaluate efficiency of AFABP in diagnosis and quantification of histopathological status of NAFLD in Egyptian patients.

A total of 90 subjects (45 male and 45 female) were included in the study and were divided into 3 groups: NASH, steatosis and control. All participants were subjected to calculation of HOMA-IR, NAFLD score, BARD score, complete blood counts, lipid profile, fasting and post-prandial blood glucose level, liver function tests, HCV-Abs, HBsAg, serum AFABP, liver biopsy and abdominal ultrasound.

Results: A significant increase was detected in fasting insulin, HOMA-IR, serum AFABP level and NAFLD score in NASH group ($p < 0.01$) and there was significant increase in BMI in both NASH and steatosis groups compared to control ($p < 0.05$).

The AUROC cut off level (pg/ml), sensitivity, specificity and accuracy of AFABP in diagnosis of fibrosis according to Brunt score in NASH were (0.838, 10.6, 75, 72.7 and 83.8 respectively) ($p = 0.005$ and 95% CI: 0.686–0.991). Also, AUROCs of non invasive markers for diagnosis of NASH have been showed highly significant value of BARD score, NAFLD score and HOMA-IR. Highly significant value of AFABP in diagnosis of significant histological grade (A2-A3) according to Brunt score in NASH was found ($p = 0.001$).

While in steatosis, AUROCs showed highly significant value of BARD score, NAFLD score, HOMA-IR and AFABP. As regards AFABP, the AUROCs, cut off level (pg/ml), sensitivity, specificity and accuracy were (0.928, 9.36, 100, 80 and 92.8 respectively) ($p = 0.003$ and CI: 0.830- 1).

Conclusion: AFABP proved to be a promising marker in predicting fibrosis stages, histological grades and activity.

Introduction: Hepatocyte growth factor (HGF) is a hepatic mitogen and is considered an initiator of liver regeneration. Liver regeneration following partial hepatectomy (PHx) is a complex process where liver sinusoidal endothelial cells (LSEC) play an important role. LSEC are regarded as one of the most important liver cell types that produce HGF, but the exact contribution of LSEC to liver regeneration remains to be defined.
Aims and Methods: To investigate the effects of hepatic angiocrine HGF signaling on liver regeneration, Stab2-Cre$^{tg/wt}$;HGF$^{fl/fl}$ (HGF-LSEC-KO) mice, where HGF is specifically knocked out in LSEC, were used. 70% PHx was performed on these mice and the kinetics of liver to body weight ratio, hepatocyte proliferation, HGF/c-MET signaling pathways, and cell-cycle-associated genes were analyzed at different time points after PHx.
Results: We observed that HGF-LSEC-KO mice have a significantly reduced liver to body weight ratio compared to the control group at 72 hours after PHx. HGF-LSEC-KO mice had a higer mortality after PHx and the proliferation of hepatocytes was significantly impaired at 48 hours after PHx in HGF-LSEC-KO mice.
Conclusion: Angiocrine HGF signaling plays a crucial role in the early stage of liver regeneration after PHx in mice. Hepatic angiocrine HGF signaling is not only essential for liver regeneration after injury but also for the growth of the liver and even the whole organism.

Introduction: There are no approved drug treatments for liver fibrosis and non-alcoholic steatohepatitis (NASH), an advanced stage of fibrosis which has rapidly become a major cause of cirrhosis. Therefore, development of anti-inflammatory and anti-fibrotic therapies are desired. Mesenchymal stem cell (MSC)-based therapy, which has been extensively investigated in regenerative medicine for various organs, can reportedly achieve therapeutic effect in NASH via paracrine action. Extracellular vesicles (EVs) encompass a variety of vesicles released by cells that fulfill functions similar to those of MSCs including induction of cell proliferation as well as anti-inflammatory, immunomodulatory, anti-fibrotic, and anti-apoptotic effects.
Aims and Methods: We herein investigated the therapeutic effects of EVs from amnion-derived MSCs (AMSCs) in rats with NASH and liver fibrosis.
AMSC-EVs were collected from supernatant of AMSCs with ultracentrifugation. NASH was induced by a 4-week high-fat diet (HFD), and liver fibrosis was induced by intraperitoneal injection of 2 mL/kg 50% carbon tetrachloride (CCl_4) twice a week for six weeks. AMSC-EVs were intravenously injected at weeks 3 and 4 in rats with NASH (15 μg/kg) and at week 3 in rats with liver fibrosis (20 μg/kg). The extent of inflammation and fibrosis were evaluated with quantitative reverse transcription polymerase chain reaction (qRT-PCR) and immunohistochemistry. The *in vitro* effect of AMSC-EVs on inflammatory and fibrogenic response was investigated using rat hepatic stellate cells (HSCs) and Kupffer cells (KCs). In addition, the effect of AMSC-EVs on lipopolysaccharide (LPS)/toll-like receptor (TLR) 4 signaling pathway was investigated in HEK293 and 293/hTLR4-MD2-CD14 cells.
Results: Dynamic light scattering demonstrated that the diameter distribution of AMSC-EVs ranged from 50 to 150 nm, with a single peak at approximately 100 nm. Additionally, the expression of the EV marker CD81 was observed by western blotting of AMSC-EVs. Animal experiments demonstrated that AMSC-EVs significantly decreased the number of KCs in the liver of rats with NASH and the mRNA expression levels of inflammatory cytokines such as tumor necrosis factor (TNF)-α, interleukin (IL)-1β, IL-6, and transforming growth factor (TGF)-β. Furthermore, AMSC-EVs significantly decreased fiber accumulation, KC number, and HSC activation in rats with liver fibrosis. *In vitro*, AMSC-EVs significantly inhibited KC and HSC activation. AMSC-EVs dose-dependently suppressed the expression of *TNF-α*. In addition, the increase in LPS-induced NF-κB transcriptional activity was significantly suppressed by AMSC-EVs. Furthermore, LPS-induced phosphorylation of IκB-α and p65 was inhibited by AMSC-EVs. AMSC-EVs suppressed the LPS/TLR4 signaling pathway.
Conclusion: AMSC-EVs ameliorated inflammation and fibrogenesis in a rat model of NASH and liver fibrosis, potentially by attenuating HSC and KC activation. AMSC-EV administration should be considered as a new therapeutic strategy for chronic liver disease.

P0636 INTRODUCTION OF CRYOPRECIPITATE INTO THE LIVER LEADS TO IMPROVEMENT OF PORTAL BLOOD FLOW

D Kazakova, Y Poluektov, R Karpova
Sechenov First Moscow State Medical University, Faculty surgery №1, Moscow, Russian Federation

Contact E-Mail Address: kazakova.daria@gmail.com
Introduction: Liver cirrhosis is a very common pathology in the structure of gastrointestinal diseases. The amount of five-year survival rate is 62% in the compensation stage of cirrhosis whereas it decreases to 19% in the decompensation stage. However, the hepatic tissue has a unique ability for regeneration due to hypertrophy and hyperplasia of ultrastructure of hepatocytes. In this respect, we give preference to minimally invasive techniques with the use of agents influencing an inflammation process and liver regeneration such as cryoprecipitate. The cryoprecipitate is a highly concentrated solution of fibrinogen derived from donor plasma by cryoprecipitation, which consist of growth factors to decrease macrophage activity and cirrhosis progress.
Aims and Methods: To study the changes in portal blood flow in patients with liver cirrhosis after introduction of cryoprecipitate into cirrhotic liver tissue.
40 patients (28 men and 12 women) aged from 25 to 60 (the mean age 45 years) with liver cirrhosis were supervised from 2000 to 2017 in Faculty Surgery Clinic №1. 27 patients had alcoholic cirrhosis and 13 patients had mixed (viral and toxic) cirrhosis. Cirrhosis of Class A according to Child-Pugh was diagnosed in 8 patients, Class B in 13 patients, Class C in 19 patients. Cryoprecipitate was injected into liver tissue (1.5–2 ml in each segment) by percutaneous puncture under ultrasonic guidance. The portal blood flow study was conducted before and 6 and 12 months after the procedure using duplex ultrasound examination.
Results: Statistically significant changes were obtained after 6 months in 92% of patients.
Stagnation index (ratio of the linear velocity of flow to the diameter of the vessel) became normal in 6 months in all patients, which correlates with the risk of bleeding from esophageal veins. In patients with long-term cirrhosis of the liver class A, B and C, the circulation in the portal system was normalized, and the risk of bleeding from the esophageal veins was minimal in 6 months. The results obtained 12 months after the procedure did not changed.
Conclusion: Stimulation of liver regeneration with cryoprecipitate in patients with long-term cirrhosis reduces portal hypertension after 6 months in 92%.

P0637 TOLL-LIKE RECEPTOR 3 PROMOTES LIVER REGENERATION AFTER PARTIAL HEPATECTOMY

C Stöß, B Wang, S Schulze, M Lu, D Hartmann, H Friess, N Hüser, B Holzmann
Chirurgische Klinik und Poliklinik, Klinikum rechts der Isar, München, Germany

Contact E-Mail Address: christian.stoess@tum.de
Introduction: Following two-thirds partial hepatectomy (PHx), the liver restores its organ mass due to compensatory growth of the remnant liver. Inflammation plays a crucial role inducing regeneration by stimulating adult G_0 hepatocytes to enter G_1 phase.[1] The endosomal Toll-like receptor 3 (TLR3) detects double-stranded RNA and activates signaling pathways that can either lead to cell survival or cell death. Further, it promotes inflammation via inducing the expression of pro-inflammatory cytokines (e.g. TNFa, IL-6).[2] Previous work has shown that TLR3 supports tissue regeneration during dermal wound repair, but seems to have either host-protective or detrimental effects in the intestine.[3] In contrast, the exact role of TLR3 in the process of liver regeneration needs further clarification.
Aims and Methods: The present study aims to evaluate the role of TLR3 in liver regeneration. Therefore, we examine TLR3-deficient mice (TLR3-/-) and wild type (WT) controls by applying a standardized PHx. With regard to distinct cell cycle phases, we demonstrate the biomolecular characteristics of both mouse strains. Male TLR3-/- on C57BL/6 background and C57BL/6 WT control mice were subjected to surgery. PHx in mice was performed according standard procedures.[4] Animal experiments were performed in accordance with Federal Animal Regulations and were institutionally approved by the District Government of Upper Bavaria. Assessment of liver regeneration was conducted by calculating the liver/body weight ratio. Hepatocyte proliferation was analyzed via IHC applying anti-BrdU monoclonal antibody. For cell cycle analyses Western blotting with following primary antibodies was applied: p-STAT3 (Tyr705), p-Rb (S807/811), p-CDK2 (T160), CDK1, GAPDH and ß-tubulin. The cell cycle inhibitor p21 was examined by quantitative real time-PCR and IL-6 concentrations in serum were measured by an ELISA assay. P values < 0.05 were considered significant.
Results: Liver regeneration was significantly reduced in TLR3-/- according to liver/body weight measurement at 72 hours, 168 hours and 336 hours. Further, TLR3-/- did not reach the WT ratio level at the end of the regeneration process. 4 hours after PHx serum levels of IL-6 were higher in TLR3-/- but no difference in

the protein levels of pSTAT3 was detectable. Cell cycle examinations via Western blotting revealed significantly lower levels of p-Rb protein and p-CDK2 at 32 hours and 40 hours, respectively. In line with G_1/S transition block, less BrdU-positive hepatocyte nuclei in S phase at 32 hours and 40 hours were detectable in TLR3-/- compared to controls. Supporting this finding, also CDK1 in G_2 phase was diminished in TLR3-/-. The cell cycle inhibitor p21 showed a significant increase at 32 hours after PHx in TLR3-/-.

Conclusion: According to our results, TLR3 appears to have a tissue growth promoting effect on the liver after PHx. This was shown by a diminished liver-to-body weight ratio in TLR3-deficient mice. Supporting this finding, the levels of proliferation promoting effector proteins such as CDK2 or Rb protein were reduced. Finally, these results were confirmed by IHC where less BrdU-positive hepatocyte nuclei were found in TLR3-/-. The elevated fold induction of cell cycle inhibitor p21 on mRNA level at 32 hours after PHx could explain the delay of cell cycle progression in our TLR3-/-. However, further investigation of TLR3 influencing liver regeneration is warranted. In this respect, the main objective continue to be the revelation of TLR3-associated signalling pathways inducing cell proliferation upon acute tissue loss in the liver.

Disclosure: Nothing to disclose

Introduction: 3D organoids represent an advanced culture technology in the field of stem cells and regenerative medicine, recapitulating embryonic organ development. Adult or fetal biliary tree represent ideal cell sources of stem/progenitor cells to be used for the regenerative medicine of liver and pancreas. The aim of our study was to generate 3D organoid cultures of hBTSCs and differentiate them toward hepatocyte cells which are suitable for cell therapy and regenerative medicine of liver.

Aims and Methods: The fetal biliary tree (N = 3, obtained from elective pregnancy termination) was digested, mechanically and enzymatically, to isolate *EpCAM/LGR5*-enriched hBTSCs, we also used the fragments of undigested bile duct to cultivate the organoids. Cells and bile duct fragments were then embedded in Matrigel and cultured in an expansion organoid medium containing soluble factors typical of the stem cell niche (e.g. EGF, FGF, Noggin, R-Spondin1) that represent LGR5 ligands and Wnt agonists and favor the expansion of stem cells and maintenance of stemness. Culture medium was also supplemented with Forskolin, a cAMP activator, and with a TGFβR inhibitor to induce cell proliferation and arrest of differentiation. After 7 days the medium was changed to differentiation medium for a period of 10 days. We analyzed colony formation efficiency, organoid size and morphology, cell proliferation and gene expression by RT-qPCR. Also to assess hepatocyte function we used ELISA to analyze albumin secreted in medium of culture.

Results: An average of 85 ± 7 million (N = 3) *EpCAM/LGR5* enriched fetal hBTSCs were obtained. The cells isolated from fetal biliary tree showed a high tendency to generate organoids with high colony formation efficiency (> 60%). Cell proliferation and population doubling in organoids was significantly higher compared to 2D conditions ($p < 0.05$). Fetal biliary tree organoids were composed of single layered cuboidal epithelium and inner cell masses. RT-qPCR analysis demonstrated that organoids in expansion condition expressed multipotency stem cell markers (SOX2, NANOG, OCT4), endodermal stem/progenitor cell markers (LGR5, EpCAM, PDX1, SOX17), hepatic progenitors and ductal markers (CK19, CK7) and stem/progenitor surface genes (NCAM, CD133, CD44), recapitulating major processes of self-organization during embryonic development, whereas the differentiated organoids expressed high level of mature hepatocyte marker like CYP3A and ALB. Interestingly, LGR5 Expression reduced notably in organoids in differentiation condition compared to organoids in expansion condition ($p < 0.01$). Moreover differentiated organoids acquired a hepatocyte morphology, including polygonal cell shape and secreted significant high level of Albumin in to medium respect to the same cells in 2D culture.

Conclusion: We have demonstrated that organoids expand clonogenically stable *in vitro* for at least two months, maintaining a stable phenotype of multipotent stem cells and they can differentiate toward mature functional hepatocyte. This system has potential applications in regenerative medicine of liver and pancreas and in disease modeling.

Introduction: Branched chain amino acid (BCAA) supplementation may benefit patients with liver cirrhosis and hepatocellular carcinoma. In this study, we attempt to elucidate the effects of BCAA on protein synthesis and hepatocyte regeneration in mice after hepatectomy.

Aims and Methods: Mice were subjected to hepatectomy and then supplemented with or without BCAA. The expression and activity of various proteins were evaluated to determine the mechanistic effects of BCAA supplementation. In addition, the effects of various doses of BCAAs on HepG2 cells were evaluated.

Results: BCAA supplementation for 1 day significantly increased the body weight, liver/body weight ratio, and epididymal fat weight of hepatectomized mice. BCAA intake for 7 days significantly increased serum albumin levels and increased the expression of phosphorylated mammalian target of rapamycin (p)-mTOR and p- eukaryotic translation initiation factor 4E binding protein 1 (4E-BP1), thereby promoting liver protein synthesis. BCAA supplementation for 1, 3, and 7 days increased DNA synthesis in mouse hepatocytes after liver hepatectomy and activated p-protein kinase B (Akt). In HepG2 cells, 1×, 2×, and 5× concentrations of BCAAs increased cell proliferation. All doses of BCAAs activated p-mTOR and p-Akt, while 2×, 5×, and 10× doses of BCAAs increased the protein expression of p-4E-BP1 and only 1× BCAA increased cyclin D1 protein levels.

Conclusion: These results suggest that BCAA supplementation may represent a therapeutic strategy for patients undergoing liver operation by increasing liver protein synthesis and may play a role in hepatocyte regeneration. The beneficial effects of oral BCAA supplementation may involve the mTOR/4E-BP1 and Akt pathways.

P0640 NEW OPPORTUNITIES OF COMBINED DIAGNOSTICS OF HEPATIC FIBROSIS AND STEATOSIS IN CLINICAL PRACTICE

I Pirogova, S Yakovleva, T Neuymina
South Ural State Medical University, Chelyabinsk, Russian Federation

Contact E-Mail Address: irina_pirogova@inbox.ru

Introduction: Non-invasive diagnoses of hepatic fibrosis (HF) have become a part of clinical practice over the past 10 years. Non-invasive techniques for quantification of hepatic steatosis (HS) remains not always available.

Meanwhile, the clinical importance of steatosis determination is great, since HS is the morphological substrate of alcoholic (ALD) and non-alcoholic liver disease (NAFLD), metabolic and drug-induced liver injury (DILI), HS accompanies chronic viral hepatitis (CVH) and aggravates the progression of HF.

Transient elastography using the FibroScan® 502 Touch with XL probe and CAP technology allows to reliably define HF and HS in obese patients.

Aims and Methods: We aimed to evaluate the capabilities of the FibroScan 502 TOUCH with XL probe and CAP technology in non-invasive diagnostics of the combined determination of HF and HS.

1265 outpatients with first gastroenterologist's appointment were included in the study. Men 728 (59%), mean age 36.4 ± 5.7 years, duration of the disease -1.0 ± 1.9 years, BMI ≥30–407 (33%), hepatic steatosis according to ultrasound in 456 (37%). Patients were divided into 3 groups:

1) with cytolysis more than 1.5 norms, 2) with the presence of steatosis by ultrasound; 3) patients with CVH. All participants underwent general examination to find out the etiology and activity of the disease.

Results: Patients from group 1 have had the following diseases: NAFLD (35%), ALD (28%), opisthorchiasis (5%), hypothyroidism and autoimmune thyroiditis (4%), primary biliary cholangitis (3%), DILI (25%). According to FibroScan 502 TOUCH with XL probe and CAP evaluation the HS was identified in 88% of cases (ALD, NAFLD, DILI).

In group 2: NAFLD (55%), ALD (28%), DILI (17%), all patients had HS. In group 3: CHC (100%), HS - in 75%, in half of cases HS was not associated with BMI ≥25. 82% of patients had genotype 3.

Conclusion: Transient elastography using the FibroScan® 502 Touch with XL probe and CAP technology allows to reliably define HF and HS in normal weight and overweight patients. It helps to prescribe the patients correct medications.

[5]*University of Medicine and Pharmacy Craiova, Endocrinology Department, Craiova, Romania*

Contact E-Mail Address: dananeagoe@rdslink.ro
Introduction: NAFLD includes a pathological spectrum of phenotypes ranging from simple steatosis to steatohepatitis (NASH), the progressive from of fatty liver disease associated with inflammation and cellular injury. Dehydroepiandrosterone -s (DHEA-s), is a steroidal hormone present at highest concentration in the body, with an improving effect on insulin resistance, an antioxidant effect and antifibrotic effect. Aim of our study was to correlate DHEA-s level with presence of NASH and also with insulin resistance and leptin level.
Aims and Methods: We included 153 patients with NAFLD and we divided into 2 groups: 73 patients NASH group and 80 non- NASH group, age and sex-matched. The diagnostic criteria for NASH was fatty liver accompanied by the presence of steatohepatitis in biopsy samples. Severity of NASH was diagnosed by activity (grade) and fibrosis (stage). In all patients we determined BMI, aminotransferases, insulin level, HOMA -IR, leptin level and DHEA-s level.
Results: In NASH group BMI was 32.5 ± 3 and in non- NASH group BMI was 30.3 ± 3, without statistic significance. In NASH group, DHEA-s level was lower than normal value adjusted with age and gender and also lower compared with non- NASH group where the DHEA-s level was normal. In NASH group DHEA-s correlated with leptin level ($p = 0.038$) and insulin resistance ($p = 0.042$), but didn't correlated with fibrosis degree ($p = 0.282$), aminotrasferases (ASAT $p = 0.143$ and ALAT $p = 0.119$). If we selected from NASH-group only 52 patients with low degree of fibrosis (0–2) based on Brunt's Criteria, we observed that DHEA-s level correlated with fibrosis progression, in the others 21 patients with high degree of fibrosis or cirrhosis DHEA-s didn't correlated with progression of the disease. In non-NASH group DHEA-s didn't correlated with any parameters (aminotransferases, leptin, insulin or HOMA-IR).
Conclusion: In our study, decreased level of DHEA-s was associated with inflammation and progression of fibrosis in early stages of disease and, also, correlated with leptin and insulin resistance. In patients with simple steatosis or high degree of fibrosis/ cirrhosis DHEA-s didn't prove to be a marker for disease's evolution
Disclosure: Nothing to disclose

P0642 BERBERIS ARISTATA, ELAEIS GUINEENSIS AND COFFEA CANEPHORA EXTRACTS IMPROVE HEPATIC STEATOSIS THROUGH THE MODULATION OF THE METABOLIC PROFILE AND OF MIR-122 LEVELS IN AN ANIMAL MODEL OF NAFLD

V Lembo[1], **V Cossiga**[1], C Nigro[2], P Mirra[2], G Mazzone[1], A Rossi[1], G D'Argenio[1], A Leone[2], F Beguinot[2], C Miele[2], N Caporaso[1], F Morisco[1]

Contact E-Mail Address: valentina.cossiga@gmail.com
Introduction: NAFLD and metabolic syndrome seem to have insulin resistance as a common pathophysiological mechanism. Recently, a number of studies have described microRNAs (miRNAs) as mediators in the pathogenesis of both insulin resistance and NAFLD.
Aims and Methods: The aim of this study is to evaluate whether and how a mixture of plant extracts consisting of *Berberis Aristata*, *Elaeis Guineensis* and *Coffea Canephora* may affect the development of obesity, hepatic steatosis and insulin resistance, conceivably associated to the modulation of miRNAs levels, in an animal model of NAFLD induced by a high fat diet. Three groups of C57BL/6 mice ($n = 8$ each) were randomized into one of the following 24 week diets: 1) standard diet (SD); 2) high fat diet (HFD, 60% fat); 3) HFD enriched with plant extract (HFD+E) (140 mg/Kg/die). Body weight was monitored during the diet protocol. At the end of the treatment all mice were fasted for 4 hours and intraperitoneally injected with a bolus of insulin (0.75U/kg) to test the insulin tolerance by ipITT. Blood samples were used to measure glycaemia by a portable glucometer, insulinemia by ELISA essay, transaminases and lipid profile by a clinical chemistry benchtop analyzer. After sacrifice, liver biopsies were collected to examine the hepatic histology by H&E staining and to isolate total RNA and measure miRNA expression by q-PCR.
Results: The HFD+E mice show lower body weight (40±3.6 g vs 47.4±6 g, HFD+E vs HFD, $p = 0.008$), the amelioration of insulin sensitivity (10138±1620 mg/dl*120min vs 7529±1469 mg/dl*120min, iAUC of HFD+E vs HFD, $p = 0.008$) together with the reduction of insulinemia (725,8±270 pg/ml vs 1156.3±307.4 pg/ml, HFD+E vs HFD, $p = 0.04$), total cholesterol (178±17 mg/dl vs 209±19 mg/dl, HFD+E vs HFD, $p = 0.007$), low density lipoproteins (10.7±3.2 mg/dl vs 19.3±1.6 mg/dl, HFD+E vs HFD, $p < 0.001$), triglycerides (86.3±11 mg/dl vs 130.3±22 mg/dl, HFD+E vs HFD, $p < 0.001$) and alanine-aminotrasferase (38.7±24 U/l vs 81.3±47 mg/dl, HFD+E vs HFD, $p = 0.03$) compared to HFD mice. H&E staining show macro- and microvesicular steatosis with ballooning degeneration in mice fed with HFD, which is improved in mice fed with HFD+E. Moreover, a down-regulation of miR-122 hepatic levels is observed in HFD mice compared to SD mice (0.95±0.6 REU vs 2.17±1.5 REU, HFD vs SD, $p = 0.03$). Interestingly, this effect on the miRNA levels is prevented by the combination of plant extracts with HFD (1.39±0.03 REU vs 0.95±0.6 REU, HFD vs SD, $p = 0.03$).
Conclusion: In conclusion, the combination of *Berberis Aristata*, *Elaeis Guineensis* and *Coffea Canephora* added to HFD is able to ameliorate obesity, insulin resistance and hepatic steatosis, which are developed by C57BL/6 mice fed with a HFD. Moreover, this metabolic profile associates to the modulation of hepatic miR-122 levels, which are down-regulated in HFD mice and remain unchanged in mice fed with HFD+E compared to SD mice. These data suggest a possible role of miR-122 in the beneficial effects of Berberis Aristata, Elaeis Guineensis and Coffea Canephora combination on metabolic syndrome.
Disclosure: Nothing to disclose

P0643 MANAGEMENT THE PATIENTS WITH GALLSTONE DISEASE

I Pirogova, I Ufimtceva
South Ural State Medical University, Chelyabinsk, Russian Federation

Contact E-Mail Address: irina_pirogova@inbox.ru
Aims and Methods: Development of a diagnostic and therapeutic algorithm for optimizing the treatment of gallstone disease based on ultrasound and CT of the gallbladder.
235 patients (31% of men) were included in the study, mean age (Mediana) = 48 years, mean duration of the disease (Mediana) = 1.8 years. In all cases gallstones have been diagnosed by abdominal ultrasound. Disease risk factors were identified: irregular meals - 78%, heredity - 40%, obesity - 35%; comorbid diseases of the gastrointestinal tract - 75%, heart ischemic disease and arterial hypertension −41%, diabetes mellitus and glucose intolerance-38%, urolithiasis and gout −11%. The technique of Philips CT scanner 'MX-8000 IDT-16CT' have been used to evaluate the stones density in Hounsfield *Units* (X-ray negative stones - < 100 Hounsfield *Units*). The same method has been used to evaluate steatosis of the liver and pancreas and atherosclerosis of the abdominal part of aorta.
Results: All patients were divided into 3 groups: 1) with biliary sludge (bile rheology disorder) −10% ($n = 24$), 2) with the gallstones density < 100 Hounsfield *Units (HU)*, 41% ($n = 98$), 3) with the gallstones density > 100 HU - 49% ($n = 113$). The patients from group 3 were recommended to perform cholecystectomy.
Patients with biliary sludge and gallstones < 100 HU ($N = 122$), which occupying < 1/3 of the gallbladder volume, were recommended to follow hypolipidemic diet, physical activity, body weight normalization, litholytic therapy with ursodeoxicholic acid (UDCA) was administered in daily dose of 15 mg / kg of body weight for 3 months. After the end of this period repeated CT was done. Depending on the result therapy with UDCA was either ended or continued. Steatosis of the liver was detected in 35% of cases ($n = 74$, $Me = 32$ units), pancreas - in 32% ($n = 70$, $Me = 28$ units). The gallstones density correlated ($r = 0.5$) with the degree of liver and pancreas steatosis, abdominal aorta atherosclerosis deformation and increased volume of gallbladder, liver cysts and hemangiomas, patients age.
After 6 months of UDCA administration biliary sludge resolved in 91.7%, gallstones with density < 100 HU resolved in 11.3%. After 9 months of such a treatment biliary sludge resolved in 100%, gallstones with density < 100 HU - in 52% of patients. After 12 months, the dissolution of stones reached 81.3%. In 18.7% of cases ($n = 18$) therapy was unsuccessful. The steatosis of the liver ($Me = 55$ units) and pancreas ($Me = 44$ units) decreased according to CT at month 6 and month 12 ($p < 0.05$).
Conclusion: Litholytic therapy with UDCA for 6 months resulted in biliary sludge resolution in 100% cases, the same therapy for 12 months resulted in resolution of gallstones < 100 HU in 82% cases which accompanied with regression of liver and pancreas steatosis. In other conditions cholecystectomy is indicated.

Introduction: Somatostatin analogues (SA) reduce liver volume in patients with polycystic liver disease (PLD). The effect tends to wear off after 6 months of therapy suggesting development of SA tolerance. Drug holidays, defined as an interruption of pharmacotherapy for a period of time, could be the answer to the development of tolerance. In this study we examined the liver volume reducing effect of SA rechallenge after a drug holiday.

Aims and Methods: We selected patients from the International PLD registry from two tertiary centers. Patients were included when treated with SA, octreotide or lanreotide, during two cycles (On-1 and On-2) separated by a drug holiday (Off-1). Each separate period lasted at least 3 months. For our primary outcome we compared the effect of SA between On-1 and On-2, expressed as percentage change in height adjusted liver volume (hTLV) assessed by computed tomography or magnetic resonance imaging. For our secondary outcomes we compared natural liver growth before SA treatment (Off-0) with liver volume change during drug holiday (Off-1).
Results: Out of 741 patients in the PLD registry, 45 patients were treated at least twice with SA. In 34 patients, the initial liver volume reducing effect was similar to that after rechallenge [−2.5% per 6 months (IQR -3.8-0.8) vs. −1.6% per 6 months (IQR -3.0-0.9), p = 0.521]. In patients who responded in On-1, defined as a decrease in liver volume, 86.4% again showed a decrease in On-2. In 25 patients, the increase in hTLV per 6 months was significant higher during the drug holiday (Off-1) compared with the natural growth (Off-0) before initial SA exposure (4.5% vs 1.6%, p = 0.009) suggesting a rebound effect. In the group of patients who responded in the first treatment cycle (On-1), hTLV decreased with 0.1% per 6 months in the total observation period (On-1, Off-1 and On-2) in which patients were treated for 53.1% of the time (−0.6% after 46.5 months).
Conclusion: These results postulate that a drug holiday resensitizes the liver to the beneficial pharmacological effects of SA. Our results support the concept of rechallenge after a drug holiday as a strategy for selected patients with PLD. This strategy avoids needless continuous therapy and reduces medical costs.

Contact E-Mail Address: liudb526@gmail.com
Introduction: Non-alcoholic fatty liver disease (NAFLD) is one of the most common liver diseases worldwide; however, the mechanisms involved in NAFLD development remains largely unknown. Cholesterol is increasingly recognized as a causative agent in NAFLD. SQLE is a one of the rate-limiting enzyme in the endogenous cholesterol biosynthesis pathway, but its role in the pathogenesis of NAFLD is unknown.
Aims and Methods: We aimed to evaluate the functional role and molecular mechanisms of SQLE in NAFLD and to assess the therapeutic efficacy of targeting SQLE in NAFLD. The biological function of SQLE and therapeutic efficacy of terbinafine (SQLE selective inhibitor) was assessed in hepatocyte-specific Sqle transgenic mice.
Results: SQLE mRNA expression was significantly up-regulated in NAFLD patients (N = 23) as compared to healthy controls (N = 16). We evaluated the biological function of SQLE in the evolution of NAFLD in SQLE transgenic (tg) animal models. Wild-type and hepatocyte-specific Sqle tg mice were fed with normal chow for 11 months. Compared to wild-type littermates, Sqle tg mice showed significant higher liver-to-body weight ratio and increased hepatic levels of triglyceride, cholesterol and free fatty acid, accompany with enhanced insulin resistance by insulin tolerance tests (ITTs). Moreover, Sqle tg mice displayed increased serum levels of aspartate transaminase (AST) and alanine transaminase (ALT). H&E staining confirmed the histological presence of steatohepatitis (NASH) in the livers of Sqle tg mice; whereas wild-type mice showed normal histology. These findings suggested for the first time that hepatocyte overexpressing SQLE in Sqle tg mice spontaneously leads NASH formation.
Additional experiments were performed to confirm the role of SQLE in NASH. Sqle tg mice and wild-type mice with fed with high fat high cholesterol (HFHC) diet for 15 weeks. Compared to wild-type mice, Sqle tg mice fed HFHC diet had a significant increased body weight, liver weight, liver-to-body weight ratio, enhanced hepatic free fatty acid, triglyceride, and cholesterol; and significantly induced serum levels of triglyceride, cholesterol, ALT and AST. ITTs and glucose tolerance test revealed the marked elevated insulin resistance in HFHC diet fed Sqle tg mice than wild-type mice. Liver histology demonstrated a pronounced steatohepatitis with fibrosis in Sqle tg mice compared to wild-type mice In keeping with this, mRNA expression of pro-inflammatory and pro-fibrotic factors including Tgfβ1, Tnfα, Ccl-20, Ccl-12, Col1α1 and Col1α2 were significanctly induced in tg mice fed HFHC diet. These data confirmed the effect of SQLE in promoting the development of NASH.
We finally evaluated the therapeutic efficacy of SQLE inhibitor (terbinafine) in NASH.
Terbinafine treatment significantly attenuated body weight, liver weight and liver-to-body weight ratio; decreased liver free fatty acid, triglyceride and cholesterol; reduced serum levels of ALT and AST; improved insulin resistance and markedly attenuated histological severity of steatohepatitis in tg mice fed HFHC diet compared to the untreated mice fed the same diet.
Conclusion: We identified for the first time that SQLE causes spontaneous NASH formation in hepatocyte specific SQLE tg mice and facilitates the development of NASH fibrosis in tg mice fed HFHC diet. SQLE inhibitor terbinafine protects against NASH formation and may serve as a potential therapeutic target for patients with NASH.
Disclosure: Nothing to disclose

P0647 EVALUATION OF CIRCULATING HORMONES IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE AS POTENTIAL BIOMARKERS

M.B Afonso[1], N Baur[2], H Cortez-Pinto[3,4], R.E Castro[1], A Normann[2], C.M.P Rodrigues[1]

Introduction: Non-alcoholic fatty liver disease (NAFLD) encompasses a spectrum of hepatic dysfunction ranging from simple hepatic steatosis to non-alcoholic steatohepatitis (NASH), which may potentially progress to liver cirrhosis and hepatocellular carcinoma. Liver biopsy remains the gold standard method to distinguish steatosis from NASH and to identify the extent of liver injury and fibrosis despite its invasive nature with potential serious complications.
Aims and Methods: We aimed to evaluate the performance of circulating levels of hormones relevant for the pathogenesis of NAFLD/NASH as potential biomarkers. Serum levels of adiponectin, leptin and insulin-like growth factor-I (IGF-I) were evaluated in a cohort of morbidly obese patients with a clinical and biopsy-proven diagnosis of steatosis (n = 26) or NASH (n = 13), using enzyme-linked immunosorbent assays (ELISA) recently developed and produced by Mediagnost. Hormone levels were correlated with fasting serum glucose and insulin, hepatic transaminases, gamma-glutamyltransferase (*GGT*), direct bilirubin, free fatty acids, triglycerides, apoliprotein A1, cytokeratin 18, high-density lipoprotein (HDL) and low-density lipoprotein cholesterol, and total cholesterol. Serum of liver disease-free individuals was also analyzed (n = 7–13).
Results: Leptin levels were significantly augmented in steatosis and NASH patients, compared with healthy controls ($p < 0.005$). The area under the receiver-operating characteristic (AUROC) related to NAFLD *versus* healthy controls was 0.88 (95% CI = 0.77–0.98; $p < 0.0001$). In turn, IGF-I concentrations were significantly diminished in steatosis and NASH patients, compared with controls ($p < 0.05$), showing an AUROC of 0.81 (95% CI = 0.68–0.94; $p < 0,05$). Finally, adiponectin levels were significantly decreased in NASH patients compared with steatosis ($p < 0.05$) or healthy individuals ($p < 0,01$), and the AUROC was 0.79 (95% CI = 0.62–0.96; $p < 0.01$). Circulating concentrations of adiponectin were negatively correlated with serum levels of glucose, insulin, GGT, alanine aminotransferase and bilirubin in the cohort of NAFLD patients (at least, $p < 0.05$).
Conclusion: Overall, these parameters are potentially valuable tools for non-invasive stratification of patients with NAFLD. Particularly, adiponectin might discriminate the presence of NASH in morbidly obese patients. Future studies should validate these biomarkers in independent larger cohorts, as well as the impact of confounding factors such as obesity.

Introduction: Dyslipidemia increases cardiovascular risk in the general population. Chronic liver disease (CLD) affects lipoprotein synthesis, but prevalence/relevance of dyslipidemia in CLD is controversial. Interestingly, statins and fibrates may have hepatoprotective effects. Therefore, we investigated lipid profiles in patients with non-cirrhotic and cirrhotic CLD of different etiologies, as well as the utilization of statins in these patients.
Aims and Methods: Patients with alcoholic liver disease (ALD; n = 121), hepatitis C (HCV, n = 1438), hepatitis B (HBV, n = 384), NAFLD (n = 532), cholestatic liver disease (n = 119), or autoimmune hepatitis (AIH, n = 114) were included. Liver stiffness values ≥15kPa defined cirrhosis. Dyslipidemia was diagnosed by either (i) total cholesterol > 200mg/dL, (ii) LDL > 130mg/dL or (iii) triglycerides > 200mg/dL.
Results: Across all etiologies, total cholesterol levels was lower in patients with cirrhosis as compared to non-cirrhotic patients. Similarly, LDL levels were lower in cirrhotic HCV, HBV, NAFLD and AIH. HDL decreased in HCV and NAFLD cirrhosis. Triglyceride levels did not differ between non-cirrhotic and cirrhotic patients. Comorbidities (arterial hypertension, NIDDM and IDDM) were more prevalent in patients with cirrhosis, while in general, the prevalence of dyslipidemia was lower in cirrhotic than non-cirrhotic patients (33.9% vs. 22.4%, $p < 0.001$). Lipid lowering therapy was underutilized in patients with liver disease as 27.9% did not receive indicated therapy (29.9% in patients without and 20.0% in patients with cirrhosis, respectively).
Conclusion: Dyslipidemia and cardiovascular comorbidities are common in patients with CLD. Progression to cirrhosis affects total cholesterol and HDL/LDL levels. Lipid-lowering therapy is highly underutilized in patients with CLD.

Introduction: Controlled attenuation parameter (CAP) is a new method for the non-invasive diagnosis of hepatic steatosis (HS) acquired by transient elastography. The aims of this study were to assess the concordance of HS measurements with the M and XL probes of Fibroscan® as well as to determine the concordance of classification of the grade of steatosis using the cut-off values determined by de Lédinghen et al [1].
Aims and Methods: In a cross-sectional prospective study, transient elastometry acquisitions were performed using the M probe then the XL probe. The inter-observer concordance for CAP measurements was assessed using the intraclass correlation coefficient and the concordance of the steatosis grade classification was characterized using the κ index. Cutoffs were (M and XL probes respectively) 246/242 for the presence of HS and 285/286 dB/m for the presence of severe HS.
Results: A total of 136 patients were included. Women accounted for 51.5%. Fifty (36.8%) patients were hepatitis C virus (HCV) monoinfected, 46 (33.8%) were hepatitis B virus (HBV) monoinfected, 17 (12.5%) had NAFLD, 5 (3.7%) were HIV/HCV coinfected and 2 were HBV/HCV coinfected (1.5%).
Thirty one percent of our patients were obese (BMI $\geq$ 30kg/m^2) and 32.6% were overweight (BMI $\geq$ 25 kg/m^2). The mean CAP value using the M probe was significantly higher than the mean CAP value using the XL probe (255.5 dB/m vs 245.4 dB/m, p = 0.007). The corresponding median liver stiffness measurements were 6.5kPA and 5.9 kPA respectively. The overall intraclass correlation coefficient for the single measures was 0.738 (95% confidence interval: 0.645–0.808).
Hepatic steatosis was present in 51.9% and 55.6% of patients with the M and XL probes respectively. Severe HS was noted in 28.9% and 25.2% of patients with the M and XL probes respectively. The κ indexes for the concordance of classification for the presence of significant HS and severe HS were 0.581 and 0.605, respectively.
The rates of CAP examinations with IQR > 50 using the M probe was 7.4% whereas it reached 46.7% using the XL probe.
Conclusion: Single CAP values with the M and XL probes are well correlated however the use of cutoff values leads to a suboptimal concordance of grade classification. The rate of examinations with an IQR > 50 is much higher using the XL probe.
Disclosure: Nothing to disclose

Introduction: Patients with cirrhosis have increased susceptibility to bacterial infections. It is critical, but frequently challenging, to diagnose an early bacterial infection in cirrhotic patients. The neutrophil-to-lymphocyte ratio (NLR) reflects systemic inflammation. It is an emerging biomarker that replicates cirrhosis' imbalanced immune response.
Aims and Methods: We aimed to determine the correlation between NLR values and infection
Retrospective, unicenter study, including patients with cirrhosis, admitted to the hospital at first decompensation, during 6 years. NLR was calculated at admission. Applying logistic regression models and testing for discriminative power, we correlated NLR with the outcome infection.
Results: We included 139 patients. The main cirrhotic etiology was alcoholic, 118 (84.9%). The major admission cause was inaugural ascites, 80 (57.6%). Infection affected 43 (30.9%) patients, 18 (12.9%) were community infections and 26 (18.7%) were hospital-acquired infections.
Higher NLR values were associated with significant increase in infection risk (p = 0.005), for each unit increase in NLR the odds of infection increased 1.15 times. Stratifying by admission cause, this association persisted on GI bleeding (OR 1.22, p = 0.012) and encephalopathy (OR 1.22, p = 0.022). We report similar Odds on community infections. On the hospital-acquired infection group, only the GI bleeding subgroup was significant (OR 1.15, p = 0.049). NLR has an acceptable discriminative power to predict infection (AUC 0.618, p = 0.027). Adjusting for admission cause, we obtained a better discriminative power on encephalopathy (AUC 0.754, p = 0.010).
On the community infections subgroup, we account the cut-off point 3.6, for better acknowledging infection risk (< = 3.6: Community infection risk 1.8%; > 3.6: Community infection risk 20.2%).
Conclusion: NLR is a simple and clinically forward approach to attest the individual infection risk on cirrhotic patients. We report the NLR cutoff 3.6 as the optimal for infection prediction.
Disclosure: Nothing to disclose

P0652 HOSPITAL READMISSION RATES IN HEPATIC CIRRHOSIS: WHICH PATIENTS PRESENT HIGHER RISK?

Introduction: Patients with hepatic cirrhosis (HC) are at high risk of hospital readmission (HR).
Aims and Methods: We aimed to determine the HR rate at 30 and 90 days after index hospitalization (IH) for decompensation, as well as the reasons and possible predictors.
Retrospective and unicentric study involving patients with HC who were hospitalized within 9 years.
Results: Included 177 patients, 85.3% with alcoholic HC.
At IH, 73.4% of the patients presented with ascites, 47.5% with variceal bleeding, 22.6% hepatic encephalopathy (HE), 7.9% hepatocellular carcinoma and 1.1% hepatorenal syndrome (HRS). Regarding intra-hospital complications, 11.9% had Spontaneous Bacterial Peritonitis (SBP), 20.9% acute kidney injury (AKI) and 20.3% other types of infections (respiratory, urinary, cutaneous).
The HR rate at 30 and 90 days was 40.1% and 28.2% respectively.
In the univariate analysis we found that patients with HE (60% vs 34.3%, p = 0.004), SBP (66.7 %% vs 36.5%, p = 0.008) and AKI (56.8% vs 35.7%; p = 0.02) were more frequently readmitted at 30 days. Patients with HE (45% vs 23.4%, p = 0.007) and AKI (43.2 vs 24.3%; p = 0.023) in IH were more frequently readmitted at 90 days.
In the multivariate analysis, the presence of HE (OR 2.485 CI 95% 1.166–5.298;p = 0.018) and SBP (OR 3.599 IC95% 1.333–9.721; p = 0.012) were predictors of HR at 30 days.
In the multivariate analysis HE was the only predictor for HR at 90 days (OR2.345 ± 95% 1.097–5.014; p = 0.028)
Conclusion: In a population of cirrhotic patients, a high rate of hospital readmission of 40.1% and 28.2% was observed at 30 and 90 days respectively. HE was a common predictor of readmission at 30 and 90 days.

Introduction: In cirrhotic patients, cerebral vascular resistance indices (resistivity index, RI and pulsatility index, PI) are good indicators of cerebral hemodynamic abnormalities and are closely correlated with the severity of cirrhosis, hepatic encephalopathy (HE) and ascites. However there are still poor data about cerebral vascular indices and minimal HE (MHE).
Aims and Methods: The aim of this study was to correlate cerebral arteries resistance indices with the presence of MHE and to evaluate their modification after treatment with rifaximin.
38 consecutive cirrhotic patients were enrolled in this study. Exclusion criteria were overt HE (West Haven $\geq$ 1), age < 18 years, active alcohol consumption, sepsis, cerebrovascular diseases, cerebral neoplasms, cardiac diseases, peripheral vascular diseases, treatment with rifaximin in the previous 30 days. Patients presenting signs of MHE at the psychometric evaluation (TMT-A, TMT-B and DST) received rifaximin 1200 mg daily for 10 days. All patients underwent TCD for the measurement of RI and PI of the mean cerebral artery (MCA) and of posterior cerebral artery (PCA) at baseline and within 2 weeks after rifaximin treatment. Median value of the right and left side arteries have been used for the analysis. Intra-abdominal vessels (renal arteries, mesenteric artery, portal vein) flow parameters were also assessed, and the Child-Pugh score was calculated.
Results: Among the patients enrolled in the study 17 had MHE (44.7%). MCA-PI, PCA-PI and RI were significantly increased in patients with MHE compared to those without (MCA-PI 1.04 vs 1.05, p = 0.05; PCA-PI 1.12 vs 0.9, p = 0.02; PCA-RI 0.64 vs 0.56, p = 0.01) while MCA-RI showed a trend towards the increase (0.65 vs 0.61, p = 0.07). No significant difference was found in the intra-abdominal vessels flow parameters between the two groups. Furthermore, cerebral arteries resistance indices were not associated with the Child-Pugh score. After treatment with rifaximin, TMT-A and B and DST showed a significant

improvement (p = 0.05, p = 0.03 and p = 0.003 respectively). Only PCA-RI was ameliorated after rifaximin treatment (p = 0.024).
Conclusion: MHE is associated with increased cerebral vascular resistance in cirrhotic patients, which remains substantially unchanged after medical therapy.

Contact E-Mail Address: luo_xuefeng@yeah.net
Introduction: The expanded polytetrafluoroethylene (ePTFE)-covered stent has been widely used in the transjugular intrahepatic portosystemic shunt (TIPS) procedure. The purpose of this study was to evaluate the incidence, clinical outcomes, and prognostic factors of acute TIPS occlusion (ATO) in TIPS recipients using ePTFE-covered stents.
Aims and Methods: A retrospective study, including 222 TIPSs created with ePTFE-covered stents between June 2015 and June 2017 was performed. Medical records were reviewed to identify demographics, underlying liver disease, and TIPS procedure data, and the influence of these variables on ATO was assessed by multivariate logistic regression analysis.
Results: TIPS technical success was achieved in 219 patients (98.6%). Two patients were excluded due to missing data, leaving 217 patients for final analysis. ATO occurred in nine patients (4.1%). In all series, parameters that were significantly different between patients with and without ATO were platelets levels, previous splenectomy, portal vein thrombosis, portal cavernoma, shortage of stent in the hepatic vein, stricture on the shunt, and residual thrombosis below the shunt. On multivariable logistic regression, stricture on the stent (hazard ratio = 36.09; 95% confidence interval [CI]: 2.93–443.96; p = .005), and previous splenectomy (hazard ratio = 22.99; 95% CI: 1.29–408.39; p = .033) were demonstrated as independent, significant risk factors for ATO.
Conclusion: ATO is not uncommon in the era of ePTFE-covered stents. The stricture on the shunt and previous splenectomy are vital prognostic factors for ATO in TIPS recipients.

P0655 NEUTROPHIL TO LYMPHOCYTE RATIO AS PREDICTOR OF SYSTEMIC INFLAMMATORY RESPONSE SYNDROME AND MORTALITY IN PATIENTS WITH DECOMPENSATED LIVER CIRRHOSIS

A Gonzalez Mendez, M Maevskaya, M Zharkova, V Lunkov, E Tsvetaeva, V Ivashkin
First Moscow Medical State University I.M. Sechenov, Moscow, Russian Federation

Contact E-Mail Address: anaglezmendez@gmail.com
Introduction: Fatal infections with signs of systemic inflammatory response syndrome (SIRS) are often seen in patients with decompensated liver cirrhosis. SIRS in these patients is associated with progressive organ dysfunction. Simple prognostic factors to predict mortality in such patients are needed.
Aims and Methods: The aim of the study was to to evaluate the role of the neutrophil-to-lymphocyte ratio (NLR) to predict SIRS and mortality in patients with decompensated liver cirrhosis during hospitalization.
In this retrospective observational cohort study were enrolled 36 patients with decompensated liver cirrhosis between January 2009 and December 2016. The primary end points of the study were survival during hospitalization and presence of SIRS. NLR along with Child-Pugh score, MELD score, leukocyte, lymphocyte and neutrophil counts were assessed for the prediction of mortality and SIRS.
Results: A strong correlation was found between mortality and the following parameters: the level of neutrophils (r = 0.720; p < 0.001), lymphocytes (r = −0.760; p < 0.001), NLR (r = 0.749; p < 0.001), presence of SIRS with proven infection (r = 0.750; p < 0.001) and MELD (r = 0.795; p < 0.001). The median NLRs were 2.4 (IQR: 1.9–3.9) and 21.6 (IQR: 9.3–30.6) in surviving and non-surviving patients, respectively (p < 0.001). Multivariable analysis showed that a low lymphocyte count was an independent risk factor for mortality (OR: 0.68 [95% CI 0.517–0.895]; p = 0.006). The AUC values were 0.958 ± 0.028 (p < 0.0001) for NLR and 0.816 ± 0.087 (p < 0.0003) for lymphocyte count. The sensitivity and specificity of the NLR > 4.033 were 100% (95% CI 73.5–100) and 79.17% (95% CI 57.8–92.9), respectively, with 70.6% (95% CI 52.2–84.0) positive and 100% negative predictive values. The sensitivity and specificity of the lymphocyte count ≤ 0.9 were 83.3% (95% CI 51.6–97.9) and 75% (95% CI 53.3–90.2), respectively, with 62.5% (95% CI 44.4–77.7) positive and 90% (95% CI 71.3–97.0) negative predictive values.
Multifactorial analysis of SIRS with proven infection showed that NLR was an independent risk factor for its development (OR: 1.21 [95% CI 1.046–1.41]; p = 0.011). The AUC value was 0.865 ± 0.085 (p < 0.0001). The sensitivity and specificity of the NLR > 4.869 were 83.3% (95% CI 51.6–97.9) and 83.3% (95% CI 57.8–92.9), respectively, with 71.4% (95% CI 49.7–86.4) positive and 90.9% (95% CI 73.6–97.3) negative predictive values.
A subanalysis of 22 patients with Child-Pugh C cirrhosis also demonstrated that lymphocyte count was an independent risk factor for the development of SIRS with proven infection (OR: 0.76 [95% CI 0.609–0.955]; p = 0.018), as well as for mortality (OR: 0.69 [95% CI 0.503–0.957]; p = 0.026). The AUC value was 0.758 ± 0.115 (p < 0.025), with a cut-off value ≤0.8 and 70% (95% CI 34.8–93.3) of sensitivity and 83.3% of specificity (95% CI 51.6–97.9), PPV - 77.8% (95% CI 48.1–93.0), NPV - 76.9 (95% CI 55.6–89.9) for SIRS outcome. In mortality analysis, the lymphocyte AUC was 0.864 ± 0.09 (p < 0.0001), with a cut-off value ≤1.3 and 90% (95% CI 58.7–99.8) of sensitivity and 81.8 % of specificity (95% CI 48.2–97.7), PPV - 83.3% (95% CI 58.5–94.7), NPV - 90 (95% CI 57.6–98.3).
Conclusion: According to these results NLR and lymphocyte count can be regarded as independent prognostic factors for the development of SIRS with proven infection and for mortality during hospitalization in patients with decompensated liver cirrhosis. Nevertheless, further research is essential to confirm these findings.
Disclosure: Nothing to disclose

P0656 HEPATIC OSTEODYSTROPHY - IS THERE CLINICAL RELEVANCE?

F Pereira[1], R Azevedo[1], M Linhares[1], J Pinto[1], H Ribeiro[1], C Leitão[1], A Caldeira[1], J Tristan[1], E Pereira[1], R Sousa[1], A Banhudo[1]
[1]*Amato Lusitano Hospital, Gastroenterology, Castelo Branco, Portugal*

Contact E-Mail Address: pereiraflavio14@gmail.com
Introduction: Hepatic osteodystrophy, including osteoporosis, is an abnormal bone metabolism related with chronic liver disease. Osteoporosis is associated with an increased risk of bone fractures, with a significant impact on morbidity, quality of life and mortality. Several factors may contribute to reduced bone mineral density (BMD) in liver cirrhosis, such as malnutrition, cholestasis, alcohol and tobacco abuse and low vitamin D levels.
Aims and Methods: We aimed to assess the prevalence of osteopenia and osteoporosis in patients with liver cirrhosis.
We conducted a prospective study between September/2017 and March/2018 including patients with liver cirrhosis. BMD was determined by dual energy X-ray absorptiometry at L1-L4 and femoral neck. As defined by the World Health Organization criteria, osteopenia was present when a t-score lied between −1 and −2.5 standard deviations (SD), and osteoporosis when a t-score was ≤−2.5 SD.
Results: 60 patients were included (87% male, mean age of 63±9 years; 91.7% alcoholic etiology; Child-Pugh A-65%, B-28.3%, C-6.7%).
53.5% had history of falls and 21.7% prior fragility fracture (mainly long bones). Osteopenia was diagnosed in 73% and osteoporosis in 22% of cases. Femoral neck was more frequently affected.
Patients with osteopenia or osteoporosis had lower weight and body mass index (p < 0.05) and higher Child-Pugh score (p < 0.01).
There was a correlation between osteoporosis and prior fragility fracture (p = 0.015, R = 0.313), esophageal varices (p = 0.04; R = 0.278), concomitant chronic pancreatitis (p = 0.002; R = 0.389) and proton-pump inhibitors (p = 0,037, R = 0.27). There was also a correlation between low vitamin D levels and the t-score at the femoral neck (p = 0.025; R = 0.296).
Conclusion: This study demonstrates a high prevalence of metabolic bone disease in patients with chronic liver disease. The prevalence of prior bone fracture is also concerning.
Osteoporosis and bone fractures have a harmful effect on quality of life and are associated with increased morbidity and mortality. BMD measurement is clinically relevant in patients with liver cirrhosis, allowing the detection of bone disorders and the institution of prophylactic measures to optimize bone health.

P0657 ROYAL FREE HOSPITAL CIRRHOSIS GLOMERULAR FILTRATION RATE (RFHC-GFR): APPLICATION AND IMPLICATIONS FOR LIVER CIRRHOSIS IN CLINICAL PRACTICE

J Carvão, V Magno Pereira, A Oliveira, C Sousa Andrade, M.G Faria, L Jasmins
Hospital Central do Funchal, Gastroenterology, Funchal, Portugal

Contact E-Mail Address: joanacarvao@hotmail.com
Introduction: Both serum creatinine and current creatinine-based equations for GFR estimation have been proven to be inaccurate in cirrhotic patients. A more accurate formula has been proposed[1] - the RFHC-GFR that warrants further validation.
Aims and Methods: To compare different creatine-based equations for GFR estimation in liver cirrhosis. We also aimed to compare the conventional and corrected Model For End Stage Liver Disease (MELD-Na) as predictors of 12-month mortality.
Clinical and laboratory data of 123 consecutive outpatients with cirrhosis between January and December of 2016 were retrospectively analysed. Patients with acute kidney failure, extra-hepatic neoplasms and history of kidney or liver transplantation were excluded. GFR rates were calculated using RFHC, Modification of Diet Renal Disease (MDRD) and Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equations. A 'corrected creatinine value' was obtained through backward application of MDRD equation using RFHC-GFR values. ''Corrected MELD-Na'' was then calculated.

Results: Of the 123 patients included in the study 78.9% were male and the mean age was 58.23 (±8.95) years. 86.2% had alcohol-related liver disease, 22.8 % had significant comorbidities and 8.9% had hepatocellular carcinoma. The percentage of patients in the Child-Pugh Score A, B and C was 53.7%, 35.8% and 10.6% respectively. Median MELD score was 13 (±12). There was a statistically significant difference in GFR depending on which formulae was used ($p < .001$). RFH-GFR was significantly lower when compared to CKD-EPI or MDRD ($p < .001$). When RFHC-GFR was used a significantly larger proportion of patients were considered to have moderate-to-severe GFR reduction than with CKD-EPI or MDRD (59.3% vs. 9.8% and 10.6%, respectively $p < .001$). The median value of 'corrected MELD-Na' was 2 points higher than conventional MELD-Na ($p < .001$) and had a higher AUC (0.788 vs. 0.775 $p = 0.56$) for 12-month mortality prediction.
Conclusion: Lower unrecognised GFR can potentially increase the risk of adverse outcomes such as renal toxicity and more importantly increase conventional calculated MELD-Na scores which could alter liver transplant priority.
Disclosure: Nothing to disclose

P0658 DANAPAROID SODIUM AND ANTITHROMBIN III FOR PORTAL VEIN THROMBOSIS: EXPERIENCE OF A SINGLE JAPANESE HOSPITAL

S Usui, A Yamaguchi, Y Takatori, Y Hosoda
National Hospital Organization Saitama National Hospital, Department of Gastroenterology, Wako, Japan

Contact E-Mail Address: usui@a3.keio.jp
Introduction: Anticoagulant therapy or thrombolytic therapy is often administered for portal vein thrombosis (PVT). However, starting these therapies is usually hesitated, especially in the patients with decompensated liver cirrhosis with bleeding tendencies. Danaparoid sodium, a heparinoid glycosaminoglycuronan with highly selective anti-Xa activity, and antithrombin III (ATIII) have been reported to be treatment choices for PVT in Japan, instead of conventional anticoagulants. In this study, we investigated its efficacy for PVT in our hospital.
Aims and Methods: Twenty-three consecutive patients treated for PVT from 2012 to 2017 in our hospital were included in this study. Treatment choices, efficacy, and complications were retrospectively studied. Efficacy is defined as the disappearance or decreased volume of PVT in the follow-up image studies.
Results: Twenty-three patients, aged from 44 to 82 years, included 12 males and 11 females. Thirteen cases (57%) were of liver cirrhosis, three of acute pancreatitis, two of acute cholangitis, two of sepsis, and 3 cases of indeterminate origin. Nine patients (39%) were treated by warfarin, 8 patients (35%) were treated by ATIII combined with danaparoid sodium or heparin, 4 patients (17%) were treated by ATIII only, and 2 patients (9%) were treated by direct oral anticoagulants. PVT disappeared or decreased in volume in 17 cases (74%). Complete obstruction of portal vein was noticed in 3 of 6 ineffective cases. In 12 cases with ATIII administration, ten cases (83%) showed effective PVT control without complications including any bleeding events. PVT was aggravated in 3 cases (13%) after initial therapy. In four cirrhotic patients that anticoagulant therapies were continued for prevention of PVT recurrence, two cases ceased anticoagulation due to bleeding events.
Conclusion: Various treatment choices had comparable effects for PVT. Ineffectiveness was frequently encountered in cases of complete portal vein obstruction, despite of prompt treatment administration. Timely treatment strategy modification should be considered in those cases. Moreover, it is important to evaluate the need of maintenance anticoagulation since PVT recurs frequently, along with the risk of complications such as bleeding.

P0659 RESULTS OF LIVER CIRRHOSIS REGISTRY IN IRAN: EPIDEMIOLOGY, UNDERLYING CAUSES AND COMPLICATIONS

A Eshraghian, V Ahmadi, A.R Safarpour, M.R Fattahi
Gastroenterohepatology Research Center, Shiraz University of Medical Sciences, Shiraz, Iran (Islamic Republic of)

Contact E-Mail Address: eshraghiana@yahoo.com
Introduction: Liver cirrhosis is characterized by chronic hepatic parenchymal damage, hepatocyte loss, fibrosis formation causing progressive hepatic dysfunction and hepatic failure. Liver cirrhosis causes significant morbidity and mortality and accounts for 2% of all annual death worldwide. The epidemiology of liver cirrhosis is variable in different geographical areas of the world.
Aims and Methods: This study is the first registered data on epidemiology of liver cirrhosis in Iran focusing on underlying liver diseases and complications. This registry has been established at Gasteroeterohepatology Research Center, Shiraz, Iran. The registry has been started from March 2015. All patients with confirmed liver cirrhosis by biopsy and/or transient elastography plus clinical clues were included. Patients with liver cirrhosis that had been admitted in hospitals due to various complications of cirrhosis were also included. Data of patients were recorded in a web-based software designed and produced based on data gathering forms and questionnaires of the registry. Demographic data, laboratory data, anthropometric indices, drug history, social history including alcohol consumption, cigarette and water pipe smoking, opium consumption, co-morbid diseases were recorded. Complications of liver cirrhosis including hepatocellular carcinoma (HCC), esophageal or gastric varices, spontaneous bacterial peritonitis (SBP), ascites, hepatorenal syndrome, portal vein thrombosis (PVT) and hepatic encephalopathy were recorded.
Results: 3287 patients were included up to 30th March 2018. 2144 patients (65.2%) were male and 1143 patients (34.8%) were female. Mean age of patients were 46.50 ± 21.28 years. Main underlying causes of liver cirrhosis in our study population were outlined in Table. Hepatitis B virus (HBV) induced liver cirrhosis was the most common cause of liver cirrhosis that was diagnosed in 664 patients (20.20%). The second and third most common etiologies of liver cirrhosis were cryptogenic liver cirrhosis and hepatitis C virus (HCV) induced liver cirrhosis that were diagnosed in 619 patients (18.83%) and 443 patients (13.47%) respectively. The highest prevalence in patients with cryptogenic cirrhosis, HBV and HCV induced cirrhosis and autoimmune hepatitis (AIH) was observed between 50–60 years. The highest prevalence of non-alcoholic steatohepatitis (NASH) was seen between 60–70 years. Ascites was detected in 1639 patients (50%) and esophageal varices in 1118 patients (36%). 969 patients had at least one episode of hepatic encephalopathy and 382 patients had at least one episode of SBP. Variceal bleeding was occurred in 636 patients and hepatorenal syndrome (HRS) in 254 patients. PVT was diagnosed in 360 patients and HCC in 293 patients. Ascites, esophageal varices and hepatic encephalopathy were the most common complications in all etiologies of liver cirrhosis.
Conclusion: Viral hepatitis is still a major cause of liver cirrhosis in Iranian population. There is also a significant male predominance among patients with liver cirrhosis secondary to HBV and HCV. Cryptogenic cirrhosis and autoimmune liver diseases including AIH and primary sclerosing cholangitis (PSC) are other main etiologies of liver cirrhosis.

	HBV	Cryptogenic	HCV	AIH	PSC	Alcoholic	NASH
Frequency	664	619	443	427	154	83	54
Percent (%)	20.20	18.83	13.47	12.9	4.68	2.52	1.64
Male/female (%)	81/19	59/41	79/20.5	50.5/49.5	64/33	98/2	61/39

[Frequencies and proportions of major causes of liver cirrhosis in the registry]

P0660 SPONTANEOUS BACTERIAL PERITONITIS: ARE WE FOLLOWING GUIDELINES?

S.M Ha[1], H Al-Hasani[1], V Jeyaprakash[1], L Crisan[2], N Siddique[2]
[1]*East Kent Hospitals NHS Foundation Trusts, Gastroenterology, Ashford, United Kingdom*
[2]*East Kent Hospitals NHS Foundation Trusts, Gastroenterology, Margate, United Kingdom*

Contact E-Mail Address: s.m.ha@doctors.org.uk
Introduction: Spontaneous bacterial peritonitis (SBP) is the most common serious infection in patients with cirrhosis, occurring in 25% of those who develop ascites. It is associated with significant morbidity and mortality rates of 20–40%.[1]
British Society of Gastroenterology (BSG) and National Institute of Clinical Excellence (NICE) guidelines recommend long-term prophylaxis (LTP) with Ciprofloxacin or Norfloxacin in patients with cirrhosis who have low ascitic fluid protein concentration (< 15g/L) with or without prior episode of SBP (primary LTP) or who have had an episode of spontaneous bacterial peritonitis (secondary LTP)[1,2].
Aims and Methods: We carried out a retrospective observational study using our electronic system for admissions with a diagnosis of ascites and cirrhosis across the East Kent Hospitals NHS Foundation Trust from April 2014 to April 2017. Ascitic fluid analysis results were reviewed against discharge summaries to audit whether LTP was started according to national guidelines.
Results: 337 cases of ascites with cirrhosis were identified (93 female: 244 male) with a median age of 58 (range 30–92 years).
61 out of 337 cases had a current or previous diagnosis of SBP. 5 out of 61 died during their admission. 10 out of 61 were discharged on secondary LTP and 46 patients were discharged without LTP.
11 out of 337 cases had low ascitic fluid protein with no current or previous episodes of SBP. None of these patients were discharged with primary LTP.
Conclusion: East Kent Trusts followed national guidelines in starting secondary LTP for SBP in 18% (10 out of possible 56) of cases and 0% of cases requiring primary LTP from April 2014 to April 2017. This low adherence rate may reflect lack of clinician awareness of guidelines for prescribing LTP for SBP in patients with ascites. There may also be a relation to local microbiology guidelines not following BSG or NICE guidelines on initiation of primary or secondary LTP for SBP. This study serves as a reminder to clinicians to carefully consider LTP in patients with ascites secondary to cirrhosis on each admission. We also recommend that trusts review local microbiology guidelines to ensure it adheres to national guidelines.

Introduction: Recent studies propose a subclassification of stage 1 of acute kidney injury (AKI) in patients with cirrhosis, according to the serum creatinine value (sCr) at the time of diagnosis.[1,2,3]

Aims and Methods: The aim was to evaluate the association of subclassification stage 1 of AKI in patients with cirrhosis with the presence of acute-on-chronic liver failure (ACLF), progression of AKI and 30-day mortality.

A retrospective assessment of patients with cirrhosis admitted for acute decompensation with AKI stage 1 was performed. AKI stages were determined based on sCr at the time of hospital admission and according to criteria defined by the International Ascites Club. Stage 1 was subclassified in 1A if sCr < 1.5 mg / dL and 1B if sCr ≥ 1.5 mg / dL.

Results: Ninety patients were included, 45 in stage 1A 45 (50%) and 45 (50%) in stage 1B.

The mean differences between sCr at diagnosis and baseline were higher at stage 1B compared to 1A, 0.7 ± 0.23 vs 0.43 ± 0.11, $p < 0.001$.

Progression of AKI occurred more frequently in patients with stage 1B (40%) compared to patients 1A (4.4%), $p < 0.001$. Hepatorenal syndrome occurred more frequently in stage 1B than in 1A, 20% vs 2.2%, $p = 0.007$.

ACLF was more frequent in patients with stage 1B (42.2%) compared to patients with stage 1A (4.4%), $p < 0.001$.

There was a higher mortality at 30 days in 1B patients compared to patients with 1A, 40% vs 8.9%, $p = 0.001$.

Conclusion: Stage 1B patients are at higher risk for progression of AKI, higher mortality, and more frequently present ACLF, thus requiring more attention in identifying, monitoring and treating them early.

Introduction: Hepatic fibrosis and portal hypertension are major determinants of clinical outcome in advanced chronic liver disease. Liver fibrosis is driven by persistent activation of hepatic stellate cells, with TGF-β being the key fibrogenic cytokine. SerpinB3 (or SCCA1) has been reported to activate hepatic stellate cells and SerpinB3 transfected cells up-regulate TGF-β1 production, an effect shown to rely on the integrity of the reactive site loop of this serpin. The polymorphic variant SCCA-PD presents a substitution in the reactive center loop of the protein (Gly351Ala), determining an improved anti-protease activity of this isoform.

Aims and Methods: To assess the effect of SCCA-PD polymorphic variant on TGF-β1 expression by using *in vitro* models and to disclose the clinical characteristics and the outcome in a cohort of cirrhotic patients carrying or not this polymorphic variant.

TGF-β1 transcripts and protein levels were determined in HepG2 and in Huh7 cells transfected with either wild-type SerpinB3 (SCCA-WT) or with SCCA-PD polymorphic variant. Cells transfected with the plasmid alone were used as control. TGF-β1 expression was also evaluated in the human stellate cell line LX2 in response to recombinant SCCA-WT or SCCA-PD proteins. In addition, SCCA polymorphism was assessed in 59 cirrhotic patients (72.9% male; mean age±SD: 53.9 ± 9.1 years), prospectively followed up at our outpatient Clinic for a median period of 114 months (range 60–120). The results were analyzed in relation to clinical data, hemodynamic features at baseline and the onset of new complications during follow up.

Results: Transfected cell lines showed increased TGF-β1 expression, compared to controls and this finding was more prominent in cells transfected with SCCA-PD, both at transcript and protein levels (SCCA-WT vs SCCA-PD, mRNA: $p = 0.027$, protein: $p = 0.009$). Accordingly, the addition of recombinant SCCA-PD to human LX2 cells induced higher TGF-β1 production, compared to SCCA-WT protein ($p < 0.01$). SCCA-PD polymorphism was detected in 27% of the enrolled patients that at baseline, despite they had similar age than patients carrying SCCA-WT (52±8 vs 54±9 years), presented signs of more advanced portal hypertension, including portal vein dilation (portal vein >14 mm: 50% vs. 34%), marked splenomegaly (spleen >16 cm: 62.5% vs. 25%, $p = 0.008$), and varices at higher risk of bleeding (F2-F3: 33% vs. 15%). In addition, patients carrying SCCA-PD variant presented a significantly higher MELD score (14 vs. 11 $p = 0.01$) and during a 5 years follow-up they developed a higher number of cirrhosis complications (40% vs. 11.6%, $p = 0.016$). In the multivariate Cox regression analysis, SCCA-PD (OR $= 3.78$, $p = 0.026$) and MELD score (OR:1.16; $p = 0.016$) were identified as independent predictors of cirrhosis complications development.

Conclusion: The polymorphic variant SCCA-PD is able to increase TGF-β production *in vitro* more efficiently than the corresponding wild type protein. Patients with advanced liver disease carrying the SCCA-PD polymorphism present signs of more severe portal hypertension and develop more frequently cirrhosis complications during follow up, supporting a role of this polymorphic variant in liver disease progression.

Introduction: There has been a marked increase in studies revealing that oral antiviral treatment can suppress the replication of hepatitis B virus (HBV) and induce the regression of liver fibrosis, in which the degree of liver fibrosis is of great significance. In addition to liver biopsy, the gold standard, liver stiffness measurement (LSM) by non-invasive transient elastography has shown its outstanding value in monitoring the progression and regression of fibrosis and chronic hepatitis B (CHB)-related complications. In this study, we aim to evaluate the prognosis performance of LSM in predicting the subsequent regression of liver fibrosis in patients receiving long-term entecavir (ETV) treatment.

Aims and Methods: The study was designed to explore the correlation between improvement in longitudinal liver stiffness and fibrosis regression during long-term antiviral therapy in CHB patients. We prospectively recruited a total of 120 consecutive adult patients with CHB, which received oral antiviral therapy with ETV after enrollment. Five-five CHB patients were enrolled in the non-cirrhosis group and 65 CHB patients were enrolled in the cirrhosis group. In study, liver stiffness was serially performed by Fibroscan apparatus (Echosens pavis, France) every 26 weeks. At baseline and week 78 of ETV therapy, paired liver biopsies were performed for every patients. The liver tissue was obtained by ultrasonography-guided percutaneous biopsy (Bard@ Magnum@16G;USA). Serum fibrosis markers, Fibrosis-4 (FIB-4) and aspartate aminotransferase (AST) to platelet ratio index (APRI) scores were assessed at baseline and every 26weeks. Continuous variables were summaried as mean ± standard deviation or median and interquartlie range (IQR) and categorical variable as frequency and percentage. Analyses of unpaired data were evaluated by the Mann-Whitney U-test, Chi-squared test and Fish's exact test. Statistical analyses were performed using SPSS software version 22.0 (SPSS INC Chicago, USA)

Results: Compared with non-cirrhosis group, gamma-glutamyltransferase, international normalized ratio (INR), APRI, FIB-4 and LSM were significantly higher in cirrhosis group at baseline. Marked decreases were found sequentially at time point of week 26, week 52 and week 78 during antiviral treatment. The serum levels of ALT, AST and INR gradually decreased after antiviral therapy. While albumin and cholinesterase levels were significantly increased after initiating ETV treatment. The serological fibrosis scores (APRI and FIB-4) also declined gradually during the antiviral treatment. Dynamic changes of LSM and serum biomarkers also show the association of LSM improvement with fibrosis regression at 78 weeks after ETV treatment. Moreover, percentage decline of 78-week liver stiffness was moderately predictive of fibrosis regression (AUROC $= 0.694$, $p < 0.001$). while the optimal cut-off values were different between non-cirrhosis and cirrhosis patients (38% vs. 45%). Fibrosis regression could be predicted with a high positive predictive value (96%) in non-cirrhosis patients and could be excluded with a high negative predictive value (94%) in cirrhosis patients.

Conclusion: Serial liver stiffness measurement could be applied for longitudinal monitoring of fibrosis status in CHB patients. Continuous decline of liver stiffness after effective antiviral treatment could partially reflect fibrosis regression at an optimal cut-off value.

Introduction: Sustained virologic response (SVR) to interferon (IFN)-free therapies ameliorates portal hypertension (1–4). However, the impact of the hemodynamic response on hepatic decompensation has yet to be investigated in this setting.

Aims and Methods: Seventy-seven patients with portal hypertension (HVPG ≥6mmHg) who underwent hepatic venous pressure gradient (HVPG) and liver stiffness (LS) measurement before (baseline [BL]) and after (follow-up [FU]) IFN-free therapy were retrospectively studied.

(Further) hepatic decompensation was defined by variceal (re-)bleeding, incident ascites/worsening of ascites (requirement of paracentesis), or incident hepatic encephalopathy (HE)/worsening of HE (admission for grade 3/4 HE).

Results: Patient characteristics at BL: Child-Pugh A: 81%, B: 19%; MELD: 8 (interquartile range [IQR]: 2) points; HVPG: 13 (IQR: 8) mmHg.

In the subgroup of patients with a BL-HVPG of 6–9mmHg (n = 22), no patient progressed to clinically significant portal hypertension (CSPH; HVPG ≥10mmHg). Among patients with BL-CSPH, a HVPG-decrease ≥10% was observed in 65% (36/55), while 24% (13/55) had a FU-HVPG < 10mmHg (i.e., resolved CSPH).

During a median FU of 24.9 (IQR: 15.1) months after the end of HCV treatment, 10 patients developed (further) hepatic decompensation, with variceal bleeding (n = 1), ascites (n = 4), or HE (n = 5) being the first events. Two patients underwent liver transplantation (both had further decompensation) and one patient died (non-liver-related).

In patients with BL-CSPH, a HVPG-decrease ≥10% tended to decrease the risk of (further) hepatic decompensation at 2 years (10% vs. 27%, p = 0.072). Overall, the absence of FU-CSPH was fully protective of the development of (further) hepatic decompensation (0% vs. 21%, overall p = 0.002). This was confirmed in the subgroup of patients with BL-CSPH (p = 0.004).

The area under the receiver operating characteristic curve (AUROC) of FU-LS for diagnosing FU-CSPH/predicting (further) hepatic decompensation was 0.923/0.887. None of the patients with FU-LS values < 12kPa or < 18.9kPa had FU-CSPH or (further) hepatic decompensation, respectively.

Conclusion: The resolution of CSPH after SVR to IFN-free regimens is associated with a negligible risk of (further) hepatic decompensation, while a HVPG-decrease ≥10% is not fully protective. Moreover, FU-LS seems to provide prognostic information.

Disclosure: M.M. has served as a speaker and/or consultant for AbbVie, Bristol-Myers Squibb, Gilead, Janssen, and W. L. Gore & Associates.

P0665 NUTRITIONAL PARAMETERS IN PATIENTS WITH DECOMPENSATED CIRRHOSIS, THEIR INFLUENCE IN EARLY READMISSION AND 1-YEAR MORTALITY

L Franco[1,2], M Rodriguez[1], A Navascues, C Fraile[1], M Siguairo[1], O Fernandez[1], C Ferrusquia[1], J Gonzalez-Dieguez[1], L Valle[1], C Varela[1], M.D.W Victor III[2]
[1]*Hospital Universitario Central de Asturias, Oviedo, Spain*
[2]*Houston Methodist Hospital, Houston, United States*

Contact E-Mail Address: francolissa@hotmail.com

Introduction: The prevalence of malnutrition among patients with cirrhosis is particularly concerning due to its association with mortality and inherent complications. Multiple studies described a rate of protein-calorie malnutrition around 50–100% in patients with decompensated cirrhosis, and at least 20% with compensated cirrhosis. Early hospital readmissions (within the next 30 days after discharge) among patients with decompensated cirrhosis predict a poor outcome and increase the 1-year mortality. We consider that early re-hospitalization could be predictable and therefore, potentially preventable. This study aims to recognize an association between the nutritional status of the patients with decompensated cirrhosis and early readmissions.

Aims and Methods: This is a prospective study performed in a tertiary referral hospital of Spain. This study included 136 patients admitted to the Hepatology Unit with decompensated cirrhosis. Before the discharge, we collected clinical and laboratory data from the medical chart. We evaluated the following nutritional parameters: weight, height, body mass index (BMI), albumin at income, brachial perimeter, tricipital skinfold, and scapular skinfold. We also calculated the "dry weight" known as the weight adjusted to the ascites grade (subtracting from the total weight: 2.2 kg. in grade I, 6 kg. in grade II, and 14 kg. in grade III). The follow up was performed 30 days, 6 months and 1 year after the discharge, via telephone or in the clinic if the dates matched with the visits.

Results: The median of BMI in patients with early readmission was 26.0 kg/m^2 (p = 0.01). Nutritional parameters with statistic significance in the univariate analysis related with early readmission were: BMI < 18.5 (0.0 vs 10.8%; p = 0.001) BMI 25–29 (47.5% vs 21.6%; p = 0.02), Dry BMI < 18.5 (0.0 vs13.5%; p < 0.01), brachial perimeter in mm. (270 vs 250 mm; p = 0.03) and albumin (32 vs 29 g/L; p = 0.02). The early readmission rate was 27.2%. The 1-year overall mortality was increased in those patients who had early readmission (56.8% vs 20.2%). In the multivariate model two nutritional parameters showed association with early readmission: Dry BMI < 18.5 (HR 4.23, 95% CI: 1.14–15.74; p = 0.03) and albumin as a protector factor (HR 0.89, 95% CI: 0.82–0.96; p = 0.004). None of the nutritional factors presented an association with 1-year mortality.

Conclusion: Dry BMI < 18.5 and albumin are the nutritional parameters that influence in 30-day readmission. Therefore, nutritional status should be a target of preventive actions of early readmission. As these variables are also related to progression of liver failure, more studies with advanced nutritional measurements are needed in this population.

P0666 SEROLOGICAL INDICES OF LIVER FIBROSIS IN THE COURSE OF ALCOHOLIC LIVER CIRRHOSIS - A PILOT STUDY

A Michalak[1], H Cichoż-Lach[1], M Guz[2], M Cybulski[2], B Kasztelan-Szczerbińska[1]

Introduction: Liver biopsy has been described as a gold standard in the assessment of the severity of liver fibrosis so far. However, due to its limitations, it is crucial to look for noninvasive laboratory parameters, which make it possible to monitor liver stiffness.

Aims and Methods: The aim of our investigation was to determine the usefulness of selected serological indices in the assessment of liver fibrosis in the course of alcoholic liver cirrhosis (ALC). We enrolled 55 participants in the survey and among them 22 patients with ALC in research group together with 33 persons in control group. The diagnosis of ALC was based on commonly known criteria. We measured concentration of direct indicators of liver fibrosis in serum of all participants: platelet-derived growth factor AB (PDGF-AB), transforming growth factor α (TGF-α), N-terminal propeptide of type III collagen (PIIINP), procollagen I carboxyterminal propeptide (PICP) and laminin. Several indirect parameters of liver fibrosis were obtained too: aspartate aminotransferase (AST) to alanine aminotransferase ratio (AAR), AST to platelet (PLT) ratio index (APRI), fibrosis-4 (FIB-4) score and red cell volume distribution width (RDW) to PLT ratio (RPR). To evaluate a clinical outcome of patients, we assessed Model for End-Stage Liver Disease (MELD) score and neutrophil to lymphocyte ratio (NLR). Finally, we also measured PLT indices: mean PLT volume (MPV), PLT distribution width (PDW) and plateletcrit (PCT). We looked for any correlations between assessed parameters in patients with ALC, too.

Results:

	ALC patients (n = 22)	Controls (n = 33)	p value
PLT (10^9/L)	***135.14 ± 83.62***	***275.3 ± 73.15***	p < 0.01
RDW (%)	17.12 ± 2.26	17.98 ± 23.73	p < 0.01
RPR	0.22 ± 0.19	0.06 ± 0.07	p < 0.01
MPV (fl)	9.9 ± 1.73	8.72 ± 0.91	p = 0.01
PCT (%)	0.14 ± 0.08	0.28 ± 0.12	p < 0.01
PDW (%)	59.98 ± 6.74	53.02 ± 6.83	p = 0.027
NLR	11.38 ± 11.89	2.62 ± 1.49	p < 0.01
AAR	2.79 ± 2.35	1.27 ± 0.46	p < 0.01
APRI	4.81 ± 7.12	0.29 ± 0.13	p < 0.01
FIB-4	6.04 ± 6.14	1.01 ± 0.48	p < 0.01
MELD	15.41 ± 7.44	–	–

(continued)

Continued

	ALC patients (n = 22)	Controls (n = 33)	p value
PICP (ng/mL)	93.51 ± 29.44	78.64 ± 37.15	p = 0.037
PIIINP (ng/mL)	7.81 ± 3.47	8.87 ± 3.48	p > 0.05
PDGF-AB (pg/mL)	8518.49 ± 5427.92	17241.85 ± 10041.99	p < 0.01
TGF-α (pg/mL)	38.23 ± 9.94	38.04 ± 15.26	p > 0.05
LAMININ (ng/mL)	1331.53 ± 941.16	717.57 ± 299.74	p < 0.01

[The results of performed tests in examined patients presented as mean ± SD. A value of p < 0.05 was considered statistically significant.]

Obtained results are presented in Table 1. Significantly lower concentration of PDGF-AB and higher concentrations of laminin and PICP were found in ALC patients. Subsequently, we observed significantly higher values of AAR, APRI, FIB-4, RPR, NLR, MPV and PDW in research group. PCT value was significantly lower and correlated negatively with APRI, FIB-4 and RPR ($p < 0.01$). Furthermore, APRI correlated positively with both FIB-4 and RPR ($p < 0.01$). Another positive correlation was observed between between NLR and AAR ($p < 0.01$). Finally, we observed a negative correlation between PIIINP and TGF-α ($p = 0.038$).

Conclusion: Our survey indicates that noninvasive parameters embracing liver, PLT and red blood cells indices might be useful in the assessment of liver fibrosis in the course of ALC. Additionally, higher concentrations of laminin and PICP and lower values of PDGF-AB seem to accompany ALC.

Introduction: Current guidelines recommend screening HVB in patients with chronic HCV before starting DAA therapy since HBV reactivation cases under treatment have been reported.. The objectives of our study were: 1) To know the screening rates of HBV in our community; 2) To assess the prevalence of HBV / HCV coinfection in HCV patients starting DAA therapy in our population, and 3) To determine the incidence of HBV reactivation in treated patients and its clinical relevance.

Aims and Methods: We retrospectively evaluated 1337 patients with HCV treated with DAA in 2 general hospitals in the southern region of Madrid from January 2015 to June 2017. We investigated HBV screening rates, the prevalence of HBV / HCV coinfection, and the incidence of virological reactivation by HBV (viral load elevation > 1 log), and biochemical reactivation.

Results: Ninety five (7.1%) out of the 1337 treated HCV patients did not have done HBV serology before treatment; 293 (21.9%) had negative HBsAg and HBcAg 584 (43.6%) had vaccination pattern; 9 (0.7%) were HBSAg positive and 356 (28.6%) had antiHBc and/or antiHBc antibodies as sign of past HVB infection.

Two hundred and twenty five (61%) out of 365 HCV patients with HBV or past HBV infection were male, with a mean age of 59 years (range: 20–85), 357 (98%) of Caucasian race, 118 (51.5%) genotype 1b, 164 (44.9%) were F4 and 252 (69%) had been previously treated with IFN. DAA regimens were Sofosbuvir / Ledipasvir (n = 155; 42.4%), Paritaprevir / Ombistasvir / Dasabuvir (n = 111; 30.4%) and other combinations (n = 99, 27.2%). SVR was obtained in 298 (99%) out of the 301 patients who could be evaluated.

Among HBsAg-positive patients, 5 out of 9 were receiving nucleos(t)ide analogs (NUCs) before starting DAA therapy. Two out of 4 patients without HBV treatment (50%) developed HBV virological reactivation but not biochemical flare. Reactivation occurred early at week 4 in the first patient and achieved virological response after 4 weeks of tenofovir; and in the second patient, reactivation was detected at week 4 of follow-up, with spontaneous decrease in viral load to baseline.

All of the 356 with HBV past infection pattern (100%) maintained normal transaminases at the end of treatment and during follow-up. Although HBV DNA was not available a biochemical reactivation can be excluded.

Conclusion: In our community, there is a high rate of HBV screening in patients with HCV prior to DAA therapy. The prevalence of HBV infection (positive HBsAg) in chronic HCV patients in the southern region of Madrid is low. HBV reactivation in HCV/HBV coinfected patients receiving AAD is frequent, but without clinical relevance.

Introduction: Vitamin D is an important immune modulator that plays an emerging role in inflammatory and metabolic liver diseases, including infection with hepatitis C virus (HCV), wich has been intensively studied. However, studies on the potential interaction between vitamin D level and chronic hepatitis B are still limited.

Aims and Methods: This study aimed to explore whether any association existed between serum vitamin D level and clinical determinants in patients with chronic hepatitis B infection. Therefore, we quantified 25(OH)D3 serum levels in a cohort of 187 treatment naıve patients with chronic hepatitis B virus (HBV) infection and tested for their association with clinical parameters of CHB.

Results: Mean 25-hydroxyvitamin D value was 21.90ng/ml. The percentage of patients with different concentration of 25-hydroxyvitamin D (adequate ≥20ng/ml, insufficiency10–20ng/ml, deficiency < 10ng/ml) were 29.5%, 43.2% and 27.3%, respectively. In both uni- and multivariate analyses, HBV DNA viral load (log10 IU/mL) was a strong predictor of low $25(OH)D_3$ serum levels (P50.0008 and P50.000038, respectively) and vice versa. Mean $25(OH)D_3$ serum concentrations in patients with HBV DNA < 2,000 versus 2,000 IU/mL were 18 versus 12 ng/mL, respectively ($p < 0.00001$). In addition, hepatitisB early antigen (HBeAg)-positive patients had lower $25(OH)D_3$ serum levels thanHBeAg-negative patients (P50.0013). 25-hydroxyvitamin D serum level is not associated with viral load or fibrosis stage in chronic hepatitis B patients. Finally, $25(OH)D_3$ and HBV DNA serum levels showed inverse seasonal fluctuations.

Conclusion: We demonstrate a significant association between low $25(OH)D_3$ serum levels and high levels of HBV replication in chronically infected patients. Future studies to evaluate a therapeutic value of vitamin D and its analogs in HBV infection may be justified.

Introduction: Hepatitis B virus (HBV) is a public health problem in the world and in Tunisia. Hemodialysis (HD) patients are at high risk of infection and vaccination against HBV remains the best prevention option for these patients. However, the immune deficiency of chronic renal failure (CRF) patients leads to a low seroconversion rate after vaccination and a faster decrease in antibody levels compared to healthy subjects.

Aims and Methods: To evaluate the efficacy of the vaccine protocol in chronic renal failure patients at the hemodialysis stage and to identify the factors that may influence the immune response.

This was a descriptive and cross-sectional retrospective study conducted in six hemodialysis centers in the southern suburbs of Tunis, in patients who had received an accelerated vaccination against hepatitis B virus., in single dose and deltoid intramuscular protocol by a recombinant vaccine of 2nd generation without pre-S2. The endpoint is the titer of anti-HBs antibodies. The response was described as non response, low response and good response for an anti-HBs antibody titer of less than 10 IU / L, between 10 and 100 IU / L and greater than 100 IU / L, respectively. Age, sex, diabetes, high blood pressure and the notion of active smoking were tested according to an analytical scheme in univariate and multivariate studies. The Chi-square test was used. A threshold of 5% was considered significant.

Results: In total, 61 patients were included in our study. The mean age of patients was 56.9 ± 17.3 years with a sex ratio of 1. The notion of active smoking was found in 47.5% (n = 29) of patients. Comorbidity was noted in all patients of

which 70.5% (n = 43) were diabetic and 72.1% (n = 44) were hypertensive. C-Viral serology was positive in only one patient and HIV serology was negative in all cases. Vaccine seroprotection was obtained in 54% of patients after a primary vaccination. The patients were low responders in 33.3% (n = 11) of cases and good responders in 66.7% (n = 22) of patients. In univariate and multivariate studies, the predictors of non-response and low response to the B virus vaccine were advanced age, female gender, active smoking, and the presence of diabetes.
Conclusion: In our series, anti-viral B vaccination in hemodialysis patients is less effective compared to literature data. Smoking control and a review of the legislation governing the modalities of vaccination for hemodialysis may improve immunization coverage.

P0671 COMPARISON BETWEEN TWO POPULATION-BASED SEROSURVEYS, SIXTEEN YEARS AFTER THE IMPLEMENTATION OF UNIVERSAL HEPATITIS B VACCINATION IN A HEPATITIS DELTA ENDEMIC AREA IN GREECE

V Papastergiou[1], G Ntetskas[2], F Papakonstantinou[2], A Chasiou[2], M Stampori[2], D Kozikopoulou[2], S Karatapanis[2]
[1]*General Hospital Of Rhodes, Gastroenterology, Athens, Greece*
[2]*General Hospital Of Rhodes, Rhodes, Greece*

Contact E-Mail Address: vasi.pap@hotmail.com
Introduction: The prevalence of hepatitis B virus (HBV) and hepatitis delta virus (HDV) infections has declined significantly in Greece, particularly after the introduction of universal HBV vaccination (1997). A rural area in Greece (Archangelos, Rhodes) was reported to be highly endemic for HBV/HDV during the 1980s, with 10.5% of the local population testing positive for hepatitis B surface antigen (HBsAg) and 27.3% of the HBsAg carriers testing positive for anti-HDV.
Aims and Methods: To compare between two population-based HBV/HDV serosurveys with a 16-year interval (1997–2013) in a highly-endemic area in Greece. Two population-based cross-sectional serosurveys were performed among the population aged 1–75 years in the same sample area (Archangelos, Rhodes, Greece), in 1997 (n = 1938; M/F = 900/1038, children: 29.5%, immigrants: 0%) and 2013 (n = 1076; M/F = 505/571, children: 21%, immigrants: 17.4%), respectively. From each individual, a blood sample was obtained and tested for HBsAg; all HBsAg-positive individuals were tested for anti-HDV. The demographic and ethnic origin data were recorded.compare between two population-based HBV/HDV serosurveys with a 16-year interval (1997–2013) in a highly-endemic area in Greece.
Results: In the 1997 serosurvey, 223/1938 (11.5%) subjects were positive to HBsAg and among them 56/223 (25.1%) were positive to anti-HDV. In children, 5/571 (0.9%) were HBsAg-positive, with no anti-HDV positivity. In the 2013 serosurvey, 35/1076 (3.76%) were HBsAg-positive and among them 7/35 (20%) were positive to anti-HDV. All children were HBsAg-negative. The seroprevalence of HBsAg was significantly higher among immigrants compared to native Greeks [12/187 (6.4%) vs 23/889 (2.6%) respectively, p = 0.01], although no significant difference was found concerning the prevalence of anti-HDV [2/12 (16.7%) vs 5/23 (21.7%) respectively, p = ns). The HBV-infected and HBV/HDV-coinfected immigrants were younger as compared to the respective native Greek population [HBV-infected: mean 51 vs 59.6 years respectively, p = 0.07; HBV/HDV-coinfected: 43.5 vs 60 years respectively, p = 0.04].
Conclusion: In a high endemic area, implementation of universal vaccination has led to a dramatic decline in the seroprevalence of HBV. However, a consistent reservoir of HDV remains, likely sustained by two different pools of infected individuals: a residual ageing domestic pool, and a newer one composed by younger patients migrating from countries where HBV/HDV remains endemic. Our findings deserve further investigation by phylogenetic analyses.

P0672 THE USE OF THE PATIENT SAFETY FORM APPLICATION IN PATIENTS RECEIVING IMMUNOSUPPRESSIVE THERAPY CAN IMPROVE THE LOW RATES OF HEPATIS B VIRUS SCREENING AND ANTIVIRAL PROPHYLAXIS IN REAL LIFE

M Demir[1], M.M Celik[2], E Ucar[2]
[1]*Mustafa Kemal University, Gastroenterology, Hatay, Turkey*
[2]*Mustafa Kemal University, Internal Medicine, Hatay, Turkey*

Contact E-Mail Address: drmehmetdemir@yahoo.com
Introduction: Hepatitis B virüs(HBV) prophylaxis in patient receiving immunosuppressive therapy can effectively prevent reactivation (1). However the rate of HBV screening and starting HBV prophylaxis is low in daily practice (1). While starting the biological agents treatments, use the patient safety form is mandatory in Turkey but there is no mandatory for other immunosuppressive treatments.
Aims and Methods: The aim of this study was to determine how much screening and rates of antiviral prophylaxis in patients receiving immunosuppressive therapy in daily practice and to evaluate the relationship between the patient safety form and rate of HBV screening and antiviral prophylaxis. This is a retrospective study. Patients who received biological agents (group 1; including anti-tumour necrosis factor-α and other monoclonal antibodies, use of the patient safety form mandatory)and cytotoxic chemotherapy, rituximab, long-term high-dose steroids (group 2: use of the patient safety form not mandatory) in Medical University of Mustafa Kemal were included in the study. HbsAg and Anti-HbcIg tests performed during the period up to 1 year before treatment of immunosuppressive agent were accepted as screening. Methylprednisolone or equivalent steroid of its use for at least 4 weeks and at least 20 mg /day were considered to be as long-term high-dose. HbsAg and/or HbcIg positivity was defined as a riskly patients for HBV reactivation.
Results: A total of 1302 patients were included in the study. The immunosuppressive treatment distributions of the patients were as follows; 648 cytotoxic chemotherapy (356 combined with steroids), 325 long-term high-dose steroids, 218 biological agents, 111 rituximab. Six hundred and fifty two (50.1%) of the patients had screened for HbsAg and/or anti-HBcIg. HbsAg positivity was found in 6.6% (43/652) of patients and HbsAg negative and anti-HBcIg positivity in 29.7% (113/380) of patients. The rates of HBsAg and/or anti-HBcIg screening were 94% (205/218) in group 1 and 42.7% (447/1084) in group 2. There was a statistically significant difference group 1 compared to the group 2 ($p < 0.001$). The rates of HBsAg and/or anti-HBcIg screening according to the immunosuppressive treatment were as follows;in patients receiving cytotoxic chemotherapy was 53% (348/648), in rituximab patients was 51% (57/111) and in patients with long-term high-dose steroid treatments was 13% (42/325). There was a statistically significant difference in the patients receiving biological agent treatment compared to other treatment groups (biological agent vs cytotoxic chemotherapy $p < 0.05$, biological agent vs rituximab $p < 0.05$, biological agent vs long-term high-dose steroid $p < 0.001$). Rates for risky patients for HBV reactivation were found in 23.4% (48/205) in group 1 and 23.9(108/447) in group 2 ($p > 0.05$). Rates antiviral prophylaxis were 98% (47/48) in group 1 and 49.1% (53/108) in group 2. There was a statistically significant difference group 1 compared to the group 2 ($p < 0.001$).
Conclusion: The screening rates are very low in patients receiving cytotoxic chemotherapy, rituximab and long-term high-dose steroids and it was found that only half of risky patients received antiviral treatment. Interestingly, almost all of the patients using the biological agent had screened and starting HBV prophylaxis. We suggested that the patient safety form, which is mandatory in patients receiving biologic therapy, is effective at this end. We also believe that the use of the patient safety form application in patients receiving immunosuppressive therapy can improve the low rates of HBV screening and antiviral prophylaxis in real life
Disclosure: Nothing to disclose

Introduction: Reactivation of hepatitis B virus (HBV) can occur during treatment of hepatitis C with direct-acting antivirals (DDAs). It has been almost exclusively described in the cases of positive AgHbs and in no case of positive antiHBs. The risk in cases of isolated anti-HBc positive (anti-HBcPI) is minimal and its surveillance is not well defined.
Aims and Methods: The aim of this study was to investigate the risk of reactivation of HBV during treatment with DDAs in anti-HBcPI patients.
A prospective study was conducted in a cohort of 329 chronic hepatitis C patients treated with DDAs from February 2015 to March 2017. Virological reassessment of HBV infection was performed in the 12 and 24 week posttreatment period. Definitions of HBV reactivation: DNA detectable HBV with or without elevated transaminases and increased HBV DNA > = 1 log10 in cases of positive DNA initially.
Results: At baseline, HBV infection was identified in 125 patients (77% men, 53 years ± 8.1 years): 2 positive AgHBs (one with treatment criteria who started) and 123 with past infection (negative AgHBs and positive AcHBc with or without positive AcHBs - 55 and 68, respectively).
Fibrosis stage: F0 / F1 (n = 47); F2 / F3 (n = 31); F4 (n = 47). The 68 AntiHBcPI patients had undetectable DNA. Viral load follow up was achieved in 29 patients (mean follow-up time of 87.8 weeks). The sustained virologic response (SVR12) was 92% (115/125): 3 relapses, 4 deaths and 3 lost to follow-up. All cases of SVR12 maintained normal transaminases at follow up. There was no biochemical or virological reactivation in cases of antiHBcPI.
Conclusion: In this cohort, past HBV infection with HBcPI was prevalent (21%). However, none of these patients had biochemical or virological reactivation at short-term follow-up. The frequency of surveillance of these patients remains to be defined.

Introduction: The evaluation of fibrosis has been based on liver biopsy. The use of non-invasive tests is more and more common, despite they are still not recommended in hepatitis B due to lack of data.

Aims and Methods: The aim of this study was to compare the results of some biological non-invasive tests with those of liver biopsy in chronic hepatitis B (CHB).

We investigated all the CHB patients admitted in our department in the period between January 2009 and December 2015. Only patients who underwent a liver biopsy were enrolled. The following scores were calculated: ratio aspartate aminotransferase (AST)/alanine aminotransferase (RAA), APRI, FIB-4 and Pohl's score. The results of these scores and liver biopsy were compared.

A significant fibrosis (SF) was defined by a fibrosis score $\geq$ F2 and an advanced fibrosis (AF) by a fibrosis score $\geq$ F3 on liver biopsy.

Results: Eighty eight patients were included in our study. Their mean age was 38.5 years [18–63] and the sex ratio was 3.4 (68M/20F). HBeAg was positive in 28.4% of cases. Mean serum HBV DNA level was estimated to 6.3 Log 6 UI/ml [20 - 1.7 Log 8]. The mean levels of AST and ALT were 1.6 times ULN [0.5 - 36.6] and 1.9 times ULN [0.4 - 40] each. Mean Platelet count was 196×10^9/L [66–397]. On liver biopsy, 29.5% of patients had a SF and 11.4% had an AF. The mean values of RAA, APRI and FIB-4 were respectively estimated to 0.99 [0.38 - 1.89], 0.8 [0.15 - 18.48] and 1.36 [0 - 7.1]. Pohl's score was positive in 9.1% of cases.

SF was correlated to APRI and FIB-4 scores with AUC calculated to 0.766 and 0.668 each, and inversely correlated to platelet count with an AUC estimated to 0.692. This correlation wasn't found with RAA (AUC = 0.457).

AF was also correlated to APRI and FIB-4 scores with AUC respectively estimated to 0.854 and 0.821, and inversely correlated to platelet count with an AUC of 0.756, however, this correlation was not significative with RAA (AUC = 0.482).

In addition, Pohl's score was comparable to AF ($p = 0.014$) but not to SF ($p = 0.18$).

Conclusion: In our study, APRI, FIB-4 and Pohl's scores in addition to platelet count were useful in predicting advanced fibrosis. These simple tests could in some cases be sufficient, without need to a liver biopsy.

Disclosure: Nothing to disclose

P0675 SERO-PREVALENCE OF DELTA HEPATITIS ANTIBODIES, LIVER FUNCTION TEST PROFILE AND SEVERITY OF LIVER DISEASE AMONG INDIVIDUALS WITH CHRONIC HEPATITIS B INFECTION SEEN IN A TERTIARY HOSPITAL IN ABUJA, NIGERIA

Contact E-Mail Address: lukkareem@yahoo.com

Introduction: Hepatitis D virus (HDV) is a defective RNA virus that requires the helper function of hepatitis B virus (HBV) to be infectious. About 5% of the 350 million HBV carriers worldwide are estimated to have HDV infection. There is paucity of studies in Nigeria on the contribution of HDV to the burden of HBV infection.

Aims and Methods: The study aimed at determining the prevalence rate of delta hepatitis antibodies (IgM and IgG anti-HDV) among subjects with chronic hepatitis B (CHB) infection. The other objectives were to compare the liver function test (LFT) profile and disease severity, using the Child-Turcotte-Pugh (CTP) score, among the anti-HDV positive and anti-HDV negative subjects.

The study was a cross-sectional study of 180 consecutive chronic hepatitis B infected individuals presenting to the Gastroenterology Unit of U.A.T.H. The IgM and IgG anti-HDV were assayed using ELISA test kits manufactured by Creative Diagnostics, N.Y, U.S.A. LFT profiles were done using test kits manufactured by Randox Laboratories Ltd, U.K. Severity of liver disease was assessed using the CTP score.

Results: There were 180 subjects comprising of 150 (83.3%) subjects with uncomplicated CHB infection and 30 (16.7%) subjects with complicated CHB infection (14 liver cirrhosis and 16 hepatocellular carcinoma). Thirty-four (18.9%) of all the participants were positive for anti-HDV. This comprised of 16 (8.9%) participants who were positive for IgM anti-HDV and 24 (13.3%) were positive for IgG anti-HDV. Six (3.3%) were positive for both IgM and IgG anti-HDV. The prevalence rate of IgG anti-HDV+ve was significantly higher among the subjects with complicated CHB (26.7%) than those with uncomplicated CHB (10.7%) ($p = 0.019$). The mean serum ALT, AST, albumin levels and INR in all the anti-HDV positive subjects were 16.5 $\pm$ 13.8 IU/L, 26.3 $\pm$ 32.6 IU/L, 38.9 $\pm$ 7.6 g/L, and 1.2 $\pm$ 0.2 respectively. On the other hand, the mean values for the same parameters in all the anti-HDV negative subjects were 10.8 $\pm$ 9.5 IU/L, 13.4 $\pm$ 11.2 IU/L, 41.4 $\pm$ 6.0 g/L and 1.1 $\pm$ 0.2 respectively ($p < 0.05$). Among the patients with complicated CHB, only the mean serum AST was significantly higher in those who were anti-HDV positive (63.6 $\pm$ 46.5 IU/L) compared to those who were anti-HDV negative (27.3 $\pm$ 20.8 IU/L) ($p = 0.006$). The LFT parameters were, however, not significantly different in the patients with uncomplicated CHB irrespective of their anti-HDV sero-status. The mean CTP scores in the anti-HDV positive and anti-HDV negative subjects were 6.1 $\pm$ 2.1 and 5.5 $\pm$ 1.2 respectively ($p = 0.025$). However, within the different diagnostic groups, the CTP scores were not significantly different in the anti-HDV positive compared to the anti-HDV negative subjects.

Conclusion: The sero-prevalence rate of anti-HDV in this study is higher than previously reported in Nigeria. HDV may contribute to the progression of liver disease in chronic hepatitis B infected individuals. Screening for HDV should be part of the routine evaluation for all individuals with CHB in Nigeria

Introduction: Non-invasive tests for the evaluation of the severity of chronic liver diseases seem to be an alternative option designed to replace liver biopsy. These new non-invasive methods are including radiological techniques or biochemical markers like Diffusion weighted MRI and microRNAs.

Aims and Methods: To assess diffusion-weighted MR imaging (DWI) and microRNAs (miR) (200b, 21 and 29b) in diagnosis and staging of hepatic fibrosis in patients with chronic hepatitis C. Comparative cross-sectional study was conducted upon 208 patients and 82 age and sex-matched controls underwent DWI of the abdomen, miR and liver biopsy. The pathological score was classified according to METAVIR scoring system. The ADC and miR were calculated and correlated with pathological scoring.

Results: The ADC value was decreased significantly from controls (F0), patients with early fibrosis (F1 and F2) and those with late fibrosis (F3 and F4), (median 1.92, 1.53 and $1.25 \times 10^{-3} mm^2/s$) respectively ($p = 0.001$). The cutoff ADC value used to differentiate patients from controls was (1.83×10^{-3} mm^2/s) with area under curve (AUC) of 0.992. Combined ADC and miR-200b revealed highest AUC (0.995) for differentiating patients from controls with accuracy (96.9%). The cutoff ADC to differentiate early fibrosis from late fibrosis was $1.54 \times 10^{-3} mm^2/s$ with AUC of 0.866. Combined ADC and miR-200b revealed best AUC (0.925) for differentiating early fibrosis from late fibrosis with accuracy (80.2%). The ADC correlated with miR-200b ($r = -0.61$, $p = 0.001$), miR-21 ($r = -0.62$, $p = 0.001$) and miR-29b ($r = 0.52$, $p = 0.001$).

Conclusion: Combined ADC and miR (200b, 21 and 29b) offer an alternative surrogate noninvasive diagnostic tool for diagnosis and staging of hepatic fibrosis in CHC patients.

Introduction: The outcome of patients with chronic hepatitis C virus infection (HCV) and advanced, compensated liver disease who have obtained a sustained virological response (SVR) to treatment with direct-acting antivirals (DAAs) has not yet been completely depicted. In particular, previous studies included heterogeneous patients populations, or patients with advanced, decompensated liver disease.

Aims and Methods: In this prospective study, our aim was to assess the clinical and instrumental outcome of patients with advanced, compensated chronic HCV-related liver disease who had obtained a SVR to DAAs treatment, and who had at least 1-year follow-up following the end of treatment. We included 52 patients with cirrhosis (n = 27) and a METAVIR fibrosis stage F3 (n = 25) who

were followed-up for a median of 60 weeks (95%CI, 52–68 weeks) following the end of successful DAAs treatment. Clinical work-up, liver transient elastography, and measurement of the spleen bi-polar diameter were carried out before treatment and at the end of follow-up. The transient elastography results compatible with the presence (*i.e.*, ≥21.0 kPa) or absence (*i.e.*, < 13.6 kPa) of clinically significant portal hypertension were obtained from the current literature.
Results: We observed that liver stiffness decreased ($p < 0.0001$) from a median baseline of 15.2kPa (12.0–20.0kPa) to 9.3kPa (7.5–12.0kPa) at follow-up. Overall, absolute liver stiffness values decreased in 45 patients (86.6%), were unmodified in 2 patients (3.8%), and increased in 5 patients (9.6%). At the end of follow-up liver stiffness values were compatible with a METAVIR stage F4 in 17 patients (32.6%), F3 in 8 patients (15.4%), F2 in 7 patients (13.5%), F1 in 13 patients (25.0%), and F0 in 7 patients (13.5%). Moreover, we observed that a liver stiffness value suggestive of the presence (*i.e.*, ≥21.0kPa) of clinically significant portal hypertension was found in 13 patients (25.0%) at baseline and in 7 patients (13.5%) at follow-up ($p = 0.037$). Platelet count significantly increased [143×10^9/L (117–176×10^9/L) to 153×10^9/L (139–186×10^9/L), $p = 0.003$], while spleen bi-polar diameter significantly decreased [120mm (112–123mm) to 110mm (102–116mm), $p = 0.0009$] from baseline to the end of follow-up.
Conclusion: In patients advanced, compensated chronic liver disease, liver stiffness significantly improves in the long-term after SVR, and this improvement is accompanied by an amelioration of indirect indices of portal hypertension.
Disclosure: Nothing to disclose

P0678 A REPORT OF EFFICACY AND SAFETY OF THERAPY WITH OMBITASVIR, PARITAPREVIR/ R+DASABUVIR+RIBAVIRIN IN 5853 PATIENTS WITH LIVER CIRRHOSIS

Contact E-Mail Address: preda_monicaa@yahoo.com
Introduction: We previously reported a very high rate of HCV- SVR in a large cohort of 2070 patients: 96.6% in intention-to-treat and 2.9% rate of serious adverse events (SAE) leading to discontinuation of therapy (1).
Aims and Methods: The aim of this study is to report the incidence and the predictive factors of SAE in a large cohort of 5853 subjects with liver cirrhosis treated with ombitasvir, paritaprevir/ r+dasabuvir+ribavirin (OBV/PTV/r + DSV). In Romania, through a nationwide government-funded programme in 2015–2016, 5853 patients with virus C liver cirrhosis received fully reimbursed DAA therapy with OBV/PTV/r+DSV+RBV for 12 weeks, all with genotype 1b. The only key inclusion criteria was advanced fibrosis (Metavir stage F4) confirmed by Fibromax testing (or liver biopsy/Fibroscan). Efficacy was assessed by the percentage of patients achieving SVR 12 weeks post-treatment (SVR12). Only SAE leading to discontinuation of therapy were reported. Ordinal and scale variables with non-normal distribution were summarized as median (min, max), and compared by Mann-Whitney U test, while categorical variables were summarized as number (%) and compared by Fisher exact test.
Results: 55 patients were lost to follow-up. 65 stopped the treatment because of hepatic decompensation (1.1%), 38 patients stopped because of other adverse events. This cohort was 51% females, mean age 60 years (25÷82), 67% pretreated, 70% associated NASH, 67% with severe necro-inflammation (severity score 3-Fibromax), 37% with co-morbidities, 10.4% with Child Pugh A6, 0.5% B7. The median MELD score was 8.09 (6 ÷ 22). SVR by intention to treat was reported in 5654/5853 (96.6%), 41/5853 failed to respond. Liver decompensation was statistically associated in multivariate analysis with platelets < 10^5/mm^3 ($p = 0.03$), increased total bilirubin ($p < 0.001$), prolonged INR ($p = 0.02$), albumin < 3.5g/dl ($p = 0.03$). Other SAE were the following: pancreatitis (9), bacterial or viral infections (8), cardiovascular events (7) (probably unrelated to DAA therapy), psychiatric events (7), alergic reactions (4), severe anemia (3). The main predictors for these other SAE in multivariate analysis were: advanced age ($p < 0.001$), female sex ($p < 0.001$), presence of comorbidities ($p = 0.01$). Mortality was 71% for cardiovascular SAE (probably unrelated to DAA therapy), 32% for hepatic decompensations and 25% for infections.
Conclusion: OBV/PTV/r+DSV+RBV proved to be highly efficient in our population of cirrhotics with a 96.6% SVR in ITT. Safety of this DAA therapy in our difficult to treat- patients was very good, as long as SAE leading to therapy discontinuation were reported in 103/5853 (1.8%), most of them liver decompensation (1.1%), related to hepatic dysfunction, and lower platelet count.

Contact E-Mail Address: d.caroli@libero.it
Introduction: Hepatitis C virus (HCV) epidemiological data in Italy is changing due to the decline of iatrogenic etiology and the persistence of infection in populations at risk. To analyse the trend of hospitalization for liver HCV-related disease in Veneto Region in order to report the impact of HCV treatment with different therapeutic schedule over the time period.
Aims and Methods: This is a retrospective cohort study based on Veneto Region anonymous computerised database of hospital discharges between 2000 and 2017. All Veneto residents discharge records with principal diagnosis of hepatitis (cod. ICD9-CM: 070.41, 070.44, 070.51, 070.54, 070.70, 070.71, 571.5, 571.9) were included in the study. The Standardised Hospitalisation Ratio (SHR) per five-year age group (ref. pop. Veneto 2008) was calculated and expressed per 100 000 population.
Results: In the period considered 37046 hospital admissions diagnosed with HCV have been recorded. Approximately half of patients were males (56%). Despite their lower age (56.2±7.2 vs. 65.2±8.3), they had the greatest ospitalisation rate (49.4 vs. 36.3; OR: 1.36; 95% CI: 1.33–1.39; $p < 0.001$).
The analysis of the hospitalisation trend shows a 14% increase in the average age of patients (from 57.3±9.5 to 65.9±9.9) and a substantial decrease in hospital admissions (X^2 per trend: 9315,644; $p < 0.001$). Between 2000 and 2017, there has been a 78% decline in hospital admissions (i.e. from 78.9 to 17.3). with a comparable decrease in both genders/sexes (ratio M:F 1.5) and in the last year considered (2017) SHR were respectively 20.3 and 14.3 It can be observed that the introduction of new therapies has been followed by several reductions in SHR, all with statistically significant values. The decline of hospitalization rate from 2000–2005 (73.6) to 2006–2012 (73.6 to 35.5; OR: 0.48; 95% CI: 0.47–0.49; $p < 0.05$) reflects the efficacy of Interferon standard and the subsequent improvement of the cure through the use of Peg Interferon plus Ribavirin. Then with new therapies SHR felt from 21.3 of triple therapy 2013–2014 (OR: 0.29; 95% CI:0.28–0.30; $p < 0.05$) to 18 of DAAS 2015–2017 (OR: 0.24; 95% CI: 0.24–0.26; $p < 0.05$).
Conclusion: HCV liver-related disease as cause of hospital admission is in progressive and constant decline. The slope of the curve representing the decline of hospitalization rate is significantly related to the treatment schedules available in each period and care setting.

Introduction: GT 4 accounts for 20% of hepatitis C virus (HCV) infections in Greece. Pts with GT4 are underrepresented in phase 3 clinical trials. Results from real-world cohorts from regions with increased prevalence would add important knowledge to the management of these pts.

Aims and Methods: We analyzed the efficacy of regimens with different combinations of DAAs in HCV GT4 pts from a large cohort of 14 Greek centers. All GT4 pts who received DAAs in the HERACLIS cohort were included. All pts fulfilled the national criteria for DAA reimbursement [F4 naive, F3-F4 retreated, decompensated cirrhosis (decomp-Ci), OLT, severe extrahepatic manifestation] were analyzed in this cohort. SOF+SMV±R, SOF+DCV±R, SOF/LDV±R, 3D±R (2D+R for GT4), SOF/VEL±R & EBR/GZR±R considered as currently recommended regimens according to the international and local guidelines. The primary efficacy endpoint was SVR12; predictors of response to treatment were assessed.

Results: 259 pts with GT4 from a total 1309 HCV pts (19.8%) were included (males 58%, age 55±10 yrs, PDU 28%; F0-F2 3%, F3 20%, F4 66%, decomp-Ci 10.4%, treatment experienced 63%, DAA failures 7.3%). The DAA regimens employed were Peg-IFN + RBV (PR) + SMV in 4 (1.5%), PR+SOF in 14 (5.4%), SOF+R in 2 (0.8%), SOF+SMV±R in 33 (12.7%), SOF+DCV±R in 15 (5.8%), LDV/SOF±R in 42 (16.3%), 2D+R in 139 (53.7%), SOF/VEL+R in 3 (1.2%), EBR/GZR±R in 7 (2.7%). Treatment duration was 12 weeks for all combinations except for PR+SMV and another 6 pts (24 weeks; 2 SOF+R, 2 LDV/SOF+R, 2 2D+R). SVR12 rates for the first 189 pts who completed post-treatment follow-up was 100% for PR+SMV, 64% for PR+SOF, 100% for SOF+R, 90% for SOF+SMV±R, 93% for SOF+DCV±R, 89% for LDV/SOF±R and 97% for 2D+R and 100% for EBR/GZR. SVR12 was 100% for F0-F2, 97.4% for F3, 92.6%, for F4, and 82.6% for decomp-Ci ($p = 0.153$). Pts without than with SVR had higher BMI [(28.5 vs 26.2 kg/m^2); $p = 0.01$]], lower PLT ($p = 0.018$), or albumin ($p = 0.061$), and more frequently albumin < 3.5g/dl [41.7% vs 15.3% ($p = 0.032$)], PLT $< 100 \times 10^9$/L (33.3% vs 14.1%; $p = 0.063$), decomp-Ci (26.7% vs 10.1%, $p = 0.072$) and use of non-recommended regimens [33.3% vs 7.9%; $p = 0.006$]. SVR rates in pts with decomp-Ci treated with currently recommended DAAS was 81% (17/21). Logistic regression analysis showed that lower SVR rate was independently associated only with the use of non-currently recommended regimens (OR: 0.2163, 95% CI:0.033–0.81; $p = 0.027$).

Conclusion: The currently recommended combinations of two DAA +R for 12 weeks has excellent efficacy in HCVGT4 pts with F3 fibrosis and compensated cirrhosis, achieving SVR rates 95%–100%. Further treatment optimization seems to be required in GT4 pts with decomp-Ci.

Contact E-Mail Address: julius.spicak@medicon.cz

Introduction: HCV infecton represents the most common indication for liver transplantation (OLT) in Western world. Recurrence of HCV in the liver graft negatively influences survival. The use of Direct-acting antivirals (DAA) substantially improved treatment efficacy. The aim of the study was to assess DAA efficacy in OLT recipients who were treated between 7/2014 and 5/2017 and analyze DAA treatment impact on post-transplant survival.

Aims and Methods: We retrospectively analyzed 195 (14.2% of 1373 total OLT) patients who underwent OLT between 7/1995 and 5/2017 for HCV infection, 127 males and 68 females, average age 54.7 ± 8.2 years. 97% of patients were infected with genotype 1b. In Czech Republic, DAA became available in 5/2014 (DAA era, N = 43). Until that time, patients were treated with peginterferon-α and ribavirin (PEG-α/RBV) (pre-DAA era, N = 152). Treatment efficacy (sustained virological response, SVR) in individual groups was assessed by Fisher's exact test, patient survival 3 years post-transplant by log-rank test.

Results: In the DAA era, we treated 64 patients with biopsy-proven recurrent HCV infection. The choice of DAA was determined by DAA availability at the respective time: 2 patients were treated with sofosbuvir (SOF)/RBV combination, 11 patients with SOF/daclatasvir, 12 patients with SOF/simeprevir, 26 with SOF/ledipasvir and 13 with paritaprevir/ritonavir/ombitasvir/dasabuvir. DAA were administered at an average of 100 months post-transplant as a *salvage therapy* to 38 patients with graft cirrhosis in whom previous PEG-α/RBV treatment had failed, or as an *immediate therapy* in 26 patients at an average time of 6 months after OLT. SVR was achieved in 97.4% and in 88.5% patients in the salvage and immediate treatment groups, respectively (P = NS). In the DAA era patients, only 1 died. This translated into significantly better 3-year survival, when compared to a historical cohort of 152 patients with HCV graft recurrence from pre-DAA era (97% vs. 78%, $p < 0.001$). After DAA introduction, none of the patients died of fibrosing cholestatic hepatitis and none underwent re-OLT owing to chronic HCV graft failure, as compared to pre-DAA era patients out of whom 6.7% died of fibrosing cholestatic hepatitis and 5.7% required re-OLT.

Conclusion: The introduction of DAA in the treatment of post-transplant HCV recurrence achieved excellent SVR rates and significantly increased post-transplant survival in patients with HCV recurrence in the liver graft.

Introduction: The prevalence of hepatitis C in Romania is estimated to 3.2%, over the European reported average data [1], [2]. The peculiarity of Romanian epidemic is the predominance of genotype 1b (99%) [1]. Interferon-free antiviral treatment with Dasabuvir, Ombitasvir, Paritaprevir and Ritonavir (DOPR) is available in our clinic since 2017, according to a national protocol.

Aims and Methods: We assessed the results of DOPR in the end of the treatment (EOT).

This prospective study included patients with Hepatitis C, treated with DOPR for 12 weeks, in the Infectious Disease Clinic Galati, Romania. The eligibility criteria were limited to advanced fibrosis (FibroMax F3/F4; Child-Pugh score ≤6). The demographic data, Hepatitis C Virus - Ribonucleic Acid (HCV-RNA), co-morbidities and the rate of EOT were statistical analyzed.

Results: Demographic characteristics of 103 eligible patients are the old age (median age: 61±10.8 y.o) and predominance of female gender (62%). The baseline data are: HCV-RNA average 2026243±2741998 IU/ml, F3/F4 ratio 0.98, Alanine Aminotransferase (ALT) 98,1 ± 63.0 IU/l, Aspartate Aminotransferase (AST) 81.6 ± 52.7 IU/l, total bilirubin 0.8 ± 0.3 mg/dl, serum albumine 4.2 ± 0.3 mg/dl, prothrombin concentration 80.8 ± 17.2%, Alpha Fetoprotein 11.3 ± 15 IU/ml, degree of esophageal varices 0: 79.6% patients, 1: 15.5% patients, 2: 3.8% patients, 3: 0.9% patients. As minimum one co-morbidity was counted in 61% patients, most frequent hypertension (26%), diabetes (18%), depression (10.6%), oncologic history (8%), ischemic cardiopathy (5.8%), hepatitis B co-infection (4.8%). The rate of the complete 12 weeks treatment was 97%. All patients achieved viral suppression (HCV-RNA < 15 IU/ml) in EOT and had normal transaminases. The interruption of DOPR was decided for 3 patients, due to adverse events (nausea, vomiting, renal failure, acute pancreatitis, increase over 5 times the initial transaminases), but these events were not serious and there were not any deaths. The follow-up on 24 weeks is available to 35% patients, all of them with sustain virologic response.

Conclusion: The antiviral regimen with Dasabuvir, Ombitasvir, Paritaprevir and Ritonavir was 100% effective after 12 weeks for the patients with hepatitis C who completed the therapy. Very good tolerability and safety was proved in difficult to treat patients, including old age, advance fibrosis and multiple co-morbid conditions.

Introduction: The prevalence of hepatitis C infection (HCV) in Bulgaria is estimated to be 1.28% in multicenter study in 2010, but no national representative study on HCV prevalence in general population exists so far.
Aims and Methods: The aim of this study is retrospectively to analyze HCV screening programme in Military Medical Academy (MMA), for the period January 2014 – December 2016.
HCV screening programme of the MMA consists of: risk-based screening for all clinics in in- and out-patient settings; voluntary screening offered to everyone admitted in surgery clinics/entering emergency department; obligatory screening for all blood donations; obligatory screening for all candidates for military service. Serological anti HCV Ab tests (III/IV generation) were used. For the period January 2014 – December 2016 29,600 patients, 22,717 males/ 6,883 females, age between 18–87 years old, were screened.
Results: The prevalence of HCV in 29,600 screened patients was 0.65% (n-194). In the Group of blood donors (n-17,394) the HCV prevalence was 0.59% (n-104), but in first-time blood donors (n-6,700)–0.35% (n-27). In the Group of in/out-patients (n- 9,050) the HCV prevalence was 0.92% (n-84) and in Group of candidates for military service (n-3,156)–0.19% (n-6). There was no gender difference in the HCV prevalence (0.68% in males and 0.55% in females). The most frequently affected age group was 31–40 years old (32.6%). Linkage to care was achieved in 82.5% (84/104) of HCV-infected blood donors and in 61% (61/100) of in/out patients and candidates for military service. Viremic prevalence was found to be 73% (106/145) and out of them 68% (72/106) initiated antiviral treatment.
Conclusion: Screening for HCV in hospital setting is feasible options for the countries where no national screening programme exists and provide excellent opportunity for linkage to care.

Introduction: Acetaminophen is one of the most commonly prescribed drugs and the leading cause of poisoning and acute liver injury (ALI) in developed countries. For more than four decades, prediction of the risk of liver toxicity has been based on the Rumack-Matthew nomogram, which has helped determine when N-acetylcysteine (NAC) is indicated as preventive antidote. However, this nomogram is not validated 1) after repeated acetaminophen exposure; 2) if time to presentation is unknown or > 24 hours; and 3) as a predictive measure of liver injury in vulnerable patients, despite NAC administration. Consequently, there is a current need for predictive biomarkers in addition to the nomogram to better identify acetaminophen-poisoned patients with increased risk of ALI despite NAC therapy. Since the liver has been considered as potential source of sepsis-related procalcitonin (PCT) production, we aimed to assess the diagnostic value of plasma PCT, commonly used in the intensive care unit (ICU) to identify bacterial infections, in patients likely to develop acetaminophen-induced ALI.
Aims and Methods: All consecutive acetaminophen-poisoned patients admitted in our ICU and requiring NAC treatment were prospectively included between January 2011 and December 2017. The primary outcome was the occurrence of ALI defined as a peak of alanine aminotransferase (ALT) >100 IU/L. Liver function tests, PCT and acetaminophen levels were measured on admission. Data was reported as median (interquartile range) or absolute value (percentage) as required. Multivariate analysis based on a Cox proportional-hazard regression model was used to identify parameters associated with ALI. The corresponding hazard ratios and 95%-confidence intervals (CI) were determined.
Results: 116 patients were included [age: 32 (21–53)], with a median ingestion of 16 g (9–30) of acetaminophen. Multidrug ingestion was noted in 77% of the patients. The Rumack-Matthew nomogram could not be used in 47% of the cases. ALI occurred in 36 patients (31%) despite NAC treatment provided after a median 6-hour (4–12) delay. In these patients, plasma PCT concentrations were significantly increased as compared to patients without ALI (23.13 vs 0.08 ng/mL $p < 0.001$). The increase in PCT preceded the increase in ALT by 33 hours (10–74). Multivariate analysis showed that PCT levels > 1ng/mL was significantly associated with ALI [hazard ratio: 4.72 (95% CI, 1.76–12.66); $p = 0.002$], independent from the dose of ingested acetaminophen, the delay of NAC administration and the presence of suspected community-acquired infection (Table 1). PCT levels predicted ALI with a sensitivity, specificity, and area under the ROC curve of 0.94, 0.83 and 0.88 (95% CI, 0.81–0.95), respectively.
Conclusion: Our results suggest that plasma PCT is predictive of acetaminophen-induced ALI. PCT is a potential useful biomarker for the early identification of 1) high-risk ALI patients whom may benefit from closer monitoring and should be referred to a specialized liver ICU and 2) lower-risk ALI patients requiring abbreviated NAC regimens and early discharge safely. Our findings require further validation in larger studies.

Contact E-Mail Address: sarahshalaby18@gmail.com
Introduction: Patients with hepatocellular carcinoma (HCC) are at higher risk for second primary malignancies compared with the corresponding general population. Such risk could be even higher after liver transplantation (LT), due to chronic immunosuppression. It has been consistently demonstrated that patients transplanted for alcoholic liver disease and primary biliary cholangitis are at higher risk for the development of post-LT *de novo* neoplasms (DNN). However, evidence on the additional risk that pre-LT HCC could confer to transplanted patients are lacking. As HCC has become the leading indication for LT, it is important to investigate whether such patients deserve more intensive post-LT DNN screening compared to other transplanted patients.
Aims and Methods: A cohort study was conducted using data collected among 9 Italian centers between 1985–2014. Patients were excluded if: ≤18 years old, follow-up shorter than 30 days after LT, cancer diagnosis within 30 days after LT. Person-years (PYs) at risk for DNN were computed from 30 days post-LT to the date of death, date of cancer diagnosis or end of follow-up, whichever came first. Hazard ratios (HR) of DNN development (excluding non-melanoma skin cancers) and 95% confidence intervals (95% CI) for patients transplanted for HCC (HCC-patients) compared to those undergoing LT without any pre-transplant neoplastic history (non-HCC patients), were estimated using Cox proportional hazards models, irrespectively from liver disease etiology. All models were adjusted for sex, age at transplant, and calendar year at transplant.
Results: A total of 2,801 patients were followed up for 18,021 PYs of observation [median follow-up: 5.3 years (IQR 2.4–9.9)] during which 194 (6.9%) developed 206 DNNs. Out of 991 HCC-patients (median age at LT 57 years, 86% males) 64 (6.4%) developed 66 DNNs, while out of 1810 non-HCC patients (median age at LT 51 years, 69% males) 130 (7.2%) developed 140 DNNs. No significant association with the risk of all DNN emerged for HCC-patients as compared to non-HCC (HR = 1.18, 95% CI 0.85–1.64), after median follow-ups of 3.6 (IQR 1.9–6.7) and 6.2 years (IQR 2.7–11.1), respectively ($p < 0.01$). However, there was a significant difference in occurrence timings: median time from LT to first DNN diagnosis was 2.5 years (IQR 1.5–4.3) for HCC-patients and 4.3 years (IQR:1.8–7.9) for non-HCC ($p < 0.01$). In the analysis by specific tumor types (Table 1), a significant increased risk emerged for bladder cancer only (HR = 8.66, 95% CI 1–74).
Conclusion: In our cohort, patients transplanted for HCC were not at higher risk for DNN than other transplanted patients. Nonetheless, DNN seemed to occur earlier in HCC-patients, probably due to their higher susceptibility to carcinogens and shared risk factors with primary cancer, leading to a possibly accelerated carcinogenic process. Pre-LT liver neoplastic history could therefore represent an additional risk factor for early DNN occurrence and should be taken into account for surveillance-individualization, to improve early detection and management. Further investigations in wider cohorts with different patients' characteristics are necessary to confirm these results.

Introduction: Innate immune defenses against infection are altered after liver transplantation (LT) and may increase the risk of infection after transplantation. Toll like receptors (TLRs) are a large section of pathogen associated molecular patterns recognition (PAMP) receptors of the innate immunity. These receptors help stimulation of downstream signaling pathways in reaction to many antigens, mainly to Gram +ve and Gram-ve bacteria, all related to release of cytokines and enhancement of the inflammation. One of the most important elements of these innate defenses is Toll like receptors (TLRs) particularly TLR2.

Aims and Methods: The aim of this work is to assess Association of Toll-Like Receptor -2 single nucleotide genetic polymorphism and its serum level with infection in Recipients after living donor liver transplantation.

Out of 125 subjects enrolled in our work, 109 subjects completed this cohort case control prospective study. Subjects were classified into two groups: 66 patients who undergone LDLT and 43 healthy donors as a control group. Serum TLR2 protein was measured using 3rd generation ELISA technique in the serum of the recipient's pre and post transplantation and as well as in the serum of the donors before transplantation. In addition, single-nucleotide polymorphisms (SNPs) of 3 snips of Toll-like Receptor-2 (TLR2) gene (rs3804099 +597, rs5743708 +75, rs121917864 +677) were studied where the allelic genotyping of each DNA sample was performed using real-time PCR reaction.

Results: post liver transplantation developed in 84.8% of the recepients where 55.36% infected with single organisms while 54.69% with mixed infections. Serum TLR2 was significantly higher in recipients post transplant period when compared with recipients and donor in pre transplant period ($p < 0.001$). Conversely, no significant difference was detected in post transplant serum TLR2 of recipients on comparing non infected group with infected groups (gram positive, gram negative and fungal infections) regarding blood, urine and sputum cultures ($p = 0.9$, $p = 0.097$ and $p = 0.36$) respectively. On the other hand, serum TLR2 in recipients post LDLT is significantly higher in cases showing CMV infection when compared with those without CMV infection ($p=0.02$). As Regard the analysis of SNPs of TLR2 it was found that T allelle of rs3804099, G allele of rs5743708 and the C allele of rs121917864 were significantly higher in non infected group when compared to both non infected (OR: 0.1471, 0.148 and 0.1838 respectively, $p < 0.05$) and control groups (0.1238,0.2044 and 0.2528 respectively $p < 0.001$) but no significant association was found with type of infections $p > 0.05$.

Conclusion: The current study showed that serum level of TLR2 was increased in the recipients after post LDLT in comparison to pretransplant level but no significant association with the type of infection except CMV infection. In addition **T allelle of rs3804099, G allele of rs5743708** and the C allele of **rs121917864 are protective alleles against the development of infection but no significant association with the type of infection.**

P0687 PROTECTIVE EFFECT OF APELIN PRECONDITIONING IN A RAT MODEL OF HEPATIC ISCHEMIA REPERFUSION INJURY; POSSIBLE INTERACTION BETWEEN APELIN/APJ SYSTEM, ANGIOTENSIN II/ANGIOTENSIN I RECEPTOR (ANG II/AT1R) SYSTEM AND ENDOTHELIAL NITRIC OXIDE SYNTHASE (ENOS)

Introduction: Hepatic ischemic reperfusion (I/R) injury, a major cause of liver damage, occurs in multiple clinical settings. It is responsible for nearly one third of delayed graft function cases in liver transplantation. Recently, a number of peptides have been developed to attenuate hepatic I/R injury in several animal models. However, novel potential protective agents are still needed, hoping for promising results for alleviating hepatic I/R injury with the potential to increase the number of livers suitable for liver transplantation.

Apelin, a small regulatory peptide, is the endogenous ligand of the G protein coupled receptor APJ. It has various isoforms, among which Apelin-13 is the most active isoform. The apelin-APJ axis is widely expressed in hepatic parenchymal, Kupffer, stellate and endothelial cells.

Recently, exogenously administered apelin was shown to protect against I/R injury in different organs including the heart and the brain. However, the protective mechanism of apelin on hepatic I/R injury is not yet clear.

Aims and Methods: We aimed to evaluate the effect of apelin-13 preconditioning on hepatic I/R injury and its effect on hepatic expression of Angiotensin-1 receptor (AT1R), endothelial Nitric Oxide Synthase (eNOS) and hepatic tissue level of apelin in an attempt to clarify the possible interaction between apelinergic, Renin-Angiotensin System (RAS) systems and eNOS.

60 male albino rats were randomly assigned to one of the following 4 groups (15 rats each); Control sham-operated (group I), ischemia reperfusion (group II), Apelin-treated I/R (group III) and Apelin + L-NAME-treated I/R (group IV). Apelin-13 and L-NAME (N-nitro-L-arginine methyl ester) were administered intraperitoneally at dose of 2 μg/kg/day, 3 days prior to surgical hepatic I/R procedure and10mg/kg/day, 2 weeks prior to the surgical procedure, respectively. Ischemia was induced for 30 minutes. After 2 hours of reperfusion, serum samples were collected for measurement of serum ALT and AST. Hepatic tissue specimens were harvested for biochemical (MDA; Malondialdehyde, apelin, gene expression of CASP-3; Caspase-3, eNOS and AT1R) and histopathological analyses.

Results: Compared to I/R group, apelin pretreatment provided marked hepatic protection with significant reduction in the serum levels of ALT and AST, hepatic MDA (oxidative stress marker), hepatic expression of CASP-3 (apoptosis marker) and AT1R, while hepatic apelin level and hepatic eNOS expression were significantly increased in group III. Moreover, apelin preconditioning reduced the hepatic histological damage induced by the I/R injury. Hepatic apelin level was positively correlated with hepatic expression of eNOS, while it was negatively correlated with serum liver enzymes, hepatic MDA, hepatic expression of CASP-3 and AT1R.

Co-adminstration of L-NAME with apelin in group IV partially reversed the hepatoprotective effect of apelin.

Conclusion: Exogenous apelin-13 preconditioning exerts protective effect against hepatic I/R injury, probably by modulating the oxidant stress together with its antiapoptotic effect. Several signaling pathways may be involved including suppression of hepatic AT1R expression and elevation of hepatic apelin levels. The hepatic apelinergic system may be implicated in vasodilatory effects during hepatic I/R injury through increase the hepatic expression of eNOS which counteracts the pathologic effects of Ang II/AT1R system. These results clearly demonstrate a strong interaction between Apelin/APJ system, RAS and eNOS signaling pathways in hepatic I/R injury pathophysiology.

Disclosure: Nothing to disclose

P0688 CORRELATES OF MORTALITY IN PATIENTS ON WAITING LIST OF LIVER TRANSPLANTATION: A 4-YEAR PROSPECTIVE COHORT STUDY

K. Bagheri Lankarani[1], B. Honarvar[1], H. Raeisi Shahraki[2], V. Seifi[1], B. Geramizadeh[3], H. Salahi[3], S. Nikeghbalian[3], A. Shamsaeefar[3], S.A. Malekhosseini[3]

Introduction: Liver transplantation (LT) is the most effective treatment for end stage liver disease but due to demand-supply imbalance and prolonged waiting time, LT candidates may die before transplantation. This study aimed to detect prevalence and new predictors of mortality in LT candidates.

Aims and Methods: In this 4 years prospective cohort study, 544 LT adult candidates who referred to Shiraz LT center of Iran were followed on arrival and in 3 months intervals. A comprehensive check list including socioeconomic, nutrition, medical history, physical examination, laboratory and imaging data and death causes (in dead cases) was filled for each patient. Data analysis was performed in Nutritionist, SPSS and R software. Kaplan-Meier test was done and Cox proportional hazard (HRc) and LASSO Cox regression hazard (HRL) were measured.

Results: Mean age of patients was 46.7 ± 13.7 years while 336 (61.7%) were male. Till the end of study, 414 (76.1%) were alive and 130 (23.9%) dead, while 33.1%, 57.7% and 79.2% of deaths were occurred in the first 3, 6 and 12 months of waiting period. Hepatopulmonary syndrome ($HRC = 4.7$, $HRL = 1.8$), history of myocardial infarction (MI) ($HRC = 3.3$, $HRL = 1.6$) and low carbohydrate (CHO) diet ($HRC = 2.7$, $HRL = 1.5$) showed strong association with mortality of patients. In addition to the MELD score, CA 125, high PMN count, weight loss, high level of ALT, positive HBV markers, high MCV of RBCs, ascites, edema of gall bladder wall, high level of BUN and psychological problems showed significant association with death in LT candidates.

Conclusion: About one-fourth of patients die while they are waiting for LT. Therefore to achieve a better outcome besides MELD score, HPS, MI, malnutrition and psychological status of patients should also be considered and managed at the beginning and during the waiting time for LT.

Introduction: Metabolic syndrome (MS) is a common condition among liver transplanted patients, resulting in an increased mortality and morbidity in the long term after liver transplantation (LT).

Aims and Methods: This prospective study assessed the short and mid-term prevalence of MS and metabolic complications after LT. Patients who underwent LT at the Padova Liver Transplant Centre between April 2013 and August 2015 and regularly followed-up at Multivisceral Transplant Unit were prospectively included. Paediatric patients, multiorgan transplantation or re-transplantation and patients who had MS before LT were excluded. For each patient general and metabolic variables were collected at time of LT and at 3, 6, 12 and 24 months after LT. MS was evaluated according to the modified NCEP-ATP III criteria.

Results: Twenty-eight patients were included in the study (78% male, mean age 54.2 ± 8.1 years). The most common indication to LT was HCV cirrhosis (42.9%), 25% of the patients presented HCC and the mean MELD at transplantation was 23 ± 8.7. Prevalence of MS at 3, 6, 12 and 24 months after LT was 35.7%, 28.6%, 42.9% and 39.3% respectively ($p = 0.003$). After LT a significant increase in diabetes mellitus (46.4% vs. 17.9%, $p = 0.02$) and hypertension (25% vs. 7.1%, $p = 0.07$), as well as in total cholesterol (mean values 171.7 ± 46.7 vs. 94.6 ± 41.1, $p < 0.001$) and triglyceride levels (135.6 ± 62.2 vs. 95.4 ± 73.9, $p = 0.01$). The higher prevalence of MS, diabetes mellitus, and hypertension was observed at 12 months after LT, whereas cholesterol and triglyceride levels did not show significant differences overtime. Considering body weight, the proportion of obese patients progressively increased overtime, moving from 4% at 6 months to 23% at 24 months.

Conclusion: Occurrence of MS is an early phenomenon after LT, affecting nearly half of patients at 12 months post-LT. Diabetes, hypertension and increased in body weight are the main responsible factors for developing post-LT MS. A strict metabolic and weight control is necessary, starting early after LT period.

Introduction: The influence of donor-recipient sex mismatches on graft failure after liver transplant (LT) is still controversial.

Aims and Methods: The aim of this study was to assess graft failure and to evaluate postoperative analitic outcomes after LT, regarding donor-recipient gender mismatch. This was a restrospective unicenter cohort study during one year (2016) including patients hospitalized in an intensive care unit (ICU) after LT.

Results: 136 patients were included (72.8% men, with a mean age of 54.09 ± 11.25 years). The main reason for LT in male patients was hepatocellular carcinoma (26.3%), followed by decompensated alcoholic cirrhosis (21.2%) and in female patients was acute fulminant hepatic failure due to drug toxicity (16.2%) and biliary cholangitis (8.1%).

Of the patients included, 42.6% ($n = 58$) had donor-recipient sex mismatches (13.2% male donor-female recipient and 29.4% female donor-male recipient).

The female sex was the prevalent sex donor organ in patients with donor-recipient sex mismatches ($p < 0.001$). The mean ICU stay was 4.7 days, with no difference between patients with donor-recipient sex mismatches and donor-recipient sex matches (4.91 vs 4.54, $p = 0.383$).

Patients with donor-recipient sex mismatches revealed lower values of ALT (1762 UI/L Vs 3075 UI/L $p = 0.022$), AST (1206 UI/L Vs 2040 UI/L, $p = 0.05$) and LDH (2304 UI/L Vs 4304 UI/L $p = 0.06$) than patients with donor-recipient sex matches in 48 hours postoperatively. There was no difference in the use of postoperative vasopressors among patients with donor-recipient sex mistmatches and matches ($p = 0.341$). 49 patients (36%) had graft failure, however there was not signficantly difference between graft failure and patients with donor-recipient sex mismatches and matches ($p = 0.262$).

Conclusion: There was no difference in graft failure in patients with donor-recipient sex mismatches and matches after LT. Although lower values of liver enzymes and LDH can point less hepatic injury at immediate postoperative outcome in patients with with donor-recipient sex mismatches.

Disclosure: Nothing to disclose

P0691 IMPACT OF ENTECAVIR IN REDUCING THE RISK OF HEPATOCELLULAR CARCINOMA IN PATIENTS WITH HEPATITIS B RELATED CIRRHOSIS

Y. Said[1], A. Mensi[2], K. El Jeri[2], S. Khedher[2], C. Bouguerra[3], R. Debbeche[2]

Introduction: Chronic hepatitis B virus (HBV) infection is the most frequently identified cause of Hepatocellular carcinoma (HCC). The newer nucleos (t) ide analogues such as Entecavir (ETV) or Tenofovir have been shown to be effective in terms of virological response and improvement of liver function. However their impacts on the incidence of HCC are still not clear

Aims and Methods: The aims of this study were to investigate the incidence of HCC in patients with HBV-related cirrhosis and evaluate the effect of ETV in reducing this incidence. We performed a retrospective analysis of data from consecutive patients with HBV-related cirrhosis recruited from 2009 to 2016 and who were followed up for at least 12 months. The diagnosis of HCC was based on computed tomography scan and magnetic resonance imaging or liver biopsy. We evaluated the incidence of HCC among ETV treated patients and untreated patients.

Results: A total of 75 patients were included (78% male, age = 57 ± 12 years, follow up for 37 ± 24 months). Our patients were classed Child Pugh A, B, C in 29%, 49% and 22% of cases respectively. After a median of 19 months, 15 patients developed HCC (20%). The HCC was classed BCLC A, B, C and D in 20%, 33%, 7% and 40% of cases respectively. The treatment was curative in one patient (radiofrequency) and palliative in the 14 others cases (transarterial chemoembolization: 4 patients, Sorafenib : 1 patient, symptomatic treatment: 9 patients).

In the ETV group, HCC developed in 8 patients (21.1%). In the untreated group, HCC developed in 7 patients (18.9%). Log rank test did not reveal a statistically significant difference between the incidence of HCC in the ETV group and the untreated group ($p = 0.81$).

Conclusion: HCC still develop in patients with HBV-related cirrhosis treated with ETV. For this reason, patients under effective long term nucleos (t) ide analogues therapy should remain under surveillance for HCC.

Introduction: The number of elderly patients diagnosed with hepatocellular carcinoma (HCC) has been increasing because the increase in the longevity of the general population. But there is no proper management based on age stratification in elderly patients.

Aims and Methods: The aim of our study was to compare the clinical characteristics, outcomes and treatment efficacy and safety between oldest-old (aged more than 85 years), middle-old (aged between 80 and 85 years) and young-old (aged between 75 and 80 years) patients with HCC from January 2010 to December 2016. A total of 550 elderly patients whose data included demographics, comorbidity, etiology of liver disease, presence of cirrhosis, staging of HCC, treatment modality and treatment related adverse event were evaluated retrospectively. Also overall survival was assessed in enrolled patient.

Results: Fifty-one patients (oldest-old; median 87 years old), 153 patients (middle-old; median 82 years old) and 346 patients (young-old; median 77 years old) were diagnosed with HCC. Both oldest- and middle-old patients, compared to young-old patients, had significantly higher rate of hepatitis C-related disease (HCV antibody positivity 41.2% vs. 29.4% vs. 22.0%, p= 0.007) but had significantly lower rate of alcohol-related disease (11.8% vs. 19.0% vs. 30.3%, p=0.002). There were no significant difference in underlying sex, body mass index, presence of co-morbidity, hepatitis B-related disease and stage of HCC. The Child-Pugh class (CPT class A 88.9 vs. 84.1% vs. 83.6%, CPT class B 11.1% vs. 15.9% vs.15.0% and CPT class C 0.0% vs. 0.0% vs. 1.3%, respectively, $p = 0.912$) and Model for End Stage Liver Disease score (mean MELD score 8.89 ± 2.00 vs. 8.80 ± 2.78 vs. 9.19 ± 3.28, $p = 0.600$) were no significant difference between the patients with active treatment. The modified UICC staging (stage I 5.6% vs. 17.1% vs 18.6%, stage II 55.6% vs. 46.3% vs 47.3%, Stage III 22.2% vs. 24.4% vs 24.8%, Stage IV-A 11.1% vs. 6.1% vs. 4.9% and Stage IV-B 5.6% vs. 6.1% vs. 4.4%, respectively, $p = 0.826$) and Barcelona Clinic Liver Cancer staging (stage 0 5.6% vs. 9.8% vs.9.3%, stage A 16.7% vs. 17.1% vs. 22.1%, stage B 27.8% vs. 29.3% vs. 24.8%, stage C 50.0% vs. 43.9% vs. 41.2% and stage D 0.0% vs. 0.0% vs. 2.7%, respectively, $p = 0.878$) were no significant difference between the patients with active treatment. Furthermore, there were no difference between the age groups in treatment modality (Surgical resection 0.0% vs. 3.3% vs. 5.2%, $p = 0.442$; Radiofrequency ablation 2.0% vs. 8.5% vs. 11.0%, $p = 0.484$; Transcatheter arterial chemoembolization 21.6% vs. 34.6% vs. 41.6%, $p = 0.959$; Best supportive care 62.7% vs. 40.5% vs. 29.2%, $p < 0.001$), adverse event related treatment (p=0.731) and disease-free survival days (356.4 ± 321.3 days vs. 284.7 ± 459.5 days vs.

354.2 ± 561.1 days, p=0.299). Multivariate analysis showed that performance status, MELD score, modified UICC staging, presence of portal vein thrombosis and ruptured HCC are risk factors for mortality.
Conclusion: Clinician should make an active treatment in elderly patients with HCC not a age but performance status, liver function and disease status of cancer.
Disclosure: Nothing to disclose

P0694 IS THERE STILL A ROLE FOR ALPHA-FETOPROTEIN IN HEPATOCELLULAR CARCINOMA SCREENING?

J.C. Silva, A.P. Silva, S. Leite, S. Fernades, A. Ponte, J. Rodrigues, M. Sousa, A.C. Ribeiro Gomes, J. Carvalho
Centro Hospitalar Vila Nova de Gaia/Espinho, Gastroenterology, Vila Nova de Gaia, Portugal

Contact E-Mail Address: joaocarosilva@gmail.com
Introduction: Alpha-fetoprotein (AFP) is the most tested biomarker in hepatocellular carcinoma (HCC), and sustained elevated levels are a well-known risk factor. Only a suboptimal yield for screening purposes has been yet been described. Recently published guidelines on HCC treatment from AASLD, take in consideration the use of AFP for HCC surveillance.
Aims and Methods: The aim of this study was to evaluate the role of AFP in HCC screening by comparing two groups with different surveillance strategies. Incidence of HCC in each group was determined and correlated with early stage detection, curative therapeutic options and long-term survival.
In a retrospective study, 110 cirrhotic patients were included over a 12 year follow-up period, in a single center. Cirrhosis was defined on basis of clinical, biochemical and radiologic investigation. All patients underwent HCC screening each 6 months by US alone in one group and US plus AFP in the other.
Results: A hundred and ten patients were included (70.9% males). Surveillance strategy relied in US plus AFP in 46 cases (41.8%), and US alone in 59 cases (53.6%). Five patients had imagological evidence of suspected lesions in the first evaluation and were not included in any of the groups. The median age was 62,2 years (SD ± 12.4) and mean follow-up period was 4.6 years (SD ± 3.3). Most common etiologies of cirrhosis were alcohol (49.1%) and hepatitis C (27.3%). Of 110 patients 17 (15.4%) developed HCC, yet only 12 (10.9%) had a HCC diagnosis in surveillance setting. The mean period for HCC diagnosis was 3.7years (SD ± 2.8).
In the US plus AFP group, 8 patients (18.2%) were diagnosed with HCC. In 5 cases US findings were abnormal and AFP levels were normal while 2 patients had elevated AFP and abdominal US without suspicious lesions. Five patients (62.5%) had an intermediate stage (B) according to the Barcelona-Clinic Liver Cancer (BCLC) system, and were treated with transarterial chemoembolization (TACE).
Considering the group screened solely by US, 4 patients (6.9%) had HCC. In this group only 1 patient, with early stage (A) HCC was eligible for radiofrequency ablation (RFA).
Three-year survival rate was equal in both groups (25%). Overall mortality was higher (75%) in the US group when compared to the US plus AFP group (62.5%).
Conclusion: AFP should be considered in HCC surveillance once it allows diagnosis in patients with otherwise normal radiologic investigation.
Disclosure: Nothing to disclose

P0695 CANCER-ASSOCIATED FIBROBLASTS PROMOTE THE CANCER STEM CELL PLASTICITY OF CD24+ LIVER STEM CELLS VIA PARACRINE SIGNALLING

B. Cheng[1], **Y. Li**[2], R. Wang[2]

Introduction: Cancer stem cells (CSCs) contribute to treatment resistance and tumor relapse in hepatocellular carcinoma (HCC). Cancer-associated fibroblasts (CAFs) have been reported to support tumor progress. However, the mechanisms by which CAFs contribute to stemness maintenance remain largely unknown. Here, we hypothesized that HGF and IL6 secreted by CAFs promote the stemness properties of $CD24^+$ HCC cells through the activation of STAT3 signaling.
Aims and Methods: CD24+ cells were isolated from HCC cell lines, and their stemness characteristics were demonstrated in vitro and in vivo (Xenograft tumors in NOD/SCID mice). CAFs isolated from fresh HCC samples were co-cultured with CD24+ HCC cells, and CSC functions were measured. HGF/c-Met, IL6/IL6R and STAT3 pathways were detected and then manipulated with pharmacologic and genetic approaches in CD24+ HCC cells with ot without CAF-CM. Finally, the expression of CD24, alpha-smooth muscle actin (α-SMA) and phospho-STAT3 in tissues from HCC patients were examined by immunohistochemistry.
Results: We found that the expression of CD24 was high in HCC tissues, and positively correlated with the poor prognosis and α-SMA expression in CAFs. Meanwhile, CD24+ cells isolated from HCC cell lines exhibited higher self-renewal, chemotherapy resistance, invasion and migration abilities in culture, and formed more xenograft tumors in mice than CD24- cells. Moreover, CAF-derived HGF and IL6 enhanced the stemness properties of CD24+ HCC cells via promoting STAT3 Tyr705 phosphorylation. Both the neutralizing antibodies of cytokines and blockade of HGF/c-Met or IL6/IL6R signaling significantly abolished the effect of CAFs on stemness properties, which compromised the activation of STAT3 pathway in CD24+ HCC cells. While knockdown of STAT3 in CD24+ HCC cells notably attenuated CAF-induced stemness characteristics of CD24+ HCC cells. Furthermore, in HCC patients, higher expression of phospho-STAT3 were also demonstrated to be positively correlated with poor clinical outcomes.
Conclusion: These findings suggested that HGF and IL6 secreted by CAFs promoted the stemness properties of $CD24^+$ HCC cells through the activation of STAT3 signaling.

P0696 LIVER STIFFNESS AS A PREDICTOR OF HEPATOCELLULAR CARCINOMA BEHAVIOR IN PATIENTS WITH HEPATITIS C-RELATED LIVER CIRRHOSIS

S.A. Lashen[1], M.M. El-shafae[2]
[1]*University of Alexandria, Faculty of Medicine, Internal Medicine, Alexandria, Egypt*
[2]*University of Alexandria, Faculty of Medicine, Diagnostic and Interventional Radiology, Alexandria, Egypt*

Contact E-Mail Address: sameh.lashen@alexmed.edu.eg
Introduction: Hepatocellular carcinoma (HCC) is a leading cause of death in cirrhotic patients. For improvement of patient outcome, early detection and treatment of HCC are mandatory, so strategies for screening, risk stratification and prognostication of HCC are important.
Aims and Methods: To explore the role liver stiffness measurment (LSM) inside HCC lesion, in peritumoral tissue and in cirrhotic non-malignant liver tissues in the prediction of HCC clinical behavior. We included 121 naïve patients with hepatitis C related HCC. Liver profile as well as serum alfa-fetoprotein (AFP) were done. The aspartate aminotransferase (AST) /platelet ratio (APRI) score was calculated. HCC evaluation (number of lesions, maximum diameter, tumor capsule, vascular invasion, and extrahepatic spread) was done based on the triphasic CT. HCC staging was done (TNM, OKUDA, CLIP and BCLC staging). LSM was measured (by acoustic radiation force impulse (ARFI) apparatus) inside the tumor mass, within 1 cm around the tumor and at the non-malignant cirrhotic liver tissue [expressed as meter/second (m/s)]. Patients were assigned to appropriate treatment according to the BCLC stage. Tumor recurrence-free interval was calculated from last CT evidence of HCC ablation to 1st CT evidence of recurrence.
Results: Patients were divided into 2 groups (early HCC including BCLC stage A and B [n = 54]; and late HCC including BCLC stage C and D [n = 67]). The mean value of LSM inside the tumor was 1.49 ± 0.79 (IQR = 0.91–2.02) m/sec, in the peritumoral area was 2.49 ± 1.07 (IQR = 1.38–3.39) m/sec, and in non-malignant cirrhotic tissue was 2.65 ± 0.63 (IQR = 2.35–2.95) m/sec. The mean value of LSM inside the tumor and in the peri-tumoral tissue were significantly lower in the late HCC group compared to the early HCC group (1.16 ± 0.53 m/s vs. 1.91 ± 0.87 m/s, $p < 0.001$ and 1.99 ± 0.87 m/s vs. 3.12 ± 0.98 m/s, $p < 0.001$ respectively) while there was no statistical difference between the two groups as regards LSM in the cirrhotic non-malignant tissue. The mean values of LSM inside the tumour as well as in the peri-tumoral tissue showed strong negative correlation with serum AFP, tumor number and diameter, portal vein invasion, CLIP, TNM, and BCLC stages ($p < 0.001$) and OKUDA stage ($p < 0.05$), and direct significant correlation with presence of tumour capsule and recurrence-free interval ($p < 0.001$). The mean value of LSM in the cirrhotic non-malignant tissue showed strong negative correlation only with the presence of vascular invasion ($p = 0.004$), and recurrence-free interval ($p = 0.001$). At a cut-off values of 1.25 m/s, LSM inside the tumour has sensitivity and specificity of 77.8% and 71.6% (AUC = 0.759; 95% CI = 0.67–0.85) in differentiating early from late HCC. On univariate analysis, platelet count, AST, Child-Pugh class, AFP, LSM inside the tumor, and LSM in the peri-tumoral tissue ($p < 0.05$) could predict early HCC. However, in multivariate analysis, AFP was the only predictor (OR = 1.07, $R^2 = 0.968$, $p = 0.044$). In addition, multivariate analysis showed that APRI score, AFP, LSM inside the tumor and peritumoral tissue, tumor number and diameter, and BCLC stage were independent predictors for the recurrence-free interval ($p < 0.001$).
Conclusion: Liver stiffness measurement inside the tumor and peritumoral tissue in patients with HCV related HCC is suggested as a potential non-invasive marker for prediction of HCC clinical behavior as well as recurrence-free interval following locoregional treatments. A cut-off value of 1.25 m/s of LSM inside the tumor could differentiate early from late HCC with 77.8% sensitivity and 71.6% specificity.

Introduction: Sorafenib is so far the only approved systemic therapy for advanced Hepatocellular Carcinoma (HCC) in patients with preserved liver function. More recently, Regorafenib (RESORCE trial) succeeded in improving survival in second-line treatment in patients progressing under Sorafenib. Despite this, the new systemic drug does not satisfy the needs of patients intolerant to Sorafenib. Recent data suggested the efficacy and tolerability of Capecitabine in the treatment of advanced HCC.
Aims and Methods: The aim of our study was to retrospectively evaluate efficacy and safety of Capecitabine in a cohort of patients with advanced HCC, also in relation to the different therapeutic schemes previously administered.
In this multi-centre retrospective study we analysed 143 Capecitabine-treated patients, 111 treated with Metronomic Scheme (MS, 1000 mg/day administered continuously) and 32 treated with Non-Metronomic Scheme (NMS, 2000 mg/day administered for 14 days followed by 7 days of interval). The tolerability and the efficacy of the treatment, evaluated in terms of Overall Survival (OS) and Progression Free Survival (PFS), were determined.
Results: Considering the entire cohort, hepatic cirrhosis was present in 112 patients (78%); 89 patients (62%) were Child-Pugh A, 130 (91%) were BCLC C, 56 (39%) patients had PVT e 74 (52%) patients had metastasis. NMS patients had significantly better Child-Pugh score, a better ECOG-PS, smaller nodules and less frequently PVT (all $p < 0.05$). Capecitabine was administered in I/II/III line in 43 (30%), 75 (52%) and 25 (18%) patients, respectively. Median duration of treatment was 5.6 months. Median OS and PFS for MS+NMS patients were 6.9 months [95% CI 5.73–8.13] and 2.6 months [95% CI 2.17–3.09], respectively. Median OS was 10.5 months [95% CI 7.2–13.7] for NMS patients versus 5.7 months [95% CI 4.0–7.3] for MS patients ($p = 0.0005$). Median PFS was 2.5 months [95% CI 2.11–2.89] in MS patients versus 3.9 months [95% CI 2.22–5.51] in NMS patients ($p = 0.005$). The disease control rate was 28.3% (complete response in 1.5% and partial response in 5.1%); 71.7% of patients had disease progression. A correlation between OS and radiological response to treatment was demonstrated ($p = 0.0002$). Median OS was 4.7 months [CI 95% 3.60–5.74] in patients treated with BSC after Capecitabine discontinuation compared to a median OS of 13.8 months [CI 95% 6.95–20.65] in patients subsequently treated with additional chemotherapy. In patients forced to Sorafenib discontinuation for toxicity, OS was 8.4 months [CI 95% 5.95–10.79] versus 5 months [CI 95% 3.60–6.34] in patients in cancer progression ($p = 0.024$). The most common drug-related adverse events were thrombocytopenia (38%), anemia (34%), fatigue (22%), leukopenia (18%), with no substantial differences between MS and NMS; only in 13 patients (9%) side effects lead to treatment discontinuation. At the Cox multivariate analysis number of nodules, response to Capecitabine and therapy after Capecitabine discontinuation were identified as independent predictors of survival.
Conclusion: Capecitabine is an effective treatment for patients with advanced HCC, useful also in those intolerant to Sorafenib. Non-Metronomic Scheme seems to be more efficient in terms of OS than Metronomic Scheme, but conclusions cannot be drawn in consideration of the marked differences between the two groups. Capecitabine confirms in our study its safety profile in patients with advanced HCC.

P0698 "TORONTO HCC RISK INDEX": USEFUL TO PREDICT HEPATOCELLULAR CARCINOMA IN ALL PATIENTS WITH CIRRHOSIS, REGARDLESS OF ETIOLOGY?

R. Gaspar[1], M. Patita[2], P. Andrade[3], G. Macedo[4]
[1]*Hospital São João, Gastrenterology, Porto, Portugal*
[2]*Hospital Garcia de Orta, Almada, Portugal*
[3]*Centro Hospitalar São João, Dept. de Gastroenterologia, Porto, Portugal*
[4]*Centro de Hospitalar São João, Porto, Portugal*

Contact E-Mail Address: ruilopesgaspar@gmail.com
Introduction: The actual guidelines for liver cirrhosis recommend hepatocellular carcinoma (HCC) screening with ultrasound every 6 months, regarding of the etiology of liver disease. Toronto HCC risk index" (THRI) is a recent score used to predict the risk ok HCC that was validated in the Canadian and Dutch population.
Aims and Methods: The aim of this study was to evaluate the THRI for prediction of HCC development in Portuguese population.
Methods: Retrospective study of patients with liver cirrhosis under HCC screening with ultrasound and alpha-phetoprotein every 6 months in a tertiary center.
Results: We included 269 patients with liver cirrhosis, 70.3% male, with mean age of 66.3 ± 13.3 years. The median time of follow up was 54.5 [32.3–85.0] months. The main causes of liver cirrhosis were alcohol (53.5%), HCV infection (13.4%) and NASH (10.8%). Sixty percent of the patients revealed alcohol consumption more than 30g/day, 58.7% were classified as Child A and the median MELD was 7[6–9]. During the period of follow-up were diagnosed 44 HCC (incidence of 16.4%).
According to THRI, 59.9% of the patients were classified as high risk group patients for development of HCC, 36.4% as intermediate group and 3.7% as low risk group of HCC.
In the high risk group, 21.1% developed HCC, in the intermediate group 9.2% developed HCC and in the low risk group 10% of the patients developed HCC. The groups created according to THRI presented a low correlation with the development of HCC ($r_s = 0.155$, $p = 0.155$).
The THRI score presented a low correlation with the development of HCC ($r_s = 0.231$, $p < 0.001$).
Conclusion: Although validated in the Canadian and Dutch population, Toronto HCC risk index
was not a good tool to predict the development of HCC in the Portuguese population. One reason for this could be the main etiologies of chronic liver disease in our population, namely alcoholic and non-alcoholic fatty liver disease, much different from the population where THRI was validated (the major causes were HCV infection and autoimmune liver diseases).

Contact E-Mail Address: el_naqueeb@yahoo.com
Introduction: The first-line treatment option for intermediate -stage Hepatocellular Carcinoma (HCC) was Transarterial chemoembolization (TACE). Inflammation has been proved to play an important role in tumor progression and invasion. Inflammation profile, such as lymphocyte-monocyte ratio (LMR), neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), Monocyte Granulocyte Lymphocytic Ratio (MGLR) and Red blood cell distribution width (RDW) have been identified as prognostic biomarkers in multiple cancers.
Aims and Methods: We aimed to investigate these different blood indices and MELD score as prognostic predictors for early recurrence of hepatocellular carcinoma after TACE.
Methods: NLR, LMR, MGLR, RDW and PLR were calculated and values determined in 147 patients (111 male and 36 female). Sensitivity and specificity of different indices for HCC recurrence were estimated by receiver operator characteristic curve. Relation between best predictors and recurrence free time in TACE treatment of HCC cases were studied by Kaplan-Meier curve
Results: MGLR had the best diagnostic performance for detection of early recurrence of HCC after TACE at cut off value 2.75 with sensitivity 70.7%, specificity 59.2%. MELD score at cut off value 9.5 had the best diagnostic performance for detection of early recurrence of HCC after TACE with 80% sensitivity and 55.8% specificity; also risk estimates for HCC recurrence was 2.489 with 95% confidence interval (1.280–4.838).
Conclusion: This study concluded that higher both MGLR and MELD score were associated with increasing occurrence of HCC recurrence after TACE and could be used as novel, simple, low-cost, non-invasive prognostic tests for HCC patients.

Contact E-Mail Address: antonellasantonicola83@gmail.com
Introduction: Patients with liver cirrhosis and liver transplant (LT) candidates show sleep disturbances that negatively impact their quality of life. Data about the quality of sleep after LT are scanty.
Aims and Methods: We aimed to evaluate the quality of sleep in a cohort of adult LT patients from Southern Italy.
Adult LT patients were recruited from two Liver Following Transplant Centers of Southern Italy (Salerno and Gragnano). We collected the following data: age, gender, marital status, cause of transplantation, presence of hepatocarcinoma at the time of transplantation, early liver rejection, time from transplantation, type of immunosuppression, and presence of comorbidities. Age- and gender-matched healthy controls (HC) were also enrolled. All participants completed the Pittsburgh Sleep Quality Index (PSQI), the Zung Self-rating Depression Scale and the State-Trait Anxiety Inventory (STAI).
Results: 129 LT patients (91 males, mean age 60.2 ± 9.8 years) and 51 HC (29 males, mean age 60.3 ± 8.6 years) were enrolled. The most common indications for LT were HCV-related cirrhosis (44.3%), HBV-related cirrhosis (35%),

alcoholic cirrhosis (3.9%). The mean time from LT was 11.5 ± 6.7 years. Forty/129 patients (31%) were on Tacrolimus, 21 (16.3%) on Everolimus, 13 (10.6%) on Cyclosporine, 12 (9.3%) on Mycophenolate-Mofetil. Other patients (43/129, 33.3%) were on a combined treatment.

Table 1 showed no significant differences between LT patients and HC in PSQI mean score and the prevalence of pathological sleep; however, LT patients had a significantly higher score in Zung than HC and a borderline significance for STAY 1.

The univariate analysis did not show any significant association between PSQI scores as dependent variable and gender, age, marital status, type of immunosuppressive therapy, indication for LT.

Tables 1 Mood disorders in LT patients compared to HC. Data were expressed as percentage (%) or mean (Standard Deviation).

Conclusion: More than half of LT patients had sleep disorders. Age, gender, type of immunosuppressive therapy, indication for LT did not relate to the presence of sleep disorders. The improved LT patients survival stresses the importance of characterizing psychosocial aspects, including anxiety, depression, and sleep quality after LT. New strategies focused on recognizing and treating alteration of the sleep pattern of LT patients are needed because a better sleep may promote a better quality of life.

	LT patients N = 129	Healthy Controls (HC) N = 51	p
PSQI mean (SD)	6.7 (3.9)	6.4 (3.6)	0.7
% pathological sleep (PSQI > 5)	69 (53.9)	27 (52.9)	0.9
STAI Y1	40.2 (13.0)	36.9 (8.9)	0.08
STAI Y2	38.6 (10.2)	36.4 (8.8)	0.2
ZUNG	38.7 (10.0)	33.7 (6.0)	0.002

P0701 TRANSLATING POLICY TO REAL WORLD IN RARE LIVER DISEASES REGISTRIES; A EUROPEAN PERSPECTIVE

M. Pericleous[1,2], C. Kelly[1,2], S. de Lusignan[2], A. Ala[1,2]
[1]*Royal Surrey County Hospital, Department of Gastroenterology & Hepatology, Guildford, Surrey, United Kingdom*
[2]*University of Surrey, Department of Clinical and Experimental Medicine, Guildford, Surrey, United Kingdom*

Contact E-Mail Address: pericleousmarinos@gmail.com

Introduction: A rare disease is defined by the European Health Commission (EHC) as a disorder found in less than 5/10,000 population. The importance of collaborations in the field of rare diseases where data is scarce and fragmented is well-known.

The OrphanXchange project was set up by Orphanet to promote collaborations between academia and industry. Moreover, the European Union Committee of Experts on Rare Diseases (EUCERD) encouraged the exchange of relevant experience, policies and practices in rare diseases among member states and promoted cooperation across Europe and beyond, including Japan. The committee identified multiple important challenges for successful registry utilisation; discrepancy in coverage with multiple fragmented registries for some conditions, complete lack of registries for other conditions and registries that were mainly academic rather than clinical.

A critical output of EUCERD was the provision of a basic framework for European data collection and registration in rare diseases across 6 domains:

- International Operability
- Sources Of Data,
- Collection Of Data,
- Good Practices,
- Use Of Data For Regulatory Purposes
- Sustainability.

There are approximately 20 rare liver diseases (RLD), meaning the hepatology community can be influential in informing and developing such registries.

Aims and Methods: Our aim was to identify how many of the defined non-cancer orphan conditions have an established registry in keeping with EHC's recommendations. A Pubmed and google scholar search using the MESH terms ''registries'', ''database management systems'', ''database'' and the non-MESH terms ''database$'', ''registry'', ''repository'' and ''repositories'' for English literature in humans was performed. The results were screened manually.

Results: Registries were identified for most RLD in many countries. The results are summarised in the table below. Slovenia, Slovakia, FYROM, Malta, Luxemburg, Lithuania, Estonia and Cyprus do not appear to have RLD registers.

Abbreviations: Alpha 1 antitrypsin deficiency (A1AD), autoimmune hepatitis (AIH), acute liver failure (ALF), biliary atresia (BA), Caroli's disease, hereditary haemorrhagic telangiectasia (HHT), IgG4 disease, primary biliary cholangitis (PBC), primary sclerosing cholangitis (PSC), polycystic liver disease (PLD), porphyria, vascular liver disorders (VLD), Wilson disease (WD) and hepatitis D (HDV).

Conclusion: Despite concerted efforts of the European Union, there is variability in the number of registries for RLD. The EUROPLAN was set up to provide a framework and support EU countries in developing their national strategies. Currently, 24/28 member countries have rare disease strategies. Thus far, action plans could not be found on the EU portal for Estonia, Finland, Malta, Poland. Interestingly, despite whilst not demonstrating a national strategy for rare diseases, Poland and Finland currently have registries for RLD and surprisingly, countries with established national policies such as Lithuania, Luxemburg, Cyprus, Slovenia, Slovakia and FYROM do not.

[2]*Radboud University Medical Center, Medical Microbiology, Nijmegen, Netherlands*

Contact E-Mail Address: marleen.vandijk@radboudumc.nl

Introduction: There are an estimated 23,000 chronic Hepatitis C-infected patients in the Netherlands. An unknown proportion has been lost to follow-up and received no adequate treatment. The advent of direct antivirals offers the prospect of safe and efficacious therapy.

Aims and Methods: We designed this study to examine a retrieval strategy that identifies chronic HCV (cHCV) patients lost to follow-up (LTFU) and brings them back into care. We also mapped disease and patient characteristics of this cohort. Our diagnostic pipeline started with data analysis of patient records of a virology laboratory that serves 2 hospitals : a tertiary referral and liver-expert centre and a rehabilitation clinic. Records from patients with positive HCV antibodies, immunoblot and/or HCV quantitative RNA PCR measurements between 2003–2017 were identified and linked to personal data. Chart review was performed to assess possibility of loss to follow-up and to map phenotypical characteristics of the LTFU cohort. Identification data was checked with the governmental citizen administration to adjust for death or change of municipality.

Results: Of all tested patients (n = 45276), 372 had at least one positive HCV RNA. Prevalence in this cohort would be estimated at 0.22%, which is similar to the prevalence in the Netherlands. In 175/372 patients (47%) the last measured RNA was still positive. Of these cHCV patients, 4 were still in care and 72 deceased. A total of 81 cHCV patients (22%) is LTFU and could benefit from linkage to care. Demographics, probable mode of infection, treatment attempts and disease severity are depicted in table 1. In approximately 50% disease severity is unknown, with data on imaging or fibrosis severity missing.

Age at last contact (mean, SD)	45 (13)
Male gender (n, %)	66 (82%)
Non-Dutch resident (n, %)	44 (55%)
Deceased since last contact (n, %)	8 (10%)
Probable mode of infection:	
Blood transfusion / IV drug use / Other (MSM/tattoo/needle stik injury) / Unknown	25% / 48% / 7% / 21%
Known HIV/HBV co-infection	12 (15%) / 2 (3%)
Previously in care of hepatitis specialist (n, %)	53 (63%)
Previous treatment attempt (n, %)	19 (24%)
PEG-interferon + ribavirin (n, %)	11 (58%)
Genotype (% 1/2/3/4/unknown)	42% / 4% / 16% / 5% /33%
Viral load (IU/L, median, IQR)	8 × 106 (3 × 106-40 × 106)
Unknown viral load (n, %)	10 (12%)
ALT (U/L, median, IQR)	58 (37–88)
ALT elevated (>2× ULN, n, %)	30 (37%)
ALT Unknown (n, %)	5 (6%)
Signs of fibrosis/cirrhosis on imaging (n, %)	15 (19%)
No imaging present (n, %)	39 (48%)
Fibrosis stage (% with F0/F1/F2/F3/F4)	9% / 10% / 9% / 0 / 5%
No liver biopsy (n, %)	54 (67%)

[Table 1 Characteristics of LTFU cohort]

Conclusion: Identification of patients through analysis of archival laboratory results and chart review is feasible. Disease severity is unknown in a significant part of the LTFU population. These patients could be at risk for serious complications. Together with the high percentage of LTFU patients observed in this centre, this emphasizes the need for a nationwide retrieval project to bring this group back in care.

Disclosure: This investigator-initiated study was funded by an unrestricted grant from MSD.

P0703 TREND IN HOSPITALIZATION RATE FOR ALCOHOL HEPATITIS IN VENETO REGION (NORTHEAST ITALY)

E. Rosa-Rizzotto[1], **D. Caroli**[2], M. Saia[3], S. Vicario[4], S. Lobello[5]
[1]*St. Anthony Hospital Gastroenterology Unit Dept. of Medicine, Dipto. di Gastroenterologia, Padova, Italy*
[2]*St Antonius Hospital, Dept. of Gastroenterology, Padova, Italy*
[3]*Veneto Region, Padova, Italy*
[4]*St Antonius Hospital, Padova, Italy*
[5]*Addiction Treatment Service Unit, Padova, Italy*

Contact E-Mail Address: d.caroli@libero.it

Introduction: WHO Europe 2014 database reports a declinein per capita pure alcohol consumption in Italy, with a reduction from 18.1 to 7.1 litres from 1970 up to date. Despite this, Italian Report on Alcohol 2016 showed an increase in drinking outside meals and a rise in alcohol consumption and binge drinking among young people (age ranges 18–24, 14–17), particularly in males.

Aims and Methods: To evaluate the trends of hospitality discharge for alcoholrelated diseases in the period 2000–2017 in Veneto Region in North Eastern Italy (4.8 million inhabitants). This is a retrospective cohort study based on Veneto Region anonymous computerised database of hospital discharges between 2000 and 2017. All Veneto residents discharge records with principal diagnosis of alcohol-related disease (cod. ICD9-CM: 571.0, 571.1, 571.2, 571.3) were included in the study. The principal diagnosis was chosen as it is considered the primary reason for hospital admission. Standardised Hospitalisation Ratio (SHR) per five-year age group (ref. pop. Veneto 2008) was calculated and expressed per 100 000 population.

Results: Over the period 2000–2017, 30.089 hospital admissions for alcohol-related diseases were recorded. Most part of subjects were males (74%), who held the higher hospitalisation rate (52 vs. 17.5; OR: 2.95; 95% CI: 2.88–3.09; $p < 0.05$). The longitudinal analysis of the hospitalisation trend shows a 7% increase on average age in both sexes (from 58.8 ± 9.2 to 62.4 ± 9.7) and a substantial decrease of 63.5% in SHR ($\chi 2$ trend: 4099,827). Noticeably, in the last year of observation the hospitalisation rate tends to 20.9, confirming the greater risk for the male population (32.7 vs. 9.1; OR: 3.79; 95% CI: 3.28–4.38; $p < 0.001$). Considering the age groups, emerges as the highest SHR can be found in the ranges 45–64 (67) and >65 (67.8), which in 2017 was respectively at 35.6 and 46. Finally, hospitalization for alcoholic liver disease in population 25–44 appears clearly more limited. However, in this age range a slightly rising trend has been recorded betweeen 2013 and 2017.

Conclusion: Italian epidemiology of alcohol consumption is changing. In Veneto Region, the reduction in alcohol intake over the last 30 years has lead to a marked reduction in hospital admissions for alcohol-related diseases. These data suggest that the changing style of alcohol consumption, especially in young people, may explain both the decrease in hospitalisation for alcoholic liver disease, and the upward SHR trend in 2013–2017. Thus, it will be likely to observe in the next years an increase in hospital admissions for alcohol-related diseases. New strategies in Public Health approach are needed to address the new styles of consumption, especially in young populations.

Disclosure: Nothing to disclose

P0704 DEFINING AND CHARACTERISING THE BLUEPRINT FOR THE DEVELOPMENT OF A SUCCESSFUL REGISTRY FOR RARE LIVER DISEASES

M. Pericleous[1,2], C. Kelly[1,2], S. de Lusignan[2], A. Ala[1,2]
[1]*Royal Surrey County Hospital, Department of Gastroenterology & Hepatology, Guildford, Surrey, United Kingdom*
[2]*University of Surrey, Department of Clinical and Experimental Medicine, Guildford, Surrey, United Kingdom*

Contact E-Mail Address: pericleousmarinos@hotmail.com

Introduction: A rare disease (RD) is defined by the European Health Commission as a disorder occurring in < 5/10,000 population whereas the United States definition sets a numerical maximum of < 200,000 affected individuals in the country. RDs are now a clinical priority of the European Union (the Europlan project and Eurordis), Asia-Pacific, USA and the World Health Organisation (WHO). The European Union Committee of Experts on Rare Diseases (EUCERD) was set up with the purpose of encouraging the exchange of relevant experience, policies and practices in rare diseases among member states. One of the most important output activity of EUCERD is the provision of the basic governance and foundation in data collection and registration in RDs across 6 domains:

1. International operability
2. Sources of data
3. Collection of data
4. Good practices
5. Use of data for regulatory purposes
6. Sustainability

Despite this core framework, a comprehensive guideline of how to create an effective and contemporary registry for rare liver diseases does not exist, despite there being approximately 20 non-cancer rare hepatic conditions.

Aims and Methods: Initial pilot work to identify governance, technical and data issues led to successful development of local registries for rare liver diseases including IgG4-Related disease, Wilson disease and hepatocellular carcinoma. This was then used as a platform to successfully develop a novel regional primary biliary cholangitis (PBC) registry in the UK which provides data-linkage from primary to secondary care in conjunction with various stakeholders including

hepatologists, the RCGP (Royal college of General Practitioners, the NIHR (National Institute of Health and Research), patient groups, charities and industry partners.

Results: The design process of creating a registry can be primarily divided into three main phases (theoretical, technical and data collection) and spans across 9 domains. The blueprint for these is shown in the table below:

1 Aims, objectives and endpoints	What is the purpose of the registry?
2 Define study population	Define the disease ontology and case eligibility
3 Information, research and clinical governance	1. Safety & Wellbeing of patients and investigators 2. Competence and adequate qualifications 3. Scientific and Ethical Conduct. Peer-reviewed research proposal 4. Patient, service user and public Involvement 5. Integrity, quality and transparency 6. Protocol to clearly explain the design of the study 7. Legality 8. Benefits and Risks to patients should be identified and stated 9. Approval by regional ethics committee, confidentiality advisory group (if necessary) and ultimately by the health research authority 10. Information about the research to be made publically available 11. Accessible findings (positive or negative) 12. Respect autonomy of participants and afford respect and choice in relation to consent or refusal of consent. Develop robust opt-out mechanisms. 13. Insurance and Indemnity to cover liabilities 14. Respect for Privacy by practising strict information governance rules and ensuring safe keeping of data 15. Compliance
4 Sponsorship & Funding	
5 Identify stakeholders & set up collaborations	Seek locoregional, national and international collaborations
6 Registry design and data quality	1. Define data fields and set core/mandatory and desired components 2. Is there a need for patient-identifiable information? 3. Create pseudonymised record identifier for each patient recruited 4. Create various levels of access for users 5. Build in data validation checkpoints 6. Engage with patients, the public and relevant charities
7 Data entry	1. Enable remote access and data entry 2. User-friendly interface for quick data entry
8 Data processing	1. Data linkage to other repositories available 2. Develop a strategy for handling missing data 3. Presentation of outcomes in local, regional and international meetings
9 Ensure sustainability	1. Form a steering committee 2. Regular consultations with stakeholders including patients and the public 3. Long-term funding 4. Continental/international data feeding into bigger datasets

[Blueprint for the design of a comprehensive registry for rare liver diseases]

Conclusion: Overall, the development of a bespoke registry for rare liver diseases is complex and requires a wide array of skills and expertise including clinical, IT, cyber security and information governance. Our experience was that the key element is clearly defining both the study population and the purpose of the registry. This will provide a solid foundation for the design and utility of the database which can be then be expanded appropriately and sustainably. The efforts should be guided by a carefully-selected steering committee which should also promote the establishment of loco-regional, national and international collaborations.

Introduction: Adiposity due to a positive energy balance starts with the accumulation of fat in the subcutaneous adipose tissue, with relatively less influence on insulin sensitivity, until the limit is expanded through adipose tissue dysfunction. The lipids then overflow and the accumulation of visceral and ectopic fat sets in, resulting in insulin resistance and related cardiometabolic problems. Several factors differentiate the subcutaneous and visceral adipose tissues, including adipokine and cytokine production, adipogenic potential, and the ability to store and mobilize lipids. It has been widely accepted that liver fat is a type of ectopic fat and that it is strongly associated with visceral obesity. However, there is not yet a unified view about the association between nonalcoholic fatty liver disease (NAFLD) and subcutaneous obesity.

Aims and Methods: NAFLD is recognized as a hepatic manifestation of metabolic syndrome because of the association with visceral obesity. However, the association between NAFLD and subcutaneous fat accumulation remains unclear. The study population included 3197 subjects who consumed < 20 g of alcohol per day. They were divided according to the quantiles of subcutaneous (SFA) or visceral (VFA) fat areas on CT. Fatty liver was diagnosed using ultrasonography (FL-US).

Results: The prevalence of FL-US increased across the SFA categories, even after adjusting for the VFA, in both men (S-Q1, 13.7; S-Q2, 37.8; S-Q3, 52.3; S-Q4, 75.4%, $p < 0.001$, Mantel-Haenzel test) and women (S-Q1, 8.4; S-Q2, 19.0; S-Q3, 33.6; S-Q4, 50.4%, $p < 0.001$). The risk of FL-US increased with SFA—independently of VFA—in men (Odds ratio [95% confidence interval]: S-Q1, 1; S-Q2, 2.21 [1.54–3.18]; S-Q3, 3.57 [2.48–5.13]; S-Q4, 6.67 [4.52–9.86]) and women (S-Q1, 1; S-Q2, 1.74 [1.07–2.84]; S-Q3, 3.03 [1.90–4.82]; S-Q4, 4.12 [2.60–6.54]). In addition, the prevalence of FL-US increased across the VFA categories, even after adjusting for the SFA in men (V-Q1, 13.2, V-Q2, 41.9; V-Q3, 54.9; V-Q4, 69.4%, $p < 0.001$) and women (V-Q1, 8.4; V-Q2, 19.0; V-Q3, 33.6; V-Q4, 50.4, $p < 0.001$). The risk of FL-US increased with the VFA, independently of the SFA, in men (V-Q1, 1; V-Q2, 2.21 [1.54–3.18]; V-Q3, 3.57 [2.48–5.13]; V-Q4, 6.67 [4.52–9.86]) and women (V-Q1, 1; V-Q2, 1.74 [1.07–2.84]; V-Q3, 3.03 [1.90–4.82]; V-Q4, 4.12 [2.60–6.54]). In addition, this significant association between FL-US and the SFA was already detected from the second SFA quantile. It is noteworthy that the mean BMI values of the subjects in the second quantile were 23.7 kg/m^2 in men and 22.6 kg/m^2 in women, as these values were close to the in normal body weight range according to the Japanese criteria (obesity $\geq$ 25 kg/m^2 in both men and women). On the other hand, the components of metabolic syndrome were independently associated with the VFA, but were less associated (or not associated) with the SFA.

Conclusion: NAFLD may be independently associated with both visceral and subcutaneous adiposity, which is a characteristic that distinguishes NAFLD from other components of metabolic syndrome.

Contact E-Mail Address: golf4to@yahoo.co.jp

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is a common method for tissue sampling in patients with biliary strictures by bile aspiration cytology, biliary brush cytology and forceps biopsy. However, the sensitivities of bile aspiration cytology, brush cytology, and forceps biopsy for biliary strictures varies from 6 to 72%, and hence remains unsatisfactory. Furthermore, the incidence rates of post-ERCP adverse events, which were reported as 4.0–6.9%, including pancreatitis (2.6–3.5%), bleeding (0.3–1.3%), and perforation (0.1–0.6%), can't be ignored. Recent studies reported that endoscopic ultrasonography guided fine needle aspiration (EUS-FNA) is superior to ERCP related tissue sampling in evaluating suspected malignant biliary strictures. However, there have been few studies comparing the diagnostic utility of EUS-FNA and that of ERCP related tissue sampling only for extrahepatic cholangiocarcinoma (ECC).

Aims and Methods: The aim of this study was to evaluate the efficacy and safety of the EUS-FNA for the diagnosis of ECC compared with ERCP related tissue sampling.

The patients who were received EUS-FNA or ERCP related tissue sampling, to differentiate ECC from benign biliary disease, were enrolled retrospectively

between October 2011 and March 2017 at our hospital. We evaluated the diagnostic performance of EUS-FNA and that of ERCP related tissue sampling on the basis of the pathological evaluation. We also compared the adverse event of EUS-FNA and that of ERCP related tissue sampling. The diagnosis of ECC was based on the pathological diagnosis of bile aspiration cytology, transpapillary forceps biopsy, EUS-FNA or surgical specimen. In histological findings, malignancy or suspicion of malignancy was considered as positive in this study. Patients without a malignant disease had a final benign diagnosis based on clinical and radiological follow-up data after 12 months or more.
Results: Seventy three patients with biliary disease were enrolled. Patients included 49 men and 24 women: age range 42–88 years; mean age, 71.3 years. An ECC was present in 37 patients and a benign lesion was present in 36 patients. We performed EUS-FNA for 19 patients and ERCP for 54 patients. The sensitivity, specificity, positive predictive value, negative predictive value, and accuracy for ERCP related tissue sampling were 76.0%, 100%, 100%, 82.9%, and 88.9%, and for EUS-FNA were 81.8%, 87.5%, 90.0%, 77.8%, and 84.2%, respectively. There were no significant differences in the statistic value of ERCP related tissue sampling and EUS-FNA. The adverse event frequency of ERCP related tissue sampling was 25.9% (pancreatitis: 14.8%, infection: 11.1%). No adverse events were associated with EUS-FNA in any of 19 patients. The adverse event frequency of EUS-FNA was significantly less than that of ERCP related tissue sampling ($p = 0.033$). No serious adverse events such as perforation or hemorrhages were observed. Tumor seeding was not seen in any patients during follow up.
Conclusion: The diagnostic ability of EUS-FNA for ECC is similar that of ERCP-related tissue sampling. EUS-FNA is a safer tissue sampling modality for the evaluation of biliary disease than ERCP.

Introduction: Development of optimal screening method is required to improve prognosis of pancreatico-biliary malignancies. Recently developed microfluidic device showed high diagnostic yield to detect circulating tumor cells (CTCs) in the blood of cancer patients.
Aims and Methods: We aimed to investigate the clinical utility of measuring CTCs in diagnosing pancreatic-biliary cancer.
Thirty-two cases were enrolled in this study (12 pancreatic cancer, 10 biliary cancer and 10 healthy volunteer controls).
Peripheral venous blood (2 or 8 ml) was collected and stored in a special blood collection tube which minimized degradation of blood cells until measurement. Using a microfluidic chip device and image analyzer, circulating blood cells were selected based on their size and immunocytochemistry staining pattern. CTC was negative for white blood cell marker CD45 and positive for either pan-cytokeratin or vimentin. Primary endpoint was the positive rate of CTCs in cancer patients and controls. We also investigated diagnostic yield of serum tumor markers (CEA $>$ 5.1 ng/ml and CA 19-9 $>$37.0 U/ml) distinguishing cancer and control in the same cohort.
Results: CTC was negative in all controls (specificity was 100%). In pancreatic cancer patients (6 men and 6 women with a median age of 56 year-old, cStage III/IV: 6/6), CTC was positive in 83% of patients. CA 19-9 had high sensitivity of 100% while sensitivity of CEA was only 33%. Diagnostic accuracy was 91% in CTC, 95% in CA 19-9 and 60% in CEA. In biliary cancer (5 men and 5 women with a median age of 67 year-old, cStage I-II/III-IV: 5/5), CTC was positive in all cancer patients. Sensitivity was 70% in CA19-9 and 20% in CEA. Diagnostic accuracy was 100% in CTC, 80% in CA19-9 and 60% in CEA.
Conclusion: Newly developed microfluidic device could diagnose pancreatico-biliary cancers by detecting circulating tumor cells.
Disclosure: Nothing to disclose

P0708 PERORAL CHOLANGIOSCOPY BY SPYGLASS DS VERSUS CHF-B260 FOR EVALUATION OF THE LATERAL SPREAD OF EXTRAHEPATIC CHOLANGIOCARCINOMA

Y. Kanno, S. Koshita, T. Ogawa, H. Kusunose, K. Masu, T. Sakai, K. Yonamine, Y. Kawakami, Y. Fujii, T. Murabayashi, F. Kozakai, Y. Noda, K. Ito
Sendai City Medical Center, Sendai, Japan

Contact E-Mail Address: yoshi-hk@openhp.or.jp
Introduction: A newly developed peroral cholangioscopy (POCS) system, SpyGlass DS (Boston Scientific Co., Marlborough, MA, USA) has high maneuverability, whereas its image quality appears relatively low in comparison to that of a traditional cholangioscope, CHF-B260 (Olympus Co., Tokyo, Japan).
Aims and Methods: The aim of this study was to evaluate acceptability of the accuracy of SpyGlass DS accompanied by simultaneous POCS-guided biopsy compared with that of CHF-B260 after fluoroscopy-guided biopsy to diagnose the lateral extent of extrahepatic cholangiocarcinoma.
Patients who underwent surgical resection after preoperative examinations to diagnose lateral extent were evaluated. Between January 2004 and September 2015, patients who underwent mapping biopsy under X-ray fluoroscopy (ERC) without POCS were included (CHF group, $n = 56$). POCS using CHF-B260 was performed only when ERC-guided mapping biopsy findings was questionable because of possible discrepancy between the mapping biopsy findings and other examinations, such as ERC, intraductal ultrasonography, EUS, CT, and MRI. Between October 2015 and March 2017, SpyGlass DS accompanied by POCS-guided mapping biopsy was used in all candidates for surgery (SpyDS group, $n = 14$). The accuracy of overall preoperative diagnosis of lateral cancer extent, which was defined based on all examinations, including POCS, and was compared with the final diagnosis confirmed using the resected specimen, was the main outcome. The accuracies of optical evaluation by POCS, which was retrospectively reviewed by authors, and accuracy of EUS-guided mapping biopsy were evaluated.
Results: Accuracy of the overall preoperative diagnosis of lateral cancer extent for both the liver side and the ampullary side were 93% and 100%, respectively, in the CHF group, and 85% and 100%, respectively, in the SpyDS group ($p = 0.34$ for the liver side; p, not available for the ampullary side). Sensitivity and specificity for liver-side estimation were 92% and 93%, respectively, for the CHF group, and 70% and 100%, respectively, for the SpyDS group ($p = 0.13$ for sensitivity; $p = 1.00$ for specificity). Both the sensitivity and specificity for ampullary-side estimation were all 100% for both groups.
Diagnostic accuracy of simple optical evaluation by using POCS for both the liver side and the ampullary side were 81% and 100%, respectively, for the CHF group, and 69% and 80%, respectively, for the SpyDS group ($p = 0.44$ for the liver side; $p = 0.26$ for the ampullary side). When comparing groups, the accuracy rates seemed lower for the SpyDS group, although statistical significance was not detected.
The accuracy of the ERC-guided mapping biopsy in the CHF group was 80% (44/51) for the liver side and 92% (12/13) for the ampullary side. The reasons why the tumor spread toward the liver side was misdiagnosed in seven patients was due to contamination in five patients (false positive), inappropriate biopsy site (i.e., unintended upstream bifurcation of which the tumor spread did not reach) in one patient (false negative), and impossibility of advancement of the biopsy forceps beyond the obstruction in one patient (specimen was not obtained).
Conclusion: The SpyGlass DS system was found to be acceptable for the diagnosis of lateral cancer extent when cholangioscopy-guided biopsy was applied, although the accuracy rates of simple optical evaluation seemed lower than those using the traditional cholangioscope. It could be a standard approach for determining resection lines in an era in which preoperative histological confirmation is increasingly demanded.

P0709 RISK FACTORS FOR RECURRENT BILIARY OBSTRUCTION AFTER ENDOSCOPIC METALLIC STENT PLACEMENT IN PATIENTS WITH UNRESECTABLE MALIGNANT DISTAL BILIARY OBSTRUCTION

T. Ogawa, K. Ito, S. Koshita, Y. Kanno, K. Masu, H. Kusunose, T. Sakai, K. Yonamine, Y. Kawakami, Y. Fujii, T. Murabayashi, F. Kozakai, Y. Noda
Sendai City Medical Center, Department of Gastroenterology, Sendai, Japan

Contact E-Mail Address: t-ogawa@openhp.or.jp
Introduction: Recurrent biliary obstruction (RBO) is one of the most common complications after endoscopic metallic stent (MS) placement for unresectable malignant biliary obstruction. However, there have only been a few reports regarding its risk factors.
Aims and Methods: The aim of this study was to investigate the risk factors for RBO after endoscopic MS placement in unresectable distal malignant biliary obstruction. Between January 2005 and June 2017, 200 patients (mean age, 76 ± 11 yrs.; 117 males, 83 females) with unresectable malignant distal biliary obstruction who underwent endoscopic MS placement were included in this study. Patients with less than 90 days of follow-up were excluded from the study. Main outcome measurements were time to RBO and risk factors for RBO. RBO was defined as stent occlusion and stent migration. Time to RBO was analyzed by using the Kaplan-Meier method and risk factors for RBO were assessed by using log-rank test and Cox regression analysis.
Results: One hundred and seventeen patients had pancreatic cancer, 57 had bile duct cancer, 11 had gallbladder cancer 11 had lymph node metastases from other cancers, and 6 had ampullary cancer. The stents used were uncovered MS in 31 patients, partially covered MS in 66, and fully covered MS in 103. Cholangitis at the time of stenting was seen in 22% (43/200). The mean time to RBO was 583 days (median, 324 days). Non-RBO rate at 3, 6, and 12 months after MS placement was 90%, 71%, and 44%, respectively. Univariate analysis including 17 factors revealed that sex (male, $p = 0.088$), bile duct cancer ($p = 0.068$), MS except WallFlex (Boston Scientific, Co., Ltd., Natic, MA, USA) ($p = 0.023$), and cholangitis at the time of MS placement ($p = 0.001$) were risk factors for RBO. Multivariate analysis showed that cholangitis at the time of MS placement (HR 2.0, 95%CI 1.3–3.2, $p = 0.003$) and MS except WallFlex (HR 1.9, 95% CI 1.1–3.1, $p = 0.017$) as the significant risk factors for RBO.
Conclusion: Endoscopic MS placement for unresectable malignant distal biliary obstruction should be considered after improvement of cholangitis due to the high risk of RBO. WallFlex is recommended as a MS for unresectable malignant distal biliary obstruction.

P0710 PREOPERATIVE BILIARY DRAINAGE USING PLASTIC STENTS VERSUS SELF-EXPANDABLE METAL STENTS FOR PERIAMPULLARY CANCER

H. Toyonaga, Y. Taniguchi, M. Wada, T. Inokuma
Kobe City Medical Center General Hospital, Gastroenterology, Hyogo, Japan

Contact E-Mail Address: toyonaga.pc@gmail.com

Introduction: Periampullary cancers frequently present as obstructive jaundice, which might lead to liver dysfunction, coagulation disorders, cholangitis, and immune system dysfunction. Preoperative drainage has become popular for patients with periampullary cancers suffering from acute cholangitis or intense pruritus, or receiving neoadjuvant chemotherapy or delayed surgery. If the stent dysfunction occurs during the preoperative period or neoadjuvant chemotherapy, surgery must be postponed or chemotherapy must be interrupted, so it is increasingly important to place self-expandable metal stents (SEMSs) that have a longer stent patency than plastic stents (PSs).

Aims and Methods: The aim of this study was to investigate the superiority of fully covered SEMSs over PSs as preoperative drainage for patients with resectable periampullary cancers and obstructive jaundice. We retrospectively reviewed 26 consecutive patients from September 2015 to February 2018 with resectable periampullary cancers who received preoperative biliary drainage with PSs or SEMSs (13 patients each). We excluded cases that received SEMS placement for repeated occlusion of PSs. Stent patency rates, time from endoscopic retrograde cholangiopancreatography (ERCP) to surgery, adverse events of stent placement, operating time, amount of bleeding during surgery, rate of negative resection margins (R0), and adverse events of surgery were compared between the PS and SEMS groups.

Results: In the PS group, the preoperative stents patency rates were significantly lower than in the SEMS group (54% vs. 100%, $p<0.05$). There were no significant differences between the PS and SEMS groups for median time from ERCP to surgery (33 vs. 35 days, $p=0.78$), median operating time (528 vs. 542 minutes, $p=0.77$), median amount of bleeding during surgery (644 vs. 660 ml, $p=0.69$), rate of R0 (15% vs. 0%, $p=0.54$), adverse events of stent placement (elevated serum pancreatic enzyme levels alone: 8% vs. 0%, $p=0.50$), or adverse events of surgery (pancreatic fistula: 15% vs. 15%, $p=1$; surgical site infection: 23% vs. 15%, $p=0.66$; or delayed gastric emptying: 0% vs. 8%, $p=0.50$).

Conclusion: Preoperative biliary drainage with SEMSs in patients with resectable periampullary cancers showed higher patency rate than that with PSs and a low complication rate similar to that with PSs.

Introduction: Appendectomy is one of the most commonly performed surgeries worldwide. Recent epidemiologic studies have suggested that appendectomy could be a risk factor for primary sclerosing cholangitis (PSC) although the results were inconsistent.

Aims and Methods: This systematic review and meta-analysis was conducted to summarize all available evidence with the aim to better characterize the relationship between the two conditions. A comprehensive literature review was conducted using MEDLINE and EMBASE database through January 2018 to identify all studies that reported the risk of PSC among individuals who had appendectomy versus those with no history of appendectomy. Effect estimates from each study were extracted and combined together using the random-effect, generic inverse variance method of DerSimonian and Laird.

Results: A total of 6 case-control studies with 2,432 participants met the eligibility criteria and were included in the meta-analysis. The risk of PSC in individuals who had appendectomy was significantly higher than those with no history of appendectomy with the pooled odds ratio of 1.37 (95% CI, 1.15–1.63). The statistical heterogeneity was insignificant with an I^2 of 0%. Moreover, the funnel plot is relatively symmetric and does not suggest the presence of publication bias in favor of positive studies.

Conclusion: A significantly increased risk of PSC among individuals who had a history of appendectomy was found in this study.

Disclosure: Nothing to disclose

Introduction: PSC is a rare auto-immune liver disease with significant impact on quality and quantity of life for patients. Modern health care delivery has the potential to change care for rare disease but before appropriate changes can be made to improve patient care, we must understand the healthcare burden and natural history of the disease.

Aims and Methods: We sought to evaluate our current service over a 10 year period, to identify patient and clinical themes of relevance to service redesign. We performed a retrospective service evaluation of all pre-transplant patients with PSC who were first seen at our centre between October 2005 and October 2015, to allow for a minimum of 12 months follow up data. Data was gathered on patient demographics, geographical location, referral source, symptom burden and clinical events.

Results: 484 patients were identified and their electronic records reviewed; 64% were male with a mean age of 44 years (range 16–84 years). 85% were Caucasian and 72% had large duct involvement, with 65% having co-existing inflammatory bowel disease. Median ALP at first clinic appointment 461 (range 48–5051) with median UKELD of 48 (range 40–66). Median distance travelled via road from the patient's home to our centre was 48 miles (range 2–380) with a median travel time by road of 80 minutes (range 9–500). In total we received referrals from 64 different centres; 88% of patients were from outside our local area; 20% were referred from another UK tertiary liver centre, 45% from secondary care services, and 19% via their GP. 28% were referred for diagnosis whereas 25% were referred for ongoing management, 20% for transplant assessment and 12% due to possible cholangiocarcinoma. The diagnosis of PSC was preceded by chronic symptoms in 23%, an acute hospital admission in 17% and incidentally on blood tests in 35%, often due to monitoring for pre-existing IBD. 85% of patient's experienced PSC-related symptoms at some point in their follow up; 36% described significant pruritus, 32% fatigue, 28% recurrent cholangitis and 16% right upper quadrant pain. During this period, median number of clinic appointments was 8 (range 1–74) with 38% of patients requiring at least one hospital admission; 11% required EUS and 7% underwent ERCP at our centre during their follow up. Overall, 39% have been assessed for transplantation, 85% of which were activated on our transplant list. Of the entire cohort there was a 21% mortality rate, with 23% undergoing transplantation and 3% were diagnosed with cholangiocarcinoma.

Conclusion: Parallel to the essential development of new treatments for PSC, is a need for clinicians to recognise the total burden PSC places on patients and to use such insights when considering a patient-centred service redesign relevant to 21st century healthcare. Given the large distances many PSC patients travel for vital specialist care, novel alternatives to conventional management, such as the use of telemedicine, should be considered.

[5]*Institute of Applied Health Research, Birmingham, United Kingdom*

Contact E-Mail Address: k.arndtz@nhs.net

Introduction: Telemedicine is the use of telecommunication systems to deliver healthcare at a distance. It is potentially one way of improving access to healthcare as well as efficiency. However, the 2016 Cochrane review concluded that questions remain about the acceptability of this to patients (1). Patients with rare diseases face geographical hurdles to accessing disease specific care that may be improved by the introduction of telemedicine. Primary sclerosing cholangitis (PSC) is a rare auto-immune liver condition and University Hospitals Birmingham (UHB) is preparing to introduce a virtual clinic via video link, commencing first in the PSC clinic.
Aims and Methods: We aimed to investigate the patient burden of attending specialist care and the acceptance of the virtual clinic, in this patient group. We distributed anonymous questionnaires to all patients attending the weekly PSC clinic over a 5 week period. The questionnaire included questions on demographics, employment, travel to appointments, diagnosis and opinions on the introduction of the virtual clinic. Analysis was completed including Fisher's exact tests, with $p < 0.05$ deemed to be indicative of statistical significance.
Results: A total of 101 questionnaires were completed; a 66% return rate. 74% had a diagnosis of a rare auto-immune liver disease, 83% of which was PSC. 47% of all respondents had previously received a liver transplant. 79% of respondents stated that UHB was not their local hospital and 34% of patients travelled for over 2 hours for appointments. There was an overall mean travel cost of £28.72 per patient visit. Overall, 59% stated they would accept a virtual appointment however 22% would not and 13% were unsure. 84% stated they used a desktop computer, laptop or tablet at least weekly and this was associated with increased acceptance of the virtual clinic ($p = 0.001$). Travel time was not associated with acceptance. In the post-transplant group only, patients seen at 6 monthly intervals were more likely to accept a virtual appointment than those seen at 3 monthly intervals ($p = 0.04$).
Conclusion: This audit shows that despite time and financial burdens placed on many patients attending our specialist centre for their PSC care, patient acceptability of the virtual clinic is not universal. We are planning further research to more fully understand patient opinions about the use of virtual clinics, via a series of semi-structured interviews.

Introduction: Ascites is a common complication of cirrhosis and is associated with poor prognosis. Post-paracentesis circulatory dysfunction (PPCD) is overall seen in one-third of cirrhotic children who undergo single-time large volume paracentesis (SLVP)[1]. It is not known whether PPCD occurs with multiple LVP (MLVP).
Aims and Methods: Our study aimed to analyse the safety, complications and effect of albumin infusion during MLVP on PPCD in children with severe ascites due to chronic liver disease. Enrolled children with severe ascites underwent single time or multiple LVP with albumin infusion. Plasma renin activity (PRA) assessed at baseline and day 6 of last performed LVP. Maximal PRA value in MLVP was noted. Delta PRA was defined as PRA difference from day 6 and baseline. Worsening PPCD was defined as ≥1.5 times increase of delta PRA of any 2 sessions of LVP in MLVP group. ''At-risk'' group was defined as any cirrhotic child with ≥2 worsening PPCD episodes. Their outcome at 3 months and maximal follow-up were noted. Poor outcome was defined as failure of definitive therapy, need for liver transplantation or mortality.
Results: Table 1 shows baseline characteristics of 37 children (SLVP, n = 17; MLVP, n = 20). 92% had high PRA at the onset. The overall incidence of PPCD was 43% (SLVP: 12%, MLVP: 70%; $p = 0.003$). Baseline pediatric end-stage liver disease (PELD) score >27 was associated with PPCD (sensitivity: 90%; specificity: 50%, $p = 0.01$) in MLVP group. Worsening PPCD (n = 28; 54%) and at-risk children (n = 9; 45%) were identified in 52 sessions of MLVP. In the MLVP group, PPCD occurred if cumulative ascitic fluid extraction volume was >585 mL/kg/week (sensitivity: 90%; specificity: 50%, $p = 0.01$), cumulative albumin infusion <4.2 g/kg/week (sensitivity: 93%; specificity: 55%, $p = 0.03$) and frequency of sessions were >2.3/week (sensitivity: 91%; specificity: 57%, $p = 0.02$). In those who developed PPCD, lowest volume of ascites extracted in SLVP and MLVP groups were 117 and 471 mL/kg/week respectively. MLVP patients (80%) were susceptible to asymptomatic, persistent hyponatremia (baseline vs. day 6 from first LVP, 131 ± 4 vs. 124 ± 4 mEq/L; $p = 0.001$), hemodynamic changes (25%), renal impairment (35%), recurrence of ascites (60%) and hospital readmission (70%). At risk patients had worsening of PELD scores (baseline: 25 ± 8 vs. follow-up 31 ± 6; $p = 0.01$) at 3 months. Poor outcome at maximal follow-up (18 ± 7.4 months) was seen in 35% (n = 1, SLVP; n = 12, MLVP) especially in the at-risk group (n = 8; 89%).
Conclusion: PPCD occurs in majority of those underlying multiple LVP. One third have poor outcome, more in the at-risk group. Risk factors of PPCD with multiple LVP are baseline PELD >27, cumulative extracted ascites >585 mL/kg/week, cumulative albumin infusion <4.2 g/kg/week and frequency of sessions >2.3/ week.

	Single time LVP group (n = 17)	Multiple LVP group (n = 20)	p value
Age (y), boys (n)	9.8 ± 4.4, 13	8.3 ± 5.1, 15	0.77, 0.81
Duration of ascites (months)	3.6 ± 5.3	7.1 ± 11.0	0.20
Weight Z-scores	−1.69 ± 2.21	−2.51 ± 1.84	0.26
Height Z-scores	−0.98 ± 1.75	−1.39 ± 1.32	0.46
PELD score	22 ± 6	28 ± 10	0.05
Volume of ascites extracted (mL/kg/week)‡	143 ± 77	506 ± 105	0.001
Ascitic fluid infection (n)	4	7	0.47
Baseline PRA (ng/mL/h)	27.5 ± 18.4	29.1 ± 20.7	0.65
D6 or Maximum cumulative value of PRA (ng/mL/h)	28.3 ± 21.2 (D6)	73.1 ± 19.8	0.01
Folds elevation from baseline*	1.1 ± 0.5	6.4 ± 5.3	0.02
Number of subjects with PPCD (n)	2	14	0.003

Note: values expressed as mean ± SD; LVP: large volume paracentesis PELD: pediatric end-stage liver disease, PRA: plasma renin activity, PPCD: post-paracentesis circulatory dysfunction. ‡Volume of ascites extracted (mL/kg) = Total volume (mL) ÷ Dry weight (kg); dry weight was calculated after completion of LVP. *Folds elevated = Day 6 PRA (SLVP) or maximum noted PRA after 6 of any LVP (MLVP) ÷Baseline PRA value. High PRA defined as PRA >2SD of normal. PPCD: PRA rise of >50% of baseline value on day 6 of paracentesis to a level 2 standard deviation (SD) above age-appropriate mean pediatric cut-off. Normal mean PRA (+ 2SD) are variable for different age groups, 0.5–1 y: 6.27 (14.49); 1-4 y: 4.47 (10.71); 5-10 y: 2.33 (4.79); 11-17y: 2.07 (6.11) ng/mL/h
[Table 1: Comparison of single time and multiple large volume paracentesis groups]

P0715 HEMODYNAMIC CHANGES IN THE VESSELS OF THE ABDOMINAL CAVITY IN THE POSTPRANDIAL PHASE IN HEALTHY CHILDREN

O. Zaytseva[1], E. Spivak[2], I. Akkuratova[1]

Introduction: The postprandial test provides valuable information about the state of the digestive system. It is most often used to determine the function of the pancreas. Changes in the parameters of regional circulation of the abdominal cavity after eating are analyzed much less frequently. There are no standards of postprandial reaction of hemodynamic parameters in arteries and veins of the abdominal cavity in children. That fact complicates its evaluation in patients with gastroenterological pathology.
Aims and Methods: The aim of the work is to characterize the reaction of abdominal vessels to the food load in healthy children and to determine the reference values of postprandial changes in the regional blood flow.
44 healthy children aged 3 to 15 years were examined. Doppler study of hemodynamics in abdominal vessels was performed twice: on an empty stomach and 30 minutes after a standard breakfast. The parameters of blood flow in veins (inferior vena cava, portal vena) and arteries (abdominal aorta, ventral trunk, superior mesenteric, common hepatic and splenic) were evaluated. Vessel

diameters, resistance index (IR) and volumetric blood flow velocity (BFV) were determined.
Results: It was found that changes in hemodynamic parameters after eating in healthy children of different ages and sex has no statistically significant differences. The diameters of the abdominal aorta and the inferior vena cava after eating remain the same in most children (70.5% and 77.2%, respectively) or change slightly (within 10% of the initial values). 30 minutes after a standard breakfast dilation of the superior mesenteric artery (on average 22.4% of the initial values), the ventral trunk (22.6%), the common hepatic artery (17.7%), the splenic artery (24.4%) and the portal vein (34.2%) is recorded. The spleen vena in the postprandial phase is not expanding so much (7.1%). In the majority of cases (79.5%) the IR values do not change or reduce slightly. In all the examined vessels, an increase in the volume velocity of the blood flow is determined, which reflects the intensification of hemodynamics of the abdominal organs in the postprandial phase. In the superior mesenteric it averages 85% of the baseline, in the common hepatic artery – 38%, in the splenic artery – 56%, in the ventral trunk – 72%, in the portal vena – 161%, in the splenic vein – 15%. The minimum growth rates of BFV are observed in large vessels – abdominal aorta (5%) and in the inferior vena cava (13%).
Conclusion: In healthy children dilation of the ventral trunk, superior mesenteric, hepatic and splenic arteries, portal and splenic veins is registered in the postprandial phase. The transverse dimensions of the abdominal aorta and the inferior vena cava in most cases remain the same or change slightly. There is a significant increase in the volume rate of blood flow in all the vessels studied, which reflects the intensification of blood circulation in the abdominal cavity.

P0716 THE NATURE OF THE HEMODYNAMIC CHANGES OF THE ABDOMINAL CAVITY IN CYSTIC FIBROSIS IN CHILDREN

E. Spivak[1], O. Zaytseva[2]

Contact E-Mail Address: spivak58@mail.ru
Introduction: Disorders of the hepatobiliary system are diagnosed in 80% of children with cystic fibrosis (CF), in 5–10% of cases multilobular cirrhosis of the liver is formed accompanied by portal hypertension syndrome.
Aims and Methods: The aim of the work was to determine the nature of hemodynamic changes in abdominal vessels in children with cystic fibrosis and their relationship with the degree of structural disorders of liver.
33 patients aged 3–17 years with severe CF were examined. According to the results of the standard ultrasound examination, 3 groups were identified: 1. Normal structure of liver (n = 15) 2. Moderate changes (n = 11) and 3. Significant changes (n = 7). Hemodynamics in the abdominal vessels was evaluated by dopplerography. To assess the adaptive reserve of the vascular system a postprandial sample was used, for which dopplerography was carried out twice: on an empty stomach and 30 minutes after a standard breakfast.
Results: It was found out that in the absence, as well as in the moderate severity of changes in liver parenchyma in patients with CF, the average value of the diameters of the abdominal cavity vessels corresponds to the indicators of healthy children. In the group of patients with significant violations of the structure of the organ, dilation of celiac trunk (on average by 25.5% compared to the normal range), superior mesenteric (23.4%), common hepatic (26.8%) and splenic (21.7%) arteries, portal (74.1%) and especially splenic (102.0%) vein was recorded. BFV in these patients increases significantly in the common hepatic artery (by 41.2%), portal (59.7%) and splenic (62.3%) veins. The IR rises in the ventral trunk and common hepatic artery to 0.75 ± 0.006 and 0.78 ± 0.02 against 0.71 ± 0.007 and 0.75 ± 0.006 in healthy children ($p < 0.05$). The postprandial test revealed a significant decrease in the growth of the diameter of the abdominal cavity arteries and veins after eating, which had already been determined in the group of patients with normal liver structure. In the group of patients with significant organ impairment postprandial response of abdominal vessels was practically absent. It is known that under normal conditions, eating causes a significant (in some cases, multiple) increase in the volume rate of blood flow in the abdominal arteries and veins. At CF there is a sharp decrease or absence of BFV growth in the postprandial phase. Doppler changes are observed in the group of children whose standard ultrasound examination results have not yet revealed structural disorders of the liver. This makes it possible to consider the change in Doppler indices (the degree of increase in vascular diameters and BFV in them) as the signs of early liver damage at CF.
Conclusion: Standard Doppler imaging of abdominal vessels in children with cystic fibrosis reveals changes in regional hemodynamics only in the presence of pronounced structural disorders of liver. This is manifested by dilation of abdominal vessels, increased arterial inflow and venous outflow in the vascular system of the liver, an increase in the resistance index in the ventral trunk and common hepatic artery. Postprandial test can detect a reduction of adaptive reserve of the abdominal cavity vascular system before structural changes in the liver are detected by ultrasound. This is manifested by the lack of adequate vasodilatation and increase in the volume of blood flow in arteries and veins after eating.

Introduction: Sub-acute hepatic failure (SAHF) is a grey zone area of liver dysfunction which has a smouldering, variable course and is poorly understood. Though spontaneous recovery is known, case fatality is high. Pediatric experience of SAHF is poorly highlighted in literature.
Aims and Methods: We aimed to identify the high risk subset that determine poor outcome of SAHF in children. Children with SAHF (appearance of ascites ± encephalopathy occurring from 4th–24th week of onset of acute hepatitis with coagulopathy in the absence of pre-existing liver disease) were analysed. Poor outcome (PO: death or liver transplantation within 90 days) were compared with spontaneous recovery (SR: complete normalisation of liver functions in native liver) for risk factors. Pediatric End-stage Liver Disease (PELD) score and King's College Criteria (KCC) were applied as measures of outcome.
Results: SAHF (n = 60) constituted 15% of all liver failure (n = 351) referrals. Seven had cirrhosis on biopsy and were excluded. Etiological workup (n = 53) was hepatitis A (n = 19), co-infection hepatitis A and E (n = 7), hepatitis B (n = 6), hepatitis E (n = 1), cytomegalovirus (n = 1), autoimmune hepatitis type 2 (n = 1) and indeterminate etiology (n = 18). Table 1 compares SR (n = 14, 26%) with follow-up of 6 (1–24) months versus PO (n = 30, 57%).

Parameters	Poor outcome (n = 30)	Spontaneous recovery (n = 14)	P value
Age (years)	5.5 (2–16)	6 (3–15)	0.79
Male	22 (73%)	8 (57%)	0.31
Duration of illness (days)	52 (30–180)	50 (30–150)	0.33
Jaundice to ascites/ encephalopathy interval (days)	30 (22–150)	30 (22–120)	0.85
Prodrome	19 (63%)	13 (93%)	0.06
Ascites	28 (93%)	13 (93%)	1.0
Pallor	20 (67%)	5 (36%)	0.05
Edema	19 (63%)	7 (50%)	0.40
Total bilirubin (mg/dL)	19.4 (4.8–41.6)	22.5 (2.9–36)	0.29
Serum albumin (g/dL)	2.4 (1.6–3.5)	2.7 (2.1–3.9)	0.06

[Table 1: Baseline clinical and laboratory data of poor outcome versus spontaneous recovery groups]

Nine (17%) had improving trend but had follow-up duration < 30 days and were not analysed for outcome. Risk factors on univariate analysis between PO vs. SR were known viral etiology (8% vs. 43%, p = 0.03), international normalised ratio [5.5 (2.0–14.4) vs. 2.6 (1.6–5.1), p = 0.003], PELD score [40 (17–57) vs. 25 (13–39), p = 0.002], hepatic encephalopathy (77% vs. 36%, p = 0.02), bleeding manifestations (33% vs. 0, p = 0.02), systemic infections (83% vs. 43%, p = 0.01), ascitic fluid infection (27% vs. 0, p = 0.04), acute kidney injury (43% vs. 7%, p = 0.03), all significantly higher in PO group. On multivariate logistic regression analysis, indeterminate etiology (specificity 93%, positive predictive value 92%) and PELD score cut-off > 32 (AUC: 0.79, sensitivity 67%, specificity 79%) independently determined PO. King's college criteria (KCC) showed a sensitivity of 87%, specificity 36%, positive predictive value 74% and negative predictive value 56% for PO.
Conclusion: Hepatitis A is the most common cause of SAHF (49%). SAHF with indeterminate etiology, advanced or symptomatic coagulopathy, hepatic encephalopathy, infective focus and acute kidney injury determine poor outcome. PELD score with cut-off > 32, an independent risk factor has better specificity than KCC for poor outcome. A large proportion (43%) may escape liver transplantation.

Introduction: Congenital dilatation of the biliary tract (CDBT) is a rare and heterogeneous congenital malformation affecting the bile ducts in variable way. The aim of this study was to describe the various radiological aspects of this pathology and analyze its therapeutic management in our medical center.
Aims and Methods: From 2002 to 2017 all the patients with the diagnosis of congenital dilatation of the biliary tract were retrospectively enrolled. The diagnosis of CDBT was based on the imaging data (MRI and / or ERCP) and histology in operated patients. Biliary duct anomalies were classified according to Todani's classification. Therapeutic modalities whether surgical or endoscopic were identified for each patient.
Results: 32 patients were enrolled. The mean age was 46 years and the sex ratio was 1.1 [M / F = 17/15]. According to the Todani classification, patients were

classified as type I = 13 cases (40%), III = 4 cases (12.5%), IV = 4 cases (12.5%), V = 11 cases (34.4%). Therapeutic management was based on this radiological classification. Indeed, in the case of malformations type I, IVb : 6 patients were operated (resection of the choledochal cyst with hepaticojejunal anastomosis). One of them was secondary operated after a non-controlled cholangitis (after ERCP). In 7 other cases endoscopic sphincterotomy in ERCP was indicated according to the bad state of the patient's field or the good spontaneous evolution of symptoms and biology. Regarding the 4 cases of choledococele, endoscopic treatment (based on the ERCP with pre-cutting on the top of the choledococele) was recommended, only one patient was complicated of duodenal perforation leading to a surgical treatment. For the 11 cases of Caroli: 3 had congenital liver fibrosis indicating liver transplantation. This one was however not carried out for lack of availability. For the 8 other cases it was a left caroli disease: 5 patients were operated on (left lobectomy in 4 cases and biliodigestive anastomosis in 1 case). The remaining 3 patients were treated with ursodeoxycholic acid with endoscopic treatment in case of complications (acute cholangitis, lithiasis). No cases of degeneration were observed in our series.
Conclusion: Our study underlines the complexity of the therapeutic management of the congenital biliary tract dilatation. Surgery, whenever possible can prevent the risk of degeneration. However, endoscopic treatment has a fundamental place in case of impossibility of operating the patients or the occurrence of complications.

P0719 ANTIBIOTICS IN ACUTE PANCREATITIS IN THE LAST YEARS – EXPERIENCE OF A TERTIARY REFERRAL CENTER

J.R. Carvalho, S.R. Fernandes, M.T. Antunes, J. Velosa, R.T. Marinho
North Lisbon Hospital Centre, Gastroenterology, Lisbon, Portugal

Contact E-Mail Address: joana.rita.carvalho@gmail.com
Introduction: Antibiotic therapy in acute pancreatitis (AP) does not influence clinical course and mortality and it is not endorsed by current international guidelines [1]. Concerns regarding the increase in multidrug resistant bacteria has led to the implementation of measures to mitigate inappropriate antibiotic use in our center.
Aims and Methods: We aimed at comparing the patterns of antibiotic use and associated clinical outcomes over two different timelines. We included 200 patients with AP: 100 admitted between 2012 and 2017 (retrospective cohort, group A) and 100 patients admitted after 2017 (prospective cohort, group B). We defined inappropriate antibiotic therapy if: (1) no bacterial agent was isolated in microbiologic tests, (2) infected necrosis was not present, and (3) antibiotics were not due to documented extra-pancreatic infection. Statistical analysis was performed with SPSSv23; A p value < 0.05 was considered significant.
Results: No differences were found between demographics, etiology and severity of AP in both groups (table). In group A there was a significant higher use of antibiotics (52% vs 24%; $p < 0.001$) but no difference was found in mortality (5% vs 2%; $p = 0.200$). The prescribing of carbapenems was high in both groups (43.3% vs 50.0%; $p = 0.530$). In 2012 there was a significantly higher rate of extra-pancreatic nosocomial infections (7% vs 1%; $p = 0.030$). In group A nosocomial infections occurred in 71.4% of the cases of inappropriate antibiotic therapy; in multivariate analysis (including age, gender, etiology and severity) inappropriate antibiotic therapy was an independent predictor of nosocomial infection (OR 17.248 CI95% [2.1–144.0]; $p = 0.009$). In both groups, there was a significant association between severe AP and use of antibiotics (Group A: OR 8.251 CI95% [2.11–51.91]; $p = 0.004$; group B: OR 7.255 CI95% [2.32–22.67]; $p = 0.001$).
Conclusion: A significant decrease in inappropriate antibiotic therapy and nosocomial infections in AP was seen in our center. Higher use of antibiotics in the past was not associated with a decrease in mortality in AP. Inappropriate antibiotic therapy in AP was an independent predictor of nosocomial infection.

	2012	2017	p
Female gender (%)	60	51	0.200
Age (mean years)	63.06 [22–93]	63.12 [22–91]	0.467
Alcoholic AP (%)	21	27	0.321
Biliary AP (%)	39	42	0.666
Post-ERCP AP (%)	11	15	0.517
Idiopathic AP (%)	22	16	0.279
Other etiology AP (%)	7	4	0.352

Introduction: Pain is a very common symptom in acute pancreatitis (AP), therefore, understanding its characteristics and predictive role is important. Until now, the detailed characteristics have not been investigated. Here, we aimed to analyze the predictive role and clinical characteristics of pain on admission in AP.
Aims and Methods: The Hungarian Pancreatic Study Group (HPSG) has prospectively collected multicenter clinical data of 1435 adult patients between 2012 and 2017. The specific pain questionnaire contained data in four categories: intensity (visual analog scale, 1–10, mild (mildP):1–3, moderate (modP): 4–6, severe (sevP):7–10), duration of pain prior to admission (hours), localization (upper, middle, and lower abdomen), and type (sharp, dull, or cramping). These data were compared with parameters on admission and with the outcome of AP. Statistical analyses were performed accordingly.
Results: Most of the patients had severe abdominal pain (mildP: 5.23%, modP: 24.48%, sevP: 70.29%). The intensity of pain was directly associated with the severity of AP (mildP: 0% severe AP, modP: 2.81%, sevP: 4.50%; $p < 0.05$), mortality (mild:0% moderate: 1.98% severe: 1.76%; mildP vs modP and sevP: $p < 0.05$), local (mild:15.79% modP:28.09% sevP:25.25%; mildP vs modP and sevP: $p < 0.05$) and systemic complications (mildP:2.65% modP:9.55% sevP:7.83%; mildP vs modP and sevP: $p < 0.05$), higher white blood cell count, elevated lipase and amylase levels, but not with CRP level. The duration of pain was not associated with mortality and severity; however, it markedly influenced the laboratory parameters on admission. The level of amylase and lipase, the amount of RBC and hemoglobin, and pain intensity were decreasing, whereas the level of CRP and the amount of thrombocyte were increasing. Concerning the localization, most of the patients had upper abdominal and epigastric pain. However, localization was not associated with the above-mentioned parameters. Sharp pain was associated with higher mortality, severity, local, and systemic complications vs the other types of pain.
Conclusion: Higher intensity of pain is associated with worse clinical outcome; therefore, its role should be investigated in clinical trials. The duration of pain prior to admission strongly influence the laboratory parameters on admission, therefore, it should be incorporated into the on admission scoring systems in AP.

Introduction: Acute pancreatitis (AP) is an inflammatory condition which commonly requires hospitalization and shows increased incidence. The prevalence of diabetes mellitus (DM) has duplicated in the last 35 years. Acute pancreatitis may result in pancreatic exocrine insufficiency and DM, but nowadays the influence of pre-existing DM in AP patients represents a hot research topic.
Aims and Methods: The aim of our meta-analyses is to understand the influence of DM on the outcomes of AP including mortality, length of hospitalization,

incidence of organ failures and intensive care unit admission. The meta-analysis was performed using the PRISMA Protocol. PubMed, EMBASE and Cochrane databases were searched, articles with AP patients including DM and non-DM groups were included, and complications, length of hospitalization (LOH), intensive care unit (ICU) admission and mortality were analyzed. The odds ratio (OR) and standardized mean difference (SMD) with 95% confidence intervals (CI) were calculated with Comprehensive Meta-Analysis software.
Results: 1417 articles were found, of which 9 articles involving 354,880 patients were analyzed. More systemic complications were seen in diabetic patients, than in non-DM patients (OR = 1.553 [CI:1.266–1.904], $p < 0.001$). ICU admission (OR = 1.799 [CI:1.442–2.243], $p < 0.001$) and renal failure (OR = 1.585 [CI:1.278–1.966], $p < 0.001$) were more frequent in DM patients than in non-DM patients. There was a tendency of higher mortality and local complications (OR = 1.276 [CI: 0.991–1.643], $p = 0.059$; and OR = 1.267 [CI:0.964–1.659], $p = 0.090$, respectively) in the pre-existing DM group. LOH was longer in DM patients than in non-DM patients (SMD = 0.217 [CI:0.075–0.360], $p = 0.003$).
Conclusion: Pre-existing DM negatively influences the outcome of AP and increases the risk of renal failure, ICU admission, local complications and mortality. More attention is necessary for AP patients with pre-existing DM.

Introduction: Acute pancreatitis (AP) is an inflammatory disease often requiring hospitalization. In the moderate and severe form of the disease organ failure and altered level of consciousness (ALC) may develop, which is often alcohol related (AR-ALC). However, the influence of ALC on the outcome of AP has not been examined yet.
Aims and Methods: We aimed to investigate the influence of ALC and AR-ALC on the outcomes such as severity, mortality and length of hospitalization (LOH) of AP. Out of the 1449 subjects in the Hungarian Pancreatic Study Groups' AP register 1220 contained the exact data on ALC. Patients were separated to non-ALC and ALC, whereas ALC was further separated to non-alcohol related ALC (NAR-ALC) and AR-ALC groups. Statistical analysis was performed by SPSS 24 Software Package, Chi-Square, Mann-Whitney, One-Way-ANOVA and Kruskal-Wallis tests were used.
Results: From the 1220 patients 47 (3.85%) developed ALC from that 23 (48.9%) cases were AR-ALC, whereas 24 (51.1%) cases NAR-ALC. ALC showed significantly higher incidence in men than in women (70.2% vs 29.8%, $p = 0.045$). Age was significantly higher in the ALC vs non-ALC group (62.19 ± 18.69 vs 56.52 ± 16.97, $p = 0.025$). The incidence of severe AP was significantly higher in the ALC compared to non-ALC group (19.15% vs 5.29%, $p < 0.001$). The mortality was significantly higher in the ALC vs non-ALC group (14.89% vs 1.71%, $p < 0.001$). LOH was significantly longer in ALC vs non-ALC group (Me: 11; IQR: 8–17 days vs Me: 9; IQR: 6–13 days, $p = 0.049$). AR-ALC showed significant correlation with the gender, it developed more frequent in men than women (91.30% vs 8.70%, $p = 0.002$), while in NAR-ALC no difference was seen between the genders. Patients with NAR-ALC were older than patients with AR-ALC (70.5 ± 18.38 vs 53.52 ± 14.95 years, $p = 0.002$). Patients with AR-ALC developed more frequently moderate severe AP vs NAR-ALC (43.48% vs 12.5%), while the incidence of severe AP was significantly higher in NAR-ALC vs AR-ALC group (33.33% vs 4,35%) ($p < 0.001$). Concerning the LOH, patients with NAR-ALC shows a tendency for longer hospitalization (Me: 13; IQR: 7–20 days vs Me: 9.5; IQR: 8–15.5 days, $p = 0.119$).
Conclusion: ALC during AP elevates the risk of moderate and severe AP and enhances the risk of mortality, therefore ALC should be avoided during hospitalization due to AP.

Introduction: Acute pancreatitis (AP) is one of the most common cause of hospitalization among gastrointestinal diseases worldwide. Although most of the cases are mild, approximately 10%–20% of patients develop a severe course of disease with higher mortality rate. Scoring systems consider age as a risk factor of mortality and severity (BISAP; >60 yrs, JPN>70 yrs (Japanese severity score), RANSON; >55 yrs, APACHE II >45 yrs). If there is a correlation between ageing and the clinical features of AP, how does age influence mortality and severity?
Aims and Methods: In this study we aimed to investigate whether ageing has any effects on severity or mortality in AP.
Comprehensive literature searches were conducted using Embase, Cochrane and Pubmed databases. A meta-analysis was performed using the preferred reporting items for systematic review and meta-analysis protocols (PRISMA-P). The searching terms were (age and acute pancreatitis and (clinical trial or cohort)). There were 502 articles found in Embase, 340 in PubMed, and 17 in the Cochrane database. After removing duplications and unsuitable articles altogether 27 articles containing 191,678 AP patients, 179,180 for mortality and 21,573 AP patients for severity were analyzed. Seven subgroups were determined: under 20 yrs (U20), 10 yrs ranges from 20 to 70yrs and above 70 yrs (A70).
Results: Concerning the risk for mortality, there was a clear elevation from paediatric to elderly people: U20: 0.9% (510/55266; pooled event rate: 0.009 CI:0.008–0.010), 20–29: 0% (0/1720), 30–39: 1.3% (137/11375), 40–49: 5.4% (76/1411), 50–59: 2.0% (825/41634), 60–69: 8.5% (2153/25452) A70: 17.3% (7312/42322; pooled event rate: 0.107 CI: −0.026–0.239). This significant elevation was also confirmed by meta-regression (coefficient: 0.038 CI:0.017–0.058, $p = 0.001$; adjusted r^2: 35.41%) and with the conventional regression analysis also ($p = 0.005$, r^2: 0.906).
Concerning severity, there was no severe AP U20, 20–29: 0%(0/36), 30–39: 6.7%(5/75), 40–49: 8.3%(586/7028), 50–59: 11.3%(1352/11933), 60–69: 16.6%(390/2344), A70:9.6% (15/157; pooled event rate: 0.098 CI: −0.054–0.142). This elevation was not confirmed by meta-regression (coefficient: 0.021 CI: −0.022–0.065, $p = 0.322$; adjusted r^2: −3.16%). In case the conventional regression analysis an exponential tendency could be observed ($p = 0.069$, r^2: 0.778).
Conclusion: Our meta-analyses shows that younger age (U20) has protective effects in acute pancreatitis, whereas ages above 50 elevates the risk for mortality and severity.

Introduction: EUS-guided transluminal drainage (EUS-TD) and sequential direct endoscopic necrosectomy (DEN) for pancreatic fluid collections (PFCs) using a dedicated biflanged metal stent (BFMS) has been reported as a useful alternative to using plastic stents or a conventional metal stent. However, current dedicated BFMSs [lumen-apposing metal stent (LAMS) such as AXIOS stent or SPAXUS stent and flared metal stent (FMS) such as Nagi stent] have limitations. Recently, a new BFMS with solidly constructed biflanges and various stent lengths (Plumber stent, 14-mm in diameter and 20-mm or 30-mm in length) matched to the PFC condition has been developed. The feasibilities and safety of the new Plumber stents are being clinically tested and discussed.
Aims and Methods: Plumber stent has both advantages of the LAMS and FMS, the so-called "hybrid BFMS". Herein, we show the prospectively evaluated clinical outcome of this new BFMS for the treatment of PFCs. From July 2015 to March 2018, EUS-TD using Plumber stent was performed in 25 patients for PFCs (5 patients with pancreatic pseudocysts; 20 patients with walled-off necrosis (WON)). When clinical resolution could not be achieved within a few days after EUS-TD, DEN was performed the following day.

Results: Plumber stent was deployed successfully with a median procedure time of 18 min (range, 11–38 min) and with no procedure-related adverse events in all the patients (25/25, 100%). DEN (n = 7) and/or additional drainage procedure (n = 6) via the stent were achieved in all the patients in whom they were attempted (10/10,100%). Stent dislocation during DEN was not observed in any of the patients, but in one patient spontaneous stent migration was observed about 4 months after stent placement. The migrated stent has been already discharged outside the body. Two WON patients died from spontaneous pseudoaneurysm rupture occurred between the endoscopic necrosectomy sessions and from multiple organ failure although hemostasis was achieved by coil embolization. The PFCs in the other 23 patients completely resolved (the clinical success 23/25, 92.0%), and later the stent was removed with no difficulty in 21 patients after a median time of 56 days (range, 30–196 days). PFC recurrence or stent-related late adverse event was not observed for a median follow-up time of 550 days (range, 83–941 days).
Conclusion: The new BFMS (Plumber stent) is technically feasible and safe for the treatment of PFCs. Though, further studies using randomized-controlled, well-designed, adequately powered studies comparing the new BFMS with previous BFMSs (LAMS or FMS) are required to validate its efficacy.

Introduction: Several studies have confirmed that obesity (BMI > 30) increases the severity and mortality of acute pancreatitis (AP), however, no information is available whether its effect is independent or joint with the components of metabolic syndrome (MS).
Aims and Methods: Our aim is to understand whether obesity is an independent risk factor for mortality and severity of AP.
The Hungarian Pancreatic Study Group has prospectively collected clinical data from patients suffering from AP between 2012 and 2017. Our cohort contains 1435 cases of which 906 cases from 26 centers had information on all four components of MS. Patient groups were formed retrospectively based on the WHO classification of BMI and the presence of the components of MS, namely obesity, hypertension, hyperlipidemia and diabetes. Logistic regression was performed to analyze the independent effects of these four factors.
Results: The obesity prevalence in our AP cohort is 29.5%, therefore it is representative of the Hungarian population (prevalence of obesity: 30.0%). High BMI is directly associated with higher rates of severity, mortality and necrosis of AP, respiratory and renal failure and more severe comorbidities. The prevalence of diabetes, hypertension and hyperlipidemia are growing with higher BMI. The rate of severe AP elevates with the number of affected components of MS (2.6%, 4.7%, 6.1%, 8.5% and 6.0% with 0, 1, 2, 3 and 4 components respectively), however, the increase was significant only in case of three components of MS compared to cases without any MS components (OR = 3.439 95% CI: 1.145–10.328). In a logistic regression model, out of the four components only hypertension is a predictive factor for severity (OR = 3.895 95% CI: 1.704–8.902) and mortality (OR = 5.900 95% CI: 1.330–26.165). Concerning complications, hyperlipidemia elevates the risk of diabetes as a complication (OR = 2.373 95% CI: 1.195–4.711) and obesity increases the risk of renal failure (OR = 2.968% CI: 1.343–6.559). Hypertension is a strong predictive factor for respiratory failure (OR = 2.667 95% CI: 1.139–6.243) and renal failure (OR = 7.565 95% CI: 1.760–32.516).
Conclusion: Metabolic syndrome, in particular hypertension factor, strongly deteriorates the outcome of AP. Obesity, hyperlipidemia and diabetes are not independent risk factors for severity and mortality in AP, however strongly elevate each other's detrimental effects.
Disclosure: Nothing to disclose

P0726 NSAIDS AMELIORATES PANCREAS INJURY AND INHIBITS INFLAMMATORY CYTOKINES IN RAT POST-ERCP PANCREATITIS

C. Geng, X. Li, X. Lei, **C. Wang**
West China Hospital of Sichuan University, Department of Gastroenterology, Chengdu, China

Contact E-Mail Address: wangch@scu.edu.cn
Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is a kind of advanced technology for the diagnosis and therapy of biliary-pancreatic diseases. However, various postoperative complications have constrained the widespread application of the technology to some extent. Post-ERCP pancreatitis (PEP) is the most common complication of ERCP. To date, although several clinical studies have suggested prophylactic use of nonsteroidal anti-inflammatory drugs (NSAIDs) is effective on PEP prevention, the effects of NSAIDs on PEP prophylaxis are still in debate. Meanwhile, the underlying mechanism by which NSAIDs prevents PEP remains poorly understand. As cyclooxygenase-2 (COX-2) is implicated in inflammatory response, thus we speculate that NSAIDs exert its protective effect mainly through inhibiting COX-2 expression.
Aims and Methods: In the present study, we aimed to determine the prophylactic effects of two different types of NSAIDs, indomethacin (COX-1 and COX-2 inhibitor) and parecoxib (selective COX-2 inhibitor) on PEP occurrence in rat model and investigate the underlying mechanisms. Thirty-two Wistar rats were equally and randomly assigned to 4 groups: PEP model group, indomethacin group, parecoxib group and pseudo-operation group. PEP rat models were established via retrograde injecting 0.4ml 30% omnipaque into bile ducts at 50mmHg pressure. NSAIDs prophylaxis rats received rectal administration of indomethacin suppository at 10mg/kg or intramuscular parecoxib injection at 4mg/kg 30min prior to surgical operation. The serum amylase, IL-6, IL-10 and TNF-α were tested, and the pancreas histological alteration were assessed. For mechanism study, the expression of COX-1, COX-2 and apoptosis-relative protein BAX was further determined.
Results: The amylase level in PEP rats dramatically increased compared with pseudo-operation rats ($p < 0.05$). Indomethacin and parecoxib treatment decreased 14% and 13% amylase levels compared with PEP rats, respectively, but without significant difference. Histological assessment showed that compared with the pseudo-operation rats, the pancreatic edema, hemorrhage, acinar necrosis and inflammatory cell infiltration scores in PEP rats obviously increased, respectively. However, indomethacin and parecoxib prophylaxis effectively declined the histological scores above mentioned ($p < 0.05$). Likewise, the serum IL-6, IL-10 and TNF-α levels in PEP rats dramatically increased compared to pseudo-operation rats, respectively ($p < 0.05$), and indomethacin and parecoxib remarkably declined the serum inflammatory cytokines levels ($p < 0.05$). Western blot analyses revealed that compared with PEP rats, indomethacin markedly inhibited COX-1 (0.99 ± 0.11 vs. 1.51 ± 0.13, $p < 0.05$) and COX-2 (1.04 ± 0.13 vs. 1.50 ± 0.12, $p < 0.05$) proteins expression while parecoxib selectively inhibited COX-2 expression (0.90 ± 0.08 vs. 1.50 ± 0.12, $p < 0.05$) Furthermore, indomethacin and parecoxib treatment decreased the expression level of BAX proteins (1.17 ± 0.13 vs. 1.62 ± 0.12, $p < 0.05$; 1.03 ± 0.09 vs. 1.62 ± 0.12, $p < 0.05$).
Conclusion: Prophylactic use of indomethacin and parecoxib could histologically mitigate pancreas injury and suppress inflammatory cytokines levels in PEP rats. NSAIDs could protect pancreatic acinar cells from apoptosis via inhibiting COX-2 expression.
Disclosure: Nothing to disclose

P0727 CHRONIC USE OF STATINS AND AMINOSALICYLIC ACID AND INCIDENCE OF POST-ERCP ACUTE PANCREATITIS. PRELIMINARY DATA FROM THE STARK STUDY, A PROSPECTIVE INTERNATIONAL, MULTICENTER, COHORT STUDY

Contact E-Mail Address: kcjaen90@gmail.com
Introduction: Acute Pancreatitis is the most frequent complication of Endoscopic Retrograde Cholangiopancreatography (ERCP). Some prophylactic strategies have been investigated to prevent it, such as the use of pancreatic stents or the use of peri-procedural NSAIDs; the incidence of Post-ERCP Acute Pancreatitis (PEP) in patients consuming aminosalicylic acid (ASA), a NSAID, is unclear. Statins are widely used lipid-lowering drugs and recent studies suggest that chronic statin intake may be associated to a lower incidence of acute pancreatitis.
Aims and Methods: Our aim is to investigate whether chronic statin and/or ASA intake is associated to a lower incidence of PEP.
Stark project (Statin and ASA for Ris k of PEP) is a prospective, international, multicenter, cohort study, developed under the auspices of the Pancreas 2000 educational program. Consecutive patients undergoing ERCP were included

prospectively. Demographic and medical data were retrieved by anamnesis. The patients were followed-up to detect those with PEP. Outcomes for PEP were retrieved from medical records. The final sample size was estimated to be 1,016 participants. A multivariate analysis (binary logistic regression) was performed; the variables included in the model were: statin intake, ASA intake, sex, age, center, difficult cannulation, procedure time, sphincter of Oddi dysfunction or previous episodes of acute pancreatitis. Adjusted odds ratios (aOR) were calculated.

Results: 638 patients were included for this preliminary analysis. Median age was 68.7 years (67.7-69.8), 333 (52.2%) patients were male, 41 patients developed PEP (6.4%), 16 patients (8.6%) under statin treatment versus 25 patients (5.6%) who were not consuming statins ($p = 0.160$). The multivariate analysis showed an aOR of 1.86 (0.874–3.986), $p = 0.107$ for PEP incidence in statin users. Regarding ASA consumption, 6 patients (5,8%) under ASA treatment versus 35 patients (6.6%) who were not consuming ASA developed PEP ($p = 0.782$). The multivariate analysis showed an aOR of 0.837 (0.292–2.399), $p = 0.740$ for PEP incidence among ASA users.

Conclusion: Our preliminary data suggest that chronic use of statins and/or ASA is not associated to a lower incidence of PEP.

Introduction: Prophylactic antibiotics (AB) are not recommended for treatment of acute pancreatitis (AP). Their use is still widespread despite several trials showing no firm evidence of efficacy.

Aims and Methods: To evaluate the effects of prophylactic antibiotics (PAB) for AP in a meta-analysis and investigate the need for further research by trial sequential analysis (TSA). Medline, Scopus and Web of Science were searched for randomized clinical trials assessing prophylactic use of AB in AP. Primary outcomes were all infectious complications and mortality. Secondary outcomes comprised infected pancreatic necrosis (IPN) and other specific infections, organ failure, surgical interventions and length of hospital stay. TSA was performed for primary outcomes, and secondary outcomes with significant results at a level of $\alpha = 0.05$ and power of 80%. Risk of bias was assessed using the Cochrane tool for bias assessment. Results for dichotomous outcomes were expressed as risk ratios (RRs) with 95% confidence intervals (CIs) and continuous results were expressed as mean differences (MDs) with 95% CIs.

Results: A total of 18 trials with 1134 pts were included in the analysis. PAB were received by 576 pts, while 558 were assessed as controls. Most of trials were assessed as being of high risk of bias. Overall mortality rate was similar in both groups with RR 0.85 (95% CI 0.64–1.14; $p = 0.27$; $I^2 = 0\%$), but the risk for infectious complications was significantly reduced in pts receving PAB (RR 0.34; 95% CI 0.22–0.51; $p < 0.00001$; $I^2 = 59\%$). This reduction was mainly due to the decreased risk of sepsis (RR 0.36; 95% CI 0.19–0.68; $p = 0.002$; $I^2 = 15\%$) and urinary tract infections (RR 0.46; 95% CI 0.25–0.86; $p = 0.02$; $I^2 = 11\%$), while a trend in risk reduction of IPN was shown with RR 0.78 (95% CI 0.60–1.00; $p = 0.05$; $I^2 = 0\%$). There was no significant difference in risk of other infections, fungal infections, organ failure and surgical interventions. Length of hospital stay was diminished in the intervention group by MD −6.65 (95% CI −8.86 to −4.43; $p < 0.00001$; $I^2 = 0\%$) days. For the detection of RRR of 30% in a 10% mortality rate among controls the required sample size is 2714 pts, while the number of included pts is 1076. A 30% RRR of 15% rate of IPN among controls requires 1725 pts, while only 959 are included so far. A 30% RRR of 30% rate of infectious complications has been achieved at 428 included pts, although the estimated sample is 1923. To show a minimally relevant mean shortening of hospital stay of 3 days requires a sample size of 391 pts and according to TSA this has already been achieved at the level of 351 included pts.

Conclusion: PAB clearly decrease the rate of infectious complications in AP, but mainly due to RRR of extrapancreatic infections, which requires no further research. No significant effect is shown on IPN and mortality, although firmer evidence requires additional trials and a larger sample size.

Disclosure: Nothing to disclose

P0729 SERUM TATI, TRYPSINOGENS 1-3, AND COMPLEX OF TRYPSIN-2 AND α_1-ANTITRYPSIN IN THE DIAGNOSIS OF ACUTE PANCREATITIS

M. Rainio[1], O. Lindström[1], A. Penttilä[1], O. Itkonen[2], E. Kemppainen[1], U.-H. Stenman[2], L. Kylänpää[1]

Contact E-Mail Address: mia.rainio@hus.fi

Introduction: Human pancreatic juice contains three trypsinogen isoenzymes: Trypsinogen-1 (cationic, T-1), trypsinogen-2 (anionic, T-2), and trypsinogen-3 (mesotrypsinogen, T-3). Tumor-associated trypsinogen inhibitor (TATI), also called pancreatic secretory trypsin inhibitor (PSTI) inhibits activated T-1 and -2 within the pancreas. Acute pancreatitis (AP) occurs when the inhibitory capacity of TATI is exceeded. Inflammation leads to leakage of pancreatic enzymes into the circulation. This can lead to 100-fold increases in the serum concentrations of TATI and trypsinogens in plasma and urine a few hours after onset of the disease. Concentrations of T-2 may stay elevated for weeks. α-macroglobulin and α--antitrypsin form complexes with and inactivate trypsin. When their inhibitory capacity exceeds, other proteolytic enzymes activates which lead to complications and organ dysfunctions (OD).TATI, T-1, T-2, T-3, and complex between trypsin-2 and α--antitrypsin (trypsin-2-AAT) have been studied as markers for AP but their prognostic value in detecting developing OD has not been cleared.

Aims and Methods: Our aim was to explore if on-admission serum levels of TATI, trypsinogens 1, −2, and −3, and trypsin-2-AAT can be used to evaluate the severity of AP and predict development of OD in AP patients, with and without OD.

We measured from 239 AP patients with onset of the disease within 72h the serum concentrations of TATI,T-1, T-2, T-3, and trypsin-2-AAT. As a normal hospital routine serum C-reactive protein, creatinine, and pancreatic amylase served as reference markers. Severity of AP was defined according to the revised Atlanta criteria.

Results: At admission, the serum concentrations of TATI ($p = 0.000$), T-1 ($p = 0.001$), T-2 ($p = 0.000$), trypsin-2-AAT ($p = 0.000$), and creatinine ($p = 0.000$) correlated with the severity of AP. The median concentrations of serum TATI ($p = 0.000$) T-1 ($p = 0.009$), T-2 ($p = 0.000$), trypsin-2-AAT ($p = 0.001$), and creatinine ($p = 0.035$) were higher in patients with developing OD than in those who did not. The diagnostic accuracy distinguishing patients who will develop persisting OD (severe AP) was estimated by receiver operating characteristic (ROC) curve analysis: TATI had the largest area under ROC curve (0.742, SD 0.062), T-2 (0.726, SD 0.063), trypsin-2-AAT (0.657, SD 0.056), creatinine (0.656, SD 0.063), T-1 (0.652, SD 0.071), T-3 (0.557, SD 0.069), and CRP (0.499, SD 0.075). TATI and T-2 were the most accurate in diagnoses. With a cutoff 166 µg/l specificity for TATI was 93%, sensitivity 48%, and DOR 11.52. With a cutoff for T-2 of 1375 µg/l, specificity was 93%, sensitivity 38%, and diagnostic odds ratio (DOR) 7.8. In multivariate logistic regression analysis, TATI was only independent predictor of severe AP among patients presenting without OD on admission ($p = 0.001$).

Conclusion: To our best knowledge this is the first study comparing the performance of TATI, T-1, T-2, T-3, and trypsin-2-AAT in distinguishing the development of OD in AP patients. We found that TATI was an independent marker of severe AP in patients who presented without OD on admission. The markers studied here, and especially TATI and T-2, are of great potential utility for diagnosis of AP and for prediction of later development of persistent OD. This could facilitate the early recognition of patients prone to develop severe AP in order to early initiation of intensive care and prevention of OD development.

Introduction: Pancreatic cancer (PC) is one of the deadliest cancers. Because of the high lethalness, PC becomes a hot spot of research. Over the last decade, many experimental models for PC have been developed. It is worth noting that PC is not a paediatric disease which may make us pay more attention to adult animal models, such as lentivirus-infected (LI) model and another model which induced by electroporation (EP). By using genetic alterations of *Kras* and *P53*, the EP model has induced PC. However, the LI model can not format PC by altering cancer genes above *Kras*, *P53*, until *Cdkn2A* and *Cdkn2B* are added. They indicate that the mechanisms of tumour formation between the two adult PC models are not similar. Moreover, inflammation, a tumour risk factor, can contribute to carcinogenesis when combined with characterized mutational events.

Aims and Methods: To investigate the difference in cancer formation mechanism of the two new humanized genetically-modified adult mouse model of PC. A reporter plasmid driven by green fluorescent protein (GFP) expression was constructed. After laparotomy, it is possible to make the pancreas accessible for intraparenchymal injection of vector DNA which co-deliver sleepy beauty (SB)13-transposase with the GFP-expressing transposon. GFP was detected by immunofluorescence staining for testing the efficiency of transfection. At day 7 and 14, after intra-parenchymal administration, H&E-stained sections and immunofluorescence of some inflammatory cells were utilized, by using antibodies against T-lymphocytes (CD3 antibodies), macrophages (F4/80 antibodies), B-lymphocytes (Pax5 antibodies), neutrophils (MPO antibodies), to determine the existence of pancreatitis. The characteristic of acinar-to-ductal metaplasia (ADM) was detected by co-immunofluorescence staining for Cytokeratin 19 (CK-19), a duct cell-specific marker, and Carboxypeptidase A1 (CPA1), an acinar cell-specific marker. Cell proliferation was detected by the immunofluorescence of Ki67.

Results: The transfected-DNA vectors could stably express in pancreatic cells between the two PC model groups. In spite of day 7 or 14, the EP pancreas had higher level of kinds of inflammatory cells than LI pancreas, although both of them showed more visible immune cells than normal mice pancreas. In addition, a few co-positive cells displayed acinar cells into a persistent duct-like state showed structures of ADM. Moreover, the expression of Ki67 in EP and LI group is stronger than normal pancreas.

Conclusion: These observations suggest the difference of process for cancer inducement between the two adult animal PC models. Apart from the mutation with *Kras* and *P53*, the EP model requires inflammation cooperated with genomic aberrations to build tumour. However, only if altering several cancer genes, PC in LI model can be induced. These findings provide considerable insight that for different research purposes, the proper use of animal model is an important step for gaining significant scientific observation. Additionally, inflammation inhibition might be a potential target in treating parts of PC whose formation required inflammation.

Introduction: The lysosomal aspartic protease Cathepsin D (CatD) is overexpressed and hypersecreted in many cancers and hereby influences cell death. Previously, in the ESPAC-3 cohort we determined a significantly increased median overall survival in cathepsin D low expressing PDAC patients. Gemcitabine treatment was significantly less effective in patients with high CatD expression compared to 5FU treated patients. Here, we present a prospective validation study.
Aims and Methods: Sample size calculation based on the $c2_{LR,\ 1DF}$ [3.58] from our previous study warranted 76 gemcitabine treated patients asking for a power of 0.8 and $p < 0.05$. Tumor tissue microarrays of 79 patients from the ''informative patients'' with PDAC receiving adjuvant gemcitabine treatment recruited at a single center were stained with anti-CatD (C-20) antibody. Patients were dichotomously distributed in lower and higher H-scores (H-score cut-off: 22.35) for generating Kaplan-Meier curves and to perform log-rank testing and Cox proportional hazards models. All statistical tests were two-sided.
Results: In our independent validation cohort with 237 cores from 79 patients (97.4%) median overall survival of patients was reported with 30.6 months (95%CI, 23.27–36.82). Median survival for patients for low CatD expression in the validation cohort was 39.8 (95%CI, 19.06–49.11) months vs 26.10 (95%CI, 18.77–34.19) months for high CatD expression, $c^2_{LR,1DF} = 5.3$; $p = 0.02$ confirming our null hypothesis. Multivariate analysis with sex, lymph node status, tumor staging and Cathepsin D expression revealed CatD expression as independent predictive marker in gemcitabine treated patients with a hazard ratio of 2.02 (95% CI, 1.03–3.97, $p = 0.04$).
Conclusion: Subject to prospective validation within a randomized trial, gemcitabine is less effective for patients with high CatD expression and could serve as a stratification marker for biomarker driven pancreatic cancer therapy.

Introduction: Pancreatic cancer (PC) is one of the most important life-threatening cancers all over the world. It is ranked fourth in deaths from cancer. In case it is diagnosed early, albeit it is infrequent, there would be a chance of long-term life expectancy. Glypican (GPC) 1 is a cell membrane protein that have an important role in oncogenesis. We aimed to investigate if there is a role for GPC1 in the diagnosis of PC.
Aims and Methods: Pancreatic cancer patients who were operated between January 2016 and January 2017 in our center and healty volunteers were included in the study. Blood samples were taken. centrifuged and stored at −80° until GPC1 measurement. ELISA and RT-PCR were used in measurement. Mann Whitney U test and Chi-square tests were used to compare the groups. Optimal cut-off value for diagnosis was calculated.
Results: Fifty patients with pancreatic cancer and 50 healthy individuals enrolled. Patients with pancreatic cancer were found to have an average protein content of 101.24 ng / ml and healthy subjects had an average protein content of 92.68 ng / ml. The optimal cut-off vale was 96.6 ng/ml. In according ROC curve sensitivity was 83.1% and specificity was 74.0%.
Conclusion: GPC 1 level was significantly higher in patients with pancreatic cancer. Considering the moderate sensitivity and specificty, it is yet to be a perfect marker. However it seems promising in comparison to existing markers. Its levels in cyst fluids may provide better prediction that is the subject of a study we are currently pursuing.

Introduction: The diagnosis of pancreatic ductal adenocarcinoma (PDAC) is associated with high mortality rates. High numbers of oncogenic mutations are commonly found. RINT1 (RAD50-interacting protein 1) is a multifunctional protein playing a role in cell cycle regulation, genomic stability, telomere maintenance, ER-Golgi trafficking and autophagy. All factors that are of high relevance in PDAC homeostasis.
Aims and Methods: Here we aim to decipher the role of RINT1 in PDAC, by in-depth characterization of primary PDAC cell lines.
Results: We can show that RINT1-depletion in PDAC cell lines leads to severe growth defects associated with massive Golgi fragmentation and G2/M cell cycle arrest leading to genomic instability. These data suggest that RINT1 homeostasis is essential for PDAC survival and represents therefore a putative therapeutic target. To characterize more in details the mechanisms of RINT1 regulation and to ultimately identify RINT1-dependent pathways that could be targeted in PDAC, we performed an extensive interaction study through yeast-two hybrid assay and mass spectrometry. We discovered hundreds of new RINT1-interaction partners including proteins involved in mitotic events supporting our preliminary data indicating an increase in genomic instability in PDAC cell lines. Moreover, we identified E3 ligases interacting with RINT1 allowing a better understanding of RINT1 biological function. In addition, we identify several post-translational modifications including ubiquitination and sumoylation and demonstrated that ubiquitination is a key regulator of RINT1 stability and biological function.
Conclusion: The data presented reveals a key role of RINT1 in PDAC homeostasis and identified multiple RINT1-post-translational modifications and protein-protein interaction partners that could be targeted in novel therapeutic approaches.

Introduction: Recently ion mobility spectrometry-based electronic nose has been shown to detect pancreatic cancer from urine (1). Until now it is not known which volatile compounds in urine are specific for pancreatic cancer. Polyamines are volatile organic compounds with strong odour and play important roles in cell proliferation, signaling, gene expression, apoptosis and organ development. Urine polyamine concentrations increase in malignant and proliferating cells (2).
Aims and Methods: To determine if pancreatic cancer can be detected from urine sample by quantitative analysis of urinary polyamines with liquid tandem mass spectrometry (LC-MS/MS).
For a proof-of-concept study in two Finnish hospitals, patients with pancreatic cancer, pancreatic pre-malign lesions, acute pancreatitis and chronic pancreatitis were prospectively recruited between January 2014 and June 2016. Patients provided urine sample at the time of the diagnosis. Controls were patients undergoing hernia reparation or elective cholecystectomy and were recruited during the same time period. Midstream urine was collected before the operation and stored in −70C° until analysis the urinary concentration of 14 polyamines including their mono- and diacetylated forms in a single run with LC-MS/MS (3). To our knowledge, this is the widest panel of polyamines analysed in a single run. Results were calculated as both absolute concentration and urinary creatinine-normalized concentration. To find optimal polyamine profiles for detection of cancer, the data was analyzed with linear discriminant analysis and cross-validated with leave-one-out cross-validation.
Results: 82 patients with pancreatic cancer, 36 with acute pancreatitis, 17 with chronic pancreatitis and 8 with pre-malign pancreatic lesion and 44 controls were recruited. 72% had stage III-IV pancreatic cancer and 27% went to radical pancreatectomy. A profile of five specific polyamines in urine putrescine,

acetylputrescine, spermide, diacetylpermide, cadaverine, and spermine distinguished pancreatic cancer from controls with a sensitivity of 79% and specificity of 79% and area under curve (AUC) was 0.86. We also compared pancreatic cancer and pancreatic pre-malign lesions with controls when LC-MS/MS revealed a sensitivity of 80% and specificity of 83% and AUC was 0.88.
Conclusion: We specified urine volatile compounds associated with pancreatic cancer and pancreatic pre-malign lesions. This novel finding has important implications when developing a non-invasive test for early diagnosis of pancreatic cancer.
Disclosure: Nothing to disclose

Introduction: Pancreatic ductal adenocacinoma (PDAC) is one of the most aggresive tumors, with a five-year survival rate of less than 5%. Probe based confocal laser endomicroscopy (pCLE), with various miniprobes available is being used as a prehistopathological tool for different types of lesions. However, in PDAC there is limited experience in imaging studies.
Aims and Methods: *Ex-vivo* freshly surgical removed PDAC specimens were assessed using pCLE and then processed for paraffin embeding and histopathological diagnostic on a pursuit of delivering new methods of assessing and differentiating pancreatic adenocarcinoma from other structures Twelve patients diagnosed with PDAC on endoscopic ultrasound and FNA confirmation underwent surgery. Removed samples from each patient were selected and sprayed with acriflavine as contrast agent, underwent pCLE with an experimental probe and compared with previous recordings of normal pancreas. Consecutively, all samples were subjected to cross-sectional histopathology, including surgical resection margins for controls. pCLE records, as well as anti-mesothelin Alexa488 labelled antibody corespondant and cytokeratin-targeted immunohistochemistry were processed on Image ProPlus AMS image analysis software.
Results: After histopathological confirmation of adenocarcinoma areas, on mesothelin fragments the proliferating ducts were clearly expressed, compared to no signal in the normal ducts and acini. On cytokeratin immunohistochemistry and pCLE correspondants the morphological classifiers clearly differentiated between tumor and non tumor areas.
Conclusion: Our study confirms that pCLE imaging might be used to differentiate between tumor and non tumor tissue with similar correspondant when using mesothelin antibody or cytokeratin immunohistochemistry imaging classifiers. This enhances the potential of chosing pCLE as a potential tool for future *in-vivo* studies for live diagnosis.

Introduction: Neoplastic pancreatic cysts are identified with increasing frequency, mainly as incidental findings. Because some have malignant potential, yearly lifelong surveillance is globally recommended and executed, even though evidence on effectiveness is lacking. A prerequisite for any surveillance program to be feasible is adherence, in which psychosocial aspects play an important role. However, the impact of such intensive surveillance on participants and their willingness to participate has hardly been studied.
Aims and Methods: To evaluate the perception and psychological burden of pancreatic cyst surveillance from a participant's perspective.
The present patient survey is part of an international cohort study (PACYFIC study, www.pacyfic.net), which prospectively records the outcome of pancreatic cyst surveillance. Participants with a newly diagnosed pancreatic cyst (<6 months) are invited to complete questionnaires after diagnosis (baseline) and each subsequent control visit (follow-up). The questionnaires contain the Hospital Anxiety and Depression Scale (HADS, with both subscale scores ranging from 0–21 and a score <7 indicating a low level of anxiety or depression) and questions concerning patients' perception of surveillance and wishes regarding follow-up frequency and duration.
Results: 103 patients with a newly diagnosed cyst returned the baseline questionnaire (median age 69 years (IQR 62–76), 35% male). 86 participants (84%) agreed or strongly agreed that surveillance reduces their concerns about pancreatic cancer and 81 (80%) confirmed that it contributes to their sense of security. Although 26 participants (25%) reported that it leads to worries and 23 (22%) found it burdensome, almost all (99 respondents, 96%) agreed that the advantages outweigh the disadvantages 'somewhat', 'rather' or 'very much'. The majority (77 participants, 75%) wanted surveillance to continue for the rest of their lives, with a yearly or even 6-monthly frequency.
In the 20 patients who already completed a second questionnaire, median HADS scores (2 for anxiety (IQR 1–6.75) and 2 for depression (IQR 0–5.75)) were unaffected by the follow-up visit ($p = 0.551$ for anxiety and $p = 0.487$ for depression, paired T-test).
Conclusion: The majority of respondents reported a highly positive attitude towards pancreatic cyst surveillance. HADS scores were low to begin with and appear unaffected by subsequent follow-up, presuming a low psychological burden. Based on these preliminary results, the adherence in a pancreatic cyst surveillance program is predicted to be high, and annual surveillance such as currently recommended in the guidelines seems feasible.

Introduction: However, assessment of pancreatic ductal adenocarcinoma (PDAC) resectability relies on different preoperative imaging modalities, no consensus about the best approach has been reached so far [1].
Aims and Methods: We aimed to evaluate the diagnostic efficacy of different imaging modalities in the preoperative resectability assessment of non-metastatic PDAC.

A retrospective comparative study including non-metastatic PDAC patients who were subjected to surgery at Nagasaki University Hospital between January 2014 and December 2017. Data obtained by different preoperative imaging modalities including contrast enhanced computed tomography (CECT), magnetic resonance imaging (MRI) and endoscopic ultrasound (EUS) were compared with the final postoperative pathologic diagnosis. The included parameters for comparison were: tumor size, common bile duct (CBD)/gall bladder (GB) invasion, duodenal wall (DU) invasion, regional lymph node (LN) spread, adjacent organs infiltration including stomach, colon, spleen, left adrenal, retroperitoneal fat and coeliac plexus, portal vein (PV) invasion/encasement, arterial (ART) invasion/encasement including coeliac artery (CA), hepatic artery (HA) and superior mesenteric artery (SMA), and the overall tumor resectability. Sensitivity, specificity, PPV, NPV and diagnostic accuracy (DA) with the corresponding 95% confidence interval (95% CI) were calculated for each individual imaging modality. Tumor invading the PV, CA, HA and SMA was defined as unresectable. When the lesion was assessed as resectable by the imaging modality, the test was defined as positive.

Results: A total of 64 PDAC patients, 28 females, with mean age 70 years ± 7 was included. Tumor size assessment was more accurate by EUS than CECT and MRI with DAs of 65% (CI: 41–85), 61% (CI: 46–74) and 59% (CI: 39–76) respectively. For CBD/GB infiltration, EUS was superior than MRI and CECT with DAs of 95% (CI: 75–99), 83% (CI: 64–94) and 78% (CI: 65–89) respectively, while for assessing DU infiltration, CECT had the best DA of 74% (CI: 60–85) versus 70% (CI: 46–88) for EUS and 65% (CI: 46–82) for MRI. All modalities had 100% specificity and PPV for ruling in adjacent organ infiltration, but the DAs was very low: 34% (CI: 18–54) for MRI, 29% (CI: 17–44) for CECT and 15% (CI: 3–38) for EUS. For evaluation of regional LN affection, CECT had the highest specificity (90%, CI: 68–99) and PPV (82%, CI: 52–95) while MRI had the highest sensitivity (31%, CI: 11–59) and NPV (50%, CI: 40–60), with comparable DAs of 53% (CI: 38–67), 55% (CI: 36–73) and 55% (CI: 31–77) for CECT, MRI and EUS respectively. Compared to CECT and MRI, EUS was the best modality for ruling in PV invasion and ART invasion. For PV invasion, DA of EUS, CECT and MRI was 89% (CI: 65–99), 80% (CI: 67–90) and 76% (CI: 56–90) respectively, while that for ART invasion was 89% (CI: 67–99), 88% (CI: 76–95) and 73% (CI: 67–89) respectively. For the overall resectability assessment, EUS had the highest DA of 85% (CI: 62–97), the lowest overstaging rate (0%) and the lowest understaging rate (15%) versus 76% (CI: 62–87), 5.8% and 17.6% for CECT, and 72% (CI: 53–87), 6.8% and 20.6% for MRI respectively. Our study was a retrospective one on a small number of patients and it did not include a cost minimization analysis.

Conclusion: For non-metastatic PDAC, CECT is the most useful preoperative imaging modality for assessing DU infiltration and ruling in regional LN spread, while EUS is the best modality for assessing tumor size, CBD/GB infiltration and the overall tumor resectability with the lowest overstaging and understaging rates.

P0738 PROGNOSTIC SIGNIFICANCE OF ADIPOSE TISSUE-DERIVED HORMONS IN PANCREATIC CANCER PATIENTS

A. Saray[1]
[1]*Clinical Center University of Sarajevo, Department of gastroenterology and hepatology, Sarajevo, Bosnia and Herzegovina*

Contact E-Mail Address: sarayaida19@gmail.com

Introduction: Evidence is increasing that various obesity-related cancers are associated with changed plasma levels of adipokine-derived hormons. We recently demonstrated an association between adiponectin levels and tumor stage in patients with pancreatic cancer (PC) suggesting its potential role in risk prediction and tumor proliferation. However, the prognostic role of adipokines in PC patients has not been well studied before.

Aims and Methods: The aims of the study were to analyze the possible associations between adipokines and clinicopathological parameters of PC patients and to investigate their potential role as prognostic indicators of PC disease.

Baseline levels of serum adiponectin and leptin were determined in 51 consecutive patients with PC and followed up for the median period of 2 years.51 Control subjects were matched to case patients by age, sex and BMI. The association between variables were evaluated using nonparametric Spearman's correlation test. Receiver operating characteristics (ROC) analysis was employed to calculate the area under the curve (AUC). Survival analysis used the Kaplan-Meier curve and the Cox proportional hazards model.

Results: In PC patients serum leptin levels were higher than i controls ($p < 0.0001$); adiponectin levels were lower than in controls ($p < 0.001$) and inversely correlated with tumor size ($rho = -0.834$, $p < 0.01$). Leptin levels were inversely correlated with adiponectin levels ($rho = -0.727$,$p < 0.01$). Thus, leptin concentrations were corrected by adiponectin values (L/A ratio). At ROC analysis the diagnostic profile of L/A (AUC 0.874; sensitivity 84%;specificity 80%) in detecting pancreatic cancer stage was superior to that of leptin alone (AUC 0.675;sensitivity 86%;specificity 50%). High L/A ratio was the only independent predictor of metastatic disease ($beta = 0.112$,$p = 0.03$). Kaplan-Meier global survival analysis revealed a low L/A ratio was associated with an increased survival compared to patients with high L/A ratio (Cox F test = 2.788, $p < 0.05$).

Conclusion: This study identified, for the first time, that the combined measurement of leptin and adiponectin (L/A ratio) might represent a better prognostic indicator than individual parameters in patients with PC. Our results support the hypothesis linking adipose-tissue derived hormon levels to tumor growth and progression of obesity-associated cancers.

P0739 K-RAS MUTATION ANALYSIS BY DIGITAL PCR IN EUS-GUIDED FNA CYTOLOGY SPECIMENS AND CTDNA IMPROVE PANCREATIC CANCER DIAGNOSIS

R. Wang, B. Cheng, J. Wang
Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Department of Gastroenterology and Hepatology, Wuhan, China

Contact E-Mail Address: wangrh1988@126.com

Introduction: Pancreatic cancer is a dismal disease and the fourth leading cause of cancer-related death in western countries. Novel methods for early diagnosis is the necessary path forward to improve the situation for patients with pancreatic cancer. Our primary aim in this study is to explore the possibility of detecting the K-ras gene mutation to supplement histo/cytopathologic evaluation of pancreatic masses. Our secondary aims of the current study were to compare the quantities of K-ras mutation of ctDNA in the circulation with FNA tissue samples in pancreatic mass of the same patients and investigate the prognostic value of K-ras gene mutation in advanced pancreatic adenocarcinoma.

Aims and Methods: Our study comprised 149 consecutive patients who underwent EUS-FNA of pancreatic solid masses between September 2014 and May 2016 at the Endoscopy Center of Tongji Hospital. After lesions were identified by EUS; aspirated samples were separated into 2 parts each for cyto/histopathological evaluation and K-ras point mutation analysis. ctDNA in serum was extracted from cell-free ctDNA in serum blood samples from these patients. We used droplet digital PCR (ddPCR) to analyse K-ras mutations (G12V, G12D, and G12R). The final diagnosis was based on pathological examinations of specimens obtained by surgical resection or following up for at least 2 years.

Results: We prospectively evaluated 149 patients, including 105 pancreatic ductal adenocarcinoma (PDAC) patients [age 58.38 ± 11.01 years; male 69/105 (65.71%)] and 44 cases with non-malignant pancreatic masses [age 52.66 ± 13.81 years; male 36/44 (81.82%)]. The sensitivity, specificity, PPV, NPV, and accuracy of the cyto/histopathological examination alone were 71.4%, 86.4%, 92.6%, 55.9% and 75.8%, respectively, whereas these values of the K-ras mutation ddPCR analysis combined with Cyto/histopathological analysis were 93.3%, 79.1%, 91.6%, 82.9% and 88.6%, respectively. The sensitivity and accuracy of EUS-FNA increased by 21.9% ($p < 0.001$) and 12.8% ($p < 0.001$), respectively, when K-ras mutation ddPCR analysis was added to standard cyto/histopathological assessment. Aiming for further investigation in a non-invasive method in highly sensitive detection of KRAS mutations, we evaluated K-ras mutation ddPCR analysis of ctDNA in all matched plasma samples. We identified KRAS mutations in 56.2% of the ctDNA in plasma samples from patients with pancreatic cancer. 26.3% of the plasma ctDNA were positive for G12D, 8% for G12V, and 3.5% for G12R. The sensitivity and accuracy of combined KRAS mutations in plasma ctDNA and CA1-19 were 78.9% and 76.2%, respectively. The median survival time was significantly shorter in patients with G12D mutations (180 days) compared with patients with other mutations (240 days) in their EUS-FNA tissue samples and ctDNA sample (long-rank test, $p = 0.001$ and $p = 0.0008$, respectively). Multivariate analysis demonstrated that both G12D mutation in EUS-FNA tissue samples (HR, 0.495, 95% CI, 0.325–0.753, $p = 0.0010$) and ctDNA (HR, 0.417, 95% CI, 0.199–0.870, $p = 0.0199$) were independently associated with poor overall survival.

Conclusion: We observed that combining K-ras mutation qPCR analysis and histo-/cytopathological findings increases the accuracy in diagnosing pancreatic cancer. The K-ras mutation in plasma ctDNA complements the use of other diagnostic techniques in the diagnosis of pancreatic cancer in clinical practice. G12D mutation in EUS-FNA tissue samples and ctDNA were independent risk factors for poor prognosis of pancreatic cancer.

Introduction: Surveillance of high-risk individuals (HRI) with magnetic resonance (MRI) or endoscopic ultrasound (EUS) can detect resectable pancreatic cancer (PC) and may reduce cancer-related mortality. There is controversy whether systematic screening and surveillance is cost-effective or not.

Aims and Methods: We aim to perform an economic analysis to identify the different clinical and cost determinants of PC screening in HRI. Three strategies

Abstract No: P0740

		No screening	*EUS-based screening*	*MRI-based screening*
Baseline: Higher risk of PC Relative risk : 5–120	Cost (U.S. dollars)	$54,741	$47,750	$27,617
	Effectiveness (QALYs gained)	19.477	21.225	21.532
	ICER ($/QALY)	-	$13,200	Dominant strategey
Highest risk of PC Relative risk : >20	Cost (U.S. dollars)	$110,441	$64,875	$66,639
	Effectiveness (QALYs gained)	14.815	20.622	20.010
	ICER ($/QALY)	-	Dominant strategy	$7,847

[Incremental cost-effectiveness ratios (ICER) for pancreatic cancer screening in high-risk individuals]

were compared: no screening, EUS-based screening and MRI-based screening. A Markov model was created with yearly interventions starting at age 40. Patients were considered HRI according to the Cancer of the Pancreas Screening (CAPS) consortium recommendations. Average lifetime risk for developing PC, survival and cost of care data were obtained from SEER Cancer Prevalence and Cost of Care Projections database and from Center for Medicare Services data. Screening effectiveness (i.e. adenocarcinoma and high-risk dysplasia cases detected) was obtained from a recent systematic review. EUS and MRI sensitivity, specificity and probabilities of developing complications after surgical or medical treatment were obtained from published literature. Only direct costs were considered. Outcomes were adjusted for utility indices with discounting.

Results: Baseline analysis of a cohort with five-fold relative risk (RR) of PC higher than the general U.S. population showed that MRI screening is the cheapest strategy and yielded highest QALYs. While this was valid for conditions with relative risk of PC < 20 (i.e. familial pancreatic cancer with 1 or 2 first degree relatives (FDR) affected, HNPCC syndrome, FAP and BRCA2 mutations), for those with the highest relative risk (≥ 3 FDR, hereditary pancreatitis, Peutz-Jeghers, and CDKN2A mutations (p16)), EUS became the dominant strategy (Table).

Sensitivity analyses showed that the model is impacted by cost and imaging performance, but still cost-effective within the range reported in published literature. Threshold analysis in the baseline scenario showed that if MRI cost is > $1,600, EUS becomes more cost-effective. Once patients reached 76 years 'no screening' was the favored strategy.

In the Monte Carlo simulation over the lifetime of the baseline cohort; 443 (12% resectable), 130 (40% resectable) and 127 (51% resectable) patients developed PC under no screening, EUS and MRI screening strategies, respectively. A relative risk reduction of 70% and a number needed-to-screen of 32 (95% CI, 27–38) were seen in both imaging strategies. The screening strategies were cost-effective in the vast majority of simulation trials over a wide range of willingness to pay.

Conclusion: Surveillance of HRI for pancreatic adenocarcinoma is cost-effective favoring MRI over EUS in moderate risk cases but EUS-based screening in those with highest relative risk. Screening should be offered starting at age 40 until 75 years old.

Introduction: Endoscopic ultrasound (EUS) plays a key role in the evaluation of solid pancreatic masses, obtaining tissue for diagnosis through EUS-fine needle aspiration (EUS-FNA). However, the diagnostic accuracy is variable, with relatively high rate of inconclusive results after the first EUS-FNA.

There are currently no consensus regarding the best diagnostic method after negative or inconclusive EUS-FNA of a highly suspicious solid pancreatic mass.

Aims and Methods: The aim of this study was to evaluate the diagnostic methods and predictive factors of malignancy after a negative or inconclusive EUS-FNA of a highly suspicious solid pancreatic mass.

Retrospective study of all cases of EUS-FNA of highly suspicious solid pancreatic masses in a tertiary center (from Jan/2012 to Dez/2016), with inconclusive or negative result for malignancy.

Results: We included 118 EUS-FNA in a total of 277 EUS-FNA, of 85 patients, 65.9% male, with mean age of 60,31 ± 14,27 years. The majority of the pancreatic masses were located in the head (56.8%) and 54.2% had an estimated size between 2 and 4 cm.

The mean number of passes were 3.0 (+/−1.4) and the most common needle size was 25G (55.9%).

Ninety-four (79.7%) of the 118 EUS-FNA were inconclusive and the other 24 EUS-FNA were negative for malignancy. After this result, 41.5% repeated EUS-FNA, 17.8% underwent surgical exploration, 16.1% kept in close follow-up and 13.6% were referred to palliative care.

More than 3 passes in EUS-FNA was statistically associated with malignancy (p = 0.022), as well as higher values of CA 19.9 (p = 0.025). The size of the lesion was statistically associated with obtaining tissue for diagnosis (p = 0.016).

After a first negative/inconclusive EUS-FNA, 72% of the cases were diagnosed as malignant (75.4% as pancreatic adenocarcinoma), being EUS-FNA and surgery the main methods for the diagnosis. Seven patients (33%) that were submitted to surgery due to high suspicion of malignancy, revealed benign lesions.

Conclusion: EUS-FNA is the best method for the evaluation of pancreatic solid masses. However, in some cases, EUS-FNA does not lead to conclusive cytological diagnosis.

After a negative or inconclusive EUS-FNA of a highly suspicious solid pancreatic mass EUS-FNA appears a reasonable choice to achieve the definite diagnosis.

Introduction: Patients with resectable pancreatic ductal adenocarcinoma (PDA) have improved survival compared to unresectable PDA. It has been shown that multidisciplinary pancreas cancer conferences (MDPC) implementation results in selection of candidates for surgery with higher stage PDA compared to patients not presented at MDPC. In addition, patients are taken to surgery earlier through MDPC management. Rates of survival after MDPC management is limited.

Aims and Methods: We aim to determine survival of resectable pancreas cancer of patients that underwent pancreatic resection after consensus from a MDPC and assess the parameters on survival time. A total of 64 patients in a MDPC group underwent upfront surgical resection from May 2013 to August 2016 at an experienced surgical PDA center. Patients were followed prospectively till November 2017 and rates of survival from the date of surgical resection were recorded. Survival analysis was performed using Kaplan Meier for age, tumor size, tumor differentiation, T-Stage and lymph node status. Log-rank tests were used to compare the difference on survival time. Independent predictors of survival were determined using Cox model. Proportional hazard assumptions were checked and a p-value < 0.05 was considered statistically significant.

Results: 64 patients were identified with successful resection of PDA. The majority (61) had a Whipple's procedure, and 3 had pancreatectomy. The average age of the Whipple's group was 69.1 years ± 10.1. 1-year survival was 78.13%, 2-year survival was 46.30% and 3-year survival was 27.27%. Overall, survival times after surgery were different according to age group (p = 0.01), tumor size (p = 0.002), tumor differentiation (p = 0.05), T-Stage (p = 0.008) and lymph node status (p = 0.001). Tumor size (p = 0.002) and lymph node status (p = 0.008) remained statistically significant after multivariate Cox regression model with all the variables included. The largest tumor size (≥50mm) had almost 53 fold mortality risk compared to patients with smaller size (<20mm). Patients with N1 lymph node status had more than 3-fold mortality risk compared to patients with N0 lymph node status.

Conclusion: Survival trends following resected PDA were followed after consensus from an experienced MDPC. Log-rank test revealed that age, tumor size, tumor differentiation, T-stage, and lymph node involvement can influence the survival pattern in the years following surgery. Tumor size and lymph node involvement were the only significant predictors of mortality. This study suggests that patients with PDA with tumor size ≥ 50 mm and/or lymph node involvement have poor survival despite being surgically resectable. Consideration for alternative management such as down-staging with neoadjuvant therapy should be investigated.

Introduction: Pancreatic ductal adenocarcinoma (PDAC) has a dismal prognosis. Biomarkers are needed to facilitate early and preferably noninvasive detection of PDAC, which may enable early diagnosis and therefore influence patients' prognosis. Circulating tumor DNA (ctDNA) was examined several times in metastatic PDAC. Its value in resectable disease with lower tumor load has not been sufficiently analyzed. CA19-9 is used as a serum marker to assess disease progression in PDAC patients but is not recommended for general screening due to lack of sensitivity and specificity. Recently it has been reported that elevated levels of thrombospondin-2 (THBS2) protein are detectable in several stages of PDAC. Here we aimed at improving sensitivity and specificity of THBS2-based detection of early PDAC by combining THBS2 analysis with further markers.
Aims and Methods: 39 patients with histologically or cytologically proven PDAC, which were enrolled to the NEONAX trial (Neoadjuvant plus adjuvant or only adjuvant nab-Paclitaxel plus Gemcitabine for resectable pancreatic cancer, clinical trial identifier: NCT02047513), were selected for this study-independent retrospective translational analysis. Mean age was 67 ± 10 years, gender 19 female/20 male, mean tumor size 31 ± 12mm, primary tumor location 27 head, 7 body, 2 tail, 1 body/tail, 2 not determined. 15 patients with benign pancreatic disease (intraductal papillary-mucinous neoplasms, IPMN) served as controls. Mean age of the IPMN-cohort was 66 ± 13 years; mean tumor size 11 ± 6 mm; location 4 head/body/tail, 6 head/body, 3 body/tail, 2 tail; gender 10 female/5 male. Blood samples were collected at the time point of disease diagnosis. Plasma was separated within 1 hour after blood draw and stored at $-80°C$ until further analyses. *KRAS* genotyping was performed after isolation of ctDNA (QIAamp MinElute ccfDNA Kit, Qiagen) by digital droplet PCR (QX200 system, Bio-Rad) for the 7 most frequently occurring *KRAS* mutations in PDAC (*KRAS* G12A, G12C, G12D, G12R, G12S, G12V, G13D; ddPCR™ KRAS Screening Multiplex Kit, Bio-Rad). Clinical data and CA 19-9 levels of PDAC and IPMN cohort were routinely assessed at initial disease diagnosis by ELISA (Roche, threshold 55 U/ml). The levels of THBS2 were assessed by Quantikine ELISA Human Thrombospondin-2, R&D Systems (threshold: 42 ng/ml). Statistical analyses followed a descriptive, hypothesis-generating approach and were done by using GraphPad Prism Version 7.00, GraphPad Software Inc.
Results: Median cfDNA level in plasma of PDAC patients (12.6 ng/ml, range: 1.1–270) was significantly higher ($p = 0.0006$, Mann-Whitney) than that of the IPMN cohort (5.5ng/ml, range: 1.7–12.6). Only 2/39 PDAC patients (5%) and 1/15 IPMN patients (6%) had *KRAS* mutations in ctDNA detectable by highly sensitive ddPCR. CA19-9 level was elevated in 22/39 PDAC patients (56%) and in none of the IPMN patients. THBS2 was elevated in 17/39 PDAC patients (44%) and in none of the IPMN patients. In contrast, parallel assessment of both, THBS2 and CA19-9 levels, was found to be most suitable to discriminate the PDAC% cohort from the IPMN cohort, with a sensitivity of 77% and a specificity of 100%.
Conclusion: THBS2 and CA19-9 panel assessed in human blood using a conventional ELISA assay may improve the definition of pancreatic lesions as PDAC even at early stages of disease. While total cfDNA amount differs between patients with benign and malignant pancreatic lesions, ctDNA genotyping for *KRAS* mutations failed to improve non-invasive diagnostic strategies in resectable PDAC most likely due to a low tumor load.

Introduction: Pancreatic cancer (PC) is a deadly disease typically diagnosed at advanced stages and its prognosis is the worst among various cancers (5-yr survival 5–10%) due to the lack of an algorithm to diagnose the disease at an early stage. Recent study showed detection of a dilated pancreatic duct or cystic pancreas lesions may facilitate an early diagnosis. Patients with chronic liver disease caused by the hepatitis B virus (HBV) or hepatitis C virus (HCV) have an increased risk of developing hepatocellular carcinoma (HCC). Thus, the guidelines strongly recommend that these patients routinely undergo abdominal imaging surveillance for HCC, regardless of whether they have symptoms.
Aims and Methods: This study aimed to evaluate whether patients with HBV- and HCV-related chronic liver disease were diagnosed with PC at early stages during abdominal imaging surveillance for HCC. This retrospective study examined 520 consecutive patients with PC who were diagnosed at the Ehime University Hospital and its affiliated centers (including a cancer institute, tertiary care hospital, and community hospital) between 2011 and 2013. Data were collected regarding HBV and HCV status, likelihood of PC diagnosis, and Union for International Cancer Control (UICC) stage. Based on the aim of the present study, 73 patients without test results for viral hepatitis markers were excluded. The chi-square test and Student's t-test were used for statistical analysis, where appropriate. Outcomes were analyzed using the Kaplan-Meier method and Cox proportional hazards regression. Differences in survival analyses were determined using the log-rank test. Local ethic boards approved the study but written consent form was waived due to the retrospective manner.
Results: The cohort included 447 patients (240 men and 207 women) with PC, who had a mean age of 72 ± 10 years (range: 33–91 years). Forty-five patients (10.0%) were positive for either HBsAg (N = 18, 4.0%) or anti-HCV (N = 27, 6.0%), although none of them had coinfection. Among the 45 patients, 26 patients had newly diagnosed HBV/HCV infections at the PC diagnosis. Among the other 19 patients, 16 patients were undergoing periodical HCC surveillance, based on HBV- or HCV-related chronic liver disease, at their PC diagnosis (the HCC surveillance group). The UICC stage distribution among the HCC surveillance group (N = 16) was stage 0 (N = 2, 12.5%), stage IA (N = 3, 18.8%), stage IB (N = 2, 12.5%), stage IIA (N = 2, 12.5%), stage IIB (N = 1, 6.3%), stage III (N = 2, 12.5%), and stage IV (N = 4, 25%). The UICC stage distribution among the non-surveillance group (N = 431) was stage 0 (N = 4, 0.9%), stage IA (N = 28, 6.5%), stage IB (N = 27, 6.3%), stage IIA

(N = 86, 20.0%), stage IIB (N = 48, 11.1%), stage III (N = 56, 13.0%), and stage IV (N = 182 patients, 42.2%). The HCC surveillance group had significantly more patients with stage 0 disease, compared to stages IA-IV (p = 0.0166). A dilated pancreatic duct led to the diagnosis of PC in all 6 patients with stage 0 disease. Similar results were observed for cut-offs of stage IA (p = 0.0066) and stage IB (p = 0.0043), but not stage IIA (p = 0.1042).
Conclusion: Patients with HBV- and HCV-related chronic liver disease had an early diagnosis of PC during HCC surveillance. Careful evaluation of the pancreas is warranted during HCC surveillance.

Introduction: For diagnosis of pancreatic neuroendocrine neoplasms (PNENs), the usefulness of various imaging examinations has been reported. However, the diagnostic ability of imaging and pathological examinations for small lesions is uncertain.
Aims and Methods: The aim of this study was to examine the diagnostic ability of ultrasonography (US), computed tomography (CT), magnetic resonance imaging (MRI), endoscopic US (EUS)/EUS fine-needle aspiration (FNA) for PNENs < 20 mm in size. From April 2004 to December 2017, 93 patients with PNENs were treated in our hospital. Thirty-four patients (48 lesions) who underwent surgery after US, CT, MRI, and EUS/EUS-FNA and whose tumours had pathological diameters of < 20 mm were included this study. The primary endpoints were detectability of each imaging modalities and calculated the cut-off line of detectable size of PNENs and the secondary endpoint was accuracy of the pathological examinations and concordance rate of the World Health Organization (WHO) grade by EUS-FNA.
Results: Ten lesions were in the pancreatic head, and 38 were in the pancreatic body or tail. The median tumour diameter was 10 mm (2–20). Four lesions were functional PNENs, and 44 were non-functional PNENs. The pathological diagnosis was based on WHO classification, and 41 lesions were G1 and 7 were G2. We performed US for 46 lesions and detected 24 (52%). On CT, 38 lesions (79%) were observed. Thirty-six lesions were contrasted in the early phase, and 2 showed delayed enhancement. MRI revealed 29 lesions (60%), of which 26 showed high signal intensity in diffusion-weighted images. On EUS, 44 lesions (83%) were detected. The boundary was clear/unclear in 43/1 lesions, the surface was adjusted/irregular in 42/2, and the internal echogenic gain was hypoechoic/hyperechoic/isoechoic in 38/4/2.
The diameters of the 38 lesions detected on CT were all ≥ 5 mm, and lesions of < 5 mm could not be detected. The cut-off size of the detectable lesions in the receiver-operating characteristic curve analysis was 8 mm on US (sensitivity, 0.87; area under the curve [AUC], 0.82), 8 mm on MRI (sensitivity, 0.86; AUC, 0.84), and 3.5 mm on EUS (sensitivity, 0.95; AUC, 0.97). EUS-FNA was performed for 26 lesions, and 25 (96%) were diagnosed as PNEN. The Ki-67 index was evaluated for 23 lesions. Regarding the pathological classification of the FNA specimens, 17 lesions were G1 and 2 were difficult to assess. However, after surgery, 17 lesions were diagnosed as G1 and 6 as G2. In the analysis of pathological classifications, 16 lesions (70%) were properly assessed using FNA specimens.
Conclusion: The most useful examination for the diagnosis of small PNENs was EUS. Although the pathological diagnostic ability of EUS-FNA was high, the grading classification tended to be underestimated.

Introduction: Pancreatic neuroendocrine tumors (PNET) are highly angiogenic tumors which – despite of various systemic targeted options including mTOR and VEGF inhibition – frequently develop secondary drug resistance. IGF2BP (IGF2 mRNA-binding proteins) represent a family of RNA-binding proteins (RBP) comprised of three members (IGF2BP1-3) which have been described as potentially oncogenic factors in different solid tumors. As posttranscriptional regulators of gene expression they control the transport, translation and degradation of their target mRNAs, thereby influencing proliferation, migration and chemoresistance of tumor cells. However, the oncofetal proteins IGF2BP1 and IGF2BP3 are well known to be associated with highly aggressive carcinomas, e.g. pancreatic ductal adenocarcinoma (PDAC), but their role and function in PNETs is still unknown.
Aims and Methods: We aim to analyze the functional role and clinical potential of IGF2BPs in PNETs to identify novel therapeutic avenues overcoming therapy resistance. Thereby the methods RNA interference, Flow Cytometry, Migration-Assay, CFU, Western Blot, qRT-PCR, RNA-IP, RNA-decay were used.
Results: In the PNET cell line BON1, we observed an exuberant expression of IGF2BP1 and MYC. Remarkably, IGF2BP1 depletion in BON1 cells significantly extenuated cell proliferation, migration and colony formation by posttranscriptional reduction of c-MYC, PCNA, CCNE1, CCNA2, CCNB1 and the methyltransferase EZH2. Simultaneously, mRNA and protein levels of p21, p27 and BCL-2 were upregulated, resulting in a G1 cell cycle arrest. Interestingly, no sign of apoptosis, senescence or reduced viability where observed. Using RNA Immunoprecipitation (RIP) we could confirm binding of IGF2BP1 to the EZH2 mRNA as well as to its known target mRNA MYC. The posttranscriptional regulation of EZH2 and MYC could explain the derepression of cell cycle arrest genes and BCL-2 in BON1 cells. In contrast to our findings on IGF2BP1, the depletion of IGF2BP2 and IGF2BP3 had no effect on the oncogenic capacity of BON1 cells. These data on EZH2 indicate a novel signaling mechanism by which the RNA-binding protein IGF2BP1 regulates methyltransferase activity and thereby influences epigenetic repression systems.
Conclusion: Our findings suggest that IGF2BP1 acts as a posttranscriptional modulator of oncogenic and epigenetic factors in PNET-cells, thereby enhancing or sustaining oncogenic hallmarks in support of an aggressive and chemoresistant phenotype.

Contact E-Mail Address: marti.boss@radboudumc.nl
Introduction: Insulinoma and focal lesions in congenital hyperinsulinism (CHI) are GLP-1R positive lesions that are characterized by excessive insulin production and thereby causing severe hypoglycaemia. The therapy of choice is surgery, however, these surgical procedures are challenging because of the necessity to preserve as much healthy pancreatic tissue as possible and in some cases due to the localization of lesions near the ducts or large vessels. Targeted photodynamic therapy (tPDT) could provide selective destruction of tumour tissue without causing damage to surrounding tissues. The glucagon-like peptide-1 (GLP-1) analogue exendin specifically binds the GLP-1R expressed on pancreatic beta cells. GLP-1R imaging using ^{68}Ga-labelled exendin is a successful pre-operative imaging technique for insulinoma and is under investigation in CHI. We hypothesize that tPDT using exendin labelled with the near-infrared (NIR) sensitive photosensitizer IRDye700DX enables specific destruction of GLP-1R positive cells.
Aims and Methods: Exendin-IRDye700DX was characterized *in vitro* and *in vivo*. A competitive binding assay was performed using CHL-cells transfected with the GLP-1R. The feasibility of inducing specific cell death was assessed by incubating different cell-types (CHL-GLP-1R cells, INS-1 cells and PANC-1 cells) with 300 nM exendin-IRDye700DX and exposing them to various intensities of NIR LED light. Cell viability was measured using a cell titer glo assay. Tracer biodistribution was determined in BALB/c nude mice bearing subcutaneous GLP-1R positive tumours. To determine therapy response, tumours of 2 groups of mice (N = 8 per group, 1 group injected with 20 µg exendin-IRDye700DX and 1 control group injected with PBS) were exposed to 120 J/cm^2 of NIR LED light of 690 nm. Mice were sacrificed when tumours reached a size of 1000 cm^3.
Results: Exendin-IRDye700DX has a high affinity for the GLP-1R with an IC_{50} value of 6.3nM, which is comparable to unlabeled exendin. In CHL-GLP1R cells as well as INS-1 cells, NIR light reduced cell viability in a dose-dependent manner with 0% viability reached at 175 J/cm^2. PANC-1 cells, which do not express the GLP-1R remained 100% viable with this tracer dose and light-intensity. Injection of 0.3 µg exendin-IRDye700DX resulted in an *in vivo* tumour uptake of 12.8 ± 6.4%ID/g, which decreased with increasing peptide doses. The survival of mice treated by PDT with exendin-IRDye700DX was significantly increased compared to control mice ($p < 0.05$).
Conclusion: These data show *in vitro* as well as *in vivo* evidence for the efficacy of tPDT using exendin-IRDye700DX. This could be a promising new therapeutic option for GLP-1R positive lesions.
Disclosure: Nothing to disclose

P0748 LOCALIZATION OF INSULINOMAS WITH ^{68}GA-NODAGA-EXENDIN-4 PET/CT

Introduction: Insulinomas are usually small, single benign tumors. Surgery is the therapy of choice and precise preoperative anatomical localization of the tumor is essential. Imaging techniques like CT, MRI as well as somatostatin receptor (SSTR) imaging have limited sensitivity (1,2). The stable glucagon like peptide-

1 (GLP-1) analog exendin specifically binds to the GLP-1 receptor (GLP-1R) (3), which is markedly upregulated/overexpressed in insulinomas (4).
^{68}Ga-DOTA-exendin-4 PET/CT has been shown to be feasible in detecting insulinomas. Replacing the chelator DOTA by NODAGA in the labeling process ensures higher specific activities, allowing imaging with sub-pharmacological peptide doses. We propose ^{68}Ga-NODAGA-exendin-4 PET/CT as a promising new method for improved localization of insulinomas.
We here present the first data of a multi center prospective imaging study to evaluate the effectiveness of ^{68}Ga-NODAGA-exendin-4 PET/CT.
Aims and Methods: 33 adults aged 24-65 with biochemically proven hyperinsulinemic hypoglycemia were included. PET/CT images were obtained one and two hours after injection of (5–7 μg) 95–105 MBq ^{68}Ga-NODAGA-exendin-4. Current standard imaging was performed within 8 weeks of ^{68}Ga-NODAGA-exendin-PET in all patients, consisting of CT or MRI and SSTR PET imaging.
Results: ^{68}Ga-NODAGA-exendin-4 PET imaging confirmed insulinoma, i.e., GLP-1R positive lesions, in 25 of the 33 patients with suspected insulinoma. In 15 of these patients, insulinoma were also confirmed by conventional imaging as well as Sst-receptor PET. In two patients, conventional imaging could not confirm the presence of an insulinoma while Sst-receptor PET as well as ^{68}Ga-NODAGA-exendin-4 PET were positive. In one patient, an insulinoma was found using conventional imaging and ^{68}Ga-NODAGA-exendin-4 PET, while Sst-receptor PET was negative In 5 patients, all other imaging modalities were negative and an insulinoma could only be visualized by ^{68}Ga-NODAGA-exendin-4 PET. In one MEN1 patient, multiple NETs were visualized by conventional imaging and Sst-receptor PET, but no decisive answer could be given on which of these lesions produced insulin leading to recurrent hypoglyceamias. In this patient, ^{68}Ga-NODAGA-exendin-4 PET/CT confirmed only one GLP-1R positive lesion. In all patients, GLP-1R positive lesions were pathologically confirmed to be insulinoma. In 7 patients, insulinoma could not be confirmed despite a positive Whipple's triad with any of the imaging techniques applied, including ^{68}Ga-NODAGA-exendin-4 PET. This result may indicate that false positive results can be excluded following ^{68}Ga-NODAGA-exendin-4 PET.
Conclusion: In conclusion, ^{68}Ga-NODAGA-exendin-4 PET/CT performed better than standard imaging methods, which indicated it is a promising new technique for non-invasive pre-operative detection of insulinomas.
Disclosure: Nothing to disclose

Introduction: Gastroenteropancreatic neuroendocrine tumours are a rare group of neoplasia, with an incidence of approximately 2.5–5/100000 people. These tumours can be non-functioning or functioning, consisting of a clinical and biochemically heterogeneous group of tumours.
Aims and Methods: In this retrospective single-center study, clinical, pathological and prognostic characteristics of gastroenteropancreatic neuroendocrine tumours were evaluated and compared with current medical knowledge. 70 patients diagnosed with an histological diagnosis of gastroenteropancreatic neuroendocrine tumours between 2008 and 2017 were included
Results: Pancreas was the most common primary location (48.6%), followed by small intestine (27.1%), ileocecal appendix (8.6%), stomach (7.1%), colon (2.8%), mesentery (1.4%) and liver (1.4%). Metastasis were detected by the time of diagnosis in 25 patients (35.7%), which had a mortality of 24%, higher than the mortality between patients without metastasis by diagnosis (15.5%). Female patients had metastasis more often than males (42.4% vs 29.7%); however, mortality was higher in male than female patients (21.6% vs 15.2%). According to primary location, metastasis were more commonly encountered in small intestine tumours (42.1%), followed by stomach (40%), pancreas (29.4%) and ileocecal appendix (16.7%). Mortality was higher in gastric tumours (60%), followed by pancreas (20.6%) and ileocecal appendix (16.7%). No patients with small intestinal tumours died during the follow-up. Patients were treated with surgery (61.4%), surgery and chemotherapy (27.1%) or isolated chemotherapy (7.1%).
Conclusion: Survival was higher in patients whose treatment included surgery, compared to those where surgery was not performed. Retrospective studies including patients with gastroenteropancreatic neuroendocrine tumours contribute to identify patients with worse prognosis and the most effective therapies, therefore allowing a more individualized, tailor made approach to these tumours.

Introduction: Endoscopic ultrasound-*fine needle aspiration* (EUS-*FNA*) has a significant role in diagnosing pancreatic tumors. Pancreatic neuroendocrine neoplasm (P-NEN) accounts for about 2–3% of pancreatic tumors, and the usefulness of EUS-FNA in P-NEN is has recently been reported. However, the ability of EUS-FNA to assess the degree of malignancy of P-NEN in pathologic diagnosis remains an issue.
Aims and Methods: This retrospective study evaluated data from clinical records that were collected prospectively. During April, 2012 to March, 2018, 169 consecutive patients with pancreatic lesions underwent EUS-FNA, 12 patients from whom a pathologic diagnosis of P-NEN was obtained were studied. Patient background and factors related to the procedure were studied. Regarding 8 patients to whom EUS-FNA was performed, the concordance rate between EUS-FNA and the operated samples in diagnosing the degree of malignancy were evaluated.
Results: The background of the 12 patients with PNEN were: male to female ratio, 4 to 8; median age, 61 yrs. [range: 31–81 yrs.]; site of lesion, pancreatic head/body and tail: 6/4; median longest diameter of the lesion: 18mm [range 8–50mm]. As factors associated with the procedure: diameter of the needle, 19G/20G/22G/25G, 5/1/7/2 (2 cases with combined use of 19G and 22G, and 1 case with combined use of 22G and 25G); median number of punctures, 4 times [range 3–6 times]; with/without side port, 6/6; slow pull/aspiration, 9/3; median procedure time, 43 min. [range 16–64 min.]. There were no complications associated with EUS-FNA.
The diagnosis made regarding malignancy were compared between that by EUS-FNA and that by the operated sample in 8 patients who received the procedure; they were G1, 6/4; G2, 2/4. The concordance was k coefficient 0.5.
Disagreement was found in 2 cases; both of the cases were diagnosed as G1 by EUS-FNA but as G2 with the operated sample. The sites of the lesion of the disagreed cases were the pancreatic head in 1 and the pancreatic body in 1. Regarding puncture needles, combined use of 22G/25G was in 1 and 22G in 1.
Conclusion: EUS-FNA has been performed safely for P-NEN. There was no problem in EUS-FNA in its histological diagnostic yield of P-NEN, but regarding diagnosis of malignancy, the concordance rate with operated samples was low, indicating the need for further devise.

Introduction: Platelet-rich plasma (PRP) is a concentrate of platelet-rich plasma protein derived from whole blood, centrifuged to remove red blood cells. Although PRP has been shown to promote healing and regeneration in various of tissue, little is known about its effect on gastric ulcer. This study aimed to investigate the efficacy of endoscopic application of autologous PRP on artificial gastric ulcer after endoscopic submucosal dissection (ESD).
Aims and Methods: A prospective randomized placebo-controlled trial was conducted at a single tertiary hospital. Consecutive patients who underwent ESD for gastric neoplasm were randomly assigned to the PRP or control group. Immediately after ESD, prepared autologous PRP or saline was applied to artificial ulcer. The ulcer diameter was measured immediately after ESD, 2nd week, and 4th week after the procedure using endoscopic ruler. The efficacy of PRP for healing of artificial ulcer was evaluated based on the ulcer size and the occurrence of post ESD complications between the two groups.
Results: Overall, twenty patients were enrolled in this pilot study (PRP group 10, control 10, age, mean ± SD, 61.00 ± 10.15, male 11). Baseline characteristics did not differ between the two groups. The mean size of long diameter of ulcer immediately after ESD was significantly larger in the PRP group than in the control (51.00 ± 11.26 vs. 38.50 ± 8.52, $p = 0.012$). When the changes in ulcer size were compared between the two groups, the mean ulcer size decreased more in the PRP group than in the control group at 2 weeks (1648.20 ± 1004.66 vs. 851.60 ± 502.53, $p = 0.043$), and 4 weeks (1898.20 ± 1021.18, 1096.30 ± 553.40,

p = 0.047) after ESD. Post ESD bleeding rate was not different between the groups. No adverse events related to the application of PRP were occurred.
Conclusion: Endoscopic application of PRP may be effective treatment modality for artificial gastric ulcers after ESD. Further larger studies are required to apply it to the clinical setting.
ClinicalTrials.gov (NCT03220334)

[2]*Serviço de Cirurgia Geral, Centro Hospitalar São João, Porto, Portugal*

Contact E-Mail Address: ruimorais20@gmail.com
Introduction: Upper gastrointestinal transmural defects are associated with a high morbidity and mortality. Stents are the first-line endoscopic approach, however, their efficacy varies considerably and are associated with important adverse events (AEs). Endoscopic vacuum therapy (EVT) is a new approach to this condition.
Aims and Methods: The objective of this study was to evaluate the preliminary efficacy and impact of EVT in the treatment of upper gastrointestinal transmural defects.
Single-center retrospective study that evaluated patients with upper gastrointestinal transmural defects undergoing EVT. EVT was performed using the Endo and Eso-Sponge system (B. Braun, Melsungen, Germany). Continuous negative pressure of 100 mmHg, generated by an electronic vacuum pump system was applied. Whenever possible the sponge was placed in an intracavitary position. Sponge replacement was performed every 3–7 days.
Results: Five patients (3 males) with a median age of 58 years were referred for EVT due to anastomotic leak after distal esophagectomy (n = 2), gastrojejunal leak following Roux-en-Y gastric bypass (n = 1), gastropleural fistula post-sleeve gastrectomy (n = 1) and esophageal-pleural fistula after esophageal diverticulectomy (n = 1). In 60% of cases, the size of the cavity was greater than 20 mm. EVT was used as the first-line endoscopic treatment in 1 patient and in the remainder after stent failure. Stent-over-sponge technique was performed in one patient. After a median of 5 procedures (IQR 4–6), complete closure of the defect was seen in 2 patients (40%). In another patient, after almost complete reduction of the cavity, effective closure was achieved after application of an OTSC (Ovesco, Tuübingen, Germany). These 3 patients were discharged after a median of 43 days (IQR 39–50) since the beginning of EVT therapy. In the remaining 2 patients, there was a decrease in dimensions of the defect, without closure, with placement of a biodegradable stent in one and need of revision surgery in the other patient.
Conclusion: EVT is a promising approach in the treatment of upper gastrointestinal transmural defects, even after stent failure. It appears to be most effective when performed intracavitarily. Despite the need for multiple procedures, it can lead to complete closure of the defect, avoiding the need for surgery.

Introduction: Endoscopic submucosal dissection (ESD) has been established as a standard therapy for treating early gastric cancer and adenoma. After ESD, artificial gastric ulcers are created. These ulcers sometimes cause complications, such as delayed bleeding and perforation. Therefore, they should be healed at the earliest. Conventional proton pump inhibitors (PPIs) have been widely used for treating ESD-induced gastric ulcers. Although PPIs are proven to shrink such ulcers, some ulcers fail to heal. Therefore, a more effective therapy is needed. Vonoprazan is a novel suppressant of gastric acid secretion and an active potassium-competitive acid blocker (P-CAB). Similar to PPIs, P-CABs inhibit gastric H+/K+-ATPase; however, unlike PPIs, P-CABs inhibit the enzyme in a K+-competitive and reversible manner. Thus, vonoprazan is more potent with a more long-lasting effect than PPIs. Although vonoprazan is expected to be superior to PPIs, and to heal ESD-induced gastric ulcers earlier than the conventional PPI-based therapy, its efficacy in treating these ulcers remains unclear.
Aims and Methods: We aimed to evaluate the effectiveness of vonoprazan in healing artificial ulcers after ESD. Patients with gastric tumor were randomly assigned to the vonoprazan group (group V) or the lansoprazole group (group L) after ESD. The exclusion criteria were as follows: remnant stomach, administration of antithrombotic agents, complication during and after ESD, need for additional surgery, and unwillingness for study participation. Patients were administered 30 mg intravenous lansoprazole twice on the day of ESD. From postoperative day2, patients in group V received 20 mg/day vonoprazan and those in group L received 30 mg/day lansoprazole. Esophagogastroduodenoscopy was performed 4 and 8 weeks after the ESD. During the following endoscopy, the length and width of the artificial ulcer were evaluated using measure forceps. The ESD ulcer index was calculated by multiplying the length with the width of the resected specimen. The 4- and 8-week ulcer indices were also calculated by multiplying the length with the width of the artificial ulcer at 4 and 8 weeks after ESD, respectively. The primary endpoint was the healing rate for the artificial ulcer at 4 weeks after ESD. Secondary endpoints were the healing rate at 8 weeks,; shrinkage rates for the artificial ulcers at 4 and 8 weeks; and complications, such as delayed bleeding and perforation.
Results: Of the 263 patients who underwent ESD from April 2015 to December 2017, 182 patients (90 in group V and 92 in group L) were eligible for the study. Thirteen patients were excluded during follow-up because of complications or the need for additional surgery. Finally, 85 patients were allocated to group V and 84 to group L. The age, sex, status of *Helicobacter pylori* infection, tumor location, and ESD ulcer index of the two groups did not differ significantly. The 4-week healing rate for artificial ulcers was not significantly higher in group V (17/85, 20.0%) than in the group L (14/84, 16.7%). Further, there were no significant differences between the 4-week shrinkage rates of group V (92.4%) and group L (92.5%). Delayed bleeding was observed in 3 subjects of group L; however, no subject of group V had delayed bleeding. One patient in group V presented delayed perforation 2 days after ESD.
Conclusion: Vonoprazan was not superior to lansoprazole in its ability to heal artificial gastric ulcer after ESD.

Introduction: : Gastrointestinal (GI) peristalsis during esophagogastroduodenoscopy (EGD) commonly requires antispasmotic agents which are administered by intravenous or intramuscular injection. Oral Phloroglucin (Flospan®) is a smooth muscle relaxant that is currently used as anti-spasmodic treatment.
Aims and Methods: This study aimed to evaluate the effectiveness and safety of oral Phloroglucin (Flospan®) as premedication for non-sedative EGD. A Prospective, double-blinded, placebo-controlled, randomized clinical trial was conducted at a single tertiary hospital. Subjects who scheduled to undergo non-sedative EGD were randomly assigned to receive oral Phloroglucin (Flospan®) and placebo at 10 minutes before EGD. The primary outcome was the degree of peristaltic movement which was graded from 1 (none) to 5 (very severe). The secondary outcomes include the degree of endoscopist's subjective difficulty for peristalsis and adverse effect.
Results: Overall, 140 subjects were included in the study (Phloroglucin 70, placebo 70, age mean ± SD, 66.31 ± 9.37, male 47.8%). The degree of peristalsis was significantly lower in phloroglucin group at initial of test. (Phloroglucin vs Placebo, 1.97 ± 0.92 vs 2.39 ± 1.15, p = 0.02). But there was no significant difference at last of test. (Phloroglucin vs Placebo, 2.27 ± 1.17 vs 2.63 ± 1.10, p = 0.064) The degree of endoscopist's subjective difficulty for peristalsis in phloroglucin group was also lower than placebo. (Initial of test : Phloroglucin vs Placebo, 1.93 ± 0.77 vs 2.34 ± 0.81, p = 0.002 / Last of test: Phloroglucin vs Placebo, 2.13 ± 0.96 vs 2.53 ± 0.83 p = 0.009). There was no difference in the willingness to take this premedication at next examination between two groups (Phloroglucin vs Placebo, 94.3% vs. 98.6%, p = 0.366). Most of subjects in each group answered the taste of the drug was good or very good. There were no significant adverse events besides each one participants who complained of dry mouth or dizziness in the placebo group.
Conclusion: Oral Phloroglucin (Flospan®) significantly suppress peristalsis during non-sedative EGD with no adverse drug reactions compared with placebo. (Clinical trial registration number: NCR03342118)

Introduction: Endoscopic therapy is effective in achieving hemostasis of bleeding peptic ulcers. Based on a systematic review, hemoclips or the combined use of injection therapy with thermal coagulation is recommended for the treatment of bleeding peptic ulcers. Recently, monopolar electrocoagulation using a soft-mode coagulation system and hemostatic forceps has been applied for the treatment of patients presenting with acute peptic ulcer bleeding. In this method, it is possible to control the bleeding by grasping with hemostatic forceps the hard base of the ulcer, and coagulation is achieved without carbonization or sparking because the voltage is held below 200V, thereby preventing perforation due to excess damage compared with conventional thermal coagulation. Several randomized controlled studies showed the efficacy of soft coagulation for hemostasis of peptic ulcer bleeding. However, there are few reports on the risk factors for treatment failure because the sample size is small. The aim of this study was to clarify the risk factors for hemostatic failure of soft coagulation.
Aims and Methods: This retrospective study included all 313 patients with peptic ulcers who were treated using monopolar soft coagulation in our department between January 2005 and December 2015. Endoscopic hemostasis with soft coagulation was performed if a patient with hematemesis or melena was admitted and presented with an actively bleeding ulcer (spurting or oozing), a non-bleeding visible vessel, or an adherent clot. Endoscopic hemostasis with soft coagulation was performed using monopolar hemostatic forceps (FD-410LR, Olympus Co.,Tokyo,Japan or HDB2418W, Pentax Co., Tokyo, Japan) and an electrosurgical unit (ICC-200, ERBE, Tübingen, Germany) at soft-mode coagulation with a 70W current. If hemostasis was not achieved using this method, injection of hypertonic saline-epinephrine, hemoclip, heater probe or argon plasma coagulation was applied. If the additional endoscopic treatment was still unable to stop the bleeding, intervention radiology or surgical treatment was performed. Rebleeding was defined as blood in the stomach and stigmata of a recent hemorrhage at the ulcer base when second-look endoscopy was performed, or fresh hematemesis and/or melena accompanied by either instability of vital signs or reduction in hemoglobin level of greater than 2g/dl within 24 hours. Factors associated with treatment failure of soft coagulation were analyzed.
Results: The study subjects were 207 men and 106 women at a median age of 69 (range, 28–97) years, with 242 gastric ulcers and 71 duodenal ulcers. Initial hemostasis with soft coagulation was achieved in 296 patients (94.6%). Of the 17 patients with treatment failure, additional endoscopic methods were required in 15, intervention radiology in 1 and surgery in 1. Rebleeding occurred in 21 patients (6.7%). Minor perforation occurred in 2 patients, and was managed conservatively in both patients. Three patients died of ulcer bleeding within 30 days of the occurrence of initial bleeding. Initial hemostasis with soft coagulation was significantly associated with an exposed vessel. In multivariate analysis, rebleeding was significantly related to duodenal ulcer and elderly patients.
Conclusion: Soft coagulation using a monopolar hemostatic forceps is effective and safe for patients with gastroduodenal ulcer bleeding. However, duodenal ulcer bleeding, exposed vessels and elderly patients are risk factors for treatment failure.

Introduction: Launching a professional program of endoscopic submucosal dissection (ESD) for the treatment of early gastrointestinal neoplasia in Western countries may be fastidious and is still debated.
Aims and Methods: After practicing few ESDs in selected indications, we sought to develop a structured ESD program by sending two advanced endoscopists (AL, VH) for 7 weeks to Japan (2015, Keio Cancer Center, Pr Yahagi) for lesion recognition and ESD learning, watching 95 ESD procedures, and performing 18 ESD on isolated pig stomach models. Further hands-on was performed on living pigs before treating patients. All ESDs were from then concentrated on these 2 operators, starting treating patients following European guidelines in June 2015. Here, we analyse the safety and efficacy of ESD from the beginning of our program. Clinical and technical data were prospectively collected from June 18th 2015 to April 10th 2018, excluding ESD performed by guest experts during live demonstrations. R0 resection rate was defined as clear margins (no dysplasia / no adenoma for lateral margins and clear vertical margin). Curative resection was defined following European ESD guidelines. All ESD were performed under general anaesthesia using a 20% glycerol submucosal injection solution and for 98% of them an adjustable tip electrosurgical knife for dissection.
Results: One hundred ESDs were performed in 98 patients (40% female; aged 68(27–98) years old) by two operators (AL,VH). Lesions were located for 29% in the oesophagus (11/29 squamous cell carcinoma), 21% in the stomach, 41% in the rectum and 9% in the colon. En-bloc resection rate was 98%, complete endoscopic resection rate was 95%. R0 resection rate was 67% globally (8% with positive vertical margin; 2% with carcinoma in the lateral margin). In detail, R0 resection rate was 79%, 84% and 57% for oesophageal, gastric and colorectal lesions respectively. Median specimen size was 40 (15–160) mm. Median procedure duration was 120 (IQR 90–180) min. In 92% of cases, there were none or conservatively managed complications. Two patients needed endoscopic hemostasis for delayed bleeding, 4 presented secondary stenosis requiring dilations, one urgent surgery for sepsis after colonic perforation. Pathological analysis revealed a carcinoma in 82% of oesophageal lesions (18 pTis/pT1a; 6 pT1b), in 28% of gastric lesions (3 pT1a; 3 pT1b) and 32% of colorectal lesions (7 pTis/9 pT1). A neuroendocrine tumor was present in 1 oesophageal, 5 gastric and 2 rectal cases. Curative ESD was obtained in 70% of cases and 15 patients required complementary oncological surgery with 61% of them having no residual tumor in the organ and negative lymph nodes. When endoscopic follow-up was recommended, data were obtained in 71% of cases with a median of 7 (range 1–24) months length and no recurrence of the lesion observed in 95% of cases. Pathological specimen processing was revised after the first 6 months implementing Japanese standards and increasing the rate of free lateral margins from 47 to 75%. For the rectum, despite a 29% positive (adenoma) lateral margin rate, 100% of patients were free of residual adenoma at the end of endoscopic follow-up, suggesting coagulation artefact effect on the specimen.
Conclusion: Nowadays, launching an ESD program in an academic European Center by experienced therapeutic endoscopists, after an observation period in an expert Japanese center, is possible, safe and quick with good results in terms of en-bloc resections and outcomes. Technical and pathological analysis efforts must be done to decrease positive lateral margins.

Introduction: Endoscopic submucosal dissection (ESD) is a difficult procedure due to lack of counter traction for unskilled endoscopists. Recently, auxiliary devices have been developed to alleviate the difficulties of ESD. We also developed new endoscopic technique using robotic manipulator. The purpose of this study is to evaluate the efficacy and safety of endoscopic detachable auxiliary manipulator (EDAM) *in vitro* animal study
Aims and Methods: A novel robotic manipulator is composed of a control panel and a working arm, which grasp and move objects at the end of scope. A total of 40 porcine stomachs were used for the test. Endoscopists were classified as expert or novice. As a preliminary work, operation time and perforation rate of the experts and novices were recorded when ESD was performed by the conventional method. (C-Expert group, C-Novice group). The same experiment was performed using EDAM (M-Expert group, M-Novice group). During this procedure, robotic manipulator lifts up dissected tissue of stomach to make better visibility. The results were compared.
Results: The safety of the operation was greatly improved when using the EDAM. Perforation rate of the EDAM method was significantly lower than that of the conventional method in the novice group. (10% vs 60%, $p = 0.002$) There was no significant difference between the conventional method and the EDAM in the operation time in the novice group.
Conclusion: As a result of this *In-vitro* test, the EDAM significantly improved the safety of ESD in the case of the novice, with no increase in operation time.

P0758 DOES SECOND-LOOK ENDOSCOPY PREVENT POSTOPERATIVE BLEEDING IN HIGH-RISK PATIENTS AFTER GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION?: A PROPENSITY SCORE-MATCHING ANALYSIS

K. Ishikawa, D. Maruoka, M. Arai, T. Matsumura, N. Akizue, K. Okimoto, T. Nakagawa, N. Kato

Contact E-Mail Address: ii9902001@yahoo.co.jp
Introduction: Postoperative bleeding (POB) is the most common and highly frequent complication in gastric endoscopic submucosal dissection (ESD). Several reports have shown that second-look endoscopy (SLE) does not significantly prevent POB in low-risk patients for bleeding (LRPs) [1], whereas it is currently performed in most institutions for high-risk patients for bleeding (HRPs). However, no studies have reported the use of SLE for HRPs. Therefore, this study aimed to evaluate the prophylactic effect of SLE on POB in HRPs.
Aims and Methods: [Study 1] HRPs who underwent gastric ESD without SLE between May 2017 and February 2018 were assigned to the non-SLE group. HRPs were defined as patients who were continuously administered low-dose aspirin, those in whom treatment was changed from warfarin or direct oral

anticoagulants to heparin replacement, and those who underwent hemodialysis. This non-SLE group was compared with a historical control group that included patients who underwent SLE after gastric ESD between November 2013 and March 2017 (the SLE group). Data were analyzed using propensity score-matching methods. We used the size of the ESD specimen and comorbidity of diabetes mellitus as covariates according to previous reports [2, 3]. The primary endpoint was POB.
[Study 2] In the entire cohort, the risk factors for POB were analyzed.
Results: [Study 1] Eighty-two patients (96 specimens) underwent gastric ESD, among whom eight (8.3%) encountered POB. After propensity score-matching, 38 subjects (19 subjects in each group) were enrolled. Significantly fewer specimens were detected at the upper location of the stomach in the SLE group than in the non-SLE group ($p = 0.03$), whereas there were no differences in the other background factors between the two groups. No significant differences were observed in the rate of POB between the two groups (SLE group, 5.3%; non-SLE group, 10.5%).
[Study 2] In the entire cohort, the rate of POB of HRPs with two risk factors for bleeding was significantly higher than that of HRPs with one risk factor (30.0% vs. 5.8%, $p = 0.04$; chi-squared test). However, multivariate analyses revealed no independent predictors of POB.
Conclusion: SLE did not reduce the rate of POB after gastric ESD in HRPs. SLE may not be recommended after gastric ESD in HRPs, as is the case in LRPs; however, it is necessary to accumulate and analyze more cases.

Introduction: Operative Link on Gastritis Assessment (OLGA) and Operative Link on Gastric Intestinal Metaplasia Assessment (OLGIM) are superordinate stages system for Gastric risk stratification.
Aims and Methods: The study aimed at evaluating the distribution of OLGA and OLGIM staging and the ralationship with age and other risk factors analysis. 632 patients who underwent endoscopy for functional dyspepsia. *Helicobacter pylori* status and histologic changes were assessed using the updated Sydney system. At least three biopsy pieces (one from the lesser curvature of antrum and corpus,respectively, one from incisura angularis) were acquired. *Helicobacter pylori* status and histologic changes graded by senior gastrointestinal pathologists according to the updated Sydney system. Stage III and IV OLGA or OLGIM stages were considered as high-risk stages.
Results: The proportion of Stage III and IV OLGA or OLGIM stages was remarkably increased with older age. Old age (OR = 4.85 (95% CI: 1.09–21.67, $p = 0.039$), 5.79 (95%CI : 1.30–25.71, $p = 0.021$),and16.61 (95% CI:3.63–76.10, $p < 0.001$) for ages in the 50's, 60's, and older than 70 years, respectively), smoking (OR = 2.07, 95% CI: 1.09–3.95, $p < 0.001$), and *H. pylori* infection (OR = 2.46,95% CI:1.37–3.95, $p = 0.002$) were independent risk factors for high-risk OLGA stages. These risk factors were also for high-risk OLGIM stages. The *H. pylori* infection was positive correction with the OLGA and OLGIM staging, the *H. pylori* positive rate of OLGA and OLGIM Stage 0-IVand IV was 23.1 and 22.4%, 22.9% and 23.9%, 31.4% and 30.8%, 39.5% and 39%, 45.0% and 50.0%, respectively, the proportion of high-risk OLGA stages was low (6.9%) before the age of 50, but increased to 9.5%, 11.7%, and 25.7% for those in their 50s, 60s, and older than 70 years, respectively. High-risk OLGIM stages showed a similar trend.
Conclusion: High-risk OLGA and OLGIM stages are uncommon under the age of 50, The *H. pylori* infection was positive correction with the OLGA and OLGIM staging,thus eradication of *H. pylori* before that age may reduce the requirement for endoscopic surveillance for gastric cancer.

P0760 ARGON PLASMA COAGULATION FOR SUPERFICIAL SQUAMOUS CELL CARCINOMA IN THE RESIDUAL ESOPHAGUS AFTER ESOPHAGECTOMY

K. Saisho, T. Tanaka, S. Matono, M. Naoki, H. Haruhiro, A. Yoshito
Kurume University School of Medicine, Department of Surgery, Kurume, Japan

Contact E-Mail Address: saisho_kouhei@med.kurume-u.ac.jp
Introduction: Patients with esophagectomy for esophageal squamous cell carcinoma (SCC) often develop metachronous SCC in the residual esophagus. Although most of the lesions are detected as superficial SCC at follow-up endoscopy, it is difficult to perform endoscopic resection for lesions near the anastomosis. We have performed argon plasma coagulation (APC) for such superficial SCC in the residual esophagus. The aim of this study is to evaluate the usefulness of APC for superficial SCC in the residual esophagus after esophagectomy.
Aims and Methods: The aim of this study is to evaluate the usefulness of APC for superficial SCC in the residual esophagus after esophagectomy. Twelve patients (15 lesions) with superficial SCC in the residual esophagus after esophagectomy underwent APC at our institution, from September 2007 to October 2016. The indications for APC was tumor in situ or mucosal cancer in the residual esophagus. We retrospectively evaluated the treatment outcomes after APC. The median of follow-up duration after the initial APC was 43 months (range: 28–103 months).
Results: The median number of treatment courses per lesion was 1 (range, 1–12 courses). The median treatment time of APC was 17 minutes (range, 4–33 minutes). There were no treatment-related complications. Complete remission (CR) was achieved in 13 (86.7%) of 15 lesions; 11 lesions (73.3%) achieved CR after the first APC course, and 2 lesions (13.3%) achieved CR after 2 or more APC courses. Of the 2 patients with residual tumor, 1 patient received 12 courses of APC over 6 years and achieved local control without metastasis. Another patient received radiotherapy (60Gy) after treatment failure with APC. He later developed local recurrence after 2 years of complete response. He underwent cervical esophagectomy and free jejunal graft reconstruction. Death occurred in 2 patients: 1 died of non-cancer-related cause and the other died of other primary malignancy.
Conclusion: APC was a safe and effective treatment, and was technically easy to perform. APC might be an alternative to endoscopic resection for superficial SCC in the residual esophagus after esophagectomy.

Introduction: Maintaining good operative field is crucial in performing endoscopic submucosal dissection (ESD) for early stage gastrointestinal tumors, but it often requires high skill or special equipment depending on the lesion location. In ESD for the lesions at the lesser curvature of the gastric body, it is often difficult to approach the lesions, although early gastric cancers are often detected at this area. A multi-bending endoscope (Olympus) is a good option for such a situation, but it is difficult for most operators to prepare it due to its particularity or cost.
Aims and Methods: We therefore recently developed handmade multi-bending system (HMBS) and performed ESD using it for 11 lesions which were located at the lesser curvature of the gastric body and tended to be difficult to approach. A fishing line was passed through the external tube (Crusher catheter, Zeon Medical, Japan), and the tip of external tube was fixed about 15–20 cm apart from the tip of the gastroscope (Olympus or Fujifilm). The fishing line was bound and fixed at the original first bending portion. Second bending portion was created by pulling the fishing line through the external tube, and fixed with three-way stopcock according to the situation during the procedure. HMBS were used at our hospital between February 2017 and August 2017. In this study, we retrospectively investigated the treatment outcome of ESD with HMBS (N = 11) for the lesions located at the lesser curvature of the gastric body and difficult to approach, and compared it with the treatment outcome before the adoption of HMBS (Conventional, N = 11). ITknife2 (Olympus), Flushknife BT (Fujifilm), or both endoknives were used for ESD. This study was approved by the ethical committee.
Results: Average tumor diameter and resected specimen diameter of Conventional and HMBS were 16.6mm vs 16.5mm, and 36.2mm vs 37.8mm (not significant), respectively. In all cases to which we applied HMBS, the tip of the endoscope could be closely approached to each lesion just after using HMBS, although it was difficult to approach the lesion without HMBS. Procedure time of HMBS (34.3minutes) was significantly shorter than that of conventional (61.5 minutes) ($p = 0.01$). In all cases, en bloc resections were achieved, and no perforation or other complication occurred.
Conclusion: This study demonstrates our handmade multi-bending system may greatly shorten the procedure time of ESD for the lesions which are located at the lesser curvature of the gastric body and difficult to approach.

Introduction: The over-the-scope clip (OTSC) is a technology that is increasingly incorporated into endoscopic practice and is utilized for applications including fistula closure, control of bleeding, perforation, management of anastomotic

leaks, endoscopic full thickness resection (EFTR), and luminal stent fixation. Our study evaluated a large body of literature to determine the overall efficacy and safety of OTSC.

Aims and Methods: A Medline search was conducted from inception to October 1st, 2017. The following search terms were used: ''over the scope clip'', ''OTSC'', ''Ovesco'', ''endoscopic fistula closure'', ''over the scope clip bleeding'', and ''endoscopic perforation closure''. Publications selected for inclusion consisted of case reports, case series, as well as prospective and retrospective single-arm clinical studies. Data were collected from each study on technical success, clinical success, and reported adverse outcomes. Weighted means (Table 1) were calculated to adjust for sample size.

Results: 238 papers were selected that met the search criteria: 81 case series/retrospective reviews/prospective studies (Group A) and 157 case reports (Group B). In Group A, technical success of OTSC placement was 95.3%, with a clinical success of 77.2% (n = 2285 patients). Indications for OTSC placement were fistula closure (30.6%), bleeding (28.9%), perforation closure (16.3%), leaks (15.1%), EFTR (8.4%) and stent fixation (0.7%). Clinical success for each indication (weighted means) is listed in Table 1. Complete luminal obstruction (one) was the only reported adverse event across all studies. 24/81 papers reported the need for surgery despite OTSC placement. In these 24 papers, total of 90/673 (13.4%) patients required surgery despite OTSC placement.

In Group B, OTSC was deployed in 177 patients. Indications for OTSC placement were fistula closure (37.9%), perforation closure (33.9%), bleeding (14.1%), EFTR (7.9%) and leaks (6.2%). Pooled technical success in this group was 99% and clinical success was 96.0%. 7/177 (4%) patients required surgical intervention despite OTSC placement. Complete luminal obstruction in 1/177 patients and small bowel fixation with pneumoperitoneum in 1/177 patients were the only OTSC-related adverse events reported.

Conclusion: OTSC is a safe and effective, surgery-sparing, endoscopic tool in today's GI practice with 77–96% of patients achieving clinical success without the need for further intervention. Technical success of > 95% has been reported across all indications. Surgical salvage is still needed in a minority of patients.

	Sample Size	Weighted Mean
Overall Clinical Success	2285	77.2%
Fistula Closure	700	61.7%
Bleeding	660	84.3%
Perforation	373	86.3%
Anastomotic Leak	346	72.9%
EFTR	191	92.5%
Stent Fixation	15	80.0%

[Table 1: Observation Studies Pooled Sample Sizes and Weighted Means of Overall Clinical Success and Individual Indications for OTSC placement]

Introduction: Patients after endoscopic treatment of Barrett's esophagus (BE) related neoplasia (BORN) should undergo regular endoscopic surveillance with biopsies to detect recurrent intestinal metaplasia (IM) or neoplasia (N). Probe-based confocal laser endomicroscopy (pCLE) offers detailed examination of cellular structures and may examine larger areas compared to standard biopsy. The role of pCLE in the surveillance of patients after endoscopic treatment of BORN has not been systematically assessed.

Aims and Methods: The aim of this prospective study was to evaluate the efficacy of pCLE (vs. standard biopsies) in detection of persistent/recurrent IM/neoplasia in patients after endoscopic treatment of BORN.

A single center, prospective, controlled and pathologist-blinded (still ongoing) study in patients undergoing surveillance endoscopy after endoscopic treatment of BORN. pCLE images were obtained from the neo-Z-line (in few cases including macroscopically visible tongues), the cardia and the esophagus. Thereafter, standard biopsies were taken and sent for histopathological analysis (minimally 4 biopsies from macroscopically normal neo-Z-line, 2 biopsies from the cardia and the esophagus and targeted biopsies from visible abnormalities, if present).

Intestinal metaplasia (IM) on pCLE was defined by the presence of regular capillaries in upper and deeper parts of the mucosal layer along with identification of dark (''non-refractile'') mucin in goblet cells in columnar-lined mucosa. The dysplastic BE was characterized by black cells with irregular borders and shapes, high dark contrast to the surrounding tissue, and irregular leaking capillaries in the mucosa.

Results: We examined 39 patients (33 males, 6 females), from these 15 patients (38.5%) had the initial diagnosis of low-grade intraepithelial neoplasia (LGIN), 9 patients (23%) had high-grade intraepithelial neoplasia (HGIN) and 15 patients (38.5%) had an early adenocarcinoma (EAC). Four patients (10%) underwent endoscopic resection (ER), in 21 patients (54%) we performed ER or dissection of all visible lesions followed by radiofrequency ablation (RFA), and 14 patients (36%) had RFA as a single treatment modality.

Persistent/recurrent IM was detected only at the level of neo-Z-line in 10 patients (26%, 10/39 pts) by both standard biopsies and pCLE.

pCLE but not biopsies detected persistent/recurrent IM in 2 patients (5%, 2/39), another 2 patients had IM present in biopsies but not in pCLE.

pCLE diagnosed one patient with recurrent LGIN in a macroscopic visible tongue arising from neo-Z-line, which was not confirmed in biopsies.

Sensitivity and specificity of pCLE in detection of persistent/recurrent IM was 83% (95% CI 51.6–97.9) and 93% (95% CI 75.7–99.1), respectively, with a positive predictive value of 83% (95% CI 56.3–95.1) and a negative predictive value of 93% (95% CI 77.8–97.8). Agreement of pCLE and histopathological findings was 90%.

Conclusion: pCLE seems comparable to standard biopsies in detection of persistent/recurrent IM after endoscopic treatment of BORN.

Supported by a grant from Ministry of Health of the Czech Republic, No. 16-27648A.

P0764 THE ROLE OF ENDOSCOPIC DILATION AND STENTS IN THE REFRACTORY BENIGN ESOPHAGEAL STRICTURES: A RETROSPECTIVE ANALYSIS

Q. Lu, **X. Zhu**, H. Ma, J. Yang
West China hospital of Sichuan university, Chengdu, China

Contact E-Mail Address: 2358856583@qq.com

Introduction: To alleviate the symptoms of dysphagia, in addition to frequent endoscopic dilation, the esophageal stents more and more were used for patients with refractory benign esophageal strictures (RBES). Our objective was to explore the role of endoscopic dilation and stents in the long-term management of RBES.

Aims and Methods: This study including patients with RBES (recurrence of dysphagia despite endoscopic therapy more than 3 sessions) by dilation and stents between January 2009 and December 2017. Endoscopic therapy success was defined as: before the end of the follow-up, no need for endoscopic interventions for at least 6 months. The primary outcome was to establish a risk-scoring model predicting RBES in benign esophageal strictures, and clinical effectiveness and adverse events. Secondary outcome was to identify factors that predicted the dysphagia-free period (the time interval of two subsequent endoscopic interventions). Multivariate analysis was used to establish a risk-scoring model and the treatment success. To explore the trend of dysphagia-free period along with times used hierarchical linear models.

Results: In the study, 469 patients with benign esophageal strictures were eligible for the inclusion criteria. The number and length of strictures, age and etiology were independent risk factors for the refractory performance of esophageal benign strictures. According to risk factors of benign esophageal strictures, a risk-scoring model for predicting RBES in benign esophageal strictures was established: the risk score ranged from 0 to 9 points, and the risk scores were divided into low risk (0–2 points), intermediate risk (3–5 points) and high risk (6–9 points). The proportions of RBES in the corresponding risk categories were 10.2%, 42.4% and 87.5%, respectively. Among 469 patients, 75 patients with RBES were eligible for the inclusion criteria. In 75 patients with RBES (54 male; median age, 59 years), 39 (52%), 20 (26.7%), 3 (4%), 10 (13.3%), and 3 (4%) were post-surgical, post-ESD, achalasia of cardia, caustic and mixed etiology, respectively. The median times of endoscopic therapy was 5 times (range 3, 21). Self-expandable metal stents were placed in 20 patients (26.7%), and the success rate of patients treated with dilation (70.9%, 39/55) was higher than with stents (35%, 7/20). Fifteen patients died during follow-up. Nineteen patients had adverse events after endoscopic therapy. In total, the mean dysphagia-free period was 3.4 months (95% CI, 2.5–4.3). The dysphagia-free period of patients treated with dilation was 3.7months (95% CI, 2.7–5), and with stents was 2.3 months (95% CI, 1.5–3). The dysphagia-free period has linear growth trend with times, increased by 12 days per endoscopic therapy.

Conclusion: In this study, 22.6% (106/469) patients with benign esophageal strictures had RBES in our hospital. The risk-scoring model predicting RBES in benign esophageal strictures could predict the long-term outcome of patients with strictures ahead. The main causes of RBES was anastomotic strictures and post-ESD strictures. The etiology of the strictures could affect the outcome of treatment, in which the anastomotic strictures were the prognostic factor for the failure of treatment. After dilation and stents, the dysphagia-free period of RBES increased by 12 days per endoscopic therapy, so the endoscopic therapy tended to be effective in patients with RBES. Compared with the simple dilation, the success rate of RBES with stents was lower and the dysphagia-free period was shorter, so stents therapy tended to not reduce the times and frequency of dilation.

P0765 ENDOSCOPIC SUBMUCOSAL DISSECTION IN EARLY GASTRIC CANCER WITH PAPILLARY HISTOLOGICAL TYPE

J.-H. Lee[1,2], Y.-I. Kim[1], J.Y. Lee[1], C.G. Kim[1], J.I. Choi[1], S.-J. Cho[1]
[1]*National Cancer Cener, Center for Gastric cancer, Goyang, Korea (Republic of)*
[2]*Inha University Hospital, Department of Internal Medicine, Incheon, Korea (Republic of)*

Contact E-Mail Address: endlesmile@naver.com

Introduction: Gastric papillary adenocarcinoma has been regarded as differentiated-type adenocarcinomas along with well- or moderately-differentiated tubular adenocarcinomas in current endoscopic submucosal dissection (ESD) indication. We aimed to investigate safety of ESD in patients with papillary early gastric carcinoma (P-EGC).

Aims and Methods: 4,264 patients with early gastric cancer (EGC) underwent curative gastrectomy between 2000 and 2017 at National Cancer Center, Korea. Among them, 45 patients were confirmed with P-EGC. We compared clinicopathological factors among differentiated-type EGC except P-EGC (n = 2,106), undifferentiated-type EGC (n = 2,113), and P-EGC. Logistic regression model was used to investigate risk factors of lymph node metastasis (LNM).

Results: Frequency of mucosal cancer of P-EGC (22.2%) was significantly lower than those of differentiated-type (48.8%) and undifferentiated-type EGC (60.4%, $p < 0.001$). Angiolymphatic invasion and LNM occurred most frequently in P-EGC (46.9% and 20.0%, respectively) compared to differentiated-type (18.9% and 9.2%, respectively) and undifferentiated-type EGCs (10.9% and 11.7%, respectively; $p < 0.001$ and $p = 0.004$, respectively). P-EGC that was not mixed with other pathological type tended to have increased risk of LNM referent to differentiated EGC. (Odds ratio [OR] 2.53, 95% confidence interval [CI], 0.99–6.50). Among 45 patients with P-EGC, 13 met the current ESD indication; 3 absolute and 10 expanded indications. One out of 13 had LNM and met expanded indication with submucosal invasion less than 500 μm. In multivariate analysis, OR for LNM meeting expanded indication of P-EGC was 40.67 (95% CI, 2.54–702.76) compared to LNM meeting expanded indication of non-papillary EGC (10.28, 95% CI, 1.37–77.04).

Conclusion: When ESD was applied to P-EGC, it should be carefully performed because of high rate of submucosal invasion and high risk of LNM even in with submucosal invasion less than 500 μm.

P0766 A STUDY OF THE POSSIBILITY OF COMPUTER-AIDED DIAGNOSIS USING MULTIPLE MACHINE LEARNING MODELS FOR THE DIAGNOSIS OF UPPER GASTROINTESTINAL ENDOSCOPIC IMAGING

R. Yamakawa, M. Harada, K. Kawauchi, S. Nyuzuki, M. Iwata
Kaetsu Hospital, Gastroenterology, Niigata, Japan

Contact E-Mail Address: yamakawa_r@niigata-min.or.jp

Introduction: There is much diversity in location, disease, the condition of background mucosa, the distance from lesion and magnification percentage in the endoscopic examination of upper gastrointestinal (GI) examination. We reported that computer-aided diagnosis (CAD) with machine learning (ML) was useful for the diagnosis of the location of the upper GI tract in UEGW 2017. However, it is unknown whether it is useful for the diagnosis of disease of the upper GI tract.

Aims and Methods: The aim of this study was to clarify the possibility of CAD using multiple ML models for the diagnosis of disease in the upper GI tract. 15,852 endoscopic images containing 603 images of laryngopharynx, 2,907 images of esophagus, 10,779 images of stomach and 1,563 images of duodenum were selected from a collection of 2,000,000 images, which were taken in our hospital between 2010 to 2017. The imagery was 0.8% of 2,000,000 images described above. In the imagery, there were 1,282 images of early gastric cancer (EGC), 559 images of advanced gastric cancer, 6,006 images of other diseases, and 8,005 images without abnormal findings. They were used as training imagery.

We trained one ML model for the detection of location, and four ML models for the diagnosis of disease of each location (laryngopharynx, esophagus, stomach, and duodenum).

817 endoscopic images were taken in 17 upper GI endoscopic examinations at our hospital in one day of January 2018. There were 26 images of EGC, 65 images of other diseases and 726 images without abnormal findings. They were used as test imagery.

We examined the test imagery by the ML model for the detection of location and then by the ML model for the diagnosis of the disease of the detected location.

Results: Overall, 673 (82%) of 817 images were diagnosed correctly. 18 of 26 images of neoplasm were diagnosed as neoplasm (all of them were EGC) and 8 images were diagnosed as non-neoplasm. 40 of 791 images of non-neoplasm were diagnosed as neoplasm and 751 images were diagnosed as non-neoplasm. The accuracy, sensitivity, specificity, positive predictive value, and negative predictive value of the CAD using multiple ML models were 94%, 69%, 95%, 31%, and 99%, respectively.

Conclusion: This study revealed the possibility of CAD using multiple ML models for the diagnosis of upper GI endoscopic imaging. However, the training imagery contains only 15,852 images (0.8% of 2,000,000 images described above). It is necessary to collect more images, and to consider how to classify the image, and how to use ML model.

Introduction: Endoscopic submucosal dissection (ESD) is the effective treatment method in the gastric adenoma or superficial adenocarcinoma. The one of major parameter to determine the resection method is the size of the lesions. Previous study showed that there were a significant discrepancy between endoscopic and pathologic sizes.

Aims and Methods: The aim of the study was to find the factors affecting size discrepancy occured after formalin fixation, propectively. 69 lesions including 50 gastric adenomas and 19 adenocarcinomas were analyzed for age, sex, location, gross shape, histologic finding, complete resection of ESD, and size immediately after excision and after fixation in formalin.

Results: Size of resected specimen decreased after formalin fixation (37.5mm vs 35.8mm, $p < 0.05$). Mean size of long diameter of the lesion was 20.3 ± 7.7mm in the time of pre-fixation, 13.4 ± 7.9mm after fixation. Size discrepancies in the lesions between endoscopic and pathologic estimate were 7.6 ± 5.7mm in adenomas and 4.6 ± 5.7mm in adenocarcinomas. In the lesions smaller than 20mm, size differences between Pre-fixation and post-fixation were larger significantly compared to that more than 20mm (7.6 ± 5.6 vs 2.5 ± 5.8, $p < 0.01$). In multivariate anlaysis, tumor size $\geq$ 20mm of the lesion was independent factor affecting size increases after formalin fixation ($p < 0.05$).

Conclusion: Endoscopic evaluation of horizontal extent of the lesions before ESD may be incorrect in large tumor more than 20mm in size. It must be resected with more careful approach to prevent incomplete resection.

Introduction: The diagnosis of cancer invasion depth is crucial for selecting the optimal treatment strategy for esophageal cancer. In Japan, magnifying endoscopy with narrow-band imaging (ME-NBI) has been used for diagnosis by observing the esophageal microvasculature architecture. This modality represents a rapid and simple diagnostic procedure without the need for additional equipment. However, some lesions have microvascular patterns which cannot be observed because the intra-epithelial papillary capillary loop is inaccessible.

Endoscopic ultrasonography (EUS) is regarded as the standard modality for diagnosing esophageal cancer invasion depth in the West. EUS is an effective modality, but needs additional endoscopy, is time-consuming, and its cost effectiveness is unknown. We investigated the role of EUS in diagnosing invasion depth in superficial esophageal cancer.

Aims and Methods: Patients with superficial esophageal squamous cell carcinoma (SESCC) and suspected muscularis mucosa or submucosal invasion in non-magnifying white light imaging (WLI) were included. All patients received WLI and ME-NBI observation followed by EUS. WLI was classified into protrusion, granular change, irregular surface, and depression. ME-NBI observation was performed by endoscope with magnification based on the Japan Esophageal Society (JES) classification. EUS was performed using a high-resolution probe by jelly-filled method [1]. Cancer invasion depth was diagnosed as T1a or T1b using each modality. Tumors without changes in the nine-layered structure, or changes involving only the first three layers, were staged as mucosal carcinoma. Tumors involving the first four layers were staged as submucosal carcinoma. All EUS images were assigned a level of confidence to the prediction (high or low). T1b High Confidence was defined as low echoic area in 4/9 layers with repeatability. T1b Low Confidence was defined as low echoic area in 4/9 layers without repeatability.

The diagnostic accuracy of WLI, ME-NBI, and EUS was analyzed while the histologic diagnosis of resected specimen served as reference standard.

Results: From May 2015 to January 2018, 119 patients with esophageal SCC with suspected muscularis mucosa or submucosal invasion in WLI were examined. Of the 119 patients, 31 were excluded from analysis because histologic specimens were not obtained. Eighty-eight patients with 88 lesions treated either by esophagectomy (n = 26) or endoscopic resection (n = 62) were included in the final analysis. Histologic diagnosis was T1a in 44 lesions and T1b in 44 lesions. The accuracy of invasion depth in WLI followed by ME-NBI and WLI, ME-NBI followed by EUS was 70% and 77% ($p = 0.30$), respectively. The overall accuracy of diagnosing invasion depth for lesions with granular change, irregular surface, and depression in WLI followed by ME-NBI and WLI, ME-NBI followed by EUS was 67% (33/49 lesions) and 71% (35/49 lesions) ($p = 0.66$), respectively. The overall accuracy of diagnosing invasion depth for lesions with protrusions in WLI followed by ME-NBI and WLI, ME-NBI followed by EUS was 74% (29/39 lesions) and 85% (35/49 lesions) ($p = 0.26$), respectively. The positive predictive value (PPV) in EUS T1b High Confidence and T1b Low Confidence was 47% (9/19) and 79% (19/24) ($p = 0.06$).

Conclusion: EUS showed a possible additional benefit to WLI followed by ME-NBI for lesions with protrusions. T1b High Confidence in EUS showed higher PPV compared with T1b Low Confidence in EUS which showed marginal

statistical benefit. Therefore, the confidence level in EUS may affect the diagnosis of invasion depth for SESCC.
Disclosure: Nothing to disclose

Introduction: Although the adenoma is a benign neoplasm, those diagnosed with a biopsy specimen sometimes prove to be malignant by pathological evaluation after ESD, indicating that the accuracy of the diagnosis for neoplasm based on a small biopsy specimen is limited. Thus, it is difficult to decide on the indication of endoscopic submucosal dissection (ESD) for adenomas. In addition, therapeutic strategy for gastric adenoma has not been well established and none has reported the appropriate approach to adenomas for the future metachronous multiple lesions. In this study, factors contributing to the decision for removing gastric adenomas diagnosed preoperatively with biopsy specimen were evaluated.
Aims and Methods: Five hundred and thirty-nine lesions of gastric epithelial tumor pathologically diagnosed after complete *en-bloc* curative resection by ESD between 2009 and 2017 were retrospectively reviewed. Among 539 lesions, 62 lesions, diagnosed preoperatively as adenomas, were enrolled in this study. The preoperative endoscopic findings under white light (WL), known as signs of potential cancer, such as a size over 20 mm, red color, tall protrusion, central depression, and positive finding in the assessment under magnified-NBI (M-NBI) were analyzed using Fisher's exact test. The assessment under M-NBI was based on VS classification system by Yao. The removed specimens, pathologically assessed by cutting with every 2 mm of interval, were classified as either cancer or adenoma. In addition, the specimens of well differentiated adenocarcinoma (tub1) were classified into 2 groups, low-grade tub1 and regular tub1. While adenomas are characterized of lesions without A (dysplasia of nucleus and disappearance of differentiation in superficial area) and B (dysplasia of glandular structure with or without invasion to submucosal layer), regular tub1 was characterized of that with A and B. Low-grade tub1 was defined as lesion with A but without B.
Results: Among 62 lesions preoperatively diagnosed as adenoma, 24 (38.7%) proved to be cancer by detailed pathological assessment after ESD. These 24 lesions (tub1) were all pathologically classified as low-grade intestinal type tub1. Among 24 lesions diagnosed as tub1 after ESD, the 4 preoperative endoscopic findings described above under WL were found in 10/2/4/2 lesions (41.7/8.3/16.7/8.3%), respectively. On the other hand, among 38 lesions diagnosed as adenoma, those were found in 9/3/2/1 lesions (23.7/7.9/5.3/2.6%), respectively, indicating that the rate of each factor was higher in tub1 than adenoma although no statistically significant difference was observed. However, the rate of above factors with more than 1 preoperative finding was significantly higher in tub1 group (62.5%(15/24) vs 34.2%(13/38), $p = 0.038$). The rate of positive findings under M-NBI was also higher in tub1 group (54.2%(13/24) vs 23.7%(9/38), $p = 0.028$). We experienced 2 metachronous cases with a scar of previous ESD for benign adenoma. The treatment time was extremely long (252, 323 min, respectively) because of the technical difficulty.
Conclusion: It is important to evaluate macroscopic findings under white light as well as magnified-NBI assessment to decide on the ESD indication for lesions with a preoperative diagnosis of benign adenoma with biopsy specimens. Considering the difficulty to remove lesions with an ESD-related scar in case with metachronous multiple lesion, lesions without risk factors of cancer can be carefully followed-up to avoid the consequent ESD-related scar because of pathologically low-grade malignancy in all cancer lesions diagnosed postoperatively.

P0770 HOW DOES LINKED COLOR IMAGE (LCI)WHICH IS ONE MODALITY OF IMAGE ENHANCED ENDOSCOPY (IEE) CONTRIBUTE TO DETECT OF THE MINUTE TO SMALL EARLY GASTRIC CANCER? A PILOT STUDY

I. Tohru, A. Sadafumi, K. Ken, T. Michiyo, K. Junji, K. Lica, H. Kazu, K. Hidekazu
Kanazawa Medical University, Gastroenterological Endoscopy, Kahoku District, Japan

Contact E-Mail Address: itotohru@kanazawa-med.ac.jp
Introduction: How can you detect minute to small early gastric cancer effectively? It is the theme that is the most important to gastric cancer screening.
If minute to small early gastric cancer is detected by untechnical Endoscopist it is effective at all.
Therefore we examined whether a detection rate of the early gastric cancer was raised by using LCL which was one of the modality of IEE which Fuji Film Company developed.
Aims and Methods: LCI expands color differences so that reddish color becomes redder and whitish color becomes whiter for image obtained by simultaneously irradiating laser light and white light with appropriate balance. Therefore, LCI enhances slight color differences close the mucosal color and may increase the visibility of the lesion as compared with the conventional white light observation.
Detectability of neoplastic lesions in stomach using ultra slim endoscope and LCI : a randomized comparison trial.
The aim of this study is to evaluate usefulness of LCI compared with White light observation for detectability of neoplastic lesions in Stomach.
Registered cases:
- WLI 750 cases
- LCI 750 cases
Total 1500 cases
Study term: March, 2017∼Feb. 2022 (5 years)
Pilot Study (100 cases) is finished
Results: In Japan, the differentiated type early gastric cancer with *H. pylori* (+) was said to tend to be multiple around 10–15% and did field setting of this study after early gastric cancer endoscopic treatment primarily. We report pilot study at a point in time when 100 registration completed it in 1,500 aims. There was four cancer detected group and was one three LCI group xenon group. There are three cases in LCI group one case in xenon group in cancer detected group. Three LCI group was recognized it as redness with a depression type together and wasgroup of xenon recognized as fading by a flat elevation. Each these cases was *H. pylori*-negative. Whereas there are 12 registration cases in the adenoma detected group, and eight cases in LCI group, xenon group was four. Only one case of LCI was *H. pylori* (+) infection, but all others were infected. One case of the LCI group was a depressive type, but all the others were flat elevations. Six of eight LCI group discoloration, and two patients recognize it as redness. In four xenon group, two cases redness, two cases discoloration. From these, eradication was done in the case of cancer group, the LCI function seems to become easy to be recognized as redness regardless of depression and flat elevation. Whereas, in the case of adenoma, there are many flat elevation.
It seems to become easy to recognize a flat elevation as fading more.
Conclusion: Both cancer and adenoma were a few in the LCI group, but were the tendency that a discovery rate was high in with a significant difference.
We may contribute to detect of the minute∼ small early gastric cancer by LCI in the detection of the early gastric cancer after eradication in future while *H. pylori* eradication states increase.
Disclosure: Nothing to disclose

P0771 COMPARATIVE STUDY OF ESD AND SURGICAL RESECTION FOR GASTRIC SETS ORIGINATED FROM MUSCULARISPROPRIA

C.B. Ryu[1], M.S. Lee[1], J.Y. Bae[2]

Introduction: Endoscopic resection for gastric subepithelialtumors (SETs) originated from the muscularispropria (GSET-PM) has offered less invasive alternatives to surgical resection.
Aims and Methods: The aims of this study were to compare endoscopic subtumoraldissection (ESD) with surgical resection for the removal of GSET-PM. This study involved 17 patients with GSET-PM removed by ESD and 76 patients who underwent curative surgical resection. ESD was attempted in GSET-PM with well marginated tumors which was below 5cm and showed an endoluminal growth pattern according to endoscopic ultrasound (EUS) finding.
Results: ESD group were more likely to have upper portion (10/17, 58.8%) and surgery group were more likely to have mid portion (41/76, 53.8%, $p = 0.039$). ESD group were smaller median tumor size (25.6 mm vs 35.9 mm, $p = 0.037$) and higher endoluminal ratio ($58.5 \pm 9.1\%$ vs $45.8 \pm 15.4\%$, $p = 0.002$). ESD group were mostly to have Yamada type III (10/17, 58.8%) and surgery group were mostly Yamada type I (52/76, 68.4%, $p < 0.001$). Complete resection by ESD was lower than by surgical resection (82.4% vs 100%, $p < 0.001$). In ESD group, 3 performed surgical resection after ESD (1 incompletely resection and 2 uncontrolled bleeding) and 1 showed perforation was completely resected with endoscopic closure. In surgery group, complications occurred in 6 patients (1 leakage, 1 stricture, 1 hernia and bowel obstruction, 1 wound infection and 2 worsened general condition after surgery). Although surgery group were lower in complication rate than ESD group ($p = 0.006$), severity of complications were higher in the surgery group and there were no mortalities in the ESD group compared with 2 in the surgery group. There was no statistical difference of recurrence and the follow-up period between two groups.
Conclusion: ESD can be one of good options for the resection of endoluminal GSET-PM and could be replace treatment by surgical resection in Yamada type III with a high endoluminal ratio.

Introduction: Heterotopic gastric mucosal patch of cervical esophagus (gastric inlet patch, GIP) is a common endoscopic finding, however, its origin, prevalence and clinical significance are not well understood. Recently gastric inlet patch detection rate (GIPDR) has been proposed as potential quality indicator of upper gastrointestinal endoscopy [1] and first guidelines mentioned about cervical inlet patches (BSG and AUGIS) [2]. Endoscopists awareness as well as endoscopy using narrow band imaging (NBI) are proposed as main factors that affect its detection, however there is lack of prospective randomized trials that may answer the question if this imaging technique should be used routinely [3–5].

Aims and Methods: The aim of the study was to investigate whether routine use of NBI and endoscopist's attention improves the GIPDR. 1000 patients were randomized into NBI or standard white light endoscopy (WL) in 1:1 ratio. During first 500 endoscopies operators were asked to perform endoscopy with the standard attention. For next 500 endoscopies the same endoscopists were asked to step up with attention on GIP presence. The difference in imaging technique was applied to esophagus inspection during withdrawal of the scope. Results were compared with 460 endoscopies performed during one year before the research (control group).

Results: Eighty GIPs were found during the study (47 NBI, 33 WL), GIPDR obtained at 8%.

There was neither significant difference in GIPDR between NBI and WL groups (9.4% vs 6.6%, $p = 0.1$), nor in 'attentive' and 'inattentive' groups (9.4% vs 6.6%, $p = 0.1$). Attention did not improve GIPDR in WL and NBI groups (WL inattentive 5.6% vs WL attentive 7.6%, $p = 0.37$; NBI inattentive 7.6% vs NBI attentive 11.2%, $p = 0.17$). NBI and enhanced attention improved GIPDR in comparison to WL and standard attention (11.2% vs 5.6%, $p = 0.001$). GIPDR in the study was greater than in control group (8% vs 4.1%, $p = 0.006$), however only increased attention was superior to the control group (inattentive $p = 0.09$; attentive $p = 0.001$). NBI was superior to the control group (NBI total $p = 0.001$, NBI inattentive $p = 0.047$, NBI attentive $p = .0003$), in WL group only increased attention was superior to the control group (WL total $p = 0.09$, WL inattentive $p = 0.36$, WL attentive $p = 0.047$).

Conclusion: NBI enables CIP detection at the same level as standard endoscopy with enhanced attention. Increased attention of GIP enhances GIPDR especially when using NBI.

P0773 EFFICACY OF HAEMOSPRAY THERAPY ON RE-BLEED AND MORTALITY RATES – A UK SINGLE-CENTRE EXPERIENCE

T. Min, **M. Mothey**, N. Sharrack, M. Panikkar, A. Agrawal
Doncaster Royal Infimary, United Kingdom, Gastroenterology, Doncaster, United Kingdom

Contact E-Mail Address: priyankajale@ymail.com

Introduction: Dual endotherapy including epinephrine injection, thermal and mechanical methods have been shown to be superior to monotherapy in reducing the risk of re-bleed (20% vs 10%) and need for surgery in patients with upper gastrointestinal bleed (UGIB) [1]. Heamospray, an inorganic powder is a chemical mechanism to achieve haemostasis. The aim of the study was to describe a single centre district hospital experience in the United Kingdom with haemospray both as monotherapy and dual therapy in UGIB.

Aims and Methods: Retrospective data for all patients who were treated with haemospray for UGIB were collected retrospectively between January 2016 to June 2017 using EndoSoft®, Sunquest ICE®, Medisec and case notes. The primary endpoints were short-term haemostasis (24 hours), long-term haemostasis (7 days) and mortality in patients where haemospray was used either as primary haemostatic agent or combination therapy with a second haemostasis modality.

Results: Haemospray was applied during 50 examinations in 48 patients – 21 male (44%) and 27 female (56%), mean age 71.9 (range 40 to 92) years. The mean Blatchford score was 9.6 (range 0–18). 33 (69%) patients were treated for peptic ulcer. The rest were used for treating 2 (4%) gastric antral vascular ectasia, 2 (4%) oesophagitis, 2 (4%) post sphincterotomy, 8 (16%) non-specific bleeding source and 1 (2%) gastric tumour. Of the 48 procedures, re-bleeding occurred in 8 patients. Overall, short-term haemostasis was achieved in 46 (95%) patients and long-term haemostasis was achieved in 42 (87.5%). A total of 12 (25%) patients died, out of which 4 (8%) died due to a re-bleed and 2 (4%) failed to achieve initial primary haemostasis. The reminder 6 patients died from non-UGIB cause.

Conclusion: In this single-centre audit, the role of haemospray as combination and monotherapy in achieving haemostasis has been shown to be comparable to other modalities of endotherapy with statistical significance. This data needs to be replicated in a larger number of patients across other centres.

P0774 MUCOSAL LOSS IS THE CRITICAL MECHANISM OF ESOPHAGEAL STRICTURE AFTER MUCOSAL RESECTION: A PILOT EXPERIMENT IN A PORCINE MODEL

B. Liu, S. Ullah
The First Affiliated Hospital of Zhengzhou University, Department of Gastroenterology and Hepatology, Zhengzhou, China

Contact E-Mail Address: 2110858887@qq.com

Introduction: Esophageal stricture is a major complication of endoscopic mucosal resection (EMR) or endoscopic submucosal dissection (ESD). To date, the critical mechanism of esophageal stricture has not been fully elucidated and there is no effective treatment.

Aims and Methods: We designed this experiment to explore the underlying mechanisms of esophageal stricture after mucosal resection in a porcine model. Twelve swines were used for this study and were randomly divided into two groups. Firstly, In all the swines, two submucosal tunnels, 5 cm in length and 1/3rd in width, were made on the anterior and posterior wall of the esophageal circumference. After that,we resected the mucosa along the edge of the tunnel in the first group meanwhile mucosal incision was made on the covered mucosa to expose the submucosal layer over each tunnel In the second group. The process of stricture formation was evaluated by endoscopic inspection after one, two and four weeks respectively. Histological examination were performed after humanely execution

Results: Ulcer formation was inspected on endoscopic observation and incisional edges tended to grow and conglutinate with each other in each group after one week. All of the swines in the first group developed mild to severe esophageal stricture with weight loss whereas no esophageal stricture was evident in the ones of the second group after two and four weeks respectively.

Conclusion: The loss of esophageal mucosa should be the crucial factor for esophageal stricture after mocosal resection. Inflammation and scar formation slightly attribute to esophageal stricture formation. These results are important for developing a suitable treatment method for esophageal stricture.

Disclosure: The two authors were involved in this work, agreed to submit it to UEGW 2018, and assumed responsibility for the accuracy and completeness of the data. The authors declare that there are no conflict of interest.

Abstract No: P0773

	Mean age	Blatchford score	Short-term haemostasis (24hrs)	Long-term haemostasis (7days)	Deaths due to primary UGI bleed	Deaths due to Re-bleed
Monotherapy n = 21	75	9.57	21/21 (100%) [OR 0.02, 95%CI 0.01–0.41, p < 0.01]	19/21 (90%) [OR 0.10, 95%CI 0.02–0.51, p < 0.01]	0/21 (0%)	1/21 (4.7%)
Dual therapy n = 27	70	9.59	25/27 (93%) [OR 0.08, 95%CI 0.02–0.37, p < 0.01]	23/27 (85%) [OR 0.17, 95% CI 0.05–0.57, p < 0.01]	2/27 (7%)	3/27 (11%)

[Summary of monotherapy vs dual therapy including haemospray]

P0775 ENDOSCOPIC SUBMUCOSAL DISSECTION WITH SPLASH M-KNIFE: A SINGLE-CENTER CONSECUTIVE CASE SERIES

M. Ono[1], M. Fujishiro[1], Y. Tsuji[2], I. Saito[1], S. Yoshida[1], Y. Sakaguchi[2], C. Minatsuki[2], K. Niimi[2], N. Yamamichi[2], K. Koike[2]

Introduction: Endoscopic submucosal dissection (ESD) is widely accepted as a standard endoscopic treatment for early stage gastrointestinal (GI) neoplasms having a small risk of lymph-node metastasis, which could not resect by traditional endoscopic resection methods. However, completion of the procedures is very laborious in some cases due to bleeding and fibrosis. The Splash M-knife is a new multifunctional ESD device with water irrigation function. In addition, a metal plate attached to its distal sheath is better for hemostasis and cutting the fibrotic tissue during the procedure than conventional devices.
Aims and Methods: We aimed to elucidate the technical outcomes of ESD for GI neoplasms by using the Splash M-knife, because no consecutive case series in the whole GI tract have been reported so far. A retrospective single-center study was conducted at the University of Tokyo Hospital between January 2015 and December 2017 in patients who had received ESD with the Splash M-knife in the esophagus, stomach or colon. Procedure time, en bloc and complete resection rates, post procedure bleeding rates and perforation rates were evaluated in each organ.
Results: During the study period, 435 patients (esophagus (E)/stomach (S)/colon (C): 89/146/200) were treated by ESD with the Splash M-knife. The gender ratio (M/F), mean age, specimen size and tumor size in E/S/C were 7.1/3.4/1.2, 67.4/71.1/65.0 years, 37.0/40.2/38.9 mm, and 21.7/18.8/29.4 mm, respectively. As for the short-term outcomes, procedure time, en bloc resection rate, complete resection rate, post procedure bleeding rate and perforation rate in E/S/C were 73.3/123.9/95.2 mins, 91.0/98.6/96.0%, 84.3/84.9/83.0%, 0.0/4.1/2.0%, and 1.1/2.7/6.0%, respectively.
Conclusion: ESD with splash M-knife resulted in favorite outcomes through the GI tract. Further prospective comparative studies are needed to elucidate the advantages of this knife over other conventional knives.
Disclosure: Nothing to disclose

Introduction: Cytomegalovirus (CMV) is a very common viral pathogen after organ transplant patients. However, endoscopic characteristics of gastric CMV infection have not been established.
Aims and Methods: We aimed to develop and validate a prediction model using endoscopic findings for gastric CMV infection in patients with renal transplantation. A retrospective study was performed in a tertiary referral hospital enrolling 354 kidney transplant recipients who received endoscopy with biopsy for suspected CMV infection from Jan. 2005 to Nov. 2015. For the development phase, endoscopic parameters were selected by univariate logistic regression analyses. Then, the prediction model was established on the basis of β coefficients of the multivariate logistic regression. For the validation of the model, the same regression equation was tested on the other group.
Results: Age, days from renal transplantation to endoscopic biopsy, erosion at antrum, erosion with exudate, raised erosion, and ulcer at antrum were selected as the predicting factors for gastric CMV infection. In the development set (n = 176) using these five markers, the sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were 92.23, 80.82, 87.16, and 88.06, respectively. In the validation set (n = 178), the sensitivity, specificity, PPV, and NPV were 83.87, 82.35, 83.87 and 82.35, respectively.
Conclusion: This endoscopic prediction model using 6 risk factors can be a reliable diagnostic tool for gastric CMV infection after renal transplantation.

Introduction: The pioneering centres for endoscopic bariatric therapies have demonstrated the strong efficacy and safety profile of endoscopic sleeve gastroplasty (ESG). However, data outside these expert centres remain scant. We report a single-centre experience of ESG performed in Australia (Sydney Adventist Hospital, Sydney).
Aims and Methods: All patients undergoing ESG between May-October 2017 had data prospectively collected. All patients had previous unsuccessful attempts at diet and exercise programs.
ESG was performed by 2 Gastroenterologists. The Apollo OverStitch device (Apollo Endosurgery) was used to place full-thickness endoscopic sutures from the incisura angularis to the fundus, creating a 'sleeve effect' using the technique previously described in detail. All patients received regular follow-up with a multidisciplinary team.
Measured outcomes included absolute weight loss, change in body mass index (BMI), total body weight loss (%TBWL) and excess weight loss (%EWL) at 1 and 6 month follow-up. The proportion of patients achieving ≥10% TBWL, ≥15% TBWL, and ≥25% EWL at 6 months was also assessed. Intention-to-treat (ITT) analysis considered patients lost to 6 month follow-up as failing to meet these thresholds.
Results: A total of 66 patients (75.8% female) underwent ESG. The mean age was 45.2 ± 10.2 years, mean baseline weight was 112.5 ± 17.0kg and mean BMI was 39.3 ± 4.7kg/m^2. The outcomes at 1 and 6 month follow-up (mean ± SD) are summarised in table 1.

	No. of patients	Weight loss (kg)	Δ BMI (Kg/ m^2)	%TBWL	%EWL
1 month	66	9.7 ± 3.3	3.4 ± 1.0	8.6 ± 2.5	25.3 ± 11.7
6 months	64	16.5 ± 7.3	5.8 ± 2.5	14.6 ± 5.7	42.7 ± 20.1

[Weight loss outcomes at 1 month and 6 months post-ESG]

Of the 64/66 (97.0%) of patients with 6 month follow-up data, 81.3% achieved ≥10% TBWL, 45.3% achieved ≥15% TBWL, and 85.9% achieved ≥25% EWL. In the ITT analysis, 78.8% achieved ≥10% TBWL, 43.9% achieved ≥15% TBWL, and 83.3% achieved ≥25% EWL at 6 month follow-up.
There were 2 (3.0%) serious adverse events. Both were a peri-gastric inflammatory collection requiring hospitilisation (4 and 8 days), intravenous antibiotics, laparoscopic washout and percutaneous drainage. Both patients recovered uneventfully without long-term sequelae.
Conclusion: This single-centre study of 66 consecutive patients undergoing ESG demonstrates reproducibility of the strong efficacy and safety profile of ESG outside the core facilities where the procedure was developed.
Patients achieved 14.6% TBWL and 42.7% EWL at 6 months. These results are comparable to the multicentre study across the pioneering centres, in which 248 patients undergoing ESG achieved 15.2% TBWL at 6 months.
In ITT analysis, at 6 months 83.3% achieved ≥25% EWL, which is the 12 month efficacy threshold for a bariatric procedure to be incorporated into clinical practice, as determined by the American Society of Gastroenterology (ASGE) Bariatric Task Force.
The limitations of this study are the lack of control group and limited long-term follow up. Weight loss at 6 months has been shown to be predict weight maintainence and further weight loss at 2 years, so we would anticipate the majority of our patients to have favourable longer-term results.
This study adds to the growing evidence that ESG is a highly effective, reproducible and safe treatment option for patients with obesity.

Introduction: *H. pylori* (Hp) eradication therapy have been thought to be useful on the gastric cancer (GC) detecting more easily before eradication due to disappearance of gastric inflammation. On the other hand, there are various new endoscopic appearances in eradicated stomach which differ from known appearances in Hp-infected stomach. And these new mucosal changes often make difficult to detect GC on eradicated stomach. We can expect that GC will decrease after Hp eradication, but we may confuse to detect GC due to endoscopic diagnostic difficulty with gastric mucosal change after eradication at a certain rate. Although this gastric mucosal change does not occur in all stomach after eradication, endoscopic examination should be done with sufficient consideration that endoscopic diagnosis becomes complicated and becomes difficult in the eradicated stomach.

Aims and Methods: The aim of this study is to elucidate what changes are occurring on the gastric mucosal surface after Hp eradication. Endoscopic images of 352 cases who received Hp eradication therapy were collected (from Jan. 2015 to Nov. 2017). We examined the presence of gastric mucosal changes on all endoscopic files before and after eradication in each case. We checked the presence of irregularities on the gastric mucosal surface, and all cases were examined histologically with biopsy samples. In the histological evaluation, we analyzed the cause of surface irregularity and were measured the thickness of gastric foveolar epithelium and proper gastric glands.

Results: The gastric mucosal change after eradication was classified into three groups (A, B, C) from the viewpoint of easiness (difficulty) of endoscopic observation. Group A is the easy group after eradication: 49.7% (175/352), This group is easy to observe after eradication due to improvement of mucus adhesion and swollen gastric fold. Group B is the unchanged group after eradication: 24.7% (87/352), endoscopic appearance did not change before and after eradication in this group. Group C is the difficult group after eradication: 25.6% (90/352), endoscopic newly appearance occurred after eradication and this change made obviously complicated and difficult to detect GC. The age, sex and other various background of each group had not significant difference in each group. We analyzed this gastric mucosal surface irregularity in histologically. We found that main reasons of gastric mucosal irregularity consisted of gastric foveolar epithelial hyperplasia and intestinal metaplasia after eradication. In other words, gastric surface irregularities after eradication became gradually apparent with foveolar epithelium growth and metaplastic change after eradication. Approximately one fourth of the stomach after eradication, it is considered that endoscopic diagnosis of detecting GC becomes difficult. In the gastric mucosa where proper gastric glands remain, foveolar epithelial hyperplasia occurs in the process of repair and regeneration after inflammation. This is considered that the main cause of surface irregularities in the gastric mucosa after eradication. On the other hand, it seems that such a change does not occur in the gastric mucosa which has been completely replaced by intestinal metaplasia without proper gastric gland remaining.

Conclusion: Surface irregularities occurring in the gastric mucosa after Hp eradication makes it difficult for endoscopic diagnosis of gastric cancer detecting. Therefore, when we examine the stomach after eradication, the endoscopic examination should be done with extremely care as well as stomach before eradication.

P0779 COMBINED TREATMENT OF OVERWEIGHT WITH INTRAGASTRIC BALLOON AND LIRAGLUTIDE AT HIGH DOSE: IS IT WORTH IT?

R.J. Fittipaldi-Fernandez[1,2], A.C. Hoff[1,2]
[1]*Endogastro Rio, GI Endoscopy Department, Rio de Janeiro, Brazil*
[2]*Angioskope, GI Endoscopy, São José dos Campos, Brazil*

Contact E-Mail Address: ricfittipaldi@hotmail.com

Introduction: Intragastric balloon and liraglutide single therapies are used worldwide to treat excess weight and obesity. However, there is no published study with both treatments combined.

Aims and Methods: We aimed to evaluate the efficacy and complications of intragastric balloon therapy alone and combined with liraglutide.

Patients with BMI above 27 kg / m2 were included. Patients at risk of baseline gastroparesis (Type II diabetes, age greater than 60 years) were excluded. Patients were randomly divided into two groups. One group was submitted to the isolated therapy with Orbera intragastric liquid balloon, with permanence of 6 months. The second group, besides the IGB implant, received a daily dose of liraglutide (maximun 3.0 mg (mean). Data were analyzed using descriptive statistical methods, Student's t-test and analysis of variance followed by the Tukey post-test. The level of significance was set at $p < 0.05$.

Results: 90 patients (64 women) were randomly divided into two groups of 45 people with the same composition (32 women and 13 men). The mean age was 34.4 (21–57), the mean initial BMI in group 1 was 33.93 and in group 2, 33.95. 42 patients in group 1 completed treatment compared to 31 patients in group 2. The results regarding the initial and final BMI, TBWL EWL, weight loss in kg are shown in table 1.

	Group 1	Group 2
BMI (Kg/m2)		
initial	33.93 ± 1.94	33.95 ± 1.77
final*	27.72 ± 1.66	26.72 ± 1.65
reduction+	6.21 ± 0.88	7.23 ± 1.07
Weight		
initial	97.98 ± 8.87	97.63 ± 8.63
final*	80.08 ± 7.34	75.92 ± 6.68
Weigh loss (kg)+	17.90 ± 2.87	21.71 ± 3.72
TWL (%)+	18.29 ± 2.16	22.21 ± 2.94
EWL (%)+	71.81 ± 14.50	86.53 ± 17.06

*$p < 0.001$ comparing final and initial values. +$p < 0.001$ between groups

[Table 01]

Conclusion: Both treatments are effective in promoting weight loss; however, the combination with liraglutide seems to promote an even greater weight loss without increasing complication. Liraglutide shows to be a great adjuvant drug for the intragastric balloon therapy.

Disclosure: Nothing to disclose

P0780 PERCUTANEOUS ENDOSCOPIC GASTROSTOMY IN AMYOTROPHIC LATERAL SCLEROSIS WITH SEVERE VENTILATORY IMPAIRMENT

Introduction: Weight loss is one of the major bad prognostic factors in amyotrophic lateral sclerosis (ALS). The placement of percutaneous endoscopic gastrostomy (PEG) is of paramount importance in patients with dysphagia to improve the diagnosis. However, there is some fear regarding the possible ventilatory complications during the procedure, as well as the exact timing for placing PEG.

Aims and Methods: The aim of this study was to evaluate the PEG insertion under non-invasive ventilation in patients with ALS and severe ventilatory impairment.

Retrospective study of all consecutive PEGs placed in our department from May/2011 to January 2018 in patients with ALS. The procedure was performed under noninvasive positive pressure ventilation for ventilatory support (oronasal mask).

Results: We included 59 patients with ALS with severe ventilatory impairment, 58% female, with a mean age of 67.2 ± 10.1 years, a median Charlson index of 3 [2–4] and a median follow-up of 6 [2–15] months.

The main indication for PEG placement was dysphagia (98%) and 15% had had a previous episode of aspiration.

The median time for PEG insertion since the established diagnosis of ALS was 12 [6–25] months and 4 [2–18] months since the beginning of bulbar symptoms.

The majority of the patients placed a 20Fr PEG (63%) and under sedation with midazolam (80%), all under non-invasive ventilation (NIV). There were no immediate complications during and after the procedure (no episodes of aspiration or orotracheal intubation) and mortality.

The 30-day, 180-day and 360-day mortality rates were, respectively, 5.1%, 27.1% e 35.6%.

Conclusion: The placement of PEG is a very important in patients with ALS and severe ventilatory impairment, improving not only the nutritious status but also the prognosis. Our collaboration between Gastroenterology and Pneumology permitted the insertion of PEG under NIV, in a safe and effective procedure in this special population, being one of the major series reported in the world.

Introduction: Sessile serrated adenoma/polyps (SSA/Ps) should be resected because they are known to be precursors of CRCs. Accurate endoscopic criteria to differentiate SSA/Ps from Hyperplastic polyps (HPs) are necessary. However endoscopic differentiation with endoscopists' eyes is considered difficult. In this study, we evaluated the performance of the newly developed artificial intelligence (AI) in endoscopic identification of SSA/Ps.

Aims and Methods: We developed the AI system based on the previously proposed model[1].

The AI system was combined with endocytoscopy which enables in vivo observation of cellular images at 500-fold magnification (CF-H290ECI or CF-Y0058, prototype from Olympus Co.). The diagnostic algorithm of the AI consisted of the sequence of image acquisition, extraction of 312 visual features from nuclear images and contrast difference of the whole image, and classification into the two pathological groups (SSA/P and non-SSA/P).

We designed this retrospective study to assess the performance of the AI system for prediction of SSA/Ps by using 18 SSA/Ps (641 images) and 49 HPs (1228 images) resected between Sep. 2017 and Feb. 2018.

The main outcome measures were diagnostic sensitivity specificity, accuracy, positive predictive value (PPV), and negative predictive value (NPV) of the AI system in identifying SSA/P in high confidence (probability > = 90%).

Machine learning for the AI was performed by using 28000 images which were acquired from Jan. 2016 to Aug. 2017. In the lesion-based analysis, diagnosis of the target lesion was defined as SSA/P when the AI system shown at least one SSA/P output.

Results: The AI system automatically output the pathological prediction of 527 images (SSA/P 102 images, HP 425 images) out of total 1869 images immediately with high confidence (probability > = 90%). In the image-based analysis, the AI system showed sensitivity of 11.8%, specificity of 99.5%. PPV in high confidence was 85.7% and NPV was 82.5%.

However, in the lesion-based analysis AI system showed sensitivity of 27.8%, specificity of 95.9%.

		Pathology	
		SSA/P	Hyperplastic polyp
AI output	SSA/P	12	2
(High confidence)	non-SSA/P	90	423

[Image-based analysis]

Conclusion: This study revealed AI system diagnosed SSA/P with high specificity, but low sensitivity in high confidence.

However, further accumulation of endoscopic images for machine learning is required to make more robust model for diagnosing SSA/Ps.

Disclosure: Nothing to disclose

Introduction: High-definition imaging should be the standard for diagnostic endoscopy and optimized patient care. However, many units still suffer from the high costs of these systems. Most recently, a novel brand offering high-definition imaging was introduced to the market which is significantly less expensive compared to most traditional endoscopy brands.

Aims and Methods: To investigate the performance parameters of colonoscopy between the new brand (Sonoscape) and established competitors (Pentax and Olympus). A prospective, multicentre, randomised controlled, parallel, non-inferiority trial conducted in 5 endoscopy units located in Germany, Italy, Thailand, China and Russia was conducted. Performance parameters assessed were cecal intubation time, withdrawal time, total examination time, number of polyps detected, and average size of polyps.

Results: A total of 252 patients were included. No significant differences were noted between the different groups regarding gender, age, previous surgery or bowel preparation. Cecal intubation time (Sonoscape 8 minutes vs. 7 (Pentax)/ 10 minutes (Olympus); p = NS) and withdrawal time (10.5 minutes vs. 8 (P)/ 9 minutes (O); p = NS) with the new brand was not significantly different to the others. Polyps were detected in 39% of patients with the new brand compared to 33% (P) and 43% (O) with the others (p = NS). Average size of the polyps detected was 5mm for the new brand and 6mm/ 5 mm for the others (p = NS). No complications were recorded.

Conclusion: The performance of the new endoscopy brand is not inferior to that of the other brands studied. Therefore, future research should now focus on the image quality and the applicability for predicting histology. Major advantage of the new system is the low price which makes it even achievable for smaller sized endoscopy units.

Introduction: Blue Light Imaging (BLI) was recently introduced as a novel imaging technology allowing for enhanced visualization of the mucosal surface and vascular pattern morphology. Data regarding the applicability of BLI for prediction of deep submucosal invasion of colorectal lesions is missing.

Aims and Methods: Main study objective was to assess the potential of BLI for prediction of deep submucosal invasion of colorectal lesions.

Consecutive patients undergoing screening or surveillance colonoscopy were prospectively evaluated using a high-definition endoscope with BLI capability. Circumscript lesions were examined with BLI before taking biopsy specimens or performing endoscopic resection. BLI images were graded according to surface and vascular pattern morphology and correlated with conventional histopathology in a prospective and blinded fashion.

Results: 120 cases were included. BLI yielded high-quality images in all cases. Based on pit pattern and vascular alterations BLI could predict the presence of deep submucosal invasion with high sensitivity (95%), specificity (91%) and accuracy (93%). Positive and negative predictive values of BLI for *in vivo* diagnosis of deep submucosal invasion were 88% and 95%, respectively.

Conclusion: BLI is a novel diagnostic tool allowing for real-time prediction of deep submucosal invasion of colorectal lesions with high accuracy. This becomes of crucial importance in clinical practice and could lead to an optimized and rapid diagnosis of neoplasic changes during ongoing endoscopy and an individualized management approach.

P0785 EFFICACY AND SAFETY OF ETOMIDATE-MIDAZOLAM FOR SCREENING COLONOSCOPY IN ELDERLY: A PROSPECTIVE DOUBLE-BLINDED RANDOMIZED CONTROLLED STUDY

J.M. Lee, S.J. Choi, H.J. Jeon, S. Jang, S.H. Kim, J.M. Lee, H.S. Choi, E.S. Kim, B. Keum, Y.T. Jeen, H.J. Chun, H.S. Lee, **C.D. Kim**
Korea University College Of Medicine, Seoul, Korea (Republic of)

Contact E-Mail Address: kumcge@korea.ac.kr

Introduction: Recent studies have shown that etomidate is associated with fewer serious adverse events than propofol and has a non-inferior sedative effect. We investigated whether etomidate-midazolam is associated with fewer cardiopulmonary adverse events and has non-inferior efficacy compared to propofol-midazolam for screening colonoscopy in the elderly.

Aims and Methods: A prospective, single-center, double-blinded, randomized controlled trial was performed. Patients aged over 65 years who were scheduled to undergo screening colonoscopy were randomized to receive either etomidate or propofol based on midazolam. The primary outcome was all cardiopulmonary adverse events. The secondary outcomes were vital sign fluctuation (VSF), adverse events disturbing the procedure, and sedation-related outcomes.

Results: The incidence of cardiopulmonary adverse events was higher in the propofol group (72.6%) than in the etomidate group (54.8%) ($p = 0.040$). VSF was detected in 17 (27.4%) and 31 (50.0%) patients in the etomidate and propofol groups, respectively ($p = 0.010$). The incidence rate of adverse events disturbing the procedure was significantly higher in the etomidate group (25.8%) than in the propofol group (8.1%) ($p = 0.008$). Moreover, the incidence rate of myoclonus was significantly higher in the etomidate group (16.1%) than in the propofol group (1.6%) ($p = 0.004$). There was no statistical significance between the two groups with respect to sedation times and sedation-related outcomes including patients' and endoscopist's satisfaction. In the multivariate analysis, the etomidate group had significantly low odds ratio (OR) associated with VSF (OR: 0.407, confidence interval: 0.179–0.926, $p = 0.032$).

Conclusion: We recommend using etomidate-midazolam in patients with high ASA score or vulnerable to risk factors; propofol-midazolam may be used as a guideline in patients with low ASA score.

Introduction: Cold snare polypectomy (CSP) is established technique for the resection of colorectal polyps up to 10 mm in size without electrical current. However, there is a lack of comparative studies using a thin wire mini-snare (designed for CSP) and thick wire mini-snare during CSP. Thus, the aim of this study was to compare the clinical effectiveness of thin wire mini-snare and thick wire mini-snare during CSP in small colorectal polyps.

Aims and Methods: This study was a prospective, randomized and controlled study. Between September and November 2017, a total of 113 neoplastic colorectal polyps (5 to 8mm in diameter) was removed by CSP and included in this study. The primary outcome was measured by complete resection rate (CRR) by gastrointestinal pathologist based on histopathologic findings. Also, endoscopist experience, polyp characteristics, technical factors during CSP, complication and histopathologic features of resected specimens were carefully analyzed.

Results: A total of 113 eligible polyps were successfully resected using CSP (thin mini-snare group ($n = 48$) and thick mini-snare group ($n = 47$)) by 4 endoscopists. The location, size, and shape of the polyps were not statistically significant difference between the two groups. The CRR was not significantly different between the two groups. (Thin mini-snare group: 75.0% vs thick mini-snare group 89.4, $p = 0.068$) There was no significant difference between the two group in immediate bleeding (18.8% vs 6.4%, $p = 0.070$), tissue retrieval (100% vs 100%), and tissue fly away (2.1% vs 0.0%, $p = 0.32$). Histopathologic features including specimen size, safety margin (996 ± 160 um vs 1358 ± 192 um) and containing submucosa tissue in the resected specimen (6.3% vs 10.6%, $p = 0.442$) were not significant difference between the two groups. Regarding CRR related factors, experience of endoscopists was associated with CRR in univariate regression analysis. (odds ratio 4.037, $p = 0.012$). However, snare type, experience of endoscopists, size of polyp, shape of polyp, location of polyp and pathologic finding were not associated with CRR by multiple logistic regression analysis.

Conclusion: Cold snare polypectomy using thin wire mini-snare is considered to have no additional benefit compared to using thick wire mini-snare in small size (5–8mm) colorectal polyps.

Introduction: Water exchange (WE) significantly improved overall adenoma detection rate (ADR) [1–7]. The clinical relevance is lessened by the predominance of diminutive adenomas of low malignant potential accounting for the increase. Advanced adenomas ($\geq$ 10 mm, > 25% villous component or high-grade dysplasia) of all sizes are the most valid surrogate markers of malignant potential [8]. Prevalence of advanced adenomas ranged from 3.4% to 7.6% [9]. Presence of fecal occult blood [10] and surveillance [11] are associated with higher and lower advanced ADR, respectively. Colonoscopists' advanced ADRs are variable, and independent of their non-advanced ADRs [12]. Despite recommendation to use advanced ADR to evaluate new screening technologies, other than split-dose bowel preparation [13], no conclusive data based on randomized controlled trials (RCTs) [14,15] have implicated colonoscopist-dependent methods (e.g., technologies and accessories) in enhancing $\geq$ 10 mm advanced ADR. WE insertion time, prolonged by salvage cleansing, was not a factor influencing ADR [16]. At the 2018 Digestive Diseases Week, we will report that compared to AI, WE significantly increased all sizes advanced ADR (5.7% vs. 8.2%, $p = 0.001$). Since size ($\geq$ 10 mm) is a more robust marker of cancer risk than histological characteristics [17], here we focus on the impact of WE on $\geq$ 10 mm advanced adenomas.

Aims and Methods: To highlight the clinical relevance of WE, the hypothesis that WE significantly increased $\geq$ 10 mm advanced ADR compared to air insufflation (AI) was tested. Data from six RCTs that compared AI to WE were pooled. The current primary outcome is based on previously unreported data.

Results:

Table 1. Demographic and procedural data pooled from six RCTs.

5407 patients were randomized to AI (2699) or WE (2708): screening 35% and 32% ($p = 0.003$); surveillance 9% and 10%; positive fecal occult blood 50% and 50%, respectively. WE showed significantly higher $\geq$ 10 mm advanced ADR (primary outcome) (4.4% vs. 6.5%, $p < 0.001$); higher overall ADR (20.9% vs. 27.4%, $p = 0.001$); higher all sizes advanced ADR (5.7% vs. 8.2%, $p = 0.001$);

Abstract No: P0787

Method (no. of patients)	AI (n = 2699)	WE (n = 2708)	p
Age, year, mean (SD);	54 (12)	54 (12)	0.807
Male, n (%)	1476 (55)	1468 (54)	0.743
Indications: Screening, n (%); {Surveillance, n (%)}; [FIT+ or FOBT+, n (%)]	949 (35); {234 (9)}; [1350 (50)]	863 (32); {270 (10)}; [1366 (50)]	0.010; {0.102}; [0.990]
Cecal intubation (insertion) time, minutes, mean (SD); [Cecal intubation rate, n (%)]	6.9 (5); [2614 (97)]	9.5 (5); [2636 (97)]	< 0.001; [0.293]
Primary outcome: Combined ≥ 10 mm advanced ADR, n (%)	120 (4.4)	176 (6.5)	< 0.001
Combined overall ADR, n (%)	564 (20.9)	742 (27.4)	0.001
Combined all sizes advanced ADR, n (%); [Combined < 10 mm advanced ADR, n (%)]	155 (5.7); [35 (1.3)]	222 (8.2); [46 (1.7)]	0.001; [0.263]

P values were obtained using t-test or Fisher's exact test, as appropriate. ADR, adenoma detection rate; AI, air insufflation; FIT, fecal immunochemical test; FOBT, fecal occult blood test; RCTs, randomized controlled trials; SD, standard deviation; WE, water exchange. Withdrawal time was > 8 minutes in both groups. RCTs included in pooled analysis: 1: *Gastrointest Endosc* 2010;72:693 (unsedated) NCT00747084. 2: *J Interv Gastroenterol* 2013;3:7 (unsedated) NCT01383252. 3. *Endoscopy* 2014;46:212 (On demand minimal sedation) NCT01781650. 4: *Am J Gastroenterol* 2017;112:568 (Unsedated or propofol) NCT02135601. 5. *Gastrointest Endosc* 2017;86:192 (Minimal or propofol sedation) NCT01894191. 6: *Endoscopy* 2017;49:456 (On demand minimal sedation) NCT02041507. 1 and 2 used non-split-dose; 3, 4, 5 & 6 used split-dose. In 1, 2, 3, 4, 5 & 6, WE bowel cleanliness during withdrawal was significantly better than AI. Total number of colonoscopists: 22. The longer cecal intubation time of WE was devoted to insertion salvage cleansing, and not a factor contributing to enhanced ADR. The trends of higher ≥ 10 mm advanced ADR, higher all sizes advanced ADR and higher overall ADR were present in all six RCTs ($p < 0.5$, sign test).

[Water exchange significantly increased ≥ 10 mm advanced adenoma detection rate.]

longer insertion time [6.9 (5) vs. 9.5 (5) min, $p < 0.001$). < 10 mm advanced ADRs (1.3% vs. 1.7%, $p = 0.263$) were comparable.

Discussion: The significantly higher overall ADR confirmed WE provides better quality. Assessment of ≥ 10 mm advanced ADR as previously recommended [8] established WE to be a tool superior to AI. The current difference was not due to variable proportions with blood in the stool or for surveillance. WE is now the only colonoscopist-dependent method that produces a significant increase in ≥ 10 mm advanced ADR. The 2% increase, albeit numerically small, is a clinically significant 47% relative increase. The favorable impact of WE on advanced ADR is primarily due to the significant increase in those ≥ 10 mm.

Conclusion: The proof-of-principle data, significant increase in advanced ADR, primarily those ≥ 10 mm, confirm WE to be highly clinically relevant. The significantly higher overall ADR (albeit mostly diminutive) demonstrates better quality. Taken together, it is appropriate to include WE in colorectal cancer prevention programs.

Introduction: Cap-assisted endoscopic mucosal resection (EMR-C) and endoscopic submucosal dissection (ESD) have been both reported to be effective treatment methods for small rectal neuroendocrine tumor (NET) in limited studies. We aimed to compare the outcomes of EMR-C and ESD to determine which one is better for the treatment of rectal NET.

Aims and Methods: We retrospectively collected 702 patients diagnosed with primary rectal NET from January 2007 to September 2017 in eight tertiary medical centers from China. Clinicopathological characteristics, en bloc resection rate, operating time, estimated blood loss, complications, postoperative hospital days, recurrences were recorded and compared.

Results: Among the 702 patients, 279 meet the criteria and were enrolled in the study. 104 patients (37.28%) received EMR-C and 175 patients (62.72%) received ESD treatment. The demographic characteristics of the patients and the tumor size were well balanced. We did not observe significant difference concerning about en bloc resection rate (100% vs. 98.85%, $p = 0.531$) and pathologic R0 resection rate (97.11% vs. 94.28%, $p = 0.382$) between EMR-C group and ESD group, respectively. However, shorter operating time and less estimated blood loss were observed in EMR-C group (7.00 ± 4.79min vs. 21.73 ± 14.36min, $p = 0.027$; 4.17 ± 2.89ml vs. 6.75 ± 3.22ml, $p = 0.039$, respectively). There was also no significant difference concerning about complications and no serious adverse events were observed. Kaplan-Meier curves for non-recurrence survival and survival analysis showed that there were no significant differences between two groups.

Conclusion: EMR-C may be preferable for removal of small rectal NET (≤10 mm) with shorter operating time and postoperative hospital days, less blood loss and hospitalization cost compared with ESD. Prospective randomized controlled trials are further needed.

ESD	Rectum	33 mm	Adenoma with high-grade dysplasia, R0

P0789 IMPROVED ENDOSCOPIC RESECTION OF LARGE FLAT LESIONS USING AN EXTERNAL ADDITIONAL WORKING CHANNEL (AWC)

B. Walter, S. Schmidbaur, A. Hann, A. Meining
Ulm University, Department of Internal Medicine I, Ulm, Germany

Contact E-Mail Address: benjamin.walter@uniklinik-ulm.de
Introduction: En-bloc resection of lateral-spreading polyps, flat lesions larger than 2 cm in size, or early stages of cancer can be challenging. Endoscopic mucosal resection (EMR) offers the opportunity for resection in piece-meal technique, but completeness (R0) of the resection remains unclear. In contrast, standard endoscopic submucosal dissection (ESD) is complex, time consuming and associated with a significant rate of perforation. Furthermore for standard endoscopes no bi-manual tasks are possible. Additionally resection technique is faced by limited steer-ability and degrees of freedom. The two channel endoscopes are expensive, not available everywhere and have a small distance between the channels.
Aims and Methods: Here, we report our first experience using a new external additional working channel (AWC) (Ovesco, Tübingen, Germany). ESD and EMR with a modified grasp and snare technique was performed. The device can be fixed at the tip of a standard gastroscope or pediatric colonoscope. The distance of the two working channels can be adjusted by the endoscopist. Via the AWC a second endoscopic tool can be inserted and used for bi-manual workflow.
Results: EMR with modified grasp and snare technique was performed successfully in 4 patients (1 upper GI tract, 3 lower GI tract). ESD was performed successfully in 4 patients (2 upper GI tract, 2 lower GI tract) (Table 1). Mean procedure time (scope-in to scope-out) was 68.5 min.
Reported complications were acute arterial bleeding post EMR in two cases. No delayed bleeding or perforation were reported. Passage with the AWC-equipped endoscope was possible in all cases.
Conclusion: So far, based on our preliminary experience, we conclude that a new developed external additional working channel (AWC) enables endoscopic resection of large lesions in the upper and lower GI tract. Potential benefits are its suitability for EMR and ESD, no need for dual-channel endoscope and an adjustable distance of working channels.

P0790 CAN SERT SCORE PREDICT HISTOLOGICAL RECURRENCE IN PIECEMEAL ENDOSCOPIC MUCOSAL RESECTION? COMPARATIVE STUDY WITH SMSA SCORE

J.C. Silva, R.T. Pinho, A.P. Silva, A. Ponte, J. Rodrigues, M. Sousa, A.C. Ribeiro Gomes, J. Carvalho
Centro de Hospitalar Vila Nova de Gaia/Espinho, Gastrenterology, Vila Nova de Gaia, Portugal

Contact E-Mail Address: joaocarosilva@gmail.com
Introduction: Piecemeal endoscopic mucosal resection (pEMR) allows resection of larger non-invasive colorectal lesions. Histological recurrence (HR), determined in surveillance colonoscopy after pEMR, is still a difficult to predict. SERT score (Sydney EMR-recurrence tool) predicts endoscopic recurrence (ER), nevertheless it has not been validated as a predictor of HR.
Aims and Methods: The present study aimed to validate SERT score as a predictor of ER and HR and compare its predictive value to the SMSA score (size, morphology, site, access).
SERT and SMSA score were calculated for all lesions resected by pEMR between 2012–2018. At first surveillance colonoscopy, performed at 3–6 months, RE and RH were evaluated. In the absence of ER, biopsy of pEMR scar was performed in most cases. In patients with ER the removal of the residual lesion was attempted.
Results: 188 pEMR were considered. In the studied population, 61.7% were men and the mean age was 66.1 ± 9.8. Most lesions were located at the right colon (59.0%). The average size was 30.99 ± 13.8 mm. Considering Paris Classification, lesions 0-Is + IIa (42.0%) and 0-IIa (39.4%) were more common.
The overall HR rate was 23.4% (n = 44). ER occurred in 27.1% (n = 51), and in 72.5% of these cases (n = 37) HR was confirmed. In patients without ER, the HR rate was 4.9% (n = 7). There was a strong correlation between the SERT and SMSA scores ($p < 0.001$; $r = 0.61$). There was a significant association between SMSA score and ER ($p < 0.001$) as well as HR ($p < 0.001$). A SERT ≥ 2 score was significantly associated with ER ($p = 0.002$) and HR ($p = 0.015$).
Conclusion: SERT score correlates with the SMSA score and both can be used to predict ER and HR in lesions removed by pEMR. SMSA score showed greater discriminative power for recurrent lesions. SERT score is less complex and allows predicting not only ER as RH.

P0791 CLINICAL OUTCOMES AND PATIENTS' SATISFACTION FOR NOVEL PATIENT REFERRAL SYSTEM CALLED 'SAME-DAY POLYPECTOMY'

S.Y. Shin, J.J. Park, H. Park, Y.H. Youn, J.-H. Kim, D.H. Jung
Yonsei University College of Medicine, Seoul, Korea (Republic of)

Contact E-Mail Address: mdthepage@gmail.com
Introduction: Substantial number of patients who diagnosed with polyps on screening colonoscopy undergo subsequent colon polypectomy on a separate day at referral hospital. We developed novel patient referral system called 'Same-day polypectomy' that performs colon polypectomy in tertiary hospital after same day referral from private clinics.
Aims and Methods: The aim of this study was to compare the clinical outcomes between conventional elective polypectomy and 'Same-day polypectomy' and to evaluate the patient's satisfaction with this novel system.
We retrospectively reviewed prospectively enrolled colonoscopy database in a single referral center. A total of 122 patients were referred to Gangnam Severance hospital for polypectomy between July 2017 to December 2017. Among them, 57 patients received 'same-day polypectomy', and remaining 55 patients underwent conventional elective polypectomy. Polyp characteristics, complications, degree of bowel cleanliness using Boston Bowel Preparation Scale (BBPS) were compared between these two groups. Patients' satisfaction for the 'same-day polypectomy' was assessed through questionnaires.
Results: There were no significant differences in the location and average number of resected polyps between two groups. However, the polyps in 'same-day polypectomy' group were smaller in size than those of elective polypectomy group (6.3 ± 3.2 mm vs. 10.9 ± 8.7 mm, $p < 0.001$), and were more frequent in polypoid type. Moreover, mean total BBPS score was lower in 'same-day polypectomy' group than in elective polypectomy group (6.8 ± 1.6 vs. 8.4 ± 1.0, $p < 0.001$). Meanwhile, procedure related complications were not identified in both groups. Regarding patients' satisfaction for 'Same-day polypectomy', 95% of the patients were satisfied with this novel system and most common reason for satisfaction was absence of repeat bowel preparation (70.8%).
Conclusion: Our novel 'same-day polypectomy' is safe and acceptable patient referral system with high patients' satisfaction.

Contact E-Mail Address: yanchu03@gmail.com
Introduction: Colonoscopy with polypectomy reduces incidence and mortality from colorectal cancer. Post-polypectomy surveillance recommendations are aimed at balancing the need for surveillance on one side and ensuring adequate use of medical resources on the other. Surveillance intervals are often determined by features of the removed polyps during the index colonoscopy. Current data on physician adherence to societal guidelines is mixed and limited and to our knowledge none investigated the influence of intervention on adherence.
Aims and Methods: We aimed to improve accuracy and consistency in post-polypectomy surveillance recommendations.
In the first phase of the study we assessed the current practices of 10 gastroenterologist at a tertiary academic center by prospectively collecting colonoscopy reports containing polypectomies over a 3 month period. The exact time frame of data collection was not disclosed to the endoscopists. Data collection included the index colonoscopy report, the pathologic report, and the recommendations given by the physician. We then performed an intervention – we presented the first phase results to the all the physician, giving a personal reports to each physician. We also conducted a study group meeting where post polypectomy surveillance guidelines were reaffirmed and a dedicated form for reporting post-polypectomy surveillance recommendations, created in the patient's electronic medical file was presented. The second phase of the study included a second prospective, post-intervention collection of post-polypectomy recommendations.
Results: Prior to the intervention, only 76% of the post-polypectomy colonoscopies included a clear written recommendation for surveillance, of which 57% received a recommendation consistent with societal guidelines. After the intervention, 85% of the post-polypectomy colonoscopies had clear written recommendation for surveillance, of which 72% received a recommendation consistent with the guidelines ($p = 0.044$ and $p = 0.004$ respectively). Before intervention, various methods were used by the physicians for recommendations regarding surveillance

Abstract No: P0792

	Recommendations		Recommendations		Recommendations non-adherent to guidelines	
	Had recommendation	Didn't have recommendations	Adherent	Non-adherent	Too late recommendations	Too early recommendations
Prior to Intervention	130	41	72	58	15	41
After intervention	153	28	110	43	5	38
Total	283	69	182	101	20	79
P-value	0.044		0.004		0.063	

[Table 1; Documentation and consistency of post-polypectomy surveillance recommendations before and after intervention.]

colonoscopy (as part of the endoscopic report, or added to the pathologic report, or handwritten on the pathologic report, or in a follow-up clinic visit report). After intervention, 62% of recommendations were written in the new electronic form, of which 79% were consistent with guidelines. When the electronic form wasn't used, only 59% were consistent with the guidelines ($p = 0.009$).
Conclusion: Intervention, by guideline re-affirmation, and creation of a dedicated reporting form, significantly increases the number of well documented follow-up recommendations after polypectomy, and their consistency with societal guidelines.

Introduction: Assessment and rate of adequate bowel preparation are important quality measures for colonoscopy according to European Society of Gastrointestinal Endoscopy (ESGE) guidelines.[1] We aimed to assess factors influencing the likelihood of adequate bowel preparation for colonoscopy.
Aims and Methods: The development of the European Colonoscopy Quality Investigation Group (ECQI) online questionnaire has been previously described.[2,3] We analysed data collected between 2/6/16 and 31/1/18. A univariate logistic regression analysis was performed to assess which factors influence achievement of adequate bowel preparation, defined as a Boston Bowel Preparation Scale (BBPS) score ≥ 6.
Results: Data from 4447 completed questionnaires were analysed. 126 procedures were excluded due to insufficient information to establish adequacy of bowel cleanliness; of the remainder, 3726 (86%) procedures scored BBPS ≥ 6 and 595 (14%) BBPS < 6.
The achievement of adequate bowel cleansing was significantly affected by age (< 50 vs. ≥ 50 odds ratio (OR) 2.05, $p < 0.001$), gender (male vs. female OR 0.77, $p = 0.004$), inpatient status (inpatient vs. outpatient OR 0.42, $p < 0.001$), total quantity of fluid consumed ($p < 0.001$), dosing regimen ($p < 0.001$), the quantity of bowel preparation consumed ($p < 0.001$), and the duration between procedure and the last intake of bowel preparation ($p < 0.001$) (table 1). Reason for procedure also had a significant affect ($p < 0.001$), with screening due to familial risk increasing the likelihood of BBPS ≥ 6 (vs. clinical signs and symptoms OR 2.02, $p = 0.004$). Whether the patient followed instructions has a large influence on bowel clearance (yes vs. no OR 7.07, $p < 0.001$). Body mass index and the time of procedure (am vs. pm) had no significant impact.
Conclusion: Adequacy of bowel preparation can be affected by age, gender and in/outpatient status. Indication can also influence adequacy of bowel clearance, along with both the total quantity of fluid and the quantity of bowel preparation consumed. In addition, using a split-dosing regimen with the last dose taken within 5 hours of the procedure appears to increase the likelihood of a BBPS ≥ 6. Ensuring good explanation of how to take the bowel preparation and stressing the importance of following instructions to the patient could also improve bowel clearance. Further information can be found at www.ecqigroup.eu

Variable	Proportion achieving BBPS ≥ 6	Odds ratio (95% CI)	p value	p value for variable
How much fluid was consumed in total, including additional products?				**<0.001**
Less than 1 litre	70/96 (72.9%)	Reference

Introduction: Direct oral anticoagulants (DOACs) are increasingly used for the prevention of stroke in patients with atrial fibrillation and prevention and treatment of deep vein thrombosis or pulmonary embolism. However, little is known about the outcome after polypectomy of patients under DOACs medication.
Aims and Methods: We performed a retrospective study of patients who had colonoscopy polypectomy at Asan Medical Center from November 2010 to December 2017. We compared the frequency of delayed post-polypectomy bleeding (PPB) for the patients taking DOACs (DOAC group) with patients taking clopidogrel (clopidogrel group).

Results: A total of 405 patients underwent polypectomy during the study period; 320 were on DOACs and 685 were on clopidogrel. The duration of drug discontinuation before colonoscopy was mean 2.9 ± 1.7 days in DOAC group and 5.9 ± 2.5 days in clopidogrel group, respectively. Patients in each group resumed taking DOACs on mean 1.9 ± 2.9 days and clopidogrel on mean 2.0 ± 1.5 days after polypectomy, respectively. Logistic regression analysis revealed no significant difference in frequency of PPB between DOACs users and clopidogrel users. (1.6% vs 1.6%, p = 0.968, unadjusted OR = 0.977, 95% CI 0.312–3.058).
Conclusion: The risk of post-polypectomy bleeding in patients taking DOACs seems not to be higher than the one of post-polypectomy bleeding in patients taking clopidogrel. Further studies are necessary to evaluate the risk of post-polypectomy bleeding related to DOACs.

Introduction: Colonic spasm can interfere with colonoscopy, but the number of antispasmodic agents is limited, and they can cause complications. Topical administration of lidocaine may inhibit intestinal spasm induced by colonoscopic movement. In this study, we aimed to assess the inhibitory effect of topical lidocaine compared with a placebo control.
Aims and Methods: In five tertiary-care hospitals in Japan, 128 patients requiring endoscopic resection of a colorectal lesion were enrolled and randomly and double-blindly allocated to colonoscopy with topical administration of 2% lidocaine solution 20mL (LID, n = 64) or normal saline 20mL (control, n = 64). During colonoscopy, the assigned solution was applied with a spray catheter near the lesion and the area was observed for three minutes. The primary endpoint was the inhibitory effect at three time-points (1, 2 and 3 minutes after dispersion), using a three point scale (excellent, fair, poor). The secondary endpoints were rebound spasm and adverse events. Serum lidocaine levels were measured in 32 patients (LID 16, control 16). The study was approved by the Institutional Review Board of all five participating institutions and registered with the UMIN Clinical Trials Registry (UMIN000024733).
Results: There were no significant differences in patient demographics between groups. The proportion of patients with "excellent" scores was greater in the LID group than the control group, with significant differences observed at 2 minutes (p = 0.02) and 3 minutes (p = 0.02). In LID group, the rate of "excellent" scores increased by 12.5% at 2 minutes and was maintained at 3 minutes. Rebound spasm did not occur in the LID group, compared with 15.6% of the control group (p = 0.001). There were no adverse events. All serum lidocaine levels were below detectable levels.
Conclusion: Topical lidocaine is an effective and safe method for suppressing colorectal spasm during colonoscopy.

Introduction: Colonoscopic polypectomy can prevent colorectal cancer. Polyp detection rates vary considerably due to human error and missed adenomas may contribute to interval colorectal cancers. Automated polyp localisation using deep learning may avoid these problems. Previous work focused on detecting the presence of polyps in individual frames captured from videos. Our aims in this pilot study were to extend this to polyp localisation within video sequences and to explore future-proofing by using algorithms trained on old image processors to locate polyps found using newer endoscopic technologies.
Aims and Methods: We trained and validated a Convolutional Neuronal Network (CNN) on 18517 frames created by merging research colonoscopy datasets from the Medical Image Computing & Computer Assisted Intervention Society challenges. 75% of frames contained polyps in both standard and high definition (HD) from older processors including Olympus Exera II (160/165 series) and Pentax EPKi 7000 (90i series). Our test set consisted of 11 HD videos featuring polyps in white light collected using the latest Olympus 290 endoscopes. Estimated median polyp size was 4mm (range 2–15) and morphology included (Paris Classification IIa = 4, Is = 6 and IIa+IIs LST-G = 1). Images were manually annotated by drawing bounding boxes around polyps and quality controlled by removing uninformative frames (e.g. blurred). A total of 2,611 polyp-containing frames were analysed in the test set. A true positive was scored if the computer-generated segmentation mask prediction overlapped with the bounding box. A false positive indicated a non-overlapping location (more than one can occur per frame).
Results: Our network operated at real-time video rate. F1 score accuracy was 92.5%. Sensitivity for polyp localisation was 98.5% and per-frame specificity 75.4%. Positive predictive value was 90.1%. Incorrect segmentation mask locations were predominantly limited to 3 videos and were generated by artefacts not represented during training.
Conclusion: We demonstrate through analysis of video frames that a CNN can locate polyps with high accuracy in real-time. The algorithm was trained using multiple endoscopy processors and worked with HD images from a new processor. Crucially the algorithm had not previously viewed or trained with any of the images from the new processor. This suggests that the CNN could remain useful as new endoscopic technologies are introduced. Further work will train our model on larger datasets including complete colonoscopy procedures. This should improve accuracy further. Such a system could be used as a red-flag technique to reduce missed adenomas during colonoscopy.

Introduction: Endoscopic resection of all colonic adenomas improves the mortality caused by colon cancer. Cold polypectomy has been widely accepted for removal of small colorectal polyps on the basis of safety and technical ease. However, careful endoscopic diagnosis for identifying advanced neoplasia is essential at cold polypectomy because of its relative risk of incompete resection and inappropriate histological evaluation.
Aims and Methods: Our aim is to investigate clinicopathological characteristics of colon polyps < 10mm and assess the usefulness of Narrow-band imaging (NBI) magnifying endoscopy for diagnosis of advanced neoplasia. We retrospectively analyzed all colorectal lesions < 10mm which were diagnosed by NBI magnifying endoscopy and resected endoscopically from March 2014 to February 2018. Various clinicopathological characteristics were analyzed. The diagnosis by NBI magnifying endoscopy was performed according to The Japan Narrow-band imaging Expert Team (JNET) classification, which is a consensus

criteria Japanese working group has recently established for the evaluation of colorectal lesions. We assessed the efficacy of JNET classification for diagnosis of advanced neoplasia.
Results: 1374 lesions in 644 patients (64% men, with a mean age of 67.8 years +/- 9.9years) were analyzed. The mean size of lesions was 4.65 +/- 1.68mm. Of the 1374 lesions, 843 (61.4%) were located in the right side of the colon (the cecum, ascending colon, and transverse colon), 458 (33.3%) in the left side of the colon (the descending colon and sigmoid colon), and the other 73 (5.3%) in the rectum. Macroscopically, 562 (40.9%) were polypoid type and 812(59.1%) were flat or depressed type. Pathologically, 1227 lesions (89.3%) were confirmed as adenomas (LGA or HGA). 15 lesions (1.1%) and 5 lesions (0.4%) were determined to be Tis and T1 cancer, respectively, counting 1.5% cancer-carrying rate. 62 lesions diagnosed as JNET1 included no neoplasia and 1279 lesions diagnosed as JNET Type2A harbored only 6 neoplasia (0.5%). In sharp contrast, 32 lesions diagnosed as JNET Type2B comprised 13 neoplasia (40.6%) and one lesion diagnosed as JNET3 was neoplasia (100%). Moreover, all T1 cancers were diagnosed as Type2B or 3.
Conclusion: We detected non-negligible number of advanced neoplasia even among small colorectal polyps < 10mm. JNET classifications Type2 and Type3 are useful diagnosis criteria to pick up neoplasic lesions making it possible to select an appropriate treatment method for achieving complete resection.

[2]*RIKEN, Image Processing Research Team, Wako, Japan*

Contact E-Mail Address: khori@east.ncc.go.jp
Introduction: In the gastrointestinal endoscopic survey, the small neoplastic lesions are reported to be overlooked. Recently, artificial intelligence (AI) has been shown the remarkable progress in image recognition. The application of AI system for the endoscopic images are expected to be the favorable assistance. The recent AI progressions are primarily due to the availability of large-scale annotated datasets. But the high-quality images of gastrointestinal endoscopy are limited, especially with annotated and segmented datasets. The efficient machine learning system with lower-scale datasets of endoscopic images are needed.
Aims and Methods: The aim of this study is to develop the novel diagnostic AI model for colon polyp detection with efficient learning system. We indicated the single deep convolutional neural network (CNN) named single shot multibox detector (SSD) [1] and the pre-trained mode by the 4952 natural images of PASCAL-VOC 2007 for developing the AI diagnostic model. Learning for fine tuning with the small number of non-magnified still images with annotation and segmentation data of protruded small colon polyps (≦10mm) with White Light Imaging, and additional learning by images of normal colon were conducted. The diagnostic model was validated at each points of learning with additional images for learning as follows: (the number of colon polyps: 50, 100, 200, and 300 images, colon polyps and normal colon: 300+300 and 400+400 images) and diagnostic ability was obtained. The validation were conducted by using 200 number of still images of small colon polyps (≦10mm) and 200 number of normal colon which were not used for learning. Additionally, the recognition test for video images by the diagnostic model learned 400 images of polyps and 400 images of normal colon are conducted.
Results: The sensitivity, specificity, accuracy for detecting the small colon polyps were improved as learned images of colon polyps was adding (60.0%, 94.3%, 82.3% by the 50 images learning, 85.0%, 91.8%, 89.5% by the 100 images learning, 90.5%, 93.5%, 92.5% by the 200 images learning, 93.0%, 92.8%, 92.8% by 300 images learning). Additional learning model with normal colon images show improvement of specificity, and the diagnostic model learned by 400 images of colon polyps and 400 images of normal colon show the sufficient diagnostic ability (95.0%, 98.5%, 97.3% by the 300 each images learning, 96.5%, 98.5%, 97.8% by the 400 each images learning). The pilot test by the video endoscopic images show the high frame ratio detection for small colon polyps (frame rate > 25/sec).
Conclusion: This AI diagnostic model suggested that the machine learning by latest deep CNN with fine-tuning enables high efficiency of learning for detecting small colon polyps with limited number of teaching image datasets.

Introduction: Using novel endoscopic optical diagnosis techniques, expert endoscopists are able to predict and differentiate between neoplastic and non-neoplastic colonic polyps with high accuracy and are able to meet the PIVI (Preservation and Incorporation of Valuable Endoscopic Innovations) thresholds recommended by the American Society for Gastrointestinal Endoscopy. However, this performance has not been replicated in non-expert endoscopists and thus cannot be currently recommended in clinical practice.
Aims and Methods: The aim of this randomised trial was to establish the optimum method of training, self-training vs. didactic training, to increase the diagnostic accuracy of diminutive/small colonic polyp histological prediction by trainee gastroenterologists.
Gastroenterology trainees from several institutes across the West Midlands, UK, reviewed 78 videos (48 i-Scan-OE and 30 NBI) of diminutive/small in the pre-training assessment. Participants were randomised to receive computer-based learning or didactic training (teaching materials and videos were identical). The same 78 videos, in a different randomised order, were assessed following training. The NICE (NBI International Colorectal Endoscopic) classification and SIMPLE (Simplified Identification Method for Polyp Labelling during Endoscopy) classification systems were used to classify diminutive/small polyps (Figure 1).
Results: 16 trainees (12 gastroenterology trainees and 4 naïve endoscopists-non-GI trainees whom have no prior experience of endoscopy) were randomised to receive either self-training (n = 8) or didactic training (n = 8). A higher proportion of high confidence predictions of polyps were made by the self-training group vs. didactic group both using the SIMPLE classification 77.1% [95% CI 73.4–80.3] vs 69.9% [95% CI 66.1–73.5%] ($p < 0.005$) and using the NICE classification 77% [73.2%−80.4%] vs 69.8% [95% CI 66–73.4%] (p = 0.006). When using NICE classification, the sensitivity of the self-training group compared with the didactic group was 72% vs 83% $p < 0.0005$, and the accuracy 66.1% vs 69.1%. When using SIMPLE classification the sensitivity was 78% vs 83% (p = NS) and accuracy 65.7% vs 69% (Table 1).
Conclusion: Self-learning for the prediction of diminutive/small polyp histology is a method of training that can achieve results similar to the more labour intensive and expensive didactic training. The availability of adequate self-learning teaching modules that teach how to differentiate neoplastic vs. non-neoplastic colonic polyps with high accuracy could enable more widespread implementation of optical diagnosis in clinical practice.

Introduction: ESD being the preferred method for big and complex lesions in the GIT, but some disadvantages of ESD are obvious:
1. Long and flat learning curve
2. Long-lasting and complex procedure
3. Relatively high rate of complications, bleeding and especially perforations
4. Uneven plane of resection
5. Hence, ESD is confined to expert endoscopists.

Thus, a new method, called "Endoscopic Submucosa Resection (ESR)" incl. innovative instruments, called "Flat Adenoma Resection Instruments (FARIn)", have been developed to overcome these drawbacks.
ESR consists like ESD of different steps. First a primary circumferential incision, but then followed by application of and resection with an innovative snare-like resection effector of a FARIn allowing vertically deep end even plan RF-surgical cutting close the muscularis propria without danger of perforation.

Aims and Methods: First systematic clinical study in 22 patients with 15 big lesions in the rectum, 6 in the colon and one in the stomach. The lesions were bigger than 2 cm or had a high risk of perforation (e.g. submucosal lesion, because of location).
To evaluate safety and efficacy of ESR with FARIn especially the intended pressing of the instrument against the wall of the GIT during RF-application to remove the specimen close at the muscularis propria.
In a step-up approach these first patients have been treated without circumferential incision as the first step.
Results: In all 22 patients the lesions were removed successfully without relevant complications and without perforation. The rate of en-bloc resection or resection of one large piece with few small pieces was 15 of 22.
Optimal cutting quality, no delay of cutting even in very big lesions, a completely even cutting plane close to the muscularis propria and very low thermal artifacts allowed a representative, high-quality histopathology. A pure resection time less than 30 seconds could be achieved in all cases.
The new method of ESR using FARIn proved to be promising, especially the possibility of vertically deep resection without risk of perforation, the high quality of cutting and specimen showed clear advantages compared to conventional snare-resection or to ESD.
These findings and a short learning curve due to high ergonomics of the instrument justify further studies including circumcision of the lesion as a first step before application of the snare-like effector of a FARIn to evaluate, if ESR may become a superior alternative to EMR and ESD in therefore suitable cases.
Conclusion: ESR, a new method with innovative instruments for resection of big and complex lesions in the GIT showed in a first clinical assessment remarkably reasonable results in term of efficacy, safety ergonomy and procedure time.

P0801 MELANOSIS COLI: A HELPFUL CONTRAST EFFECT OR A HARMFUL PIGMENTATION?

F. Abu Baker, A. Mari, D. Feldman, Y. Kopelman
Hillel Yaffe medical center, Gastroenterology and Hepatology, Hadera, Israel

Contact E-Mail Address: fa_fd@hotmail.com
Introduction: Melanosis coli is a black or brownish discoloration of the colonic mucosa that results from accumulation of lipofuscin pigment in macrophages within the lamina propria. This condition has long been considered as a harmless pigmentation associated with, but not confined to, a long-term use of anthraquinone laxatives. Several clinical and experimental studies, however, have provided some evidence of a possible relationship between long-term laxative use or melanosis coli and colorectal cancer risk. Other and more recent studies have shown no association with colorectal cancer. Essentially, the majority of these studies did not include matched controls and may be widely affected by confounders.
MC is usually reported to spare hyperplastic and adenomatous polyps. This enables enhanced visibility and improved observation of polyps in the dark background mucosa, probably linking melanosis coli with an increased polyp detection rate. Wither this association signifies also a causal relationship due to an oncogenic or toxic effect of melanosis on colonic mucosa is still unknown.
There is a common impression among endoscopists that melanosis coli is associated with difficult endoscopy and inadequate preparation. This may offset the advantage suggested by the contrast effect and raise the concern of increased cancer miss rate or decreased polyps' detection.
Aims and Methods: We performed a retrospective, large cohort, single-center study, aimed to compare the polyp detection rate and colorectal cancer diagnosis in melanosis patients against matched controls without melanosis. Patients diagnosed with melanosis coli on colonoscopy at our institution over a 15-year period were included. Each melanosis patient was matched with 3 controls by age, gender, setting (inpatient/outpatient) and procedure's indication. We determined the adequacy of bowel preparation in both groups. Cecal intubation rate, polyp detection rate and diagnosis of colorectal cancer were recorded and compared between the 2 matched groups before and after adjustment for bowel preparation. Multivariate analysis was performed to determine the effect of independent parameters associated with polyp detection rate.
Results: A cohort of 718 patients with endoscopic finding of melanosis (melanosis group) and 2154 controls (control group) were included. The polyp detection rates were 33.4% and 21.8% of melanosis and control groups respectively ($p<0.001$). Melanosis however was associated with less diagnosis of colorectal cancer than controls (0.3% vs. 3.9%; $p<0.001$). To eliminate the effect of first colonoscopy, we excluded repeated colonoscopies and performed a subgroup analysis on 596 patients (83%) who underwent first-time colonoscopy. This subpopulation revealed no change in polyp detection rate (32%) or colorectal cancer diagnosis (0.33%). In addition to the recognized positive impact of age and sex on polyp detection, multivariate analysis showed that inpatient setting (OR 1.487, 95% CI, 1.099–2.012), positive fecal occult blood test or personal polyp history as indication for colonoscopy (OR 1.825, 95% CI, 1.276–2.611; $p=0.01$ and OR 5.464, 95% CI 3.865–7.723; $p<0.01$ respectively) and melanosis diagnosis on endoscopy (OR 1.986, 95% CI, 1.626–2.425; $p<0.01$) were significantly associated with polyp detection rate. Melanosis patients tend to be less adequately prepared compared to controls (58.5% vs. 65.7%; $p<0.001$).
Conclusion: Melanosis coli is not associated with a greater risk for CRC. Rather, there is an increase in polyp detection rate, apparently due to chromo-endoscopy-like effect of melanosis.

Contact E-Mail Address: joana.rita.carvalho@gmail.com
Introduction: The effectiveness of colorectal cancer screening colonoscopy (CRCSC) in decreasing colorectal cancer incidence depends on the detection of polyps and the quality of the procedure. Several key quality measures have been proposed to improve the effectiveness of screening colonoscopies [1].
Aims and Methods: We aimed at evaluating quality indicators of CRCSC in a tertiary teaching hospital with gastroenterology trainees in endoscopy and determine if the presence of trainees influences the quality of CRCSCs. A total of 2118 consecutive CRCSC reports were retrospectively evaluated over a 5 year period. The adherence to currently utilized quality indicators was assessed. Statistical analysis was performed with SPSSv23; A p value <0.05 was considered statistically significant.
Results: The mean age of the patients was 65.5 ± 10.7 years and 56.9% (1205) were women. Sedation was performed in 77.1% (1634) CRCSCs. In 516 (24.4%) of the exams a gastroenterology trainee was present. Cecal intubation rate (CIR) was 86.5% (1833). Most common reasons for an incomplete CRCSC were: patient intolerance 46.3% (132); inadequate bowel preparation 20.4% (58) and technical difficulties with colonic loop formation and adherences in 15.1% (43). Photodocumentation of cecal landmarks (PCL) was performed in 97.3% (1783) of the cases. Polyp detection rate (PDR) was 34.3% (726), out of which 13.4% (97) of the polyps were $\geq$1cm in diameter. The Boston Long-lastingBowel Preparation Score (BBPS) for bowel preparation was used in 25% (530) of CRCSCs. Bowel preparation was considered good in 64.6% (1369) of the cases and fair in 19.7%(417) cases. In multivariate analysis (including gender, age, BBPS, PCL, CIR, PDR and sedation), the presence of a gastroenterology trainee was an independent predictor of compliance to CRCSCs quality indicators: use of BBPS score (OR 7.9, 95% CI 5.7–9.0, $p < 0.001$), PCL (OR 2.8, 95% CI 1.1–6.9, $p=0.025$) and PDR (OR 1.5, 95% CI 1.2–1.8, $p=0.001$). The presence of a gastroenterology trainee during CRCSCs was the only independent predictor of a higher PDR (OR 1.6, 95% CI 1.3–2.0, $p < 0.001$).
Conclusion: A suboptimal CIR were mostly due to intolerance and inadequate bowel preparation. The presence of a gastroenterology trainee improved adherence to quality indicators in CRCSCs, namely an adequate description of bowel preparation, the PCL and the PDR.

Introduction: For years efforts have been made to improve the quality of colonoscopy. Cap-assisted colonoscopy has been shown in some studies to increase the adenoma detection rate (ADR). Full-spectrum colonoscopes (FUSE) with 330°angle of view showed by initial studies a significantly lower adenoma miss-rate and higher ADR. Subsequent FUSE studies with already high ADR with SFV were unable to confirm these results. Our practice-based, randomized study compares the efficiency, i.e. ADR, of the relatively inexpensive cap assisted, the FUSE or SFV colonoscopy.
Aims and Methods: From March 2015 through February 2018 patients referred for ambulant colonoscopy were randomly allocated to either colonoscopy with high definition SFV Pentax i10 ($n=958$) or FUSE instruments ($n=1552$). The group of patients assigned to SFV endoscopy was since March 2017 examined with the additional use of Endocuff ®, making up another 339 patients. All procedures were performed by one experienced endoscopist.
Results: Baseline characteristics of the 2849 patients were similar within the three groups. Mean age was 64 (CI 63–66), half were male, BBPS (Boston Bowel Preparation Scale) score was 7.23 (CI 7.2–7.3). 30% were screening, 60% surveillance, the remaining diagnostic colonoscopies. Ileum intubation rate was 99% in all three groups. Patients were sedated with Propofol (mean dose overall 195; CI 190–200), significantly less with Endocuff (172; CI 165–180), $p=0.0007$. With multivariate analysis male sex, diabetes and age were significant risk factors for more adenomas. Better bowel cleansing was also significantly associated with

higher adenoma detection. ADR was 50% for FUSE, 54% for SFV and 47% for Endocuff (ns = not significant). Adenoma per colonoscopy (APC) were 1.1 in FUSE vs 1.2 in SFV vs 1 with Endocuff (ns). All polyps per colonoscopy (PPC) were 1.8, 1.9 and 1.5 respectively. 4% of all polyps in all groups were pedunculated the others sessile. 1.2 to 1.8% of polyps could not be examined histologically. 80% of the polyps were below 5 mm of size, 15% were between 5–9 mm and 5% bigger than 1 cm. One-third were right sided, one-quarter located in the tansverse colon. 76% (FUSE), 80% (SFV) and 67% (Endocuff) were tubular adenomas. For villous adenomas it was 2% for FUSE, 2% for SFV and 1.5% for Pentax with Endocuff. In the SFV group 38% serrated adenomas (SSA) were found, for FUSE 28% and for Endocuff 31%. Hyperplastic polyps were 24% in de FUSE group, in SFV 20% and in Endocuff 14% (p 0.04). 0.7% were carcinomas. Time to ileum was with FUSE 5.4 min, with SFV 5.5 min, with Endocuff 6.3 min. Intervention time was for all groups 3.3 min (showing no difference in the handling of interventions). Withdrawal time was 16.3 min with FUSE, 18.1 min for SFV and 14.1 min for Endocuff ($p = 0.04$).

Conclusion: In a collective of 2849 patients randomly assigned to 3 different types of colonoscopies neither FUSE nor Endocuff could increase the ADR in a significant way. At present if ADR reaches around 50% no further benefit can be expected from new technology. Key factor for a high ADR seems to be long withdrawal times (e.g. 14 up to 18 min in SFV). FUSE and Endocuff show significant shorter endoscopy times (FUSE little faster in ascent, Endocuff and FUSE faster in withdrawal), Endocuff even significantly less medication for sedation.

P0804 THE OBJECTIVE EVALUATION USING EYE TRACKING FOR VISIBILITY OF COLORECTAL LESIONS

K. Kumahara, H. Ikematsu, H. Sunakawa, Y. Furue, R. Ito, D. Satou, T. Minamide, N. Okamoto, Y. Yamamoto, K. Takashima, K. Nakajo, T. Murano, K. Shinmura, Y. Yoda, K. Hori, Y. Oono, T. Yano
National Cancer Center Hospital East, Department of Gastroenterology and Endoscopy, Kashiwa, Japan

Contact E-Mail Address: kkumahar@east.ncc.go.jp

Introduction: Recently, image-enhanced endoscopy (IEE) such as blue laser imaging (BLI-bright) and linked-color imaging (LCI) has been reported to improve detection and the miss rate of colorectal lesions. Improvements in visibility due to IEE have been assessed by according to endoscopists' visibility scores in many studies. However, such assessments are subjective, and objective assessments, such as quantifying the time required for endoscopists to detect lesions, are lacking. We have considered that one method of objectively measuring endoscopists' attention in real time, and thus determining the time they need to detect lesions, is eye tracking. Eye tracking uses a sensor to detect exactly where a participant's eyes are focused.

Aims and Methods: We aimed to objectively assess the detectability of BLI-bright, LCI and WLI in the colorectal lesions using eye tracking.

We recruited 11 endoscopists, 2 experts and 9 trainees, who were required to evaluate a total of 90 images of 30 colorectal lesions (28 flat lesions of less than 5 mm, one depressed lesion of 5 mm, one SSA/P of 10 mm) was used. The 3 images of each lesion comprised white light imaging (WLI), BLI-bright, and LCI at the same position in the image using the EC-L590ZP, EC-L600ZP, and EC-L600ZP7 colonoscopes (Fuji film Co, Tokyo, Japan). The lesions were not located central in the image to avoid too easily detecting. Eye movements were tracked with the Tobii X2-60 eye tracking device (Tobii AB, Danderyd, Sweden). Images were shown on a screen in random order for 5 s per image; between each image, the screen went dark for 3 s. Participants stopped eye movement upon detecting the lesion. The detection time was defined as the time between the image being displayed and the time at which the evaluator's eyes stopped. Detection time for undetected lesions was considered to be 5 s for analytic purposes. We assessed the number of missed lesions and the lesion detection time between the 3 image modalities, the difference between experts and trainees.

Results: One expert whose eye movements could not be tracked was excluded. Of the total of 300 assessed images per modality, 38 (12.6%) lesions were missed with WLI, 18 (6.0%) with BLI-bright, and 13 (4.3%) with LCI; the miss rate of the latter two groups was significantly lower than that of the WLI ($p < 0.01$), but was not significantly different between them ($p = 0.54$). The mean (± standard deviation) detection times were 1.58 ± 1.60 s for WLI, 1.01 ± 1.21 s for BLI-bright, and 1.10 ± 1.16 s for LCI. The detection times for both BLI-bright and LCI were significantly shorter than that for the WLI ($p < 0.0001$), but were not significantly different between each other ($p = 0.34$). In the miss rate and the detection time between expert and trainees, there was a significant difference in WLI, but there was no significant difference in BLI-bright and LCI.

Conclusion: Both BLI-bright and LCI improved the detection rate and speed of colorectal lesions by endoscopists, especially trainees compared to WLI when objectively assessed using eye tracking.

Introduction: Multiple evidence-based guidelines have been produced recently to address the question of how best to perform colonoscopic polypectomy.

Aims and Methods: We aimed to assess the adherence to these guidelines in 7 countries using an online survey, comparing responses to the standards presented in the 2017 ESGE Colorectal 1 polypectomy guideline. An institutional review board approved online survey was distributed to the members the gastroenterological and surgical societies of 7 countries via email during July 2017. The survey presented images of colorectal polyps and their colonic location and asked for the polypectomy technique respondents would use in their daily practice. A reminder email was sent after two weeks and the survey closed after 4 weeks.

Results: 19,467 endoscopic practitioners in 7 countries received the survey. Of 772 (4.0%) who responded, 707 (91.6%) fully completed the survey and their data was analysed. 162, 155, 131, 102, 60, 53 and 45 respondents were from Australia, USA, UK, Belgium, Canada, Israel and New Zealand respectively. 625/707 (88.8%) were physicians, 9.9% were surgeons and 1.3% were nurse endoscopists. Respondents had a median endoscopy practice duration of 18 years (IQR 10–27). Of two images of < 10 mm right sided colonic polyps presented, 51.1% of respondents suggested they would perform cold snare polypectomy in line with guidance. 11.2%, however, suggested cold biopsy forceps and 37.7% suggested endoscopic mucosal resection (EMR) / hot snare polypectomy. Of two large 20 and 45mm transverse colon LSLs with no endoscopic evidence of SMIC, 80.9% suggested EMR, undertaken themselves (48.3%) or referred (32.6%) to another practitioner in line with guidance. 13% would have biopsied the 45mm lesion prior to referral. 9% suggested they would refer these lesions directly to a surgeon. Regarding an image of a large 80mm sigmoid lesion with an endoscopically visible demarcated area consistent with deep submucosal invasive cancer, 51.6% said they would refer to a surgeon in line with guidance whereas 27% suggested they would attempt EMR, 1.4% ESD and the remainder refer the case to another endoscopic practitioner.

Comparing the adherence to guidelines throughout all questions, surgeons (50%) were less adherent than physicians (65%), $p = < 0.001$, consultants (63%) similar to trainees (67%), $p = 0.122$ and those who had undertaken an interventional endoscopy fellowship (63%) similar those who had not (64%), $p = 0.450$.

Conclusion: These data demonstrate encouraging adherence to international guidelines. The work of international endoscopy societies should focus on encouraging the use of and promoting training in cold snare polypectomy for diminutive polypectomy and techniques for endoscopic imaging of large colorectal polyps.

P0806 DETERMINING THE MOST EFFECTIVE SURVEILLANCE SYSTEM AFTER AN ENDOSCOPIC POLYPECTOMY: A STUDY BASED ON THE LONG-TERM SURVEILLANCE OF 3,038 PATIENTS

R. Nozaki, Y. Nakamura, K. Yamada
Coloproctology Centre Takano Hospital, Kumamoto, Japan

Contact E-Mail Address: rnozaki0312@yahoo.co.jp

Introduction: No guidelines have yet been established in Japan for the surveillance after endoscopic removal of colorectal polyps. However, Takano hospital has developed a periodical endoscopic follow up system which has been in place since 1983 to observe patients who have undergone an endoscopic polypectomy. Moreover, this system has been carried out according to the current surveillance system since 2006. The results of 3,038 patients have been retrospectively analised to determine the most effective surveillance method after an endoscopic polypectomy.

Aims and Methods: [The Takano Hospital surveillance colonoscopy programme] All colorectal polyps of any size that were adenomas or suspected to be adenomas were endoscopically removed and the patients were then enrolled in our surveillance programme. The subjects were basically in a clean colon condition. The programme is as follows: one year after the endoscopic removal of the polyp (s) the patients are notified by mail to voluntarily undergo a colonoscopy; polyps are endoscopically removed if detected; patients are notified again by mail the following year to undergo another colonoscopy; and if no polyps are detected the patients are then recommended to undergo a colonoscopy every two years for a set period of time. Mails to the patients are discontinued if they fail to respond after three notification attempts.

Patients (n = 3,038) who adhered to this surveillance programme were enrolled in this study. There were 1,866 males (61%) and 1,172 females (39%). The mean age was 61.2 ± 10.9 years and the observation period was 3.1 years (maximum 11 years) on average.
The detection rate of cumulative adenoma and the cumulative detection rate of advanced neoplasia (AN) that includes carcinomas, high-grade adenomas, adenomas 10mm or more in size, and adenomas with villous components were analised using the Kaplan-Meier method. All 3,038 patients were initially analised and then divided into the AN group (n = 1,180) and the non-AN group (n = 1,858) for further analysis.
Results: The overall cumulative detection rates of adenomas were 16.4% at 1 year, 40.8% at 2 years, and 58.9% at 10 years. The cumulative detection rates in the AN group were significantly higher ($p < 0.01$) than the non-AN group. They were 18.5% at 1 year, 45.5% at 2 years, and 51.9% at 9 years, compared with 15.5% at 1 year, 38.1% at 2 years, and 58.9% at 10 years in the non-AN group. Moreover, AN was detected in 104 patients (57 in the AN group and 47 in the non-AN group). The overall cumulative detection rates of AN were 0.3%, 5.1%, and 8.4% at 1, 5, and 10 years, respectively. The cumulative detection rates of AN in the AN group were significantly higher ($p < 0.001$) than the non-AN group. They were 0.4% at 1 year, 7.4% at 5 years, and 9.9% at 9 years, compared with 0.3% at 1 year, 3.8% at 2 years, and 7.1% at 10 years in the non-AN group.
Conclusion: The cumulative detection rate of AN is significantly higher than that of non-AN when the primary lesion is AN and surveillance every 2 years is effective. However, further analysis is needed to determine whether the interval can be extended to 3 or more years. The findings of this study suggest that surveillance after 1 year is unnecessary.

Introduction: Endoscopic mucosal resection (EMR) is now the standard of care for treatment of colorectal laterally spreading lesions (LSLs). The SMSA score is an effective tool in grading the difficulty of polypectomy but does not recognize EMR specific risk factors[1]. EMR specific risk assessment tools to predict procedural outcomes are currently lacking.
Aims and Methods: To develop and validate a new EMR specific endoscopic risk score (SMSA-EMR score) to predict technical success, adverse events and recurrence after EMR.
Prospective multicenter data on consecutive large LSLs (≥ 20mm) referred for EMR was included (from 9/2008–5/2017). Independent risk factors associated with difficulty of resection at EMR were identified from literature review and the existing well validated SMSA score. A binary logistic regression model was then generated from a random half of the cohort to derive the SMSA-EMR score. This new score assesses large LSLs in four domains with information gained from the EMR procedure. This score was then applied to the remainder of the cohort.
Results: 2675 lesions in 2675 patients (52.6% M, 65.2% right colon) underwent EMR. The new score was validated on 1157 lesions with a median lesion size of 35mm (IQR 25–45mm). Each lesion was scored on four variables and based on the total SMSA-EMR score divided into two groups, low-risk and high-risk (See Table 1), comprising 54.8% and 45.2% of the cohort respectively. Failed single session EMR occurred in 46 (3.9%) LSLs and was predicted by the SMSA-EMR score ($p < 0.001$), see Table 2. Adverse outcomes were observed with significantly less frequency in the low-risk group, which included intra-procedural bleeding [Odds ratio (OR) – 0.42, 95% Confidence Interval – (0.30–0.57), $p < 0.001$], post-EMR bleeding [OR – 0.54 95% CI (0.33–0.89), $p = 0.002$] and surgical referral at 2 weeks [OR – 0.53 95% CI (0.31–0.93), $p = 0.03$]. Recurrence at first surveillance colonoscopy (SC1) was significantly less likely for the low-risk group [OR 0.34 95% CI (0.23–0.51), $p < 0.001$].
Conclusion: SMSA-EMR is a novel, readily applicable endoscopic risk assessment score which identifies a subset of patients undergoing EMR who are at increased of a failed procedure, adverse events and recurrence. This score has important implications for the post-procedure care of high-risk patients such as planning for overnight hospital admission and ensuring patient adherence to attending follow up examinations. On a broader scale this score may also serve as a benchmark for assessment of trainee competency in advanced tissue resection. It may also lay the foundation to allow for assessment of EMR quality across different endoscopy units, similar to the scoring systems used in surgical audits. Further large multicenter prospective trials are however required to validate this new score for EMR.

Introduction: Colorectal endoscopic submucosal dissection (ESD) is widespread as a minimally invasive treatment for colorectal lesions. The procedure is associated with greater technical difficulty than gastric or oesophageal ESD due to poor maneuverability and structural characteristics. Amongst such cases, those involving fibrosis are extremely difficult. Large, protruding lesions are typical examples of such cases. These lesions are not only difficult to diagnose preoperatively, the muscular layer appears to be drawn by the lesion even in the case of intramucosal lesions (muscular-retracting sign), making separation both difficult and dangerous in some cases. We investigated the safety and validity of this procedure based on ESD treatment outcomes for cases of large, protruding lesions of at least 3 cm treated at Keio university hospital.
Aims and Methods: The subjects comprised 30 patients who underwent colorectal ESD at Keio university hospital between 2012 and June 2017 for large, protruding lesions of at least 3 cm in size. We investigated (1) lesion characteristics (location, macroscopic type, tumour diameter) and treatment outcomes (procedure time, endoscopic en bloc resection rate, pathological complete resection rate, procedure-related adverse events, presence/absence of fibrosis), and then compared (2) clinicopathological factors in cases with muscular-retracting sign (positive group) with cases without such findings (negative group).

Abstract No: P0807

	Low-Risk	High-Risk	Total	p	Low risk vs high risk OR (CI)	p
Total count, n (%)	634 (54.8)	523 (45.2)	1157			
Technical success of EMR, n (%)	624 (98.4)	487 (93.1)	1111 (96.0)	<0.001	4.61 (2.3–9.4)	<0.001
CSPEB, n (%)	27 (4.3)	40 (7.6)	67 (5.8)	0.01	0.54 (0.33–0.89)	0.02
IPB, n (%)	87 (13.7)	143 (27.3)	230 (19.9)	<0.001	0.42 (0.3–0.57)	<0.001
Surgical referral at 2 weeks, n (%)	22 (3.5)	33 (6.3)	55 (4.8)	0.02	0.53 (0.31–0.93)	0.03

*[SMSA – EMR Score and **Outcomes:** CSPEB (clinically significant post endoscopic bleeding), IPB (intra-procedural bleeding), *total no. underwent SC1/2]*

Results: (1) The location was the right colon in 15 cases, the left colon in 4 cases and the rectum in 11 cases. The macroscopic type was Is in 16 cases and Isp in 14 cases. The mean tumour diameter was 39.8 mm (30–67). The mean procedure time was 55.9 minutes (15–120), the endoscopic en bloc resection rate was 96.7%, the pathological complete resection rate was 86.7% and fibrosis was noted in 12 cases (40%). In terms of procedure-related adverse events, perforation was noted in 1 case and treatment had to be suspended in 1 case. (2) Findings positive for muscular-retracting sign were noted in 7 cases (23.3%). Amongst these cases, the invasion depth was adenoma in 2 cases, intramucosal carcinoma in 3 cases and submucosal invasive carcinoma in 2 cases. The endoscopic en bloc resection rate was 85.7%, the pathological total resection rate was 57.1% and procedure-related adverse events (perforation) was noted in 1 case. Although no significant difference was observed between the positive and negative cases in terms of lesion location or macroscopic type, mean tumour diameter and mean procedure time were significantly larger/longer in the positive group.
Conclusion: Our results suggested that treatment outcomes for ESD performed on large, protruding lesions of 3 cm or larger were favourable. It also appears that ESD could be used to resect even lesions accompanied by muscular-retracting sign. Some cases of adenomas also exhibit muscular-retracting sign and, if possible, endoscopic resection is optimal. However, as procedures in this investigation were performed by an experienced endoscopists, it is currently unclear as to whether ESD is unconditionally safe for such cases. It appears necessary to keep surgical resection in mind, and to judge one's own skill level as well as the level of difficulty posed by the lesion preoperatively.

P0809 THE TRACTION METHOD "RUBBER-CLIP-METHOD" CONTRIBUTES TO EFFECTIVE SUBMUCOSAL DISSECTION IN COLORECTAL ESD

T. Akamatsu, Y. Nakatani, Y. Yamashita
Japan Red Cross Society Wakayama Medical Center, Gastroenterology and Hepatology, Wakayama City, Japan

Contact E-Mail Address: aktk49@yahoo.co.jp
Introduction: In colorectal ESD, it is important to obtain sufficient traction for effective submucosal dissection. However, with gravity alone, it is often difficult to obtain sufficient traction for effective submucosal dissection. On the other hand, several traction methods have been developed and their usefulness have been reported. Although they are useful, some points remain in terms of complexity or cost, and so on. Here, we introduce another traction method using clip with rubber band, "rubber-clip-method (RCM)". The advantages of RCM are simplicity, cost effectiveness and capability to change direction of traction.
Aims and Methods: We aimed to investigate the usefulness of RCM in colorectal ESD. A retrospective, single-center, observation study. Out of 145 consecutive patients of superficial colorectal neoplasms experienced in January 2014 – August 2017, 118 patients were included. 6 cases of NET-G1, 7 cases discontinued ESD due to severe fibrosis, 2 cases performed ESD with surgical treatment, and 12 cases used traction methods other than RCM were excluded. Of the included 118 cases, 51 cases were not used traction method (non-traction group), and 67 cases were used RCM (RCM group). Study 1: The comparison of the results of the ESD of the non-traction group and the RCM group. Study 2: We divided cases into 2 groups according by operation time, 88 cases of less than 120 minutes and 30 cases of 120 minutes or more. And we investigated the influence of using RCM or differences of background factors for long operation time of ESD with univariate and multivariate analysis.
Results: Study 1: Background factors such as age, male-female ratio, tumor location, macroscopic type, specimen diameter, pathological type, depth of invasion, degree of fibrosis and operability of endoscopic maneuver showed no remarkable differences between two groups. Both the rate of en bloc resection of RCM group and non-traction group (97% vs 88%, respectively) and the perforation rate (0% vs 4%, respectively) showed better tendency with RCM. The operation time of RCM group was significantly shorter than non-traction group (63 minutes vs 114 minutes (median), respectively). Study 2: In the univariate analysis, four factors such as the specimen diameter (40 mm or more), the severity of fibrosis (moderate or more), operability of endoscopic maneuver (poor) and without traction method showed a significant relationship with long operation time of ESD. In the multivariate analysis, the above four factors independently showed a significant effect for long operation time of ESD. Therefore, the use of RCM was a factor that independently affected the operation time.
Conclusion: The traction method "clip with rubber band method" contributes to effective submucosal dissection in colorectal ESD.

Introduction: The European Society of Gastrointestinal Endoscopy guidelines (1) recommend measuring patient experience and 30-day complication rate after colonoscopy. We aimed to compare effectiveness of digital and paper-based feedback of patients experience and 30-day complications after screening colonoscopy.
Aims and Methods: We included all primary screening colonoscopies performed in two centres from September 2015 to December 2016. Consecutive patients were randomized in a 1:1 ratio either to intervention arm (choice of feedback method) or control arm (routine paper-based feedback). Participants in the intervention arm were asked on their preferred method of feedback (paper-based, automated telephone or online survey) and additionally were informed about the planned automated telephone contact 30 days after the procedure to assess complications. Participants in control group were not contacted, instead they could self-report complications in routine way. The primary endpoint was participant's response rate to feedback questionnaire. Secondary endpoint was participant's response to complications questionnaire. The study was registered as a randomized health services study (RHS_008_2015_june).
Results: We included a total of 2,541 participants, median age: 59.9 years, males:females ratio 1.05 (1,281 in intervention arm, 1,260 participants in control arm).
The response rate to feedback questionnaire for total study population was 63.16%. In the intervention arm, 155 (12.1%) participants chose online survey, 287 (22.4%) – automated telephone survey and 839 (65.5%) – paper-based survey. There was no significant difference in response rate between study groups (64.8% vs 61.5%; $p = 0.08$). Overall response rate was lower in participants aged less than 60 years (57.8% vs 68.1%, $p < 0.001$), males (61.3% vs 65.1%, $p = 0.05$), and participants in small, non-public centre as compared to large, public centre (49.1% vs 64.5%, $p < 0.001$). Free choice of feedback method significantly improved response rate among participants with baseline lower response rate: younger than 60 years (60.8% vs 54.7%; $p = 0.031$), male (64.0% vs 58.6%; $p = 0.045$) and in small non-public centre (56.2% vs 42.5%; $p = 0.043$).
In the intervention arm, 1,168 participants (91.2%) answered the phone call concerning complications. Of them, 776 (66.4%) completed the automated questionnaire. A total of 79 participants (6.2%) reported complications. When verified, 46 reported complications (58.2%) were administrative errors. Another 25 (2.1%) reported complications were not clinically relevant. Finally, only 2 participants (0.2%) reported clinically relevant complications – one post-polypectomy bleeding requiring hospital admission and one appendicitis with appendectomy one day after screening colonoscopy. No complications were self-reported in the control group.
Conclusion: The overall response rate was not significantly improved with digital feedback, yet it yielded significant improvement in participants with baseline low response rate. Our study demonstrated feasibility and efficacy of digital patient feedback on complications after colonoscopy.

P0811 THE ROLE OF PAIN CATASTROPHIZING IN PAIN EXPERIENCE DURING ENDOSCOPIC PROCEDURES

R. Palma[1], M. Lauriola[2], C. Panetta[1], M. Raniolo[1], A. Foglia[2], G. La Spina[2], M. Cremona[3], M. Tomai[3], S. Pontone[1]

Introduction: Endoscopic procedures are unpleasant and in most cases painful. Identifying the factors that may contribute to their acceptance might be beneficial for the patient and helpful for the phyisician. Pain Catastrophizing (PC) has been associated with a number of pain-related outcomes, including chronic pain in IBD and experimentally induced pain but its role in the experience of pain during medical procedures has not yet being investigated.

Aims and Methods: We investigated the role of PC and its relation to patient reported and clinician rated pain during endoscopic procedures.
143 consecutive outpatients undergoing endoscopy from September to May 2017 were enroled. Gender (57% females), age (M = 57.83; SD = 17.17), body mass index (M = 25.28; SD = 4.22) and previous endoscopic experiences (56%). During endoscopy, operators evaluated the patient using the Pain Assessment in Advanced Dementia (PAINAD) Scale. The Ramsay Sedation Scale (RSS) was used to assess patient's level of consciousness and sedation effectiveness. After endoscopy and before discharge patients reported about pain and discomfort during the procedure. A total score for self-reported pain was derived through principal component analysis of visual-analogue, verbal, numerical and face scales. The Pain Catastrophizing Scale (PCS) was also administered to retrospectively assess patient's aptitude for catastrophic pain. We carried out regression and mediation analyses to test study's main hypotheses.
Results: Age, gender, BMI and previous endoscopic experiences were uncorrelated with clinician reported pain. As it regards self reported pain, the analysis revealed marginally significant differences by gender ($p < 0.05$) and age ($p < 0.05$) with women and younger people reporting more pain. PC was significantly larger for women ($p < 0.01$). Clinician rated pain during the procedure predicted patient self reported pain (Beta = +0.646; $p < 0.001$; $R2 = 0.41$). PCS was also associated with self-reported pain (Beta = +0.584; $p < 0.001$; $R2 = 0.34$). Mediation analyses revealed that the relationship between clinician rated pain and self reported pain was accounted for by PCS (Indirect Effect of clinician rated pain on self reported pain through PCS = +0.191; [+0.142; +0.258]). Nevertheless, clinician-rated pain (Beta = +0.264; $p < 0.001$; $R2 = 0.41$) still was predictive of self-reported pain controlling for PCS. Mediation analyses results were robust controlling for gender, age and body mass index as well as for previous endoscopic experiences and types of endoscopic procedure.
Conclusion: PC was found to play a central role in the experience of pain during both upper and lower endoscopy in fact PC explains the association of clinician rated pain with patient reported pain. While similar findings have been reported in the context of chronic pain studies, this is the first study showing that catastrophizing is also important in the experience of pain during medical procedures. In order to make endoscopic procedures more acceptable and to facilitate the medical examination by the operator, non pharmacological interventions to reduce PC by a cognitive-behavioral therapy might disclose an avenue for future research and clinical practice.

P0812 SAFETY AND EFFICACY OF THE FULL-THICKNESS RESECTION DEVICE (FTRD) IN THE COLORECTUM: A POOLED ANALYSIS OF PUBLISHED RESULTS

A. Wannhoff, B. Meier, K. Caca
Klinikum Ludwigsburg, Ludwigsburg, Germany

Contact E-Mail Address: andreas_wannhoff@gmx.de
Introduction: The full-thickness resection device (FTRD) is approved for the resection of difficult adenoma and subepithelial tumors in the colorectum.
Aims and Methods: The aim of this study was to analyse the safety and efficacy of the FTRD in the colorectum. A pooled analysis of data from published studies was performed. All studies that reported on the use of the FTRD in the colon and rectum were eligible for inclusion. A literature search was done to identify published studies and relevant congress abstract databases were searched.
Results: A total of 18 studies were included, 9 of them published as full-text and 9 as congress abstracts, which comprised a total of 532 patients from 7 countries. The target lesion was reached with the FTRD mounted on top of the endoscope in 522 (98.1%) patients and technical success was achieved in 486 (91.4%). The full-thickness resection was histological confirmed in 326 of 401 (81.3%) patients, in the remaining 131 no data on this endpoint was reported. The R0 resection rate was 77.5% and achieved in 383 of 494 patients for which data on resection margings were reported. Technical problems were mostly related to the resection snare, which occurred in 34 cases. In most of these cases a successful resection however was achieved by use of a conventional resection snare following clip application with the FTRD. Complications included minor bleeding and postpolypectomy syndrome in 14 (2.6%) patients each. Severe bleeding was rare and occurred in 2 (0.4%) patients and perforations were reported in 13 (2.4%) patients. A surgical intervention due to a FTRD related complication was necessary in 9 (1.7%) patients.
Conclusion: The FTRD system provides high efficacy in the colorectum. The complication rate is low and most complications can be managed conservatively or endoscopically.

P0813 DOES POLYP DETECTION RATE CORRELATE WITH MEAN ADENOMA PER COLONOSCOPY?

G. Vojtechová[1], S. Suchanek[1], O. Ngo[2], B. Buckova[2], T. Grega[1], M. Voska[1], O. Májek[2], M. Zavoral[1]

[2]*Institute of Biostatistics and Analyses, Faculty of Medicine, Masaryk University, Brno, Czech Republic, Brno, Czech Republic*

Contact E-Mail Address: vojtechova.g@gmail.com
Introduction: Adenoma detection rate (ADR) is the primary quality indicator for colonoscopy. Mean adenoma per colonoscopy (APC) reflects colon inspection better than ADR and is more appropriate to illustrate differences between individual endoscopists. Both these factors are rather difficult to obtain in terms of time and personnel. Polyp detection rate (PDR) is a user friendly alternative of ADR that can be easily evaluated from administrative data.
Aims and Methods: The aim of our study was to assess whether PDR and APC are correlated and to determine conversion factor to predict APC from PDR in preventive (faecal occult blood test positive (FOBT+) and screening) colonoscopies.
Retrospective study included asymptomatic individuals aged 45–75 who underwent preventive colonoscopy in 2012–2016 as part of Czech prospective multicenter study monitoring metabolic risk factors of colorectal cancer. Individuals with incomplete colonoscopy and endoscopists with less than 30 colonoscopies and/or no detected adenoma in the observed group were excluded from the study. Spearman's correlation coefficient was used to assess the relation between individual PDR and APC. The resulting conversion factor to predict APC from PDR was obtained by linear regression.
Results: In total, the study included 1,614 preventive colonoscopies performed by 16 endoscopists. Correlation between PDR and APC in all preventive colonoscopies was high and statistically significant (Rs 0.70; $p = 0.0027$). There is a stronger correlation between PDR and APC in men (Rs 0.73; $p = 0.0029$) than in women. Conversion factor to convert APC from PDR is 0.0123 and 0.0108 for all preventive and screening colonoscopies respectively. In FOBT+ colonoscopies linear regression did not reflect the actual variability observed in data.
Conclusion: There is a strong correlation between PDR and APC. Because of better availability, PDR may replace ADR and APC in colonoscopy quality assessment. With some limitations, APC may be estimated from PDR using a conversion factor that varies based on colonoscopy indication and patient gender. With respect to the minimum ADR requested, i.e. 25% recommended by both ASGE and ESGE, all preventive colonoscopies should reach APC $\geq$ 0,4.

Contact E-Mail Address: barbi.lovasz@gmail.com
Introduction: LCI (Linked Color Imaging) is a new endoscopic visualization technique which may increase colorectal adenoma detection rate by the improved endoscopic image enhancement combined with virtual chromoendoscopy. However only limited data available in the literature on the effectiveness of this new technology.
Aims and Methods: We aimed to evaluate the effectiveness in the adenoma detection rate of LCI in patients referred to colonoscopy and compared to the results of the white-light colonoscopy technique.
We enrolled outpatients consecutively, between October 2016 and December 2017, who were met the study inclusion criteria. Patients with previous CRC history or incomplete colonoscopy were excluded. All of the colonoscopic procedures were made under deep propofol sedation guided by an anesthesiologist team. Eligible patients were randomly selected to undergo colonoscopy with high-definition white-light colonoscopy (HD-WLC) technology or LCI Eluxeo technology during instrument withdrawal, by Fujinon 7000 processor and with EC590Z, EC760, EC760Z colonoscopes. Each colonoscopic procedure was performed by three expert endoscopists with a minimum 6-minutes-withdrawal time.
Results: A total of 1100 patients were randomized. 552 patients were enrolled in the LCI group and 548 patients into the WLC group. Adenoma detection rate (patients having at least one colorectal adenoma) was significantly higher in the LCI group as compared to the control WLC group: 34.4% vs. 26.8%, respectively ($p = 0.007$). No significant differences were observed in the patient demographic characteristics, quality of colonoscopy preparation and withdrawal time between the two groups.
Conclusion: Based on our randomized controlled trial the LCI electronic chromoendoscopic enhancement of the Fujinon Eluxeo colonoscopy system was superior compared to the conventional HD-WLC in detecting of colorectal adenomas. This difference mainly explained by the more sensitive detection of minute colonic adenomas.
Disclosure: Study was supported by ECT grant GINOP 2.1.1.-15- 2015-00128

Introduction: Colorectal serrated lesions (SLs) include hyperplastic polyp (HP), traditional serrated adenoma (TSA) and sessile serrated adenoma/polyp (SSA/P). Our previous study shows that Type II-O pit pattern is highly specific to SSA/Ps, and additional changes in the pit patterns (III, IV or V) are associated with malignant progression to SSA/P with cytological dysplasia (CD) or high-grade dysplasia (HGD) (1). However, endoscopic features in TSAs are not fully understood.

Aims and Methods: To establish accurate colonoscopic diagnosis and treatment of TSAs, we aimed to clarify the associations among the morphological, pathological and molecular characteristics of SLs. A total of 401 premalignant and malignant colorectal lesions were enrolled in this study. Using magnifying colonoscopy, microsurface structures were assessed based on Kudo's pit pattern classification system, and the Type II pit pattern was subcategorized into classical Type-II, Type II-Open (Type II-O) and Type II-Long (Type II-L). Biopsy specimens were obtained from all lesions for genomic DNA extraction, after which lesions were treated by endoscopic mucosal resection (EMR) or endoscopic submucosal dissection (ESD). *BRAF*/*KRAS* mutations and DNA methylation of *SMOC1*, which is specifically methylated in TSAs (2) and CpG island methylator phenotype (CIMP) markers (*MINT1, -2, -12, -31, p16 and MLH1*) were analyzed through pyrosequencing.

Results: Pit patterns of the 383 colorectal lesions were as follows: Type II (n = 40), Type II-L (n = 9), Type II-O (n = 100), Type II plus III/IV (n = 21), Type II-L plus III/IV (n = 17), Type II-O plus III/IV (n = 40), Type II-L plus V (n = 4), Type II-O plus V (n = 12) and Type III/IV (n = 140). Type II-O was tightly associated with sessile serrated adenoma/polyps (SSA/Ps) with *BRAF* mutation and CIMP-high. Most lesions with simple Type II or Type II-L were hyperplastic polyps (HPs), while mixtures of Type II or Type II-L plus more advanced pit patterns (III/IV) were characteristic of traditional serrated adenomas (TSAs) (sensitivity, 73.7%; specificity, 92.1%). Type II-positive TSAs frequently exhibited *BRAF* mutation and CIMP-low, while Type II-L-positive TSAs were tightly associated with *KRAS* mutation, *SMOC1* methylation and CIMP-low.

We next assessed the association between pit patterns, molecular features and HP subtypes. We found that Type II-L was more frequent in goblet cell rich type (GCHP) (33.3%) than in microvesicular type (MVHP) (9.3%). GCHP with Type II-L frequently exhibited *KRAS* mutation, while majority of MVHP with Type II-O exhibited *BRAF* mutation. *SMOC1* methylation was less frequent in HP. These results suggest HPs with a Type II-L pit pattern and *KRAS* mutation may overlap with GCHPs and develop into TSAs with *KRAS* mutation. Finally, we analyzed a series of SLs with HGD. The Type II-L-derived cancers were strongly associated with TSA histology in the premalignant components, *KRAS* mutation, *SMOC1* methylation, CIMP-low and lack of *MLH1* methylation.

Conclusion: Our results suggest that Type II subtypes may reflect distinct molecular subclasses in the serrated neoplasia pathway, and that Type II-L plus more advanced pit patterns could be useful hallmarks for identifying TSAs at high risk of developing into CRC.

P0816 PREDICTIVE FACTORS FOR REPEATING COLONOSCOPY IN OUTPATIENTS WITH INADEQUATE BOWEL PREPARATION

K. Argyriou[1], K. Yap[1], S. Ho[1], W. Fateen[1], S. Budihal[1], S. Sansone[1], K. Ragunath[1], **A. Parra-Blanco**[1]
[1]*Queen's Medical Center Campus, Nottingham University Hospitals NHS Trust, Nottingham Digestive Diseases Centre, Nottingham, United Kingdom*

Contact E-Mail Address: adolfo.parra-blanco@nuh.nhs.uk

Introduction: Inadequate bowel cleansing has been observed in 10–25% of all colonoscopies. US Taskforce's recommendation is to repeat colonoscopy in individuals with poor bowel preparation within 1 year post index colonoscopy. However, in most cases this time interval is defined on an individual basis and is at the discretion of the performing endoscopist.

Aims and Methods: Our aim is to identify predictive factors for repeating colonoscopy in individuals with inadequate bowel preparation on the first diagnostic examination. Over a 22-month period (01/2013 to 10/2014), all patients who underwent colonoscopy in our center and had inadequate bowel preparation, were identified. Endoscopic records over at least a 3-year period after index colonoscopy were reviewed as per the quality of bowel preparation, the limit of the examination, the timing between index and repeat colonoscopy as well as the identification of polyps (size, type, number) and cancer. The quality of bowel preparation was categorized as adequate or inadequate according to each endoscopist's subjective impression. Multivariate analysis was performed in order to identify factors independently associated with repeat colonoscopy among patients with inadequate bowel cleansing.

Results: Of the 12,948 colonoscopies performed at 2 different sites, the quality of the bowel preparation was suboptimal (inadequate or poor) in 990 outpatients. Among these 990 individuals, colonoscopy was repeated within a 3-year period in 261 (26.3%).

The mean time (standard deviation) interval between the index and the repeat colonoscopy was 2.78 (4.51) months. Despite the suboptimal preparation, caecum was intubated in 69.7% of the index. Adenomas were identified in 130 cases while there were 113 cases of advanced neoplasia (65 advanced adenomas and 48 cancers).

Among the 261 repeated colonoscopies, the bowel preparation was adequate in 71.2% of the cases with 74 adenomas and 8 colorectal cancers seen only on the second examination, corresponding to an adenoma and cancer miss rate of 59.7% and 61.1% respectively.

Predictive factors for repeating colonoscopy were the "very poor" bowel preparation, the detection of polyps and of advanced adenomas on index coloscopy as well as the positivity of the faecal occult blood screening test. Reaching the caecum during index colonoscopy was negatively associated with repeating colonoscopy in the reference period.

Advanced Adenoma-1st colonoscopy	.001	2.820	1.518	5.237
Polyethylene-glycol based preparation	.164	.584	.274	1.245
Positive Fecal Occult Blood Test	.000	2.910	1.642	5.160
Complete colonoscopy (up to caecum)	.000	.273	.195	.381

[Table 1]

Conclusion: Only 1 out of 4 outpatients with suboptimal preparation repeated the examination within 3 years. Miss rates for adenomas and cancer remain high for colonoscopies with poor bowel preparation. Caecal intubation on index colonoscopy with poor bowel preparation is an independent predictor for not repeating coloscopy in the subsequent 3-year period. However endoscopists are urged to reach the caecum in each colonoscopy, as otherwise their caecal intubation rate would be penalized. Guidelines are needed to define how to proceed in cases with inadequate bowel preparation, in order to guarantee that a repeat colonoscopy will be undertaken, and with adequate bowel preparation.

Introduction: Endoscopic mucosal resection (EMR) is the reference to resect colorectal neoplasia between 10 and 30 mm. Main objective of EMR is to resect completely the neoplastic tissue (complete resection) and if possible in only one piece (En Bloc) with safe margins on histological assessment (R0). In case of R0 resection, the risk of local recurrence is 0% and control for local recurrence detection can be avoided. Conventional EMR lead to 65% of En Bloc resection for lesions under 20 mm. Anchoring the tip of the snare is a technical

trick allowing to fix the snare tip into the submucosa in order to reduce snare sliding to the lesion edges. The aim of the present study was to evaluate the effectiveness and the safety of this anchoring-EMR (A-EMR).
Aims and Methods: We performed a retrospective analysis of A-EMR procedures performed consecutively in 4 French centers between May 2017 and January 2018. In those 4 centers, anchoring was systematically attempted for all EMR using Olympus® conventional snares (10 or 25 mm). All specimens were stretched on cork for pathology.
Results: 141 A-EMR were performed in 125 patients by 9 operators during the study period. Mean lesion size was 19.8 mm (range 8–40 mm). Anchoring was technically successful in 96.5% of cases. En bloc and R0 resection proportions were respectively 81.6% and 70.0%. R0 proportion significantly reduced with lesion size with respectively 82.6% in lesions < 20 mm, 55.3% between 20 and 30 mm and 50.0% over 30 mm ($p = 0.002$). Complete perforations closed endoscopically occurred in 2.1% of cases and partial ones with target sign in 1.4% of cases.
Conclusion: Anchoring-EMR is effective to remove with margins (R0) the lesions between under 30 mm and safe with 2.1% of perforation closed endoscopically. This technique could improve R0 resection rate compared to conventional EMR but prospective randomized comparison is requested.

P0818 EFFICACY, SAFETY AND LONG-TERM OUTCOMES OF PIECEMEAL ENDOSCOPIC MUCOSAL RESECTION FOR THE TREATMENT OF LARGE NON-PEDUNCULATED COLORECTAL POLYPS IN AN ENDOSCOPY REFERRAL CENTER

G. Fiori, D. Ravizza, C.M. Trovato, G. De Roberto, I. Bravi, M. Giunta, C. Crosta
European Institute of Oncology, Endoscopy, Milan, Italy

Contact E-Mail Address: giancarla.fiori@ieo.it
Introduction: Endoscopic mucosal resection (EMR) has been demonstrated to be safe and efficient for the treatment of large non-pedunculated colorectal polyps (LNPCPs). Moreover, it is cost-effective compared to endoscopic submucosal dissection and surgery. However, most of studies include both en bloc and piecemeal EMR (pEMR).
Aims and Methods: We aimed to assess the safety, efficacy and long-term outcomes of pEMR for the treatment of LNPCPs. Medical records of consecutive patients who underwent pEMR for LNPCPs ≥20 mm in size between 2010 and 2016 were extracted from endoscopic data base of our Division and reviewed. Patients with inflammatory bowel diseases, familiar polyposis, circumferential lesions, endoscopic findings of submucosal invasive cancer or invasive cancer at the histopathological evaluation post-pEMR were excluded.
Results: 271 lesions in 245 patients were included in the study (122 males, mean age 66 years, range 35–88). Mean lesion size was 32.6 mm (20–100), median 30 mm. 257 (94.8%) were naïf lesions, 14 were remnants after incomplete EMR. 190 (70.1%) lesions were located in the right colon, 47 (17.3%) in the left colon, 34 (12.5%) in the rectum. Lateral Spreading Tumors (LSTs) granular homogeneous were 56 (20.7%), LSTs granular nodular mixed 62 (22.9%), LSTs non granular 84 (31%), sessile polyps 69 (25.4%).
pEMR was complete in 269 (99.3%) lesions. In two (0.7%) naïf LNPCPs pEMR was not completed. In one case because of intra-procedural perforation, in the second because of submucosal fibrosis. Histology revealed 218 (80.4%) adenomas (68 tubular, 123 tubulovillous, 27 villous), 49 (18.1%) sessile serrated adenomas, 4 (1.5%) hyperplastic polyps. High-grade dysplasia was observed in 159 (58.6%) lesions. Complications occurred in 47 (17.3%) LNPCPs: 14 (5.2%) intra-procedural and 28 (10.3%) post-procedural bleedings, 2 (0.7%) burning syndromes, 3 (1.1%) intra-procedural perforations. One intra-procedural bleeding and the 3 perforations needed surgical management (8.5% of complications). 234/269 (87%) completely resected LNPCPs had 1–4 surveillance colonoscopies (SCs) within a period of 3–48 months. Recurrent lesions were 48 (20.5%) at the first SC, 62 (26.5%) at any SC. 20 lesions recurred twice, 5 three times. 56 (90.3%) recurrences had further curative endoscopic resection. 6 (9.7%) recurrences underwent surgery, 3 of them (1.3% of lesions in follow up) due to of the presence of cancer in bioptic specimens.
Conclusion: Our data confirm that pEMR is a safe and effective technique for the treatment of LNPCPs. However, considering the high recurrence rate post-pEMR and the risk of cancer, a careful and prolonged endoscopic follow-up is mandatory.

Introduction: The possibility of complete curative en bloc resection is sometimes related to the presence and degree of fibrosis in the submucosal layer (SM), rather than tumor size and location. In this study, clinical outcomes of ESD for colorectal neoplasms accompanied by fibrosis were analyzed, to achieve exact diagnosis and safe treatment of such lesions.
Aims and Methods: The aim of this study was thus to establish a safe and curative ESD procedure for colorectal neoplasms showing fibrosis in the SM layer. ESD was performed for 1,512 colorectal neoplasms in 1,473 patients (male 839, female 6334, average 66.1 years old) from January 2003 to June 2017, and was completed for 1,497 lesions. Of these cases, 315 showed SM fibrosis. These cases were divided into three groups: absence of fibrosis (A), fibrosis due to benign causes (B), and fibrosis due to cancer invasion (C). Furthermore, cases were classified as mild (grade 1), moderate (grade 2), or severe (grade 3). Clinical outcomes and pathological findings of the above-mentioned ESD cases were analyzed according to these endoscopic classifications to facilitate the safe achievement of ESD. In addition, histological validation of endoscopic diagnosis was examined for the 240 of the 315 cases with fibrosis, to clarify for differential diagnosis between Type B and Type C.
Results: Of the 315 cases with fibrosis, 210 cases involved benign causes (Type B), and 115 cases were considered related to cancer invasion (Type C). As the results of the validation study ($n = 240$) for differential diagnosis between Types B and C as follows; sensitivity: 88.7%, specificity: 90.5%, accuracy: 89.2%, PPV: 96.3%, NPV: 74.0%. En bloc resection rates ($n = 315$) were as follows: A, 97.8%; B-1: 96.9%; B-2: 88.5%; B-3: 63.5%; Type C-1: 100%; C-2: 96.3%; C-3: 61.1%. The en bloc resection rates for types B-3 and C-3 were significantly lower ($p < 0.05$) than that for Type A. There were no significant differences between Type A and Types B-1, B-2, C-1, and C-2 lesions. There were 8 cases (0.5%) of perforation, 4 of which (Type B) required emergency surgery. From these results, tumors accompanied by mild to moderate fibrosis become the standard indication for ESD. The tumors accompanied by severe fibrosis should be indicated as relative indications for ESD and required high quality of ESD technique to avoid perforation.
Conclusion: Accurate diagnosis of fibrosis based on the perioperative endoscopic findings appears feasible and contributes to completing the ESD procedure safely and curatively.

Introduction: Rectal cancer patients with a clinical complete response (CR) to neoadjuvant (chemo) radiotherapy can be treated with a watch-and-wait (W&W) approach.
Aims and Methods: The aim of this study was to assess the diagnostic performance of restaging endoscopy for the selection of luminal CR after (chemo) radiotherapy. This study was performed in a single center where restaging endoscopy was routinely performed after neoadjuvant treatment for rectal cancer to assess the luminal response. All patients underwent flexible sigmoidoscopy 6–12 weeks after the end of (chemo) radiotherapy, followed by rectal surgery or a W&W approach with a follow-up of ≥2 years. All white light endoscopic images were retrospectively re-evaluated by two experienced endoscopists (one surgeon and one gastroenterologist). The presence of a white scar, flat ulcer, irregular ulcer, adenomatous tissue or tumour mass were evaluated and the likelihood for a CR was scored at a 5-point scale (1 = definite CR, 5 = definite residual tumour). Histology after surgery represented the reference standard (ypT0 = CR). In patients undergoing W&W, a regrowth free period of ≥2 years was also considered a CR. Area under the ROC-curve (AUC), sensitivity and specificity were calculated, considering a likelihood score 1 or 2 as complete response. In addition, the interobserver agreement was calculated.
Results: Sixty-five consecutive patients were included (71% male, mean age: 65 years). Forty-two patients had surgery (ypT0: 12/42) and 23 patients underwent W&W (2 year regrowth free: 20/23). Median time to restaging endoscopy was 9 weeks (IQR 8–12). Median time from endoscopy to surgery was 22 days (IQR 15–45). The positive predictive value (PPV) for a CR was 81/87% when a white

scar was present. PPV for CR were 43/75% and 35/41% when adenomatous tissue or a flat ulcer were present. PPV for CR were 0/20% and 21/30% when an ulcer with irregular border or tumour mass were present. AUC, sensitivity and specificity for the prediction of a CR with endoscopy were 0.74 (95% CI 0.66–0.89), 69% and 79% for reader 1 and 0.81 (95% CI 0.71–0.92), 66% and 91% for reader 2. The interobserver agreement was substantial (quadratic weighted k = 0.68). In 30 patients, a biopsy was taken. The addition of biopsy results to endoscopic images did not improve the diagnostic performance for the selection of CR for both readers.
Conclusion: Endoscopy predicts complete response after a median time of 9 weeks with a sensitivity of 66–69% and specificity of 79–91%. The above mentioned endoscopic features can be used to select patients for an extended observation period to select for organ-saving treatment. Endoscopy should be used in combination with MRI to provide more detailed information on the response in the deeper layers of the bowel wall and the mesorectum.

P0821 GASTRIC ADENOMA OR EARLY GASTRIC CANCER IS AN IMPORTANT RISK FACTOR FOR COLORECTAL ADENOMA

J. Lee, S.J. Kim
Chosun University, Gwangju, Korea (Republic of)

Contact E-Mail Address: leejun@chosun.ac.kr
Introduction: Patients diagnosed with gastric cancer have a higher prevalence and increased risk of colorectal cancer. But a few studies reflecting colonic endoscopy quality have investigated the risk of colorectal cancer or adenoma in patients with early gastric cancer or gastric adenoma.
Aims and Methods: The purpose of this study is to investigate the prevalence of colorectal adenoma or cancer in patient with gastric adenoma and early gastric cancer. We performed a prospective single center study. From January 2015 to December 2016, 307 patients who had treated stomach ESD due to early gastric cancer or adenoma of 110 patients were enrolled. Healthy age- and sex-matched controls were enrolled from general screening population. Demographic factors and colonoscopic findings of the cases and the controls were collected and prevalence and risk factor of colorectal adenoma and cancer of both groups are analyzed.
Results: Data from 110 patient in the gastric neoplasm group (93 with gastric adenoma, 17 early gastric cancer) and 110 healthy control group participants were included in the statisti-cal analysis. The presence of gastric adenoma or early gastric cancer was an independent risk factor for colorectal adenoma (OR = 3.4771, 95% CI = 1.9727–6.1289). The presence of gastric adenoma or early gastric cancer was an independent risk factor for colorectal high risk adenoma (OR = 5.0980, 95% CI = 1.9995–12.9986). There was no statistical relation between gastric adenoma or early gastric cancer and colorectal cancer. (p = 0.0948)
Conclusion: The risk of colorectal adenoma and advanced colorectal adenoma increased significantly in patients with gastric adenoma and early gastric cancer. Therefore, we suggest that colonoscopic surveillance should be strictly considered in patient with gastric adenoma and early gastric cancer.
Disclosure: Nothing to disclose

P0822 WHICH FACTORS ARE RELATED TO A RISK OF DEVELOPING A PERFORATION AFTER A COLONOSCOPY IN AN ORGANISED POPULATION-BASED COLORECTAL CANCER SCREENING PROGRAMME? A NESTED CASE-CONTROL STUDY

N. Imaz-Ayo[1], I. Idigoras Rubio[2], M.I Portillo Villares[2], I. Bilbao Iturribarria[2], M.J. Fernández Landa[2], I. Guierrez-Ibarluzea[3], L. Bujanda Fernández de Piérola[4], E. Arana-Arri[1]

[4]*Biodonostia Health Research Institute, University Hospital, University of the Basque Country (UPV-EHU), Leioa, Spain*

Contact E-Mail Address: natale.imazayo@osakidetza.eus
Introduction: In the Basque Country (one of the 17 autonomous regions of Spain), with an average population of 1,422.369 inhabitants, colorectal cancer (CRC) screening was introduced in 2009 for persons within 50–69 ages, by Immunochemical test (FIT) and colonoscopy under sedation as a diagnostic procedure. Colonoscopy is an invasive procedure and is not without risk. Overall pooled colonoscopy complication prevalence for post-colonoscopy perforation, bleeding and mortality is 0.5/1000 (95% confidence interval (CI) 0.4–0.7), 2.6/1000 (95% CI 1.7–3.7) and 2.9/100,000 (95% CI 1.1–5.5) colonoscopies.
Aims and Methods: To determine which independent risk factors are related with a perforation after a screening colonoscopy, with the future ambition of decreasing the post-colonoscopy complications. All screening colonoscopies after a positive FIT were analysed related to 2009–2016 invitations. All medical records were assessed by experts. 160 perforations were identified by the discharged of the Colorectal Cancer Screening Programme database. Perforation was considered either surgical or medical treatment. A multivariate model was performed and the perforations Independent Predictors were identified through a logistic regression.
Results: After 54,675 colonoscopies, perforation complication rate was 0.3%. The risk of perforation after a colonoscopy was 2.9/1,000 and the risk of post-polypectomy perforation was 2.4/1,000. The 15.6% and the 18.9% of the cases had cardiopathy and neumopathy history respectively. On the other hand the 3.8% of the patient were treated with anticoagulant therapy, the 18.2% with antiagregants and the 10% with corticoids. The 36.9% of cases had a history of abdominal surgery and the 37.4% presented diverticulosis during the colonoscopy procedure. Firstly we made an univariate analysis taking into account the following variables that may be related with a perforation during a colonoscopy: sex, age, body mass index, history of abdominal surgery, cardiopathy and neumopathy history, antiagregant or anticoagulant therapy, chronicity index, diverticulosis, polyp size ≥20 mm, polypectomy, pT1 or advanced adenoma in the diagnosis, location of major size of polyp and highest number of polyps, adenoma and polyp detection rates and bowel preparation. The variables with a significant result in the univariate analysis were; history of neumopathy, history of abdominal surgery, diverticulosis, polyp size ≥20 mm, pT1 in the diagnosis and location of the polyps.
After a multivariate analysis the perforation independent predictors were: history of abdominal surgery (OR:4.3; 95% CI:2.0–9.3), polyp size ≥20 mm (OR:4.3; 95% CI:1.9–9.7), pT1 in the diagnosis (OR:16.9; 95% CI:2.0–139.1) and right location of the polyps (OR:5.3; 95% CI:1.9–15.0). The logistic model explained 77% of the complications (95% CI 0.71–0.84, $p < 0.001$).
Conclusion: The colonoscopy is an invasive procedure with a small but not insignificant risk of perforation. That is why, it is crucial to know which factors predict the risk of perforation in order to implement countermeasures. The study that we present show that abdominal surgery, polyp size ≥20 mm, pT1 in the diagnosis and right location of the polyp are independent factors to consider while performing the colonoscopies.
Disclosure: Nothing to disclose

P0823 ROLE OF FAECAL IMMUNOCHEMICAL TESTING IN THE DIAGNOSTIC WORKUP OF PATIENTS WITH IRON DEFICIENCY ANAEMIA

D.E. Morales Arráez, G. Hernández, M. Carrillo, Z. Adrián, A.Z. Gimeno, E. Quintero
Hospital Universitario de Canarias, La Laguna, Spain

Contact E-Mail Address: daliafma@gmail.com
Introduction: Gastroscopy and colonoscopy are frequently included in the routine diagnostic workup of patients with iron deficiency anaemia (IDA). However, a high percentage of these examinations do not show any significant lesion. Faecal immunochemical testing (FIT) could be used to increase the efficiency of the IDA diagnostic workup due to its ability to detect intact globin from colorectal lesions.
Aims and Methods: We aimed to assess whether FIT may discriminate between significant colorectal or upper gastrointestinal lesions, saving unnecessary explorations in patients with IDA.
Methods: consecutive naive patients with moderate-severe IDA defined as Hb < 11.9 g/dL in men and Hb < 10.9 g/dL in women, and ferritin ≤ 30 g/dL, were enrolled from April 2016 to December 2017 in a prospective, observational study. Inpatients, patients under 18 years-old, with personal history of inflammatory bowel disease, gastrointestinal cancer, gastrointestinal surgery, evidence of bleeding, gastroscopy and/or colonoscopy in the past 5 years, pregnancy or refusal to participate were excluded. Demographic data, comorbidity (Charlson's Index), concomitant medication (corticosteroids, NSAID, anticoagulants) and laboratory variables were collected. Faecal haemoglobin was measured using 1-kit OC-Sensor^{TM}, (FIT positive ≥10 mg/g), previously to endoscopic procedures. Gastroscopy with gastric and duodenum biopsies and colonoscopy were performed in the same day. Significant upper gastrointestinal lesion (SUGIL) included: cancer, angiodysplasia, polyp ≥10 mm, erosions, celiac disease, erosive esophagitis, *H. pylori gastritis or peptic* ulcer. Significant colorectal lesions (SCL) comprised: colorectal cancer (CRC), angiodysplasia, advanced polyp, colitis or erosions. The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), the area under the curve (AUC) of FIT for SCL and CRC were calculated.
Results: 245 patients were included (66.1% female, mean age 71 ± 12 years, mean Hb 9.7 ± 3.5 g/dl). A significant gastrointestinal lesion was detected in 154 (62.8%) patients whereas the diagnosis was uncertain in the remaining 91 (37.2%) patients. The most frequent SUGIL were *Helicobacter pylori* gastritis (n = 31) and angiodysplasia (n = 11), whereas the most frequent SCL were

advanced polyp (n = 30), CRC (n = 28) and angiodysplasia (n = 19). Of 119 (48.8%) patients with a positive FIT result, 65 (54.6%) had SCL (PPV 54.6%) and 37 (31.0%) had SUGIL (PPV 31.3%). Conversely, among 126 patients with a negative FIT result, 48 (38.1%) had SUGIL and 20 (15.9%) SCL. Overall, 106 patients with a negative FIT result did not have any SCL at colonoscopy (NPV 84.1%). FIT detected 26 out 28 CRC (Sensitivity 92.8%). Only 9 (3.7%) patients had SUGIL and SCL simultaneously, having all of them a positive FIT result. The AUC of a positive FIT result for SCL and CCR was 0.78 and 0.87, respectively. In the multiple regression analysis, only non-use of NSAIDs and positive FIT were independently associated with SCL. If we had started the diagnostic workup performing colonoscopy in patients with a positive FIT result, gastroscopy in patients with negative FIT result or both explorations when the initial examination did not show any significant lesion, we would have saved 104 (21%) examinations without loss of diagnostic efficacy.
Conclusion: In patients with IDA, FIT may guide the sequence of endoscopic procedures, saving unnecessary explorations.

P0824 ENDOSCOPIC TREATMENT OF BILE DUCT STONES IN PATIENTS WITH SURGICALLY ALTERED ANATOMY

M. Kida[1], H. Yamauchi[2], E. Miyata[2], R. Hasegawa[2], T. Kaneko[2], K. Okuwaki[2], T. Iwai[2], H. Imaizumi[2]
[1]*Kitasato University, Endoscopy & Gastroenterology, Sagamihara, Japan*
[2]*Kitasato University Hospital, Sagamihara, Japan*

Contact E-Mail Address: m-kida@kitasato-u.ac.jp
Introduction: Nowadays Endoscopic treatment of Bile duct stones in patients with surgically altered anatomy have become popular with enteroscopy-ERCP and EUS-hepaticogastorostomy (EUS-HGS) technique. We have retrospectively investigated surgically altered patients with bile duct stones which ware treated by enteroscopy-ERCP or EUS-BD technique or PTBD or surgery.
Aims and Methods: We have reviewed medical records from 2009 to 2017 and finally found consecutive 188 cases (284 sessions) of bile duct stones with surgically altered anatomy. Averaged age is 74.3y/o and male: female is 141(75%): 47(25%). The group of Roux-en-Y(R-Y) with gastrectomy were 95 cases (128 sessions) which included gastric cancer 87cases and 8 others, R-Y without gastrectomy were 29 cases (70 sessions) which included biliary cancer 12 cases, maljunction 8 cases, and 9 others, PD were 35 cases (53 sessions) which included pancreas cancer 20 cases, biliary casncer 7 cases and 8 others, and Billroth-2 were 29 cases (33 sessions) which included gastric cancer 11 cases, duodenal cancer 9 cases and 9 others. Generally we started to treat these patients with enteroscopy-ERCP which were mainly short-type single-balloon enteroscopy (SBE), and EUS-HGS thechnique and PTBD were employed, if failed. In case of large stone, we dilate the papilla by 15–20mm CRE balloon, then directly insert SBE into bile duct and crash the stones by EHL under endoscopic guidance.
Results: The rate of blind reach end and success rate were 88/95 cases (92.6%) and 79/81 cases (97.6%) in the Roux-en-Y(R-Y) with gastrectomy group, 28/29 cases (96.6%) and 28/28 cases (100%) in R-Y without gastrectomy, 34/35 cases (94.3%) and 33/33 cases (100%) in pancreato-duodenectomy, and 27/29 cases (93%) and 24/24 cases (100%) in Billroth-2, respectively. Totally 164/188 cases (87%) were treated by SBE which included 13 cases of EHL treatment by directly inserted SBE and remained 2 cases by EUS-HGS, 5 cases by PTBD, 6 cases by surgery, and conservative 11 cases. The adverse events were 3.1% in pancreatitis, 0.7% in bile leakage, 1.7% in perforation, and 1.1% in bleeding.
Conclusion: We concluded that 87% of bile duct stones were treated by enteroscopy-ERCP in surgically altered anatomy cases, and EUS-HGS was seemed to be new second option.

P0825 APPLICABILITY OF ASGE CRITERIA FOR ERCP IN CHOLECYSTECTOMIZED PATIENTS

M. Sousa, R.T. Pinho, L. Proença, J. Rodrigues, J.C. Silva, A.C. Gomes, J. Carvalho
Centro Hospitalar de Vila Nova de Gaia e Espinho, Vila Nova de Gaia, Portugal

Contact E-Mail Address: mafalda_m_p_sousa@hotmail.com
Introduction: ASGE guidelines suggest that cholangiopancreateography (ERCP) should be performed in patients at high risk of choledocolithiasis after biochemical tests and abdominal ultrasound. In cholecystectomized patients the diagnostic considerations could be different since the cut-off of 6mm for dilatation of the common bile duct (CBD) may be inappropriate.
Aims and Methods: Patients with high-risk criteria for choledocholithiasis (CBD stone on ultrasound, ascending cholangitis, total bilirubin (TB)> 4mg/dL or dilatation of CBP> 6mm associated with TB between 1.8–4mg/dL) who underwent ERCP from 2014–2017 were included. The aim of this study was to evaluate the applicability of ASGE criteria for ERCP in cholecystectomized patients
Results: Included 328 patients – 259 with prior cholecystectomy (79%) and 69 without prior cholecystectomy (21%). The presence of CBD stones and the size of the stone on ultrasound were predictors of coledocolithiasis in ERCP in both groups ($p < 0.05$). Dilatation of CBD was predictive only in the group of patients without previous cholecystectomy ($p = 0.01$ vs $p = 0.199$). Ascending cholangitis and bilirubin levels were not statistically significant predictors in both groups ($p > 0.05$).
The overall positive predictive value (PPV) of ASGE criteria was 71% (29% false positives), and the PPV in the group of cholecystectomized patients was 71% vs 70% in the group of non-cholecystectomized patients.
Conclusion: Although dilatation of CBD is not a predictive factor for choledocholithiasis in cholecystectomized patients, the ASGE criteria have a positive predictive value similar to that of non-cholecystectomized patients.
Disclosure: Nothing to disclose

P0826 EFFICACY OF ETOMIDATE- VERSUS PROPOFOL-BASED SEDATION FOR ADVANCED ENDOSCOPIC PROCEDURE : A PROSPECTIVE, RANDOMIZIED NON-INFERIORITY TRIAL

S.J. Han[1], T.H. Lee[2], J.K. Yang[3], Y.S. Cho[3], Y. Jung[3], I.-K. Chung[3], S.-H. Park[3], S. Park[4], S.-J. Kim[5]

Introduction: Propofol is widely used for endoscopic sedation in advanced therapeutic endoscopy, but concerns regarding cardiopulmonary adverse events remain. Etomidate has known to have little effect on the cardiovascular or respiratory systems. We aimed to compare the efficacy and safety of balanced etomidate and balanced propofol sedation in therapeutic endoscopic procedure.
Aims and Methods: This study was a prospective, randomized non-inferiority trial that included patients who had been scheduled for advanced therapeutic endoscopy. All endoscopic sedation was based on midazolam and fentanyl, and then patients randomly received either propofol or etomidate as an add-on drug. The main outcomes were sedation efficacy measured on a 10-point visual analog scale (VAS),and sedation safety.
Results: A total of 186 patients (propofol group: n = 94, etomidate group: n = 92) was evaluated. Etomidate group failed to prove the non-inferiority for overall satisfaction of patients measured by VAS score, with a difference of −0.35 (95% confidence interval [CI] = −1.03 to 0.34, $p = 0.030$). Among endoscopists and nurses, etomidate showed non-inferiority to propofol with differences of 0.06 and 0.08, respectively (endoscopists: 95% CI = −0.55 to 0.66, $p < 0.001$; nurses: 95% CI = −0.57 to 0.73, $p = 0.001$) for a non-inferiority margin of −1. In terms of safety, overall cardiopulmonary adverse events occurred less commonly in etomidate group (27.7% vs. 14.1%, $p = 0.023$). Hypoxia occurred in 5.3% of cases in the propofol group and in 1.1% of cases in the etomidate group ($p = 0.211$). Cardiovascular adverse events tended to be more common in propofol group, but the difference was not statistically significant (23.4% vs. 13.0%, $p = 0.068$). Myoclonus occurred in 12.1% (11/92) of cases in the etomidate group only. Balanced etomidate sedation had a lower risk of overall cardiopulmonary adverse events by multiple logistic regression analysis (odds ratio 0.401, $p = 0.018$).
Conclusion: Etomidate-based sedation during advanced endoscopic procedures was fail to prove the non-inferiority to propofol based sedation in satisfaction of patients. However, etomidate-based sedation showed better safety in terms of cardiopulmonary adverse events and may be an alternative option for advanced endoscopic procedure, especially in patients with cardiopulmonary diseases.
Disclosure: Nothing to disclose

P0827 THE PERIAMPULLARY DIVERTICULUM: BOON OR BANE FOR THE ERCP ENDOSCOPIST?

J.L. Ho[1], A. Seneviratna[2], C. Anastassiades[3], C.H.B. Yip[3]

[3]*Khoo Teck Puat Hospital, Division of Gastroenterology and Hepatology, Singapore, Singapore*

Contact E-Mail Address: jingliang.ho@mohh.com.sg
Introduction: The prevalence of periampullary diverticulum (PAD) is relatively high (9% to 33%) in patients who undergo an endoscopic retrograde cholangiopancreaticography (ERCP). It is currently unclear if the presence of PAD impacts the success, difficulty and complication rates of ERCP.
Aims and Methods: The aim of the study is to investigate the success rate, procedure difficulty (ERCP grade, cannulation difficulty, procedure time) and complication rate between patients with and without PAD. In addition, we sought to determine whether there is a difference in ERCP indication and size of choledocholithiasis between the groups. Patients with PAD were further analysed according to ampulla location (within PAD, at the edge of PAD, near PAD) and size of PAD (small: < 1.5cm, large: > 1.5cm). A single-centre cross-sectional study was conducted. A total of 548 ERCP procedures were performed at our endoscopy centre from January 2015 to December 2016. Patients with

previous ERCP (sphincterotomy, stent insertion), inability to locate the ampulla or abandoned procedure were excluded. 357 procedures in 351 patients were analysed.
Results: Of the 357 procedures, 116 (32.5%) were found to have PAD. The ampulla was located within the diverticulum in 10 (8.9%), on the edge of the diverticulum in 44 (38.9%) and near the diverticulum in 59 (52.2%). There were 72 (64.3%) large and 40 (35.7%) small PAD. Patients with PAD were older (69 vs. 60 years, $p < 0.001$) and more likely to undergo ERCP for choledocholithiasis (93.9% vs. 83.8%, $p = 0.007$). Comparing the 2 groups (with PAD vs without PAD), there was no statistically significant difference in success rate (93.8% vs. 91.4%), the median procedure time (34mins vs 30.5mins), and complication rate (6.6% vs 3.5%). There was also no statistically significant difference between the 2 groups in terms of cannulation difficulty, categorized in ascending order of difficulty—level 1 (62.7% vs 63.8%), level 2 (23.6% vs 22.4%), level 3 (7.5% vs 4.3%), and level 4 (6.2% vs 9.5%). Similarly, there was no statistically significant difference in terms of ERCP grading, grouped in ascending order of difficulty—grade 1 (78.8% vs 78.5%), grade 2 (17.8% vs 19.8%), and grade 3 (3.3% vs 1.7%). Multivariate logistic regression showed that younger age was an independent predictor of cannulation success ($p = 0.023$), while older age ($p = 0.010$) and indication other than choledocholithiasis ($p = 0.038$) were independent predictors of cannulation difficulty. Patients with PAD had a 3.3 times higher odds of having choledocholithiasis compared to those without ($p = 0.006$).
Conclusion: ERCP in the presence of PAD is as successful, easy and safe as for patients without PAD. Older age and procedure indication other than choledocholithiasis may increase the difficulty of the procedure.

Introduction: Accurate diagnosis of indeterminate biliary lesions is necessary for proper treatment plan. We aim to assess the diagnostic accuracy of SpyGlass visual assessment and Spybite biopsy in patients with indeterminate biliary lesions.
Aims and Methods: Between August 2016 and August 2017, we review a retrospective analysis of the patients with indeterminate biliary stricture who had an inconclusive results on the cross-sectional imaging or endoscopic retrograde cholangiopancreatography (ERCP) guided tissue sampling.
Results: A forty-eight patients (28 men, mean age 72.3 years) with indeterminate biliary lesions underwent SpyGlass® DS peroral cholangioscopy (SDPC). The SDPC was technically success in all of the case. The final diagnosed in 48 patients were malignant tumor in 17 patients, and benign lesions in 32 patients. The sensitivity, specificity, and overall accuracy of SpygGlass visual assessment and Spybite biopsy for the diagnosis of malignancy were 94.1% (16/17), 93.5% (29/31), 93.7% (45/48), 47% (8/17), 100% (31/31), 83.8% (40/48), respectively. There was no procedure related complication.
Conclusion: The SDPC demonstrated relative accurate rate of diagnosis for indeterminate biliary lesions with excellent safety profile and high technical success rate.

P0829 COMPARISON OF ENDOSCOPIC SPHINCTEROTOMY, ENDOSCOPIC PAPILLARY LARGE BALLOON DILATION AND ENDOSCOPIC SPHINCTEROTOMY PLUS ENDOSCOPIC PAPILLARY LARGE BALLOON DILATION TREATMENT FOR REMOVAL OF LARGE BILE DUCT STONE

C.-M. Kuo[1], W.-C. Tai[1,2], K.-L. Wu[1,2], C.-C. Yao[1], C.-Y. Lin[1]

Introduction: Large bile duct stones (> 15 mm in transverse diameter) appear to be more difficult to be remove with conventional methods such as endoscopic sphincterotomy (EST) and endoscopic papillary balloon dilation (EPBD). However, EPBD is limited to small stones of < 10 mm in diameter because it dose not enlarge the bile duct orifice to the same extent as EST. Therefore, extraction of a large bile duct stone may require mechanical lithotripsy (ML) in addition to EST or EPBD. The main complication during ML is basket and stone impaction that could occur even during a routine stone extraction, and it could increase the risk of pancretaitis and cholangitis. We used EST, endoscopic papillary large balloon (12–20 mm) dilation (EPLBD) and limited EST plus EPLBD to remove large bile duct stone in our patients.
Aims and Methods: We aimed to compare and evaluate the therapeutic outcome and complications of EST, EPLBD and limited EST plus EPLBD for large bile duct stone extraction.
Methods: A total of 185 patients with large bile duct stones (> 15 mm in transverse diameter), who received EST, EPLBD and limited EST plus EPLBD treatment between 1, January 2010 and 28, February 2018 at Kaohsiung Chang Gung Memorial Hospital, Taiwan, were recruited in this retrospective study. Patients will be divided into three groups: EST group (31), EPLBD group (96) and limited EST plus EPLBD group (58). The primary outcome variables are the success rate of complete stone removal and presence of complications after three endoscopic treatment.
Results: Limited EST plus EPLBD group resulted in similar outcomes in overall successful stone removal (98.3%) compared to EST group (93.5%) and EPLBD group (92.7%). Limited EST plus EPLBD group had higher success rate of the first session treatment (98.3%) compared to EST group (83.9%) and EPLBD group (86.5%) ($p = 0.032$). ML was required in 4(12.9%) EST group, 10(10.4%) EPLBD group and 2(3.4%) limited EST plus EPLBD group, but they were no significant difference ($p = 0.215$). Post-procedure bleeding occurred in EST group (9.7%) was higher than limited EST plus EPLBD group (0%) ($p = 0.038$). Post-procedure pancreatitis and cholangitis were no significant difference in three groups. No perforation was found in three groups. Procedural time of the first session treatment in limited EST plus EPLBD group was longer (32(12–26) min) than EST group (23.5(17–68) min) and EPLBD group (25.0(14–60) min) ($p = 0.001$). Recurrent bile duct stone occurred in 4 (4.2%) EPLBD group and 5 (8.6%) limited EST plus EPLBD group. Multivariate analysis revealed that dilated bile duct with the largest common hepatic duct (CHD) or common bile duct (CBD) diameter was the only risk factor for bile duct stone recurrence in limited EST plus EPLBD group ($p = 0.022$).
Conclusion: Limited EST plus EPLBD is equally effective as EST and EPLBD for the removal of large bile duct stone. Limited EST plus EPLBD had higher success rate and longer procedural time of the first session treatment. EST group occurred post-procedure bleeding was higher than limited EST plus EPLBD group. Multivariate analysis revealed that dilated bile duct with the largest CHD or CBD diameter was the only risk factor for bile duct stone recurrence in limited EST plus EPLBD group.
Disclosure: Nothing to disclose

P0830 EVALUATION OF THE SAFETY AND EFFICACY OF ENDOSCOPIC SPHINCTEROTOMY FOLLOWING ADDITIONAL BALLOON DILATION FOR THE MANAGEMENT OF COMMON BILE DUCT STONES

S. Ishii, T. Fujisawa, S. Takahashi, Y. Takasaki, A. Suzuki, K. Tomishima, R. Kanazawa, H. Saito, S. Shiina, H. Isayama
Juntendo University, Department of Gastroenterology, Tokyo, Japan

Contact E-Mail Address: sishii@juntendo.ac.jp
Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) has high risk of complications such as acute pancreatitis, perforation, acute and delayed bleeding. Endoscopic sphincterotomy (EST) is common technique as a papillary manipulation for endoscopic removal of common bile duct (CBD) stones. However, skill of the operator is necessary to obtain enough incision and EST includes the risks of bleeding and perforation. Endoscopic papillary balloon dilation (EPBD) was simple and easy procedure on the papilla, however, EPBD was reported higher incidence of post-ERCP pancreatitis (PEP) than EST and difficulty in CBD stone removal procedure. To minimize any complications and make procedures easy, we perform EPBD (balloon diameter: 8 or 10mm) with very small incision (EPBD+EST) for the management of CBD stones from 2012. In this study, we evaluated the safety and efficacy of this new technique retrospectively.
Aims and Methods: This study is retrospective chart review analysis in single academic center. In 778 cases with naive papilla who were received endoscopic treatment with papillary manipulation from January 2009 to March 2018. There are 466 cases with common bile duct stones, EST alone was performed until 2012 and EPBD+EST was performed from 2012 through 2018, basically. The cases needed with more than 12 mm papillary dilatation were excluded. We compared the incidence of complications including PEP, acute and delayed bleeding, perforation between two groups.
Results: The EPBD+EST group had 340 cases and the EST alone group had 126 cases. There were no significant differences in the patient characteristics (age, gender, the size and number of the stones). Procedure time was not significantly different between the EPBD+EST group and the EST alone group. The EPBD+EST group had 2.1% (7 cases) of PEP and the EST alone group 2.4% (3 cases), respectively. However, there were no significant difference between them. On the other hand, bleeding rate in the EPBD+EST group was 1.8% (acute: 5 cases, after: 1 case) and significantly lower than 6.3% (acute: 7 cases, after: 1 case) in the EST alone group ($p = 0.01$). Any bleedings were mild by the severity classification of ASGE. For a hemostasis, 5 cases of balloon pressure and one case of clipping were performed in the EPBD+EST group, and 7 cases of balloon pressure and 1 case of HSE injection were performed in the EST alone group. A perforation was not occurred in the EPBD+EST group, but 1.6% (2 cases) in the EST alone group, respectively. The rate of perforation was not significantly different between the 2 groups. In the EPBD+EST group, one case had bile leakage as a major complication. It was considered that bile leakage was caused by the expanding with pinching stones between balloon and bile duct wall at the time of EPBD. There was also no significant difference in the rate of complete stone extraction. Recurrence of the CBD stones were analyzed in the cases observed over 1 year (mean observation al time: 49.4 months), and there was no significant difference.
Conclusion: EPBD with very small EST technique for removing bile duct stones was considered as a safer procedure than EST alone. An incidence of bleeding was significantly lower than EST alone without increasing of PEP. Similar procedure time despite of performing additional balloon dilation may suggest the removing procedure of stones was easier than EST alone. It was single-center

retrospective analysis with relatively small number of cases, further prospective evaluation was required to confirm the usefulness.
Disclosure: Nothing to disclose

P0831 SAFETY AND EFFICACY OF NEEDLE KNIFE PAPILLOTOMY AND NEEDLE KNIFE FISTULOTOMY IN PATIENTS 90 YEARS OF AGE AND OLDER

H. Hisai, T. Sakurai, Y. Koshiba, K. Watanabe, S. Ameda, E. Miyazaki
Japanese Red Cross Date Hospital, Department of Gastroenterology, Date, Japan

Contact E-Mail Address: hisai.hiroyuki@gray.plala.or.jp
Introduction: Needle knife papillotomy (NKP) and needle knife fistulotomy (NKF) are two major rescue techniques for facilitating biliary cannulation and are associated with post-ERCP complications. However, there are limited data, especially in the extreme elderly.
Aims and Methods: The aim of the current study was to evaluate the safety and efficacy of NKP and NKF in nonagenarians. Medical records of 184 patients with difficult biliary cannulation who underwent NKP and NKF from September 2000 and March 2018 were analyzed. Patients were divided into two groups: 90 years age and older (Group A: n = 26) and less than 90 years old (Group B: n = 158). Patient characteristics, indications for ERCP, technical success and complications were retrospectively evaluated. Success was defined as deep placement of a catheter into the common bile duct. A diagnosis and severity of ERCP complications was made according to Cotton's classification.
Results: Mean age was 92.6 ± 2.7 (range 90–101) and 75.5 ± 9.9 (range 41–89) years old in Group A and Group B, respectively. Choledocholithiasis (58.1%) was the most frequent indication followed by malignant biliary obstruction (34.8%). Ten patients (38.4%) in Group A and 70 (44.3%) in Group B underwent prior placement of a pancreatic stent ($p = 0.672$). Periampullary diverticulum was found more often in patients of Group A (23.1%) than of Group B (10.8%, $p = 0.105$). The number of patients with American Society of Anesthesiologists (ASA) physical status class ≥ 3 was significantly larger in Group A than in Group B (53.8% vs 29.1%, $p = 0.023$). Threw was no significant difference in the success rates of cannulation in the first session (61.5% vs 65.8%, $p = 0.839$) and in the final session (96.2% vs 96.8%, $p > 0.999$) between Group A and Group B. Mean time to NKP/NKF and mean procedure durations were not significant between the two groups. Three complications (11.5%) occurred in Group A (pancreatitis in 1, perforation in 1, cholecystitis in 1) and 27 (17.1%) in Group B (pancreatitis in 15, bleeding in 4, perforation in 2, cholecystitis in 6). Complication rates was not significantly different. The use of a pancreatic stent was not related to complication rate. Early mortality rate was significantly higher in Group A than in Group B (19.2% vs 2.5%, $p = 0.003$). No ERCP-related deaths occurred in both groups.
Conclusion: With adequate timing and experience, NKP and NKF can be regarded as safe and effective procedures in extreme elderly.
Disclosure: Nothing to disclose

P0832 INITIAL EXPERIENCES WITH TRANSPANCREATIC PRECUT SPHINCTEROTOMY

S. Gódi[1], D. Pécsi[2], F. Pakodi[1], I. Szabó[1], A. Vincze[1]

Contact E-Mail Address: godi.szilard@gmail.com
Introduction: In certain cases of ERCP with naive papilla biliary access cannot be obtained with standard cannulation. In these cases, advanced techniques, for example precut papillotomy may help. With transpancreatic precut sphincterotomy (TPS) the precut is performed with the sphincterotome in the biliary direction while a guidewire and the tip of the sphincterotome is inserted in the main pancreatic duct.
Aims and Methods: ERCP related procedural data (cannulation technique, cannulation time, success rate, complications, etc.) are collected prospectively in the Hungarian ERCP Registry at our department since the beginning of 2017. All TPS and needle knife precut (NKP) cases were collected from the databases and the outcomes of these advanced biliary cannulation techniques were compared.
Results: TPS was performed in 15, while NKP in 109 cases. Prophylactic pancreas stent (PPS) was inserted after TPS in 14 cases (93.3%), while in 17 (15.9%) cases after NKP. All TPS, 103 (94.4%) NKF patients received 100 mg indomethacin suppository after the procedure. All pateints received appropriate post-ERCP prevention. The success rate (86.6% vs. 85.3%), the post-ERCP pancreatitis rate (2.2% vs. 4.6%) and the perforation rate (0% vs. 4.6%) were more favourable in the TPS group compared to the NKP group. The rate for significant bleeding was better in the NKP group (13.3% vs 7.4%)
Conclusion: Our data suggest that TPS with PPS insertion can be a safe and useful tool in difficult biliary access, when the guidewire can be inserted deeply in the main pancreatic duct.
Disclosure: Nothing to disclose

P0833 IS ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY MORE RISKY AND COMPLICATED FOR THE ELDERLY? A PROSPECTIVE MULTICENTER OBSERVATIONAL STUDY

Contact E-Mail Address: mdleehj@gmail.com
Introduction: Life expectancy is continually increasing, which is coming along with an increasing the demand of endoscopic retrograde cholangiopancreatography (ERCP) in patients with advanced age. Few recent prospective studies have addressed the adverse events on the feasibility and safety of ERCP in elderly patient although technical advances and better operator experience in ERCP. In this study, we compare the differences on success rates and adverse events of ERCP in patients older and younger than age 80.
Aims and Methods: From January 2015 to December 2015, we prospectively enrolled patients with naïve papilla who referred for ERCP at 6 centers of Daegu-Gyeongbuk province. Patient and procedure related variables were recorded on data collection sheet at the time of ERCP. Patients were grouped according to age for patients ≥80 years old (group A) and patients < 80 years old (group B). Demographic data, success rate, outcome, complications, risk factors and mortality were compared between the groups.
Results: There were 1191 ERCPs performed (238 patients older than 80 years, 953 procedures in patients younger than 80 years). The median age was 70 years and male:female ratio was 1.38:1. Mean age was 83.7 years in the group A and 63.1 years in the group B. The cannulation success rate was lower in group A (95.0 vs. 97.1%, $p = 0.107$). There was no significant difference in the overall complication rates between group A and B (18.9 vs. 20.9%, $p = 0.500$) and ERCP-related mortality (0.4% vs 0%, $p = 0.200$, respectively). Post-ERCP pancreatitis was found relatively often in patients of group A (9.2%) than of group B (8.0%, $p = 0.524$). All patients of pancreatitis had full recovery with supportive and medical treatment. There was no significant difference in the other complication rate such as bleeding, perforation, cholangitis and others between two groups.
Conclusion: ERCP in the patients aged 80 years or older is safe and has a high degree of success. However, post-ERCP pancreatitis must be carefully attended in older patients because of relatively high risk. The incidence of other adverse events of ERCP is similar in older patients compared with younger ones.
Disclosure: Nothing to disclose

P0834 EFFICACY OF DOUBLE-BALLOON ENDOSCOPY FOR THERAPEUTIC ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN PATIENTS WITH SURGICALLY ALTERED ANATOMY

Y. Sumida, A. Yamaguchi, T. Kuwai, H. Konishi, K. Tao, R. Miura, Y. Miyasako, K. Kuroki, Y. Tamaru, H. Kouno, H. Kohno
Kure Medical Center And Chugoku Cancer Center, Gastroenterology, Kure, Japan

Contact E-Mail Address: sumiday@kure-nh.go.jp
Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) and associated procedures are difficult to perform in patients with surgically altered anatomy. Some studies have suggested that ERCP using a double-balloon endoscope (DB-ERCP) is useful for removing gallstones or remaining anastomotic constrictions in such patients. This procedure was first covered by the National Health Insurance of Japan in 2016, and it is expected that the demand for DB-ERCP will now increase. This study considered the efficacy and safety of DB-ERCP in patients with surgically altered anatomy.
Aims and Methods: This retrospective study included 29 patients (49 procedures, male/female: 24/5, average age: 76 [63–90] years) with surgically altered anatomy, who underwent DB-ERCP between July 2015 and February 2018 at Kure Medical Center and Chugoku Cancer Center. Procedures were performed by two endoscopists, one experienced in ERCP, another in DBE. DB-ERCP was performed using EI-530BI or 580BT (FUJIFILM systems). The treatment results, adverse events, and clinical outcomes of DB-ERCP were evaluated.
Results: Endoscopic biliary treatment was attempted with the surgical reconstruction technique for 30 procedures in 15 gastrectomy patients (Roux-en-Y reconstruction: 29 procedures in 14 patients, and gastrojejunal bypass: 1 procedure in 1 patient) and for 19 procedures in 14 choledochojejunal anastomosis patients (pancreatectomy: 14 procedures in 11 patients, and cholecystectomy/ bile duct resection: 5 procedures in 3 patients). The success rate of reaching the major papilla or target anastomosis was 91.8% (45/49), and the mean access time was 27 (5–84) min. The biliary cannulation success rate was 72.4% (21/29) on the first attempt. In 2 of the 8 unsuccessful cases, the percutaneous transhepatic cholangiography-drainage (PTCD) rendezvous technique was used, and biliary

intubation was ultimately successful in 79.6% (39/49). In patients in whom the target area could be reached, the biliary cannulation success rate was 86.7% (39/45). By the reconstruction technique, the success rates were 76.7% (23/30) for post-gastrectomy (Roux-en-Y reconstruction: 23/29 procedures, and gastro-jejunal bypass: 0/1 procedure), 92.9% (13/14) for post-pancreatectomy, and 60% (3/5) for post-cholecystectomy/bile duct resection. The procedures included dilatation in 34 procedures (endoscopic sphincterotomy (EST): 1 procedure, endoscopic papillary balloon dilatation (EPBD): 16 procedures, and anastomosis site dilatation: 13 procedures), drainage in 17 procedures (endoscopic nasobiliary drainage (ENBD)/endoscopic retrograde biliary drainage (ERBD): 15 procedures, and metallic stent placement: 2 procedures), and lithotomy in 24 procedures. The mean total procedure time was 95.3 (39–156) min. Procedural adverse events included guidewire-induced perforation in 1 patient and intra-abdominal deviation of the PTCD catheter in 1 patient; both were relieved with conservative therapy.
Conclusion: DB-ERCP for the intestinal tract with surgically altered anatomy is useful and can be performed with relatively minimal invasiveness. However, no standard procedure has yet been established. In some cases, examination duration is prolonged, and in some patients, biliary cannulation could be difficult even if the major papilla or target anastomosis was achieved. Thus, it is desirable to accumulate more cases to lead to further improvements in these endoscopes and devices.

Contact E-Mail Address: hslee60@korea.ac.kr
Introduction: Endoscopic nasobiliary drainage (ENBD) has been widely used for biliary decompression in patients with biliary disease. However, it is difficult to reposition a nasobiliary catheter from mouth to nostril. We developed a new device for repositioning of ENBD catheter (Patent pending). The new device has a curved flexible loop and handle bar. The aim of this study was to evaluate the usefulness of new loop-device for helping the repositioning of an ENBD catheter from mouth to nostril.
Aims and Methods: Between January 2016 and December 2017, a prospective observational study was performed to evaluate the time for repositioning a nasobiliary catheter in ERCP. It was compared the result of ENBD procedure between new loop-device technique and conventional technique. In subgroup analysis, we evaluated the occurrence of oral cavity injury and time to ENBD catheter moving from mouth to nostril.
Results: A total of 206 ENBD procedures were performed using these two techniques. The mean time for repositioning a nasobiliary catheter was shorter in loop device technique than conventional technique (39 sec vs. 361 sec, $p < 0.001$). Total success rate of new device technique was achieved in 98.1%. There was no complication such as oral cavity injury.
Conclusion: This technique using our new loop-device was useful for repositioning a nasobiliary catheter from mouth to nostril in ERCP. Outstanding merit of new device is that it does not require the removal of mouthpiece before ENBD positioning. It can help to perform a rapid ENBD procedure and avoid the finger injury of ERCPist.

Introduction: The first endoscopic bile duct drainage method used to treat obstructive jaundice differs according to the pathology and institutional policy. Although endoscopic nasal biliary drainage (ENBD) has advantages such as occlusion prevention by washing at bedside after indwelling, endoscopic bile duct drainage (EBD) with a plastic stent (PS) is often used owing to the complexity of ENBD. We investigated the influence of prior indwelling ENBD in obstructive jaundice on the patency of PS after EBD, endoscopic procedure frequency and hospitalisation period.
Aims and Methods: We enrolled 63 subjects with malignant distal bile ducts requiring drainage due to obstructive jaundice (34 with acute cholangitis) and 40 subjects with cholangitis due to common choledocholithiasis. The subjects were classified into prior ENBD (EBD with prior ENBD) and EBD (EBD without prior ENBD) groups.
Results: The median age was 70 (range, 54–93) and 77 (range, 55–92) years in patients with distal bile duct malignant stenosis and in those with cholangitis due to choledocholithiasis, respectively. The median PS survival was 29 ($n = 24$) and 43 ($n = 39$) days in the prior ENBD and EBD groups among patients with distal bile duct malignant stenosis and 29 ($n = 13$) and 37 ($n = 21$) days in the prior ENBD and EBD groups among those with cholangitis due to choledocholithiasis, respectively; the mean PS survival was not significant in either of the groups ($p = 0.59$). In the prior ENBD group, the serum bilirubin level before treatment was significantly higher than that in the EBD group ($p = 0.04$); however, there was no significant difference in the number of endoscopic procedures and hospitalisation period between the groups. No evidence for severe cholangitis exacerbations was observed in the initial EBD group.
Conclusion: Currently, there are few studies that have compared ENBD and EBD as the initial endoscopic drainage procedures to treat obstructive jaundice. In this study, ENBD did not result in a prolonged follow-up period for PS or increased hospitalisation period and number of endoscopic procedures. However, considering the complexity of the procedure and suffering of the patient, EBD alone should be used even in cases of acute cholangitis.

P0837 IMPACT OF PERIAMPULLARY DIVERTICULUM ON ERCP PERFORMANCE: A MATCHED CASE-CONTROL STUDY

J.E. Corral, O.Y. Mousa, P.T. Kroener, V. Gomez, F. Lukens
Mayo Clinic, Florida, Gastroenterology and Hepatology, Jacksonville, United States

Contact E-Mail Address: corral.juan@mayo.edu
Introduction: Periampullar diverticulum (PAD) is an outpouching within the ampulla that develops with aging and is usually found incidentally during endoscopic retrograde cholangiography (ERCP). PAD can interfere with biliary drainage and has been associated with the development of bile duct stones, gallstones and acute cholangitis. There is conflicting data on whether the presence of a PAD affects therapeutic success rates during ERCP.
Aims and Methods: We aimed to compare ERCP performance in patients with PAD with age and gender-matched controls using a U.S. national database. We reviewed ERCP recorded between 2000 and 2012 in the Clinical Outcome Research Initiative database.
ERCP cases in adults (≥18 years) with a periampullary diverticulum were included if the endoscopist reported a duodenal diverticulum in the CORI software. Patients were included if they had age, gender and description of major papilla visualization (achieved or not) available. Patients with PAD were compared with age and gender-matched controls, selected randomly using a 1:3 fashion from all other ERCPs, regardless of the procedure indication. Demographic variables, procedure time (from scope insertion to withdrawal), endoscopic and fluoroscopic findings, and therapeutic success (e.g. stone extraction, determined by endoscopist) were compared. ERCP complications and medication use are not consistently recorded in CORI, and were not included in our study design.
Univariate regression was performed and a multivariate regression model was elaborated with variables considered significant ($p < 0.05$). Adjusted odds ratio were reported for each variable.
Results: Initial CORI database review revealed 28,271 ERCPs. PAD was reported in 1,325 (4.7%) cases (8.6% in patients ≥70 years old). We identified 1,089 PAD cases with complete information and selected 3,267 matched controls for comparison. Average age was 68.4 ±14.3 years, and 2,400 (55.1%) were male. 42% patients with PAD had their ERCP as outpatients while 52% controls had ERCP done as outpatients. Anesthesia risk score was similar between both groups.
Biliary stones (choledocolithiasis, cholelithiasis or biliary pancreatitis) were twice more common in patients with PAD. Patients with PAD were less likely to have a cancer diagnosis or required stents (placement, replacement or removal). The presence of PAD was associated with shorter procedure time, but similar fluoroscopy time. After removing procedures where therapeutic success could not be established, there was no difference in ERCP therapeutic success between both groups (94.9% in PAD, 96.0% in controls [$p = 0.2$]). The presence of a PAD did not decrease the visualization rates of the minor papilla (endoscopic view), the common bile duct or pancreatic duct (fluoroscopy).
There was no difference in ERCP therapeutic success between both groups in univariate and multivariate analysis (OR 0.63 [95% CI 0.39–1.00]). Patients with PAD required a sphincterotomy more frequently (OR 1.27 [95% CI 1.02–1.58]). Presence of a PAD increased the chance of a procedure being completed in < 30 minutes (OR 1.70 [95% CI 1.38–2.09]).
Conclusion: No significant difference was seen for ERCP performance in patients with PAD adjusting for hospital setting, procedure duration, use of sphincterotomy and two major indications (bile stone disease or stent-related procedures). Our results support literature showing that PAD should not be considered a barrier to ERCP success. This study also substantiates the hypothesis that PAD interferes with adequate biliary drainage and promotes bile stone formation.

P0838 DEXMEDETOMIDINE IS SAFE AND REDUCES THE ADDITIONAL DOSE OF MIDAZOLAM FOR SEDATION DURING ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN VERY ELDERLY PATIENTS

R. Mizuno, O. Inatomi, Y. Owaki, S. Shintani, T. Fujimoto, S. Bamba, A. Andoh

Contact E-Mail Address: mizuryo@belle.shiga-med.ac.jp

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) often requires deep sedation. Dexmedetomidine, a highly selective α2-adrenoceptor agonist with sedative activity and minimal effects on respiration, has recently been widely used among patients in the intensive care unit. However, its use in endoscopic procedures in very elderly patients is unclear. In this study, we retrospectively investigated the safety and efficacy of dexmedetomidine sedation during ERCP.

Aims and Methods: The study included 62 very elderly patients (aged over 80 years) who underwent ERCP from January 2014, with sedation involving dexmedetomidine (i.v. infusion at 3.0 μg/kg/h over 10 min followed by continuous infusion at 0.4 μg/kg/h) along with midazolam. For comparison, the study included 78 patients who underwent ERCP before January 2014, with midazolam alone. We considered additional administration of midazolam as needed to maintain a sedation level of 4, according to the Ramsay sedation scale. The outcome measures were amount of midazolam, adverse events associated with sedatiohemodynamic.

Results: The study included 62 very elderly patients (aged over 80 years) who underwent ERCP from January 2014, with sedation involving dexmedetomidine (i.v. infusion at 3.0 μg/kg/h over 10 min followed by continuous infusion at 0.4 μg/kg/h) along with midazolam. For comparison, the study included 78 patients who underwent ERCP before January 2014, with midazolam alone. We considered additional administration of midazolam as needed to maintain a sedation level of 4, according to the Ramsay sedation scale. The outcome measures were amount of midazolam, adverse events associated with sedation, and hemodynamics.

Conclusion: Dexmedetomidine can decrease the incidence of respiratory complications and the total dose of other sedative agents. It can be used as an alternative to conventional methods with midazolam for adequate sedation during ERCP in very elderly patients.

Introduction: Bilio-digestive anastomoses are common in many operations.
The management of biliary diseases in bilio-digestive anastomosis is complex and still represents a challenging topic, especially in case of biliary anastomotic strictures. The critical points about the endotherapy are the availability to reach the anastomotic site and the capability to perform an effective endoscopic retrograde cholagiography (ERC). To improve the results of endotherapy, we propose a new type of endoscopic strategy to reach the biliary anastomosis.

Aims and Methods: To reach the anastomotic site, we perform a totally-endoscopic enteral by-pass between the duodenal or the gastric wall and the biliary jejunal loop both with fluoroscopic and endoscopic ultrasound's guide. We present our 32-case series of consecutive patients treated by endoscopic enteral-enteral anastomosis and subsequent ERC.

Results: Biliary anastomotic reach was obtained in 93.75% of cases and therapeutical ERC's rate was 93.75% (100% if biliary anastomosis was reached). Clinical success rate was 100%. Morbidity and mortality were respectively 6.25% and 0%.
Short-term complications (before 48 hours) occured 3.12% (1 self-limited bleeding).
We did not report any long-term complication (after 48 hours).
Overall recurrence rate was 6% (1 case of biliary lithiasis and 1 case of biliary strictures' recurrence). Mean follow-up lasted 2.5 (3months-5 years).
The main advantages of the new endoscopic method are hereafter resumed. The first one is to let unreachable anastomoses endoscopically-reachable again. The second one is to obtain a stable endoscopic position to use endoscopes with large operative channel. This leads to a longer and increasing dilation of the biliary stenosis, also in case of complex strictures and multiple-ducts biliary anastomosis. The third point is the availability of a stable new pathway to check the results and eventually re-treat the patient, especially in case of complex biliary anastomotic strictures.

Conclusion: This new technique seems to be safe and effective to treat the complications of the bilio-digestive anastomosis, in expert hands.

Contact E-Mail Address: livia.archibugi@hotmail.it

Introduction: In Common Bile Duct (CBD) stones the access to CBD can be achieved through the papilla orifice followed by endoscopic sphincterotomy (ES), or through a precut fistulotomy (PF) in case of difficult cannulation;the two methods alter papilla anatomy differently, therefore intuitively leading to a different rate of stone recurrence. No data on stones recurrence in patients with CBD stones after PF has been published.

Aims and Methods: The aim was to evaluate CBD stone recurrence,re-intervention rate after PF versus ES.
We performed a retrospective single-center cohort study including patients undergoing for the first time ERCP for CBD stones with PF in case of failed repeated cannulation attempts, matched for sex and age to ES patients randomly extracted from our database. T-test and Fisher's tests were used for continuous and categorical variable comparison. Recurrence probability was calculated with Kaplan-Meier curve, and Cox analysis was employed to calculate hazard ratios (HR).

Results: 85 PF patients were included, with 85 matched controls (mean age 68.7 years, 45.9% males). PF patients had the same overall reintervention rate of ES (14.1% vs 12.9%) with a HR of 1.11 (95% CI 0.49–2.50; $p = 0.81$), but mean time to reintervention was significantly lower (74.9 ± 74.6 vs 765.6 ± 961.3 days; $p < 0.0001$). HR of ERCP repetition raised to 2.52 (95% CI 1.02–6.24; $p = 0.03$) if the analysis was therefore limited to the first 1000 days. The only factor associated to ERCP repetition risk was incomplete clearing.

Conclusion: Risk of reintervention was significantly higher in the short-term after PF. Therefore, patients undergoing PF should undergo closer follow-up in the first years after ERCP.

Contact E-Mail Address: livia.archibugi@hotmail.it

Introduction: Endoscopic transpapillary biliary drainage is the treatment of choice for obstructive jaundice caused by malignant strictures. Different types of self-expanding metal stents (SEMS) are available: fully covered (FC), partially covered (PC) and uncovered (UC). The advantage of metal compared to plastic prostheses is the reduced risk of rehospitalization and complications expecially in patients expected to survive for more than 3 months. However what is the most effective type of metal prosthesis is still debated.

Aims and Methods: The aim was to evaluate the reintervention rate after positioning of metal stents, comparing FC versus PC versus UC SEMS.
We performed a retrospective single-center cohort study including patients undergoing ERCP with positioning of SEMS for the first time for CBD malignant stenosis. A repeated ERCP was indicated in case of jaundice and/or cholangitis. T-test and Fisher's test was used for comparison of continuous and categorical variables. Reintervention probability was calculated with Kaplan-Meier curve, Cox analysis was employed to calculate hazard ratios (HR).

Results: 321 patients (63 FC, 55 PC, 203 UC) were included in this preliminary analysis, (mean age 69.2 ± 11.8years, 52.6% males); 90.3% had pancreatic cancer, 3.7% cholangiocarcinoma, 6% had ampullary tumors or pancreatic neuroendocrine tumors. 29.3% patients were metastatic, 47% locally advanced, 23.7% were surgically resectable. Overall reintervention rate for FC vs PC vs

UC SEMS was respectively 31.7% vs 12.7% vs 30%. Main reason for ERCP repetition was occlusion due to sludge and ingrowth in UC stents and occlusion due to sludge and displacement in FC. Patients with partially covered SEMS vs fully covered or uncovered SEMS had a HR of 0.49 (95% CI 0.27–0.88 p = 0.058) for repetition of ERCP.
Conclusion: To our knowledge, this is the first study comparing all three different types of SEMS to each other in terms of reintervention rate in patients with malignant jaundice. The 51% reduced risk of reintervention after PC SEMS positioning should encourage controlled studies to verify their higher benefit of this stent compared to FC and UC SEMS.

Introduction: Endoscopic papillectomy (EP) can be the first-line less-invasive treatment in patients with ampullary adenoma without intraductal extension. However, the evaluation of resected margin was often difficult because of the burning effect caused by EP. This study investigated the clinical course of resection margin positive or uncertain cases after EP.
Aims and Methods: Between January 2007 and October 2017, 38 patients who performed EP for ampullary tumor were included in this study. Indication for EP was adenoma as determined by preoperative biopsy, without tumor spread into the bile/pancreatic duct by endoscopic ultrasound (EUS) or intraductal ultrasound (IDUS). EP was carried out with a standard polypectomy snare using the blended electrosurgical current, and we tried to place both bile duct and pancreatic duct stent after EP.A pathologist examined the resected specimen. The clinical outcomes after EP were retrospectively investigated. This study was approved by the institutional review board of Kobe University Graduate School of Medicine.
Results: 23 patients were men, 15 were women. The mean age of the patients was 65 years old. 34 patients (89.5%) were carried out en block resection, and 4 patients (10.5%) were piecemeal resection. Early complications occurred in 32% of all the patients (hemorrhage occurred in seven and pancreatitis occurred in eleven). 28 were diagnosed as adenoma, 10 were diagnosed as adenocarcinoma histopathologically. The resection margin was negative in 21 patients (55.3%), and positive or uncertain in 17 patients (44.7%). The resection margin at the vertical end was positive or uncertain in 13 patients (Group A), and at the horizontal end was positive or uncertain in 4 patients (Group B). In Group A, 1 patient was diagnosed as T2 (Du1) histopathologically, and received additional surgery. 6 patients were adenocarcinoma in adenoma, and 3 were received additional surgery, the other 3 were selected follow-up observation (no recurrence occurred in this investigation). In patients received additional surgery, 2 were not found residual tumor, and 1 was found residual adenoma in resected specimens. Remaining 6 patients in group Awere adenoma, and local recurrence after EP were found in 2 patients. 2 recurrent cases were successfully treated with argon plasma coagulation (APC). In Group B, 1 patient was adenocarcinoma in adenoma, and the patient received additional surgery with no residual tumor in the resected specimen. 3 patients were adenoma with no recurrence. Ampullary tumor-related death was not observed in these cases. The mean follow-up period was 1651 days.
Conclusion: Resection margin positive or uncertain cases after EP could be managed by endoscopic treatment including APC rather than surgical treatment even in the carcinoma in adenoma cases. EP would be an effective less-invasive treatment for ampullary tumors.

P0843 LOW NEGATIVE PRESSURE SUCTION YIELDS BETTER QUALITY SMEARS – PROSPECTIVE COMPARISON OF SLOW-PULL AND STANDARD SUCTION TECHNIQUES OF ENDOSCOPIC ULTRASOUND-GUIDED FINE-NEEDLE ASPIRATION

R. Bor[1], B. Vasas[2], A. Fabian[1], Á. Füredi[3], L. Czakó[1], K. Farkas[1], T. Molnár[1], S. Hamar[2], L. Tiszlavicz[2], L. Kaizer[2], Z.G. Szepes[4]

[4]*University of Szeged, First Department Of Szeged, Szeged, Hungary*

Contact E-Mail Address: bor.reni86@gmail.com
Introduction: Standard suction (SS) technique using a 10mL syringe is the recommended sampling technique of endoscopic ultrasound-guided fine needle aspiration (EUS-FNA) in the diagnosis of pancreatic cancer, but it often leads to elevated number of smears with increased bloodiness with no improvement in diagnostic accuracy. However, mainly retrospective studies are available about the detailed sampling methods of cancers of other organs, and in these cases, there are no evidence-based recommendations. Aim of our prospective study is to compare the diagnostic yield and quality of cytological and/or histological samples obtained by slow-pull (SP) and SS techniques of EUS-FNA.
Aims and Methods: 378 EUS-FNAs were performed between January 2014 and December 2016 at the University of Szeged, 1st Department of Medicine. Histological and cytological samples were obtained from a total of 462 organs. In the prospective study we assessed the data of EUS-FNA samplings in which 22G needle and both techniques were applied. Patients with cystic lesions and EUS-FNA examinations with undocumented sampling technique were excluded from the study. We separately assessed and compared the efficiency of the two sampling techniques in soft, vascularized (liver, lymph nodes, adrenal gland, etc.) and hard, fibrotic neoplasia (pancreatic cancer, submucosal neoplasia, etc.). The quality of EUS-FNA samples was assessed based on the number of obtained and diagnostic smears, bloodiness, cellularity and diagnostic yield.
Results: 56 soft (39 lymph nodes, 9 primary or metastatic liver, 2 Klatskin, 2 pararectal and 3 mediastinal lesions) and 147 fibrotic (145 pancreatic and 2 abdominal) tumors were enrolled. In cases of hard, fibrotic tumors the diagnostic yield of the sampling (67.35% vs. 68.02%) and the cellularity of smears did not differ significantly between SP and SS groups (1.44 vs. 1.27), however it was substantially higher in case of soft tumors using SP technique of EUS-FNA (60.71% vs. 46.43% and 1.34 vs. 0.77; $p < 0.001$). The SS techniques resulted in significantly higher number of smear pairs both in soft, vascularized (1.74 vs. 3.19; $p < 0.001$) and fibrotic tumors (1.62 vs. 3.28; $p < 0.001$), but at the same time the proportion of diagnostic samples decreased (46.51% vs. 36.52% and 49.17% vs. 30.67%; $p = 0.003$). The SS technique substantially increases the bloodiness of smears independently from tumor (in soft tumors: 1.50 vs. 2.06 and in fibrotic tumors: 1.48 vs. 2.05). Histological samples were obtained in almost the same proportion of soft and fibrotic cancers (76.87% vs. 82.17%), and their diagnostic yield did not differ between subgroups (69.01% and 71.74%).
Conclusion: Independently from tumor consistency, the low negative pressure suction generated by SP technique yields better quality smears. The lower bloodiness and decreased number of slides could make the pathological diagnosis faster and more cost-effective. In case of vascularized tumors, the higher negative pressure suction resulted lower diagnostic yield, therefore we recommend the SP technique as the first method in the EUS-FNA sampling of soft tissues, such as lymph nodes and liver cancers.

Introduction: The most effective investigation for suspected gallstones between MRCP and EUS is unclear. A 2015 Cochrane systematic review of their performance in common bile duct (CBD) stones concluded that the tests were of comparable accuracy. Conversely, a 2017 meta-analysis found EUS to be more sensitive. Any superiority of EUS may be due to better accuracy in detecting small stones. MRCP is routinely favoured as the 2nd line test following a non-diagnostic abdominal ultrasound and EUS subsequently performed as the 3rd line test when suspicion remains after a non-diagnostic MRCP. The yield and clinical utility of EUS in this setting is unclear. The aim was to identify the yield of EUS in patients with prior non-diagnostic MRCP undergoing EUS in our tertiary service.
Aims and Methods: All EUS reports from 2017 were reviewed along with the electronic patient records to identify cases with prior MRCP. Indication for the procedure, symptoms, liver blood tests and interval between MRCP and EUS were recorded. Findings of sludge, microlithiasis (stones < 2mm) and discrete stones were categorised together as stones. Subsequent ERCP or cholecystectomy was identified. Yield was defined as a finding that would lead to a change in management.
Results: A total of 1058 diagnostic EUS were screened of whom 253 (24%) had prior MRCP and formed the study group. Median age was 58 (16–88) years, 179 (71%) were female and 91 (36%) had a cholecystectomy. Median interval between EUS and MRCP was 5.2 (0.1–37) months. Indications for EUS were: n = 76 (30%) dilated CBD, n = 65 (26%) query CBD stones, n = 54 (21%) unexplained acute pancreatitis (AP), n = 23 (9%) right upper quadrant pain, n = 17 (6.7%) abnormal LFTs, n = 16 (6.3%) double duct sign and n = 2 (1%) dilated PD. There was a yield from EUS in 30 (12%) patients with no significant difference between those with (n = 11) or without cholecystectomy (n = 19). Stones were identified in 24 cases with median size of 4 mm (range 2–8) in: CBD (n = 16), cystic duct (n = 1) and GB (n = 7). Three had abnormal CBD without stones (calcification CBD wall, thick walled CBD, polyp), 1 patient with possible stone on MRCP had no stone seen on EUS, 1 had a pancreatic mass, and 1 had chronic pancreatitis. All patients in whom EUS findings indicated an intervention (26/30) have been referred: ERCP in 13, cholecystectomy in 9, ERCP & cholecystectomy in 3 and chemotherapy in 1.
Conclusion: EUS following non-diagnostic MRCP is a sizeable workload accounting for 24% of diagnostic activity in our unit with a clinically significant yield in 12% of predominantly small stones. Further prospective studies are required to ascertain the most cost-effective way to incorporate EUS into the investigation of suspected gallstone disease.

Introduction: Contrast-enhanced harmonic endoscopic ultrasound (CEH-EUS) is a promising imaging modality that can identify subepithelial tumors (SETs) by detecting the degree of enhancement. However, whether CEH-EUS alone can predict the malignancy risk of gastrointestinal stromal tumors (GISTs) remains unclear. This study aimed to evaluate the feasibility of CEH-EUS using a perfusion analysis software for distinguishing among SETs and for predicting the malignancy risk of GISTs.

Aims and Methods: We retrospectively included patients with subepithelial lesions who underwent preoperative CEH-EUS. In total, 44 patients with histologically proven GISTs and benign SETs were enrolled in the study. Perfusion analysis was performed using a perfusion quantification software. Area under time intensity curve (AUC), peak enhancement (PE), wash-in rate (WiR), and wash-in perfusion index (WiPI) were calculated and compared between GISTs and SETs.

Results: When we allocated the enrolled patients into high- and low-grade malignancy, and benign groups, significant statistical differences of AUC ($p < 0.001$), PE ($p < 0.001$), WiR ($p = 0.009$), and WiPI ($p < 0.001$) were identified in the high-grade malignancy groups compared to benign groups.

Conclusion: CEH-EUS with a perfusion analysis using a perfusion analysis software could be a quantitative and independent method for predicting malignancy risk in gastrointestinal SETs.

Introduction: For pathological diagnosis of the pancreatic solid tumor, EUS-FNAB is known as a standard method that is minimally invasive and accurate. Many kinds of needles have been developed to improve diagnostic yield. EchoTip ProCore has the core trap at the side of needle for receiving core sample, the shape of the core trap is forward bevel in ProCore 20G (PC20) and reverse bevel in ProCore 22G (PC22). We compared the usefulness and safety with PC20 and PC22.

Aims and Methods: We conducted a retrospective study of EUS-FNAB with a PC20 or a PC22 for pancreatic solid tumor performed between April 2013 and March 2018 at Kyorin University hospital. The main outcome was to compare the usefulness by histological as well as cytological yield. The secondary outcome was the number of passes to obtain a diagnosis, the necessity of needle change and ratio of complications. First, we collected specimens by suction method, with two passes of puncturing. In cases with a lot of bleeding and cases with the small amount of specimens which was insufficient to exam, and cases when the needle was broken, we added more passes, changed to slow-pull method and other needles. Group 4,5 in histology and Class IV,V in cytology were diagnosed as malignant tumor.

Results: A total of 110 patients were enrolled this study. PC20 was used in 50 patients and PC22 was used in 60 patients. The final diagnosis were pancreatic ductal carcinoma in 94, metastasis pancreatic carcinoma in 3, neuroendocrine tumor in 2, autoimmune pancreatitis in 7, chronic pancreatitis in 3 and solid pseudopapillary neoplasm in 1. Maximum diameter of tumor, location of the pancreatic tumor, puncturing line, mean number of passes, and final diagnosis were not significant difference. Sensitivity, specificity and accuracy combining pathology and cytology were 97.4%, 100% and 97.6% in PC20, and 76.6%, 100% and 79.2% in PC22, there was significant difference at sensitivity and accuracy ($p = 0.006$ and 0.01). Even when comparing the pathological diagnosis of PC20 with the cytological diagnosis of PC22, sensitivity and accuracy were significant difference (sensitivity 97.9% vs 68.6% $p = 0.0001$, accuracy 98.0% vs 73.3% $p = 0.0004$). The histological accuracy was achieved by the 1st, 2nd and after 3rd pass in 90.0%, 96.0% and 98.0% at using PC20, and 45.0%, 58.3% and 65.0% at using PC22 ($p = 0.0001$, 0.0001, 0.0001 respectively). The necessity of needle change was not significantly different between two needles. Mild pancreatitis occurred 1 patient in PC20, and hemorrhage occurred 1 patient in PC22, complication rate was not significant difference.

Conclusion: Our results showed that PC20 is more useful for diagnosis of pancreatic solid tumor with higher sensitivity and accuracy than those of PC22. In addition, it was suggested that the diagnosis could be obtained with fewer punctures on the PC20. As a limitation, we could not evaluate the involvement of needle shape and thickness.

Introduction: Recto-sigmoid endometriosis is an underdiagnosed disease responsible for non-specific digestive symptoms. Two surgical approach, recto-sigmoid bowel resection (segmental or patch) and shaving technique (intra-muscular layer dissection) are available. The aim of this study was to assess if pre-operative recto-sigmoid endoscopic ultrasonography (RS-EUS) findings might predict the need for bowel resection

Aims and Methods: This retrospective study was conducted between January 2012 and March 2018 on patients with recto-sigmoid endometriosis evaluated by RS-EUS who underwent a curative surgical procedure in our tertiary center. Logistic multivariate regression was used after univariate statistical analysis on nodules' RS-EUS features (thickness, width, infiltration of the sub-mucosae, presence of a bump into the digestive lumen and presence of multiple recto-sigmoid localizations).

Results: 73/362 patients with recto-sigmoid endometriosis were evaluated by RS-EUS and underwent a recto-sigmoid surgery. After univariate analysis, thickness, width and infiltration of the submucosae were identified as potential predictive factors for bowel resection. In a multivariate logistic regression model, only thickness appeared to be a significant predictive factor for bowel resection ($OR = 1.49$, IC95% [1.04–2.12], $p = 0.028$. ROC analysis showed that a thickness over 5.20 mm might be used as cut-off value with a sensitivity of 76%, a specificity of 82%, and an $AUC = 0.82$. Cut-off values for 100% sensitivity and 100% specificity were 0.90 mm and 10,00 mm respectively.

Conclusion: Presence of a recto-sigmoid nodule of endometriosis with more than 5.20 mm of thickness on RS-EUS predicts the need for recto-sigmoid bowel resection versus shaving technique. Prospective studies are needed to confirm these results.

Introduction: It is a great challenge to differentiate between the type and the malignant potential of a newly diagnosed pancreatic cyst. Our aim was to assess the role of contrast-enhanced endoscopic ultrasonography (EUS) for increasing diagnostic accuracy.

Aims and Methods: The prospective study included 49 patients with pancreatic cysts. Inclusion criteria were: age over 18, presence of an undetermined pancreatic cyst >10mm (CT, MRI), informed consent. Exclusion criteria were: severe chronic pancreatitis, cyst<10mm, platelet count<50,000/cm3, refuse of the patient to participate. We analyzed the cyst wall, the septae and the solid components of the pancreatic cyst with and without contrast enhancer (CE)(2,4ml SonoVue-Bracco,Italy). The examinations were performed using an Olympus echoendoscope and Aloka ultrasound machine. The final diagnosis was based on fine needle aspiration result, surgery or follow-up.

Results: There were 49 patients (33 females, 16 males) included. Cyst size was between 10–90mm. The pancreatic location of the lesions were the head ($n = 13$), the uncinate process ($n = 6$), the neck ($n = 11$), the body ($n = 11$), and the tail ($n = 8$). The types of cysts were serous cystadenoma ($n = 8$); mucinous cystadenoma ($n = 10$); Intraductal Papillary Mucinous Neoplasm (IPMN) ($n = 26$); pseudocyst ($n = 5$). For the serous cystadenomas, a hyperenhancement of the cyst wall and septae with a slow wash-out and honeycomb aspect was observed in 7 of 8 patients. In case of mucinous cystadenomas hyperenhanced thick walls, septae and fast wash-out was characteristic (8/10). For IPMNs, the hyperenhancement of the cyst wall and fast wash-out was found (24/26). All the pseudocyst presented hypoenhancement or no enhancement of cyst wall (5/5). Trough the enhancement pattern mucinous lesions could be differentiated from nonmucinous lesions.($Se = 88\%$, $Sp = 46\%$; $p = 0.0139$). From 18 pancreatic cysts with solid components in standard EUS, hyperenhanced mural nodules were present in 9 of them and malignancy was confirmed for all this cases (surgery $n = 12$; EUS-FNA $n = 18$).

Conclusion: The enhancing pattern was useful to differentiate malignant nodules from mucus or debris and mucinous from nonmucinous pancreatic cystic lesions.

Introduction: Endoscopic ultrasound guided fine-needle aspiration (EUS-FNA) is a well-established diagnostic tool in the upper gastrointestinal tract, but evidence is limited about its use in the rectum.
Aims and Methods: This retrospective analysis of a prospectively collected database aimed to evaluate the indications and diagnostic yield of EUS-FNA of rectal and perirectal lesions. Rectal EUS-FNA examinations performed at the University of Szeged from 2015 were involved.
Results: A total of 15 rectal EUS-FNAs were performed between January 2015 and March 2018 (mean patient age: 53 ± 4 years, 80% female). Indication for rectal FNA were the following: suspicion of endometriosis in 4 cases, lymph node enlargement in 5 cases, tumor recurrence in 5 cases, and undetermined fluid collection in 1 case. Median lesion size was 24.5 mm [6–45 mm]. Technical success was achieved in 14 cases (93%). Smears were obtained with both stylet-capillary technique and vacuum-aspiration in 11 cases, with only the former in 3 cases, and with only the latter in one case. Tissue sampling was possible in 12 cases (3 with stylet, 2 with vacuum, and 7 with both). Sampling was diagnostic in 6 cases (40%): endometriosis was confirmed in 1 case (25%), lymph node metastasis [from malignant melanoma and anal carcinoma] in 2 cases (40%), and tumor recurrence [two rectal and one ovarian] in 3 cases (60%). No adverse events were reported.
Conclusion: EUS-FNA may assist differential diagnosis of rectal and perirectal lesions by providing a safe sampling method of lesions that are often inaccessible for other modalities. It can be especially useful in confirming recurrence of malignancy and might also have additional value in the diagnosis of lymph node metastases and endometriosis that may occur as submucosal lesion endosonographically.

Introduction: Endoscopic ultrasound-guided fine-needle aspiration biopsy (EUSFNAB) is the main method for acquisition of tissue from gastrointestinal subepithelial lesions (SELs). Despite the development of new needles, diagnostic yield remains low. The reason may be an ineffective transmission of negative pressure with the dry technique, as these lesions often have high cellular cohesion. A new method of aspiration has been described, where the needle is filled with saline (wet suction technique, WST), with promising results in pancreatic lesions. This method hasn't been tested in SELs.
Aims and Methods: Prospective single-centre study to assess the diagnostic yield of EUSFNAB+WST in the diagnosis of SELs, without the use of rapid on-site evaluation. In mesenchymal tumours, the diagnosis was considered positive only when immunohistochemistry (IHC) could differentiate between gastrointestinal stromal tumour (GIST) and leiomyoma. The diagnostic yield of this prospective cohort between July 2015 and December 2017 was compared with a retrospective cohort using dry technique from the same institution.
Results: Seventy-one patients with SELs were included (49% male, mean age 66 years). Mean SEL size was 32 mm (min 10, max 120 mm), mean number of passages was 3 (±0.7). A 22G needle was used in 58 patients (82%), 19 G in 8 (12%) and 25 G in 5 (7%). We obtained a conclusive cytopathological diagnosis in 60 cases (diagnostic yield of 85%) and IHC was performed in 58 cases (82%). The most frequent diagnoses were GIST (37%), leiomyoma (14%) and metastases (13%). When compared with a retrospective cohort of 56 cases, diagnostic yield was significantly higher (85% versus 25%, $p < 0.0001$).
Conclusion: Wet suction technique allowed an excellent diagnostic yield in the EUS-guided evaluation of SELs. We suggest that, after proper replication of these results, WST may become the first-line method in the management of these lesions.

Contact E-Mail Address: k-akira@dokkyomed.ac.jp
Introduction: With the increasingly widespread use of endoscopic submucosal dissection (ESD) for early-stage stomach cancers, pre-surgical depth diagnosis for determining suitable treatment needs to be increasingly accurate. In normal endoscopic diagnosis, even if a diagnosis of intramucosal carcinoma is made, some lesions actually infiltrate the submucosa. Although there are various theories regarding the usefulness of endoscopic ultrasonography (EUS) in depth diagnosis, no fixed opinion has been arrived at. Therefore, the purpose of this study was to clarify the significance of performing EUS when diagnosing the depth of early-stage stomach cancers.
Aims and Methods: Of the cases that underwent ESD at our hospital between November 1, 2012 and October 31, 2017, subjects comprised 454 lesions in 393 cases for which detailed review of medical records was possible. Subjects were divided depending on whether they underwent preoperative EUS into an EUS group and a non-EUS group. We then retrospectively investigated accuracy rates for depth diagnosis (depths M-SM1 and SM2 or deeper) in each group. Results were then compared with accuracy rates for the tumor site (U/M/L regions), histopathological differentiation (differential type/poor differentiation and undifferentiated type), the presence or absence of ulcerous complications, and differences in the degree of experience of the surgeon.
Results: Overall, the accuracy rate of depth diagnosis in pre-operative endoscopies was 90.7%, and between the EUS and non-EUS groups, accuracy was found to be low in the EUS group (79.6% vs. 94.4%; $p < 0.001$). In the EUS group, no differences were observed in diagnostic accuracy regarding different tumor sites (U/M/L 75.7% vs.90.0% vs.77.8%; $p = 0.56$) or different histopathologies (differential type/poor differentiation and undifferentiated type 79.2% vs. 85.7%; $p = 0.56$). In the EUS group, the accuracy rate was significantly lower in cases with ulcerous complications than those without (ulcer presence/absence 72.2% vs. 90.5%; $p = 0.03$). In terms of surgeon experience, no differences were identified in accuracy rates between trainee and expert surgeons in either the EUS or non-EUS group (76.4% vs. 82.8%; $p = 0.40$) (91.3% vs. 92.3%; $p = 0.68$). Further, no difference was identified in the accuracy rates between trainee and expert surgeons in EUS group depending on whether the lesion was endoscopically-treated (depth M-SM1) (85.4% vs. 92.0%; $p = 0.24$) or non-eligible (SM2 or deeper) (14.3% vs. 25.0%; $p = 0.55$).
Conclusion: In cases that were eligible for ESD, the significance of preoperative EUS was unclear. In cases of ulcerous complications in particular, EUS accurate rates were low, with difficulty discriminating between ulcer echo signals and invasive foci cited as the cause. In cases of ulcerous complications, it appears more important to diagnose depth using regular light imaging.
Disclosure: Nothing to disclose

P0852 UTILITY OF LIVER AND SPLEEN EUS-ELASTOGRAPHY AS A DIAGNOSTIC TOOL FOR PREDICTING LIVER CIRRHOSIS AND PORTAL HYPERTENSION: A PROSPECTIVE CASE-CONTROL STUDY

C. Robles-Medranda, M. Valero, M. Puga-Tejada, **R. Oleas**, J. Autran-Nebel, S. De Britto, J. Ospina-Arboleda, M. Soria-Alcivar, H. Alvarado-Escobar, R. Del Valle, H. Pitanga Lukashok
Instituto Ecuatoriano de Enfermedades Digestivas (IECED), Guayaquil, Ecuador

Contact E-Mail Address: robertoleas@gmail.com
Introduction: Liver Cirrhosis (LC) includes hepatic and splenic structural and functional changes, with subsequent Portal Hypertension (HP). Abdominal ultrasound, upper endoscopy and Transient Elastography (T-E) constitute LC and PH standard diagnostic workup, delaying it and increasing health care cost. EUS-Elastography (EUS-E) offers all of these workups in a single step. EUS-E has not been evaluated for this purpose, especially in the spleen.
Aims and Methods: We aimed to evaluate the utility of Liver and Spleen Stiffness Measurement (LSM, SSM) by EUS-E to predict LC+PH. Prospective case-control study. Case group: patients with LC based on clinical, imaging and T-E (FibroScan®; EchoSens, Paris, France) findings. Control group: patients with no liver, biliary tract or spleen disease history, who after normal T-E, they underwent to EUS-E due to subepithelial lesions workup. Liver and Spleen EUS-E were performed in each group by 2 gastroenterologists with expertise in EUS-E, using 3.8 mm working channel linear-array echoendoscope (EG 3870UTK, Pentax Germany) with Hitachi AVIUS Ultrasound Console. LSM and SSM Strain Ratio (SR) and Strain Histogram (SH) were measured 10 times per patient. Azigos vein (AzV) diameter (D), mean velocity (MV) and Blood Flow Volume Index (BFVI) were also measured once. The association between LSM and T-E was verified by Spearman's rank correlation coefficient (rho). Then, LSM, SSM and Azygos vein (AzV) feature cut-off values to assess LC+PH were determined through ROC curve [if Area Under the Curve (AUC) ≥80%] to define overall accuracy (a sub-analyses were built for each LC etiology). A p-value < 0.01 was considered statistically significant. Analyses were performed using R v3.4.2.
Results: 61 patients were included: median age 60 (18–82) years, 36/61 (59%) female. 32/61 (52%) had LC (20/32 NASH, 10/32 Alcohol, 2/32 HBV-HCV). Table 1A shows T-E and EUS-E results between both groups. LSM-SR presented a direct association with T-E (rho = 54%, $p < 0.01$), while LSM-SH presented an indirect one (−47%, $p < 0.01$). Only LSM-SR, LSM-SH, SSM-SR, and SSM-SH, reached AUC ≥80%: 82%, 81%, 81% and 80%; with cut-off values of 5.2, 88.8, 7.5 and 39.9, respectively. They showed no difference between LC+PH etiology through sub-analysis, but AzV-D and AzV-BFVI presented higher AUC for LC+PH by alcohol: 96% and 93%; with cut-off values of 9.1 mm and 56.7 mm/s3. Corresponding overall accuracy is showed in table 1B.
Conclusion: Liver and Spleen EUS-E constitute useful diagnostic tools for predicting LC+PH, and could in a single step replace the standard workup for diagnosis of LC+PH. AzV hemodynamic features let to predict better LC+PH or related to alcoholic etiology, especially with high specificity and PPV.
Disclosure: Nothing to disclose

P0853 HIERARCHICAL ANALYSIS OF FACTORS ASSOCIATED WITH T STAGING OF GASTRIC CANCER BY ENDOSCOPIC ULTRASOUND: DECISION TREE METHOD

J. Kim, H. Chung, S.G. Kim, H.J. Kim, J.H. Choi, S.J. Han
Seoul National University Hospital, Department of Internal Medicine and Liver Research Institute, Seoul, Korea (Republic of)

Contact E-Mail Address: piejung88@naver.com

Introduction: Precise prediction of the depth of tumor invasion (T stage) in gastric cancer is important for the decision of treatment modality and endoscopic ultrasonography (EUS) is known to be the most reliable method for it. However, sometimes it can lead to overtreatment when EUS overestimate T stage or undertreatment when underestimates. Therefore, we examined what factors affect the T stage prediction of EUS.

Aims and Methods: We retrospectively analyzed gastric cancer patients who underwent EUS from September 2005 to February 2016. EUS T stage and pathologic T stage were classified as T1a, T1b, T2 or more and the accuracy of EUS T stage and factors affected over/underestimation were examined by using decision tree analysis-CHAID method.

Results: A total of 4818 patients were finally included in the study. The most significant factor affecting the accuracy of the EUS T stage was size. The rate of overestimation was higher in lesions > 3 cm. (37.2% vs 29.8% vs. 17.1%, $p < 0.001$) In the lesions > 3 cm, the rate of overestimation was higher in lesions with ulcer, compared to that without ulcer. (62.1% vs 35.0%, $p < 0.001$) Meanwhile, for the lesions ≤ 3 cm, the accuracy of the EUS T stage was more affected by differentiation, and followed by location than presentation of ulcer. The rate of overestimation was higher in undifferentiated type. (24.5% vs 13.9%, $p < 0.001$, 33.3% vs 25.7%, $p = 0.011$) In the differentiated type, the location affected the accuracy of the EUS T stage and the rate of underestimation was higher in the upper third (24.5% vs 11.5%, $p = 0.001$, 16.2% vs 9.0%, $p = 0.002$) (Figure 1).

Conclusion: In this hierarchical analysis, the most significant factor affecting the accuracy of EUS T stage was tumor size (3cm). For the lesion larger than 3cm, presentation of ulcer was related with overestimation. However, for the lesion smaller than or equal to 3 cm, differentiation and tumor location were important.

Introduction: The definitive diagnosis of solid tumors relies on immunohistochemical staining, which depends on enough tissue being submitted to the pathologist. Achieving adequate tissue acquisition from tumors by EUS-FNA remains a limitation. Advancements in needle design, however, have improved tissue acquisition and therefore may improve the definitive diagnosis by EUS-FNA. Endoscopic ultrasound (EUS)-guided fine needles with side fenestrations are used to collected aspirates for cytology analysis and biopsy samples for histologic analysis. We conducted a large, multicenter study to compare the accuracy of diagnosis via specimens collected with fine-needle biopsy (FNB) Vs. fine needle aspiration (FNA) for patients with solid tumors

Aims and Methods: We performed a prospective single-blind study at 5 tertiary care centers in China. The study comprised 408 patients undergoing EUS for a solid mass (larger than 1 cm) in the pancreas, abdomen, mediastinum, or pelvic cavity, from December 2014 through January 2016. Patients were randomly assigned to groups (1:1) for assessment by FNA (n = 190) or FNB (n = 187). After lesions were identified by EUS; samples were collected in a total of 4 passes by each needle. All procedures were performed by experienced endosonographers; cytologists and pathologists were blinded to the sample collection method. Patients were followed for at least 48 weeks, and final diagnoses were obtained after surgery, imaging analysis, or resolution of lesion. The primary objective was to compare EUS-FNA versus EUS-FNB for the cytological for histological diagnostic accuracy of malignancy using 22G EUS-FNA and the 22G EUS-FNB needles. The secondary outcome measures were rates of analysis yield (%) of malignancy on the first pass, technical failure, complications, and quality of histologic specimens.

Results: Accuracy of FNB analysis in malignancy is higher than all FNA cases (94.09% vs 91.53%,) based on final patient diagnoses. Especially the findings from histologic analysis of FNBs were accurate for 93.55% of the cases, compared to 81.75% for FNAs ($p = 0.001$). In cytology analysis of with malignant masses, samples collected by FNB accurately identified 89.78%, whereas samples collected by FNA accurately identified 85.71% ($p = 0.046$). Patients in whom diagnosis was established in first passes were 87.50% versus 79.17%, for FNA and FNB in the study. There was no significant difference in technical failure or complications between FNA and FNB needles.

Conclusion: In the prospective study of patients with solid tumors, we found EUS guided FNB samples to produce more accurate diagnoses than samples collected by EUS-guided FNA samples.

Introduction: Endoscopic IRE can be performed using a flexible, thin, needle-shaped electrode for an endoscopic ultrasound (EUS)-guided procedure. This study aimed to evaluate the feasibility and efficacy of performing EUS-guided IRE with endoscopic needle-electrode in porcine pancreas.

Aims and Methods: A 19-gauge (1.1 mm) endoscopic IRE electrode consisting of a flexible electrode covered with protective sheath, needle-shaped tip with two exposed electrode band, generator connectors, and electrode push handle. Experimental endoscopic IRE on the pancreas were performed by EUS-guided approach and compared with surgical approach. The animals were sacrificed after 24 h and their pancreases collected.

Results: IRE ablation using endoscopic needle-electrode was successful technically in EUS-guided approaches for the pancreas. Immediately following IRE, the ablated pancreatic tissue showed no gross change except focal hemorrhage. H&E staining presented a well-demarcated ablation site measuring 1.0–1.5 cm in diameter in the pancreas. TUNEL immunohistochemistry showed diffuse cell death along the puncture site 24 h after IRE. No complication was observed in pigs after endoscopic IRE ablation.

Conclusion: EUS-guided IRE ablation was feasible and effective for pancreas using the newly developed device.

Introduction: Pancreatic cystic lesions (PCL) are common. Mucinous PCL are considered to have malignant potential, albeit in a minority. Differentiating mucinous lesions from non-mucinous ones is, sometimes, challanging. We investigated the efficay of string sign (SS), a very simple test, in this respect.

Aims and Methods: We performed a retrospective analysis reviewing the electronic medical records of the patients between October 2011 and March 2018

identifying the patients with PCL in whom string sign test was performed. This test is done by stretching fluid between fingertips or glass slide and fingertip. In case the stretch is equal or more than 3 mm, we consider it positive. A few drops of fluid is suffice. CEA and amylase measurement was done in case enough fluid was obtained. Cytologic examination was also done in most of the patients. Differential diagnosis of PCL was done by surgery or cytological diagnosis. Immunohistochemical staining for MUC subtypes was performed in 10 cases, five from SS positives, five from SS negatives.
Results: A total of 587 patients with PCL were evaluated by EUS and samples were obtained by fine needle aspiration. Final diagnosis was available in 185 cases: 97 pseudocysts, 38 IPMNs, 10 MCNs, 15 IPMN related adenocarcinoma, 12 adenocarcinoma, 3 ductal adenocarcinoma, 4 Serous cystic neoplasia (SCN), 4 neuroendocrine tumor (NET) and 2 Von Hippel Lindau related cystic lesions. SS testing was done in 172 patients. Fifty-six had histologically confirmed final diagnosis: 38 were mucinous (21 IPMNs, 7 MCNs, 10 IPMN related adenocarcinoma), while 18 were nonmucinous (7 pseudocysts, 3 NETs, 2 SCNs, 6 simple cysts). SS was tested in 22 IPMNs and 7 MCNs, while CEA could be measured in 11 IPMNs and 4 MCNs. There was only one patient with negative SS and high CEA value (818,3 ng/mL). Table 1 represents the diagnostic validation of SS and CEA > 192 ng/mL in mucinous PCL.

	Sensitivity	Specificity	PPV	NPV	Accuracy
String Sign	0.78	0.89	0.93	0.68	0.82
CEA >192 ng/mL	0.73	0.80	0.82	0.70	0.76

[Table 1]

In SS positives, MUC 2 staining was positive in 3/5, while in SS negative group no MUC 2 staining observed. MUC4 staining was positive in remaining two from the former and none from the latter group.
Conclusion: String sign is a highly reliable test in the differential diagnosis of PCL in reference to mucinous etiology. It is not inferior to CEA measurement. Furthermore it may be done in cases in whom enough aspirate fluid is not available for CEA measurement. SS positivity seems to be related to the presence of MUC 2.

Contact E-Mail Address: marianna.signoretti@gmail.com
Introduction: When on-site cytology is unavailable, European guidelines recommends performing two/three needle passes with a fine-needle biopsy (FNB), although the level of evidence is low.
Core tissue acquisition theoretically improves the diagnostic yield and it is optimal for tissue sampling for immunostaining and histologic diagnosis therefore it could potentially eliminate the use of ROSE.
Recently, a new Franseen geometry needle has been developed to obtain a histologic sample for immunohistochemical staining, and histologic diagnosis.
Although few studies are present in literature, previous observations proved that Franseen biopsy needle yielded high-quality histology samples thus high diagnostic yield.
Aims and Methods: Primary aim is to evaluate the diagnostic accuracy of Franseen geometry FNB in pancreatic (PL) and non-pancreatic lesions (NPL). Secondary aim is to assess the rate of core tissue (preserved architecture specimen) obtained.
A single-center prospective cohort of patients who underwent EUS-FNB for solid lesions >10 mm were enrolled (from June 2017 to January 2018) using 22 and 25 Gauge (G) Franseen needles (Acquire, Boston Scientific needles).
For each needle pass, a different vial was use and numbered. At least three passes were required for cell-block evaluation.
The presence of core tissue was define as a sufficient material for adequate histologic interpretation.
Results: A total of 70 patients (mean age 69 years; range 87–40) were enrolled (33 female). Out of the 58 PL, the most common final diagnosis was pancreatic cancer in 50.
A median of 3.6 needle passes were performed (range 2–5), 22 G needle was used for 48 lesions.
The diagnostic accuracy was 74.2% on the first pass (79.3% in PL vs 50% in NPL), 85.7% (93.1% vs 5.8%) at the second pass and reached 90% at 3rd needle pass (94% PL).
A tissue core biopsy was obtained in 56 lesions (79%) on the first pass and 85.7% after two passes (86.2% and 88.3% in PL respectively). Overall diagnostic accuracy was 92% (95.7% of PL) and a core tissue was achieved in 87.4%.
Conclusion: According to recent guidelines, 90% of diagnostic accuracy was obtained after three FNB passes. This accuracy seems to be even higher in the setting of PL (93% after two passes).
Franseen geometry needles achieved a core tissue in 87% of lesions.

Introduction: Acute cellular rejection (ACR), which is associated with graft failure, is one of the most important vexing problems after intestinal transplantation (IT). Whether endoscopic imaging could be used to predict ACR is not well understood.
Aims and Methods: We aimed to investigate the correlation of an endoscopic scoring system using a magnifying endoscopy under narrow-band imaging (ME-NBI) system with ACR after IT.
Methods: Patients older than 7-years-old after IT were enrolled prospectively between June 2016 to March 2018. Endoscopic examinations were performed through chimney ileostomy to anastomosis site with ME-NBI. The observed endoscopic findings were recorded by five components (''V-E-N-C-H''), each was graded in order of increasing severity from 0 to 2: ''V'' (appearance of villi), ''E'' (erythema in crypt area), ''N'' (capillary network), ''C'' (widening of crypt area), and ''H'' (heterogeneity of mucosal change). The severity of histological rejection was graded as indeterminate, mild, moderate to severe. Biopsy samples were taken from endoscopically suspicious rejection areas for histopathological examination. The correlation between VENCH scoring and histological severity of ACR was analyzed.
Results: During study period, ninety endoscopic biopsies in three (two females, one male) eligible patients were enrolled. The mean ± SD age of study subjects were 39.3 ± 16.2 (range 29~58) year-old and the etiology for IT was all short bowel syndrome after intestinal resection (two ischemic bowel disease, and one chronic intestinal pseudo-obstruction). The operation, cold ischemia, and ward ischemic times were 12 ± 6 (hours), 242 ± 47 (minutes) and 25.7 ± 5.9 (minutes), respectively. The sensitivity, specificity and accuracy of V-E-N-C-H score to predict ACR were 0.97, 0.47, 0.68, and 0.95, 0.71, 0.71, and 0.97, 0.49, 0.69, and 1.00, 0.52, 0.72, and 0.97, 0.67, 0.80, respectively. Coefficient value of Pearson's correlation test for V-E-N-C-H to predict ACR were 0.79, 0.66, 0.75, 0.71, 0.74 and 0.73, respectively ($p < 0.001$).
Conclusion: Early identification of ACR, which is associated with graft failure and patient survival, by intensive endoscopic surveillance of graft is very important. The ME-NBI endoscopic 'VENCH' scoring system is a promising tool for ACR prediction and larger scale studies are warranted to validate these results.

Introduction: The gastrointestinal decompression is the initial and effective therapeutic approach for the patients with small bowel obstruction. Several recent studies showed that decompression using the long trans-nasal tube achieved favorable clinical outcomes. Our previous pilot trail method using the newly developed trans-nasal ileus tube, the anterior balloon method, achieved effective decompression to the small bowel obstruction.
Aims and Methods: The present study was investigated the effectiveness of the anterior balloon method for small bowel obstruction compared the ordinary insertion method.
The anterior balloon method used the ileus tube (CLINY double-balloon type; Create Medic Co., Ltd, Tokyo, Japan) of 300 cm length with two (anterior and posterior) balloons. After insertion of the tube into the duodenum, the anterior balloon was injected and suctioned repeatedly with 10 mL of air using the 10 mL syringe until the ileus tube reached closely to the obstruction. A total of 126 patients with small bowel obstruction treated from January 2011 to October 2017 in Ureshino Medical center were retrospectively reviewed. The patients were divided into two groups: the patients treated by the anterior balloon method (44 patients: ABM group) and the patients treated by the ordinary insertion method (82 patients: OIM group). The patients' characteristics including the causes of ileus, the treatment outcome, and the adverse events were compared between the two groups.
Results: The patients' characteristics and symptoms on admission including fever, abdominal pain, abdominal distension, vomiting and defecation were not different between the ABM and OIM groups, and the adhesive small bowel obstruction was the main cause of ileus in the both groups. The insertion time was significantly shorter in the ABM group compared to the OIM group (28.0 ± 8.3 min vs.33.5 ± 13.0 min; $p = 0.005$), whereas the length of the inserted ileus tube was significantly longer in the ABM group (220.7 ± 33.3 cm vs. 157.4 ± 31.7 cm; $p < 0.001$). The mean period of the insertion tube was relatively short in the ABM group than the OIM group (4.1 ± 3.8 days vs.

5.9 ± 5.3 days: (p = 0.034) and the meal could be re-started shorter in the ABN group (4.1 ± 3.8 vs. 6.0 ± 5.2 days; p = 0.027), indicating that the relief of the clinical symptoms was achieved faster in the ABM group. The surgery intervention in the patients with the ileus tube insertion was equivalent in the both groups (20.4% in the ABN group vs. 22.0% in the OIM group). The serious adverse events were not complicated in the both group.

Conclusion: The ABM of the ileus tube insertion achieved the insertion of the long enough ileus tube with the short insertion time compared to the OIM, leading to the better clinical outcomes. The anterior balloon method is one of initial therapeutic selections for the patients with small bowel obstruction, and the present results with the retrospective study might be confirmed by the randomized clinical trials.

Disclosure: Nothing to disclose

Introduction: High amylase does not always signify acute pancreatitis and it can occur due to focal areas of ischaemia in the pancreas due to mechanical stress during double balloon enteroscopy (DBE). The use of rectal NSAIDs to prevent post DBE pancreatitis has never been explored unlike in ERCP where patients receiving rectal NSAIDs have a lower incidence of pancreatitis.

Aims and Methods: Patients who received rectal indomethacin (100mg) 30 minutes prior to antegrade DBE were compared to a control group who did not receive indomethacin before the above protocol was implemented. Serum amylase and CRP 3 hours before and after DBE were compared.

Results: 240 patients (56 indomethacin, 184 controls; 50% males; mean age 58.5 ± SD14.0) were included.

Indications included: IDA (37.5%), obscure overt gastrointestinal bleeding (17.1%), suspected Crohn's disease and strictures (17.9%), complication of coeliac disease (1.3%), small bowel (SB) tumours / polyps (17.9%), others (8.3%). Patients had a median of 13.0 ± SD13.0 passes, 65.0 ± SD25.0minutes, 170 ± SD52.0cm of SB examined. 36.3% underwent a therapeutic procedure during DBE: APC/adrenaline/clips (27.5%), foreign body removal (0.4%), polypectomy (8.3%).

Only 4 (1.67%; 2 females) patients developed pancreatitis, all prior to implementation of indomethacin into the local protocol. They had a median age of 47.0 ± SD3.20 years, 11 ± SD29.4 passes, 90 ± SD52.0minutes, 150cm ± SD64.2cm of SB examined and median hospital stay of 14 ± SD3.70 days. 3 had polypectomies. 2 episodes occurred in the same patient. All had evidence of pancreatitis on CT scan. None of the patients received indomethacin before DBE.

Mean amylase (51.6 ± SD22.7 vs 143.0 ± SD143.9IU/L p = 0.0001) and CRP (13.0 ± SD46.1 vs 17.3 ± SD81.7mg/L p = 0.0001) after the procedure were significantly higher than before the procedure. Females had a significantly higher amylase than males post procedure (155.2 vs 130.7 IU/L p = 0.017). Mean amylase 3 hours after DBE was significantly lower in patients who received indomethacin (114 vs 152) (p = 0.044). 83.9% had a rise in amylase in the indomethacin group compared to 92.2% controls. (p = 0.064).

Whilst there was no correlation between post-procedure amylase (p = 0.552), CRP (p = 0.058) and duration of the procedure, there was a significant association between amylase post procedure and length of SB examined. (Spearman's rho 0.186; p = 0.005).

Conclusion: This study identifies a role for rectal indomethacin in patients undergoing antegrade DBE. We have demonstrated that rectal indomethacin reduces amylase post DBE and no patients given indomethacin experienced pancreatitis. Larger studies are required to assess if this also transforms into lowering risk or severity of pancreatitis.

Introduction: The management of liver transplanted (LT) patients is often complex and requires a multidisciplinary approach. Anaemia due to obscure or overt gastrointestinal bleeding and biliary complications can occur in LT patients; thus, the need for enteroscopy (capsule enteroscopy (CE), double-baloon enteroscopy (DBE)) or a double-balloon cholangiopancreatography (DB-ERCP), can be present also in LT subjects. Nowadays few data about the diagnostic success and safety of these procedures in LT patients are present. Use of DBE is increasing for the management of post-transplant biliary strictures while anecdotal case-reports are available about CE after LT.

We aimed to evaluate the need for enteroscopy after LT and to estimate the success rate and the safety of these procedures.

Aims and Methods: We analysed retrospectively 468 patients, underwent orthotopic LT (OLT), followed in our Liver Transplant Unit in the last 5 years (from January 2013 to January 2018), and collected those who performed an enteroscopy including CE, DBE and DBE-ERCP.

We collected data about the clinical and demographic characteristics of the patients (i.e. age, sex, year and reason of OLT, current medical therapy and comorbidity), the diagnostic yield/success rate of the procedures and incidence of complications. We also valued the enteroscopic success (achievement of biliary anastomosis) and the therapeutic success for DBE-ERCP.

Results: 21 patients (4.5%) underwent one or more enteroscopies (26 procedures): we collect 9 CE (one of that followed by anterograde DBE), 14 DBE-ERCP for 10 patients and 2 retrograde DBE.

Medical indications to perform CE were iron deficiency (7/9) and chronic diarrhoea (2/9).

DB-ERCP was performed primarily for stenosis of the biliary anastomosis, with recurrence cholangitis (4/10) or with asymptomatic cholestasis (1/10). Less frequent indications were gallstones (3/10), PSC-related biliary tract stenosis (1/10) and biliary fistula (1/10).

The diagnostics yield for CE was 55% (5/9) and the most frequent cause of bleeding was jejunal angioectasia (4/9), followed by duodenal ulcer and ileal erosions. The enteroscopic success of DBE-ERCP was 50% (7/14), the first cause of failure was the impossibility to find the biliary anastomosis. The diagnostic success was 50% (7/14).

One patient performed an anterograde DBE for treating a jejunal angiodisplasia, previously found on CE. Two retrograde DBE was performed in patients with suspected thickening of distal jejunal, with one diagnosis of intestinal localization of Large B-cell lymphoma and normal findings in the other patient.

No procedural complications in the long and short term were observed with all the procedures.

Conclusion: A significant number of the liver transplanted patients can have the necessity to perform a small bowel endoscopy. All the analysed procedures were safe and with a good diagnostic yield/success. We suggest that Liver Transplantation Units should have the possibility to perform enteroscopy to improve the management of LT patients.

Disclosure: Nothing to disclose

P0862 ADENOMA DETECTION RATES IS ASSOCIATED WITH RESPECTIVE WITHDRAWAL TIME IN DIFFERENT COLON SEGMENTS

Y. Cheng, Z. Qiang, X. Min, W. Hui
WUXI People's Hospital of Nanjing Medical University, Wuxi, China

Contact E-Mail Address: yang05010301@163.com

Introduction: Colonoscopy withdrawal time is significantly correlated with adenoma detection rate (ADR). The 6-minute withdrawal time for colonoscopy is widely considered the standard of care. However, there may not be appropriate if the 6-minute is equally divided into various colon segments. Since the adenoma detection in each colon segment is not the same, there may be differences with the withdrawal time in different colon segments.

Aims and Methods: We aimed to evaluate the relationships between ADR and respective withdrawal time in different colon segments. Outpatients, age range from 18 to 75 and complete colonoscopy, were selected from December 2016 to June 2017 in the digestive endoscopy center. The entire colon was divided into four different segments: ascending colon, transverse colon, descending colon and rectosigmoid colon. The respective withdrawal time and ADR in each colon segment were recorded respectively.

Results: A total of 5027 outpatients were enrolled and the general ADR was 25.1%. The positive withdrawal time (adenomas detected) was longer than negative withdrawal time (non-adenomas detected) (299.37 ± 98.19s vs 209.63 ± 69.50s, t = 20.771, p < 0.001). The age was older in patients that adenomas were detected (55.77 ± 11.18 vs 47.00 ± 13.30, t = 15.864, p < 0.001). The ADR in ascending colon, transverse colon, descending colon and

rectosigmoid colon were respectively 6.2%, 5.2%, 6.1% and 17.3%. While all of their positive withdrawal time were longer than negative withdrawal time (67.31 ± 18.62s vs 51.11 ± 17.86, $t = 10.729$; 87.94 ± 29.51s vs 60.86 ± 22.27s, $t = 12.983$; 86.12 ± 28.42s vs 58.77 ± 22.78s, $t = 13.830$; 74.88 ± 25.67s vs 53.62 ± 20.46s, $t = 18.392$; $p < 0.001$ respectively). The positive withdrawal time in ascending colon was respectively shorter than that in transverse colon and descending colon (67.31 ± 18.62s vs 87.94 ± 29.51s, 86.12 ± 28.42s, $p < 0.001$). However, there were no statistical differences between them in ADR (6.2% vs 5.2%, 6.1%, $p > 0.05$). The positive withdrawal time in transverse colon and descending colon were all longer than that in rectosigmoid colon (87.94 ± 29.51s, 86.12 ± 28.42s vs 74.88 ± 25.67s, $p < 0.001$). While the ADR in rectosigmoid colon was obviously higher than that in other three segments of colon (17.3% vs 6.2%, 5.2%, 6.1%, $p < 0.001$).

Conclusion: ADR and withdrawal time are all various in different colon segments. During the operation of colonoscopy, withdrawal time in ascending colon may be shortened appropriately. The adenomas in rectosigmoid colon are more likely to be detected and do not take longer withdrawal times.

Introduction: Premenopausal women (PMW) often have a complete study of the gastrointestinal tract without findings justifying anemia/blood loss often motivating investigation of other causes.

Aims and Methods: The present study aimed to evaluate differences in capsule endoscopy (CE) performed in the setting of obscure gastrointestinal bleeding (OGIB) among PMW and menopausal women (MW).

Retrospective, single-center study, including female patients submitted to CE in the setting of OGIB between May 2011 and December 2016. Patients were divided into 2 groups according to age, considering fertile age as ≤ 55 years and postmenopausal age as > 55 years. The diagnostic yield (DY), the rebleeding rate and the time to rebleed were evaluated and compared between groups. Rebleeding was defined as drop of $Hb > 2$g/dL or need for transfusional support or presence of melena/hematochezia.

Results: A hundred and eighty three female patients underwent CE for OGIB, of whom 30.6% ($n = 56$) were PMW and 69.4% ($n = 127$) were MW. DY was 35.4% in PMW and 12.5% in MW. The most common findings were angiodysplasias in both groups (PMW-38.8%, MW-62.7%). In PMW, only 1.8% required therapeutic endoscopy. In 18.1% of MW, CE findings led to additional endoscopic treatment. Rebleeding at 1, 3 and 5 years in PMW was 4.6%, 10.2% and 10.2% and in MW it was 22.0%, 32.3% and 34.2% ($p = 0.001$). Postmenopausal status was significantly associated with higher DY ($p = 0.002$), need for endoscopic treatment ($p = 0.003$), rebleeding ($p = 0.001$), and hospitalization ($p < 0.001$).

Conclusion: PMW with suspected OGIB are less likely to have significant findings in CE. In MW DY, need for endoscopic treatment, rebleeding and hospitalization were significantly higher.

Introduction: The treatment paradigm for Crohn's disease (CD) is changing with greater emphasis on treat to target strategies. Video Capsule Endoscopy (VCE) has potential to improve monitoring of CD activity.

Aims and Methods: This study aims to identify whether standard use of VCE in the CD care pathway would be cost effective in England.

A patient-level, care pathway model specific to CD management in England was developed. Specifically, NICE guidance for CD management was supplemented by the consensus opinion of a sample of physicians with CD and VCE expertise. The model included local pricing, NHS tariffs, incidence rates, step-up treatment, and the use of faecal calprotectin testing (FCT) to inform the need for endoscopic monitoring practices: colonoscopy or VCE, respectively. Provision of drug therapy influenced the onset, progression, or remission of CD flares, fistulae, and abscesses. Data for VCE were derived from a pan-intestinal small bowel and colon capsule, which provides pan-enteric assessment VCE (pVCE). Outcomes for 4,000 simulated patients over 20 years were assessed. Cost of care and patient quality of life (QoL) were compared between monitoring options (pVCE or colonoscopy). The willingness to pay threshold was taken as a conservative £10,000 per quality-adjusted life year (QALY) gained. Significance of results at the 95% level was calculated using probabilistic sensitivity analysis.

Results: All experts agreed that the CD care pathway had to be individualised to patient needs. However, consensus was sufficient to develop a protocolised pathway to model. Step-up treatment started with glucocorticosteroid and progressed to biologics (± azathioprine). High-risk patients (≥ 3 risk factors present) could initiate treatment with biologics directly. Need for endoscopy was informed by FCT, that is performed at least once per year.

The 20-year care costs were £69,745 (£3,487 per year) with colonoscopy and £67,806 (£3,390 per year) with pVCE. pVCE was associated with increased patient QoL, with patients accruing a mean of 7.8 QALYs compared with 7.3 QALYs with colonoscopy. The analysis suggested that the use of pVCE for monitoring is beneficial in England, saving £1,941 per QALY gained. Tests showed that pVCE would be considered cost-effective in 96.9% of 2,000 bootstrapped simulations. The 95% credible interval extended to £10,913 per QALY gained.

Key outcome drivers in the simulation were the need for surgical procedures (25% of costs) and the use of biologic therapies (24%). Use of pVCE resulted in earlier detection of inflammation and initiation of biologics, which increased care costs in the short term. In some patients, earlier treatment resulted in optimized outcomes with earlier abscess drainage preventing subsequent resection. As lower-cost biosimilars become available, the cost-effectiveness of pVCE increases.

Conclusion: Use of pVCE for monitoring of CD activity is likely to be cost-effective in England over 20 years. Improved patient outcomes, including reduced need for bowel resection, are additional benefits.

Introduction: Capsule endoscopy is a non-invasive method to exam the mucosal surface of the gastrointestinal tract. In the diagnosis of small bowel disease, it is the gold standard in various indications, since 2001. The examination of the stomach with small bowel capsule endoscopy system is not possible because we could not navigate the capsule through the entire lumen. Since 2013, there is a new magnetically controlled capsule endoscopy system (Navicam) which allows precise intraluminal navigation and positioning therefore, ensures a complete examination of the stomach.

Aims and Methods: We tested the new Navicam magnetic capsule endoscopy system in a plastic gastric model to compare the robotically controlled autoscan program modules and the free hand examination. Our study aimed to analyze whether the autoscan modules or the free-hand capsule controlling method is superior in the inner surface mapping of the plastic stomach model. We put in 12 different colored rings externally on the model (one-one on the anterior-posterior wall of the fundus, corpus and antrum, one around the cardia and pylorus, one on the angulus and three on the greater curvature) with different numbers in each quarter on the surface of the model. We make five tests in small and medium-sized stomach and five in medium and large stomach module with the autoscan function and five tests with free-hand controlling done by five trained GI fellows. We analyzed the effectivity of the surface visualization with the total sum of the numbers on the colored rings on the capsules video.

Results: The complete 100% visualization of the inner surface of the plastic stomach model with the medium and large stomach autoscan program module and with the free-hand controlling method could successfully achieved in all tests. With the small and medium stomach mode we could observe only the 97.5% of the inner surface, because of the incomplete visualization of the prepyloric region. With free hand method we needed nearly twice as much average time (749 seconds) to make complete examination as compared to the robotic maneuvering with auto scan program (390 seconds).

Conclusion: Magnetically controlled gastric capsule endoscopy system and autoscan program module are promising tools to visualize the entire mucosal surface of the stomach non-invasively. The NaviCam magnetically controlled capsule examination of the stomach without discomfort and sedation can provide a new dimension of upper gastrointestinal screening programs and can help to lower the mortality of gastric cancer.

Introduction: Data on SBCE performance and yield in the elderly are scant and conflicting. Our aim was to compare SBCE performance and yield in old and very old patients with their younger, adult counterpart in a large, prospective, multicentre study.

Aims and Methods: From October 2011 to December 2013, data of 2294 consecutive patients undergoing SBCE in 30 Centres of Lombardy Region, were prospectively collected in a dedicated database. For the purpose of this study, we included 2260 adult patients (≥18 years old). Patients were stratified by three age-related groups, namely: A (18–64 years old, n = 989), B (65–79, n = 935), C (≥80, n = 336). Diagnostic yield (DY) was defined as any small bowel (SB) abnormality, and clinical significant findings (CSF) as SB P2 lesions, in accordance to Saurin's classification. CSF were classified in five categories using a modified Capsule Endoscopy Structured Terminology (CEST): (i) stenosis, (ii) luminal blood, (iii) inflammatory (erosion, ulcers), (iv) neoplastic (polyp, mass), (v) vascular. Chi-square for independent proportions was used to compare the three groups for the following outstanding characteristics: indication, gender, outpatient status, completion rate, retention rate, DY, CSF, and category of findings. p value < 0.05 was considered statistically significant.

Results: Suspect small bowel bleeding was the leading indication to SBCE (75.3%), without differences between groups. Males were under represented in group C (45% vs 51.6 and 56% in group A and B, respectively), without statistical significance (p = 0.28). As shown in table 1, we did not find any difference among the three groups in the frequencies of the above-mentioned variables of interest.

Conclusion: In this large prospective series, in the elderly, SBCE performed as well as adults, without difference in terms of outpatient status, diagnostic yield, completion rate, retention rate, and findings.

Group	A	B	C	*P value*
N Patients	989	935	336	–
Outpatient (%)	649 (65.6)	599 (64)	202 (60)	0.19
Completion (%)	891 (90)	836 (89.4)	310 (92.2)	0.32
Retention (%)	10 (1)	4 (0.4)	3 (0.8)	0.31
DY (%)	604 (61)	529 (56.5)	190 (56.5)	0.1
CSF (%)	509 (51.4)	477 (51)	164 (48.8)	0.7
Stenosis (%)	13/509 (2.56)	12/477 (2.5)	1/164 (0.6)	0.3
Luminal blood (%)	51/509 (10)	50/477 (10.4)	21/164 (12.8)	0.59
Inflammatory (%)	137/509 (26.9)	120/477 (25.1)	43/164 (26.2)	0.81
Neoplastic (%)	93/509 (18.2)	80/477 (16.7)	22/164 (13.4)	0.35
Vascular (%)	215/509 (42.2)	215/477 (45.6)	77/164 (47)	0.48

Introduction: Small bowel capsule endoscopy (CE) has made tremendous technologic progress, due to its superior patient acceptability and safety profile. However, CE of the colon is held back by the need for a prep as good as or better than an average colonoscopy. C-Scan is a novel capsule which obviates the need for any cathartic or laxatives (Check Cap Ltd, Mount Carmel, Isfiya, Israel) (1). The X-ray imaging capsule overcomes the requirement for bowel preparation, a major deterrent for CRC screening. No prep, diet restrictions or medications are applied. The device records for 100 hours.

Developing this new colon capsule required various innovations, herein described, which are spinoffs with major side-benefits. Such benefits are in addition to helping achieve the primary goals of producing an efficient, safe capsule requiring no prep, which successfully identifies polyps, screens the colon, prevents cancer and thus saves lives.

Aims and Methods: A capsule has been produced and trials performed in over 200 humans. This capsule, in addition to identifying polyps, delivers novel information on motility, with pressure measurements and thermal measurements, and advances physiologic concepts and knowledge regarding native colonic functions in health and disease states. The CE- (Certificate European) approved capsule, used in over 200 humans to screen for polyps, has presented challenges and led to a series of exciting technological innovations, herein described.

Results: The three-point online monitor, embedded in a tracking unit attached to the back of the patient, has delivered patterns of capsule movement in a prep-less normal colon, leading to real-life tracks of how colonic contents move.

The performance of the 3D colon was examined in a uniquely designed mechanical phantom model of the colon and a high correlation between behavior in humans and the phantom was demonstrated. Accuracy of the capsule tracking by triangulation from the 3 sensors on the back of the patient is +/−5mm, including when patients (except morbidly obese) are in motion. This allows clinicians to localize findings correctly, facilitating the planning of subsequent interventions.

Two examples illustrate the accuracy of the system during clinical procedures: The new algorithms developed for the C-Scan detect the minute motion of the small bowel peristalsis and colon movements caused by ventilation.

The pressure monitors on the C-Scan Capsule deliver real-life measurements of the relative pressures throughout the segments of the colon, opening a path to reflecting on interventions which target specific sites within the colon.

The thermal monitor on the C-Scan capsule is being applied in efforts to determine whether differences in temperature and therefore in circulation, can be found in polyps vs. in normal colon. Total transit time [TTT] was measured from capsule ingestion to excretion while patients are free to follow their normal daily routine. The TTT is the sum of 3 distinct time segments: until the cecum, within the cecum and distal to cecum until excretion.

The results from 50 cases are presented in table 1.

Conclusion: Technical innovations often end in a different place than they initially envisioned. The development of the C-Scan capsule has stimulated the above five technologic innovations which may all continue to deliver new physiologic information allowing us to deliver better health.

	Total transit time	Time to cecum	Time in cecum	Passage in colon
Average in hours	57.5	15.3	21.0	14.9
STD (hours)	41.8	9.7	22.1	11.1

[Transit time measurement for C-Scan capsule]

Introduction: Lifetime risk of developing small-bowel cancer in patients with Lynch syndrome (LS) is estimated to be around 4%, which is more than 100-times the risk of the general population. This risk is almost similar to the lifetime risk of colorectal cancer in the general population, for which screening is generally recommended. Screening for small-bowel cancer in Lynch syndrome has, until now, not been included in guidelines for surveillance of families with Lynch syndrome. In 2016 Mallorca group gave the advise small bowel screening may be appropriate in mutation carriers MSH2 and MLH1 especially after 40 years.

Aims and Methods: The aim of the study was to determine the incidence of small-bowel neoplasia in asymptomatic LS patients by means of video capsule endoscopy (VCE).

Two prospectively maintained databases of VCE were retrospectively reviewed to identify all consecutive asymptomatic LS patients. These patients were compared with a group of patients without LS who underwent VCE for obscure gastrointestinal bleeding (OBS), with negative upper GI endoscopy and colonoscopy.

Results: 25 LS patients and 280 OBS patients were enrolled in the study by the two Italian centers.

In 91.5% of the procedures, caecal visualization was achieved.
Small-bowel neoplasia was detected in two LS patients and three OBS patients (p = 0.06). The two groups have a significant statistically different mean age (SD): 41.3 ys± 14.0 ys in LS group and 62.9 ys± 17.2 ys in OBS group (Table 1). Besides small bowel adenocarcinoma, LS patients and OBS patients have statistically significant difference in incidence of vascular lesion, angiectasia and minute polyps (Table 1).
Conclusion: The prevalence of small-bowel neoplasia in asymptomatic patients with LS was 8% vs 1.1%. Although the incidence of small bowel adenocarcinoma did not reach statistical significance difference, a trend through statistically significant difference was observed and this suggests further multicentric studies are needed.

Variable	Lynch Group N = 25	Obscure Bleeding Group N = 280	p
Male, n (%)	12 (48.0%)	163 (58.2%)	0.4
Female, n (%)	13 (52%)	117 (41.8%)	
Age, mean (SD), years	41.3 (14.0)	62.9 (17.2)	<0.0001
Adenoca Small Bowel, n (%)	2 (8.0%)	3 (1.1%)	0.06
Normal examination, n (%)	4 (16.0%)	53 (18.9%)	1.0
No caecal visualisation, n (%)	1 (4.0%)	25 (8.9%)	0.7
Vascolar lesion, n (%)	4 (16.0%)	118 (42.1%)	0.01
Emangioma/varice, n (%)	0	21 (7.5%)	0.2
Angiectasia, n (%)	3 (12.0%)	114 (40.7%)	0.005
Lymphangiectasia, n (%)	4 (16.0%)	42 (15.0%)	0.8
Submucosal lesion, n (%)	1 (4.0%)	29 (10.4%)	0.5
Minute polyps, n (%)	10 (40%)	35 (12.5%)	0.001

Contact E-Mail Address: chrispontas@gmail.com
Introduction: Post-operative endoscopic recurrence (POER) of Crohn's disease (CD) is frequent and unpredictable. In clinical practice, colonoscopy is recommended 6–12 months after surgery, in order to detect early POER and guide management. The aim of our study was to determine the diagnostic yield of small bowel capsule endoscopy (SBCE) in this setting.
Aims and Methods: We reviewed the records of 5471 patients subjected to SBCE in our department from March 2003 to March 2017 (males/females: 2693/2778, mean age ± SD: 50.8 ± 28.4 years). Among these patients, we identified 677 with known CD, of whom 41 had undergone SBCE 6–12 months following ileo-colonic resection. Any lesions detected in the proximal small bowel were also recorded. All these patients had also undergone ileo-colonoscopy at the same time to assess for POER using the Rutgeerts score. The findings of the two tests were compared to examine whether SBCE can detect more proximal lesions in patients who did not exhibit POER (that is a Rutgeerts score ≤1) during ileo-colonoscopy.
Results: POER was detected in 16/41 (39%) patients by ileo-colonoscopy. SBCE detected lesions in the neoterminal ileum in 15 of these 16 patients (overall rate 36.6%) as in one patient the capsule did not reach the neo-terminal ileum during the battery's life span. Concurrent lesions in the neo-terminal ileum and more proximally were detected by SBCE in 9/15 patients; however, two patients with an ileo-colonoscopic Rutgeerts score of 0 had more proximal lesions during SBCE.
Conclusion: SBCE is not cost-effective and cannot be recommended as an adjuvant to ileo-colonoscopy to identify more proximal lesions post-operatively in CD patients. However, it may substitute for ileo-colonoscopy considering local cost, disease characteristics and patient preferences

Introduction: Capsule Endoscopy (CE) is a popular non-invasive technology to provide diagnostic imaging of the small bowel. As with all endoscopic techniques, quality of CE procedures will affect patient outcomes. Unlike upper and lower gastrointestinal endoscopy there is little in the literature on CE quality measures and a low evidence base to support guideline development. Analysis of current practice with reference to procedure quality and patient outcomes may highlight potential future key performance indices (KPI) and help guide future quality assurance initiatives.
Aims and Methods: To perform an analysis of our CE service with reference to procedure quality and patient outcomes.
A retrospective review of CE procedures performed in our institution from 2010 through 2015 was undertaken. CE procedures were identified from a database. Rapid Reader and other hospital electronic patient information software was used to extract essential information. Recorded data covered Pre-Procedural, Procedural and Post-Procedural domains and included patient demographics, indication, preparation quality, caecal visualisation, findings, complications, and CE reader. Data was grouped according to outcome or potential KPI and compared using a chi2 test, a $p < 0.05$ was considered significant.
Results: In all 1,227 CE's have been included and analysed; 50% (n = 615) female, median age 56 years (range 13–93). The overall diagnostic yield (DY) was 39% (n = 477). Only 85 (7%) CEs were performed for non ESGE approved indications including abnormal radiology (n = 41). The DY was similar for ESGE and non-ESGE recognised indications 34% (n = 390) and 35% (n = 30) respectively, p = 0.92.
DY did not vary significantly by indication; obscure GI bleeding (37%), anaemia (37%), suspected Crohn's disease (38%), others (34%). Similarly, age did not affect CE efficacy. In particular, DY for anaemia in patients < 50 and > 50 years was 37% (n = 124) and 40% (n = 29) respectively, p = 0.72. However CEs performed to assess known disease had a higher DY than screening CEs; known CD (65.1%) vs suspected CD (38%), p = 0.0001, OR2.9.
Overall 8% (n = 98) of CEs were incomplete. Surprisingly DY was significantly higher for incomplete, 56% (n = 55) versus complete studies 37% (n = 422), p = 0.004, likely reflecting the pathology encountered. Similarly, DY was higher in the 38% (n = 459) of CEs with a poor-quality bowel preparation; 55% (n = 254) V's 40% (n = 302), p = 0.0001. Only 2/1227 (0.1%) experienced true capsule retention.
Trainee Gastroenterologists reported 58% (n = 710) of CEs. Trainee DY was higher, 41% (n = 292) V's Trainers 35% (n = 184), p = 0.04. All (100%) of Trainees attend a certified CE course and were supervised until fully proficient.
Conclusion: Our study suggests development of quality measures for CE will require a novel approach and further research. As expected KPIs based on standard endoscopy experience have yielded contradictory results. Incomplete studies and poor preparation quality were both associated with higher diagnostic yields, which is not that surprising as bleeding is a major indication and significant findings can inhibit or slow capsule passage. In addition, the diagnostic yield for CEs is higher for disease assessment compared to screening tests. Our data also suggests that other indications including abnormal radiology can be an appropriate indication for CE. Finally, our data supports a structured approach to CE training.

P0871 LONG-TERM OUTCOME OF ENDOSCOPIC TREATMENT OF BILIARY STRICTURE FOLLOWING LIVING DONOR LIVER TRANSPLANTATION

J.K. Lee
Samsung Medical Center, Sungkyunkwan University, Gastroenterology, Seoul, Korea (Republic of)

Contact E-Mail Address: jongk.lee@samsung.com
Introduction: Biliary strictures remain one of the most challenging aspects after living donor liver transplantation (LDLT). Endoscopic procedures are the initial choice of treatment for biliary strictures following LDLT.
Aims and Methods: The aim of this study is to assess long-term outcome of endoscopic treatment of biliary stricture occurring after LDLT and to identify risk factors of recurrent biliary stricture following endoscopic treatment in LDLT. One thousand four hundred forty one patients underwent LDLT from May 1995 to May 2014. Biliary strictures developed in 24% of patients.
Results: Among 145 patients who were successfully managed with endoscopic drainage, biliary stent could be removed in 94 patients. After for 12 months

follow up after removal of endoscopic retrograde biliary drainage (ERBD), 69 patients (66.2%) had no recurrent biliary stricture and 20 patients (21.3%) showed recurrent biliary stricture. We compared the risk factors between no recurrent biliary stricture and recurrent biliary stricture group. Younger donor age was associated with lower recurrence rate, and non-B, non-C liver cirrhosis was associated with higher recurrence rate of biliary stricture.
Conclusion: Long-term outcome of the endoscopic treatment of biliary stricture occurring after LDLT was relatively fine, but the clinician should be careful of ERBD removal and following up in the case with factors associated with recurrent biliary stricture.

Contact E-Mail Address: takuji@w7.dion.ne.jp
Introduction: Distal malignant biliary obstruction (DMBO) in patients with surgically altered anatomy (SAA) is traditionally managed with PTBD, since anatomical features complicate endoscopic approach to the biliary orifice. Recently, enteroscopy and EUS assisted approaches have emerged as alternative treatments; however, limited data comparing between the procedures has been available so far.
Aims and Methods: The aims of this study were to compare EUS-antegrade treatment (AG) with PTBD for DMBO in patients with SAA.
Patients who underwent EUS-AG or PTBD as management of DMBO and had history of upper intestinal surgery at 2 tertial centers between 4/2007 and 1/2018 were evaluated retrospectively. In EUS-AG, the bile duct was punctured under EUS-guidance, followed by guidewire placement through the obstruction, dilation of the fistula, and metallic stent placement cross DMBO. Naso-biliary drainage was placed though the fistula only if there might be any chance of stent dysfunction or active cholangitis. PTBD typically had 3 steps approach: Firstly, the bile duct was punctured under ultrasound guidance followed by external drainage tube placement. In the 2nd session, a metallic stent was deployed cross DMBO with remaining the external drainage. In the 3rd session, the external drainage was removed after confirmation of good bile flow through the stent. The study outcomes were the technical and clinical success rates and the adverse event rate. Technical success and clinical success were defined as successful internalization and decrease of serum total-bilirubin level by half, respectively. Survival duration was analyzed with Kaplan-Meier method between the groups. Possible factors which can affect the survival duration were also analyzed with multivariable analysis. Continuous valuables were described with median (interquartile range).
Results: A total of 53 patients were enrolled. Among them, 24 patients underwent EUS-AG and 29 had PTBD. Basic characteristics (EUS-AG/PTBD) were the median ages of 69.5 (61–76)/69.0 (62–74.5) ($p = 0.68$) and included 12 men/17 men ($p = 0.59$). SAAs were Billroth II (2/6), Whipple procedure (0/1), Roux-en-Y (18/19), and gastric by-pass (4/3). ($p = 0.44$) Biliary puncture was successful in 95.8%/100%. ($p = 0.45$) The median numbers of session were 1 (1-1)/3 (3–4). ($p < 0.001$) Both technical and clinical success rates were 95.8%/82.8%. ($p = 0.20$) Overall adverse event rates were 16.7%/26.4%. ($p = 0.21$) Recurrent biliary obstruction was seen in 16.7%/10.3%. ($p = 0.63$) Median survival times were 108 days (61–249)/92 days (42–277). ($p = 0.43$) Multivariable analysis showed chemotherapy after the procedure (Hazard ratio of 0.35, 95% confidential interval of 0.18–0.67) as independent risk factor for survival, but the procedure itself was not risk factor for that.
Conclusion: There were no significant differences in safety and efficacy between EUS-AG and PTBD for DMBO in patients with SAA. EUS-AG might be a treatment of choice for management of DMBO in SAA patients same as PTBD.

Introduction: Fully covered metal stent (FCMS) can be a preferred stent for distal malignant biliary stricture (MBS). However, stent migration can be a major adverse event of FCMS, especially for far distal MBS.
Aims and Methods: The aim of this study was to evaluate the usefulness of newly modified non-flared FCMS having 12mm in diameter to minimized stent migration compared with the conventional FCMS. Total 102 patients with periampullary MBS enrolled prospectively between January 2014 and September 2017; 50 were allocated to the newly modified non-flared FCMS group and 52 to the conventional FCMS group. The primary outcome was the stent migration, and the secondary outcomes were other adverse events and stent occlusion rate during follow-up period.
Results: Baseline characteristics were not significantly different between the two groups. Endoscopic stent placement was technically successful in all patients. Stent migration was observed in 8.0% (4/50) in newly modified non-flared FCMS group in comparison to 23.1% (12/52) in conventional FCMS group ($p = 0.036$). The incidence of stent-related pancreatitis was 10.0% (5/50) with newly modified non-flared FCMS and 11.5% (6/52) with conventional FCMS ($p = 0.802$). Stent occlusion was occurred 22.0% (11/50) in newly modified non-flared FCMS and 28.8% (15/52) in conventional FCMS during follow-up period ($p = 0.428$).
Conclusion: Newly modified non-flared FCMS with large diameter of 12mm significantly decreased stent migration compared with conventional FCMS in patients with periampullary MBS.

Introduction: We developed a biliary internal fistula tube (BIFT) which has been constructed with a conventional biliary stent tube and a bioabsorbable polymer seat (BAPS) for a transluminal biliary drainage. In this study we attempted to investigate the difference between the BIFT and conventional tube (CT) in biliary-enteric fistula formation.
Aims and Methods: The BIFT is a conventional biliary tube wrapped with the BAPS, which is 0.5mm thickness. The BAPS is an ideal scaffold for tissue regeneration with porous property to allow easy penetration of cells. BIFT group ($n = 6$): The pigs were laparotomized to expose the extrahepatic bile duct (EHBD). The 5cm BIFT was placed between gallbladder (GB) and duodenum (DU). CT group ($n = 6$): The 5cm CT was placed between GB and DU in a similar manner of the BIFT group. In both group these pigs were sacrificed and re-laparotomized at 4 weeks after the placement.
Results: BIFT group: At 4 weeks after the placement, the distance between GB and DU was shortened. A biliary-enteric fistula, which had 1.5cm bore diameter and 2cm length, was constructed between GB and DU. CT group: At 4 weeks after the placement, the CT became surrounded by connective tissue, and the distance between GB and DU came closer to each other. However, the connective tissue between GB and DU was fragile and easy to be divided. The lumen of the CT has biliary sludge and almost became obstructed.
Conclusion: The placement of the BIFT between GB and DU induced rapid and good fistulization, and has the potential for application as a novel device for transluminal biliary drainage avoiding the need for exchange of tubes.

Introduction: Endoscopic ultrasonography guided choledochoduodenostomy (EUS-CD) using a lumen apposing metal stent (LAMS) has been recently reported as an alternative approach in the management of patients with malignant obstructive jaundice and failed endoscopic retrograde cholangiopancreatography (ERCP).
Aims and Methods: The aim of this study was to analyze the safety, technical and clinical efficacy of EUS-CD in this setting of patients. Retrospective analysis of a prospectively maintained data base of consecutive patients with unresectable malignant distal bile duct obstruction who, between 10/2015 and 12/2017, underwent EUS-CD using the study device (Electrocautery enhanced (EC)-AXIOS, Boston Scientific Corp., Marlborough,Massachusetts, USA) after unsuccessful ERCP in a single tertiary-care academic medical center. Technical success was defined as accurate positioning of the stent. Clinical success was defined as resolution of biliary obstructive symptoms with a decrease in the total bilirubin level to 50% reduction of the initial level.
Results: Forty-six patients (47.8% female; median age 73.1 ± 12.6) underwent direct EUS-CD using the biliary EC-AXIOS(diameter 6x8mm in 21(45.7%); 8x8mm in 19(41.3%); 10x10 mm in 6 (13%)). ERCP failure was due to inability to get deep biliary cannulation in 30 patients (65.2%) and to duodenal obstruction in the remaining 16(34.8%) patients.
The procedure was technically successful in 43/46 (93.5%) patients, with a mean procedural time of 14.7 min (range 5–38).

Clinical success was achieved in 45/46 (97.7%) patients with a reduction in the total bilirubin level of 65.3% within 14 days of the initial levels.
Ten patients were treated with a single session sequential approach by deployment of EC-AXIOS and duodenal stent for biliary and duodenal obstruction. In 3 patients a duodenal stent insertion was performed before the procedure and in 3 patients after a median of 127 days (range 59–240 d). The median post-procedure hospitalization was 6.12 ± 5.98 days. The mean follow-up was 114.37 days (C.I. 73.2–155.4). During follow-up 19 patients died after a mean of 105.3 days ± 29.1 SE because of disease related complications.
Major complications occurred in 5(11.6%) patients after a mean of 83 days (range 17–148): 1 fatal bleeding 17 days after stent placement and 4 stent obstruction/migration requiring re-intervention (3 stent occlusion due to food impact; 1 spontaneous migration).
Conclusion: This study shows that EUS-CD using the EC-AXIOS is associated with high technical and clinical success rates. The rate of complications including one fatal event is not negligible and should be carefully considered before using the stent in this clinical setting. Future prospective studies are required to fully assess the long-term efficacy and safety of the stent.
Disclosure: Nothing to disclose

P0876 ARE PLASTIC STENTS "EXPANDABLE" IN THE TREATMENT OF BILIARY STRICTURES AFTER ORTHOTOPIC LIVER TRANSPLANTATION?

Introduction: In the last five decades, OTL became an option for saving the life of patients with end stage liver disease, liver malignancies or acute liver failure. The purpose of liver transplantation is to prolong and to increase quality of life.
The management of these patients is better than in the past due to optimisation of surgical techniques, immunosuppression therapy, management of infections and complications. Biliary strictures are the most frequent late complication of OLT, and are now managed almost entirely by ERCP and stenting.
Aims and Methods: To assess the stricture resolution in orthotopic liver transplantation (OLT) patients by ERCP stent placement in a tertiary care hospital. This is a retrospective study which enrolled patients from January 2013 to March 2018 with OLT anastomotic strictures and the ERCP procedures. The set-up included two groups, according to the type of stent used, either plastic (PS) or covered self expandable metal stents (SEMS) with their outcomes. We assessed the indication for transplantation, the number of ERCPs per pacient, the number of stents used, early post-ERCP complications.
Results: The study included 34 patients diagnosed with anastomotic billiary strictures post OLT. The indications for transplantation were various: cirrhosis secondary to VHB+VHD (7 patients), cirrhosis secondary to VHB (6 patients), cirrhosis secondary to VHC (5 patients), alcoholic cirrhosis (6 patients), hepatocarcinoma secondary to VHB+VHD (2 patients), hepatocarcinoma secondary to VHB (one patient), cryptogenic cirrhosis (3 patients), primary biliary cirrhosis (one patient), hepatocarcinoma secondary to VHC (one patient), Caroli disease (one patient), Budd-Chiari Syndrome (one patient). A total of 100 ERCP procedures were performed, with an overall mean of 3.22 per patient. 22 patients had plastic stents inserted, 9 had SEMS, one patient had dilation of stenosis, without stent insertion, but with a good outcome. There were 2 patients to whom stenting failed. Patients required in average 4 PS and 2 SEMS ($p < 0.05$). The SEMS group (9 patients) had a lower procedure time and also fewer interventions were performed than the PS group (1.89 vs. 3.53, $p < 0.05$). Both stents were changed after 4 months, but patients with SEMS obtained resolution of strictures after 4 months on average, while those with plastic stents required 11 months on average. The most common complication was acute pancreatitis which occured in 11% of all ERCP procedures, and it was significantly more encoutered in patients with SEMS ($p < 0.05$). One patient died with massive hemobilia after plastic stent placement.
Conclusion: Patients with PS required a larger number of ERCP procedures and a mean of 4 stents per patient, which translates in higher costs for each patient; in comparison, the SEMS group needed less procedures and on average only 2 metal stents until resolution of the strictures. From our experience, SEMS seem to be the best choice of treatment and the most cost-efficient way to solve biliary strictures after OLT. Though, it is not always fesable to insert SEMS, due to technical issues, related with the location of the stenosis. That is the main reason for which plastic stents will continue to play an important role in the management of biliary strictures after orthotopic liver transplantation.

P0877 LONG-TERM OUTCOME OF EUS-GUIDED GALLBLADDER DRAINAGE VS. PERCUTANEOUS GALLBLADDER DRAINAGE IN PATIENTS WHO ARE UNFIT FOR CHOLECYSTECTOMY: WHICH IS BETTER?

S. Jo[1], D.H. Cho[1], S.S. Lee[1], D.-W. Oh[1], T.-J. Song[1], D.H. Park[1], D.-W. Seo[2], S.K. Lee[1], M.-H. Kim[1]

Introduction: EUS guided gall-bladder drainage (EUS-GBD) has become increasingly used to treat patients with acute cholecystitis who are not eligible for surgery. However, there are limited data comparing long-term outcomes of EUS-GBD and conventional percutaneous cholecystostomy (P-GBD). We therefore performed a retrospective study to compare the efficacy and safety of EUS-GBD and P-GBD in patients with acute cholecystitis.
Aims and Methods: We studied 182 patients who required gallbladder drainage for acute cholecystitis from February 2010 to November 2014. We used propensity-score weighting to adjust for differences in all covariates (age, sex, comorbid diseases, previous drugs) between EUS-GBD and P-GBD groups, and compared early, late adverse events and need for re-intervention in each group.
Results: A total of 182 patients (75 in EUS-GBD group and 107 in PTGBD group) were enrolled in this study. The technical/clinical success rate was 98.7%/100% (74/75, 74/74) in EUS-GBD and 99.1%/98.1% (106/107, 104/106) in P-GBD group respectively. After adjustment of inverse-probability-of-treatment-weighted method, early adverse event rate was no statistical difference between two groups. However, for late adverse events including migration of stent or dislodgement of drainage tube, stent or tube occlusion, tract inflammation around percutaneous tube, bile leakage and recurrence of cholecystitis it is shown P-GBD significantly higher odds ratio compared to EUS-GBD [odd ratio 3.38 (95% CI 1.08 to 10.54)]. P-GBD also showed a higher risk of additional intervention compared to EUS-GBD [odd ratio 3.60 (95% CI 1.26 to 10.32)]. Moreover, logistic regression analysis showed that P-GBD was significantly associated with re-intervention [odds ratio 3.68, 95% CI 1.43 to 9.47, $p = 0.007$].
Conclusion: EUS-GBD and P-GBD were both effective means of achieving gallbladder drainage. However, EUS-GBD might be beneficial than P-GBD in long term management for the patients with acute cholecystitis who are not suitable for cholecystectomy.

Introduction: Endoscopic gallbladder drainage (GBD) has been performed as an alternative to percutaneous drainage for acute cholecystitis. To date, there has been no comparative study between endoscopic ultrasound-guided gallbladder drainage (EUS-GBD) and endoscopic transpapillary gallbladder drainage (ETGBD).
Aims and Methods: The aim of this study was to compare the outcomes of EUS-GBD and ETGBD. Retrospective review of an endoscopic GBD database prospectively collected at the Asan Medical Center (between July 2010 and December 2014) was performed to identify consecutive patients with acute cholecystitis who underwent attempted endoscopic GBD. Procedural and long-term outcomes were evaluated using propensity score matching and inverse probability of treatment weighting (IPTW).
Results: A total of 172 patients (76 in the EUS-GBD group and 96 in the ETGBD group) were included in this study. Seven patients who failed to undergo ETGBD crossed over to the EUS-GBD group. Technical success (99.8% vs. 83.3%, $p < 0.01$) and clinical success rates (99.8% vs. 82.3%, $p < 0.01$) was significantly higher in the EUS-GBD group than in the ETGBD group. After adjustment with IPTW method, the procedure-related adverse event rate was significantly higher in the ETGBD group (5.8% vs. 19.6%, $p < 0.01$). The cholecystitis or cholangitis recurrence rate (13.3% vs. 3.5%) was also higher in the ETGBD group than in the EUS-GBD group, as identified using Cox analysis (hazard ratio, 4.61; 95% confidence interval, 0.87–18.2; $p = 0.03$).
Conclusion: In patients with acute cholecystitis and unfit for surgery, EUS-GBD may be a more suitable treatment method than ETGBD.

[3]*Moscow Clinical Scientific Center named after A. S. Loginov, Operative Endoscopy, Moscow, Russian Federation*

Contact E-Mail Address: ivannedoluzhko@gmail.com
Introduction: Current surgical guidelines of Zenker's diverticulum treatment recommend incising the intersection of the cricopharyngeal muscle (cricopharyngeal myotomy) and performing a diverticulectomy. The working hypothesis of our scientific research assumes that the results of tunnel endoscopic crycopharyngo-esophagomyotomy will exceed the results of standard endoscopic treatment with respect to the effectiveness of eliminating clinical development of diseases and reducing the number of their relapses.
Aims and Methods: We report the results of a comparative study of the endoscopic treatment of Zenker's diverticulum.
In the period from July 2014 to March 2018 67 patients were included in our research. At the initial stage (until March 2017), all operations were performed according to the traditional method. Later, after the introduction of the new tunneling technique, it was given priority in application due to a number of advantages. The standard protocol for preoperative examination included the transnasal endoscopy and X-ray examination. In the presence of signs of diverticulitis, conservative treatment was performed before the reduction of inflammatory changes in the mucosa. The average age of the patients was 66 (from 34 to 86) years.
Results: According to the traditional method, 36 patients (group I) were operated. 34 patients (group II) were operated using the tunnel technique. No technical difficulties associated with the myotomy or the mucosal defect closure were noted. The average time of the surgical intervention was 56+7 in the first group и 60+4 minutes in the second.
No signs of emphysema or other pathological changes were detected postoperatively.
In both groups on the first day after the operation, all patients had a control X-ray study with water-soluble contrast. An interesting feature in the group of tunnel technique was the almost complete absence of the residual cavity of the diverticulum. All the patients were discharged on the second day after the operation.
Two patients in the group of traditional endoscopic treatment were re-operated because of complaints recurrence; each of them underwent two re-interventions. In two more cases the traditional endoscopic treatment was completed in two stages due to the large size of diverticulum. No recurrence of symptoms was observed after tunnel technique.
Conclusion: Tunnel surgery is a pathogenetically justified method of treating Zenker's diverticulum as a neuromuscular disease. We suppose that today the tunnel technique stands to be the preferable treatment option of the Zenker's diverticulum.

Introduction: Intestinal type gastric adenocarcinoma is preceded by a long lasting multistep precancerous process. Patients with chronic atrophic gastritis and/or intestinal metaplasia are at higher risk for gastric adenocarcinoma. Endoscopic surveillance is recommended to patients with extensive atrophy and/or intestinal metaplasia [1]. Obesity is a worldwide health problem. Surgical treatment has been shown to be the most effective treatment for severe obesity and also for its complications. Roux-en-Y gastric bypass (RYGB) is one of the most commonly performed bariatric procedures. Although gastric cancer in the excluded stomach after gastric bypass is rare [2], concerns about the risk of leaving a premalignant lesion in the excluded stomach after RYGB persist. Consensus on the necessity of esophagogastroduodenoscopy (EGD) before bariatric surgery is lacking, as well as an absence of recommendations on precancerous conditions and lesions surveillance after RYGB.
Aims and Methods: To estimate the prevalence of precancerous conditions and lesions of the stomach from patients undergoing bariatric surgery, demographics, clinical data, endoscopic and histopathological findings of preoperative EGD with biopsies performed between January 2012 and December 2017 were retrospectively reviewed.
Results: A total of 319 patients were included with a median age of 44 years (interquartile range 36–52 years); 75.2% (n = 240) were female. *Helicobacter pylori* infection was positive in 58.9% of the patients (n = 178). A positive family history of gastric cancer was present in 3.4% (n = 11). The most commonly performed bariatric procedure was RYGB (37.9%, n = 121), followed by sleeve gastrectomy (SG, 1.6%, n = 5). The remainder patients were awaiting RYGB (27.9%, n = 89), were under preoperative evaluation (24.1%, n = 77) or had contraindication/refused surgery (8.5%, n = 27). Regarding histopathological findings, 4.7% (n = 15) of the patients showed normal gastric mucosa; 63.9% (n = 204) showed chronic gastritis only; 17.5% (n = 56) atrophic gastritis; 13.7% (n = 44) intestinal metaplasia. Importantly, 11.6% (n = 37) of patients showed extensive atrophy and/or intestinal metaplasia. Thirteen of these patients were submitted to RYGB. No dysplastic lesion was found.
Conclusion: The prevalence of precancerous conditions of the stomach in candidates for bariatric surgery is considerable. The management of these patients remains unclear, both regarding the optimal surgical procedure choice (RYGB vs SG) and surveillance of the remnant gastric mucosa in those patients submitted to RYGB bariatric surgery.

Introduction: Obesity is a global epidemic and consequently bariatric surgery is increasingly performed. More recently, omega-loop gastric bypass (OGB), consisting primarily of a long linear lesser-curvature gastric tube with a terminolateral gastro-enterostomy 180–200 cm distal to the ligament of Treitz, was introduced. Thousands of these procedures have now been performed globally, being considered a safe and effective option for morbid obese patients. Despite positive effect in terms of weight loss and improvement of obesity-related co-morbidities, there are concerns about symptomatic biliary reflux gastritis and esophagitis requiring revision. Concerns have also been expressed due to chronic biliary reflux, because of a similarity with old Billroth II (BII) procedure that exposed patients to the risk of gastric cancer. However, scarce data are available on the physiopathological effect of these two procedures on gastro-esophageal function.
Aims and Methods: Since gastric and esophageal reflux can depend from proximal gastric pressure, we aimed at assessing the esophagogastric junction (EGJ) function, esophageal peristalsis and reflux exposure using high-resolution manometry (HRM) and impedance-pH monitoring (MII-pH) after OGB and BII.
Methods: Obese (body mass index, BMI, >35) patients underwent symptomatic questionnaires (GerdQ), endoscopy, HRM and MII-pH before and one year after OGB. We enrolled only obese without dysmotilty or any evidence of GERD. Intragastric pressures (IGP) and gastroesophageal pressure gradient (GEPG) were calculated. Esophageal motor function and EGJ were classified according to Chicago Classification V. 3. EGJ contractile integral (EGJ-CI) was also calculated. Total acid exposure time (AET %), total number of refluxes and symptom association probability (SAP) were assessed. A group of patients who underwent BII, referred for follow-up, was studied with the same protocol to serve as the control population.
Results: We enrolled 22 OGB patients and 12 BII subjects. After surgery, none of the patients reported de novo heartburn or regurgitation. At endoscopic follow-up 1 year after surgery, esophagitis was absent in all patients and no biliary gastritis or presence of bile was recorded. Manometric features and patterns did not vary significantly after surgery, whereas IGP and GEPG statistically diminished (from a median of 15 to 9.5, $p<0.01$, and from 10.3 to 6.4, $p<0.01$, respectively) after OGB. BII subjects had significant lower values in IGP (a median of 4.2, $p<0.001$), and similar GEPG 4.3, p = n.s. LES pressure as well as EGJ-CI were significantly lower in BII subjects than OGB ones (13 vs 22 mmHg, $p < 0.05$, and 11 vs 21.5 mmHg*cm, $p < 0.05$, respectively). A dramatic decrease in the number of reflux events (from a median of 41 to 7; $p<.01$) was observed after OGB, whereas BII patients had a statistically significant higher values in esophageal acid exposure and number of reflux episodes (57 vs 7; $p<0.001$), in particular in weakly alkaline reflux (38 vs 0; $p < 0.001$).
Conclusion: In contrast to BII, OGB did not expose to gastroesophageal reflux and in particular to weakly alkaline reflux. Also the difference in IGP and in GEPG as assessed by HRiM suggests that gastric bile reflux can occur more easily in BII than in OGB and that these two techniques share more differences than analogies.

Introduction: Laparoscopic wedge resection is widely performed for managing gastric submucosal tumors (SMTs) that measure ≤5 cm in diameter. Laparoscopy and Endoscopy Cooperative Surgery (LECS) is performed to ensure a sufficient margin while avoiding deformation or stenosis.
Aims and Methods: We conducted a retrospective review of the data of 83 patients who underwent LECS for SMTs or early gastric cancers at our institution between April 2012 and February 2018. While Non-exposed Endoscopic Wall-inversion Surgery (NEWS) and classical LECS predominantly were performed for intra luminal tumors, for extra luminal tumors, we adopted the combination of laparoscopic approaches to neoplasia with non-exposure technique (CLEAN-NET).
Results: The patients were 58.3 ± 14.2 years old. The male:female ratio was 44:39. The BMI was 22.5 ± 3.8 kg/m2. The tumor was located in the upper-/middle-/lower-third of the stomach in 55/21/7 cases. The operation time was 200.5 ± 66.4 min, and the intraoperative blood loss was 4.8 ± 12.2 cc. The major axis diameter of the tumors was 28.9 ± 11.8 mm. The histological tumor types included GIST (n = 41), leiomyoma (n = 17), schwannoma (n = 6), early gastric cancer (n = 8), etc. The surgical procedure consisted of classical LECS/CLEAN-NET/NEWS in 18/17/48 cases; all early gastric cancers were treated by NEWS. Postoperative resumption of water intake was 1.9 ± 0.9 days after the surgery, while that of oral meal intake was 3.3 ± 1.0 days. The postoperative hospital stay was 8.7 ± 3.8 days. The serum levels of C-reactive protein on POD1 and POD3 were 3.1 ± 1.9 and 4.3 ± 3.4 mg/dl, respectively.
The postoperative complications were anastomotic stenosis (n = 1), delayed gastric emptying (n = 5), exacerbation of GERD (>Grade II by the Clavien-Dindo classification) (n = 4).
In the patient group that developed complications, the postoperative resumption of water intake was later, and the postoperative hospital stay was longer as compared to the group without complications (p = 0.028, 0.006). There was the tendency for the tumor located in the lesser curvature or post wall to become postoperative complications (p = 0.051). No relationship was observed between the likelihood of development of complications and the tumor malignancy.
Conclusion: Use of minimally invasive surgical procedures such as LECS could allow deformation, stenosis and extent of resection to be minimized in resection of gastric tumors. LECS including NEWS and CLEAN-NET are feasible and effective for gastric tumors.

Contact E-Mail Address: otsuka77jp@yahoo.co.jp
Introduction: Laparoscopic distal gastrectomy (LADG) is a recent development in minimally invasive surgery for early gastric cancer in Japan, where the rate at which the population is aging is the highest worldwide. However, whether this procedure is safe and effective for elderly patients with preoperative comorbidities remains unknown. This report describes the short-term findings of a retrospective study of LADG.
Aims and Methods: Between January 2005 and December 2016, 166 patients with gastric cancer underwent LADG at our hospital, where the indication for LADG is cStage IA (T1N0M0) or cStage IB (T2N0M0). Patients with lymph node metastasis were excluded. We introduced a delta-shaped anastomotic procedure for gastrojejunostomy during 2012, which allowed a totally laparoscopic procedure. We compared 50 and 116 patients aged ≥75 (elderly) and <75 (younger) years, respectively, who underwent LADG. Preoperative physical status was assessed using the American Society of Anesthesiologists Physical Status (ASA-PS) Score, the Charlson Comorbidity Index (CCI), and the Prognostic Nutritional Index (PNI). The CCI is thought to predict the one-year mortality of patients with various comorbidities such as heart disease, AIDS, chronic lung disease, or cancer. The PNI was designed to indicate the risk of a poor outcome after surgery based on an assessment of nutritional status.
Results: Demographics of the patients, namely sex, tumor lesion, histology, and hemoglobin value, did not significantly differ. However, the mean ASA-PS score and CCI were significantly higher in the elderly group than in the younger group (1.29 vs. 1.14 and 0.60 vs. 0.28, respectively). In addition, the PNI was significantly lower in the elderly group than in the younger group (50.2 vs. 52.7). Surgical duration, blood loss, lymph node clearance, and length of postoperative hospital stay did not significantly differ between the groups. Cardiorespiratory and surgical complications developed in 2 (4.0%) and 3 (2.6%) of the elderly patients and in 5 (10%) and 12 (10%) of the younger patients, respectively, but intraoperative and postoperative complication rates did not significantly differ between them. Thus, significant complications did not arise in either group.
Conclusion: Laparoscopic distal gastrectomy for early gastric cancer is a safe, effective, and minimally invasive surgical procedure for elderly patients.

P0884 CLINICOPATHOLOGIC CHARACTERISTICS RELATED TO LYMPH NODE METASTASIS IN EARLY GASTRIC CANCER AFTER GASTRECTOMY

Y. Ma, J. Yang
West China hospital of Sichuan university, Gastroenterology, Chengdu, China

Contact E-Mail Address: yihandejiyi@163.com
Introduction: Early gastric cancer (EGC) was defined as tumour confined to the mucosa (T1a) or submucosa (T1b), irrespective of the presence of lymph node metastasis. Endoscopic treatment has became the first choice for EGC. However, endoscopic treatment of EGC was limited to the lesions that have low risk of lymph node metastasis (LNM) because of the inability to carry out lymph node dissection. We aimed to clarify the clinicopathologic characteristics related to lymph node metastasis in early gastric cancer and provide an appropriate strategy for patients with EGC.
Aims and Methods: Clinicalpathologic characteristics of patients who underwent curative gastrectomy with lymph-node dissection and finally confirmed as EGC by pathology at the West China Hospital of Sichuan University between November 2008 and October 2017 were retrospectively analysed. The clinicopathologic characteristics of lymph node metastasis group and non-metastasis group with EGC were compared. Logistic regression was used to analyze the risk factors of lymph node metastasis by univariate and multivariate analysis.
Results: Among the 5156 gastric cancer patients who underwent gastrectomy, 1044 patients (20.2%) showed early gastric cancer. Except for 111 patients without complete pathological information, 933 patients were finally enrolled in the present study. Among these 933 patients showing EGC, 246 patients (26.4%) had lymph node metastasis. The univariate analysis revealed that LNM was significantly associated with age (p = 0.024), sex (p < 0.001), tumour size (p < 0.001), tumour depth (p < 0.001), tumour location (p < 0.001), tumour differentiation (p < 0.001), perineural involvement (p = 0.043) and lymphovascular involvement (p < 0.001). Multivariate analysis confirmed that female (odds ratio [OR] 1.603; 95% confident interval [CI], 1.155–2.255), tumour size >2 cm but ≤ 3 cm (OR 1.572; 95% CI 1.082–2.285), tumour size > 3 cm (OR 1.61; 95% CI, 1.05–2.48), location in the lower third of the stomach (OR 4.090; 95% CI 1.387–12.060), submucosa tumour (OR 3.571; 95% CI 2.473–5.157), histological undifferentiation (OR 2.066; 95% CI 1.364–3.047), and lymphovascular involvement (OR 4.073; 95% CI 2.455–6.756) were independent risk factors for lymph node metastasis (p < 0.05). The rate of LNM was 1.79% in patients with EGC who fulfilled absolute indications of endoscopic resection but actually underwent gastrectomy, while the rate of LNM in patients with EGC who met the expanded indications was 10.86%. Analysis of LNM of patients with T1a tumours showed that patients with T1a tumours, differentiation and tumour located in the upper or middle third of the stomach, irrespective of the presence of lymphovascular involvement, sex and tumour size did not show LNM.
Conclusion: Female, tumour size >2 cm, submucosal tumour, undifferentiated tumour, tumour located in the lower third of stomach and lymphovascular invasion were independent risk factors for LNM. In addition, patients with T1a tumours, differentiation and tumour located in the upper or middle third of the stomach, irrespective of the presence of lymphovascular involvement, sex and tumour size were appropriate for endoscopic resection.

P0885 OPERATIVE MANAGEMENT OF PATIENTS WITH METASTATIC GASTROINTESTINAL STROMAL TUMORS: A POPULATION-BASED RETROSPECTIVE STUDY

W. Zheng, W. Hu, M. Hu, **L. Chen**
Sir Run Run Shaw Hospital, Medical School, Zhejiang University, Hangzhou, China

Contact E-Mail Address: clyemma@zju.edu.cn
Introduction: Gastrointestinal stromal tumors (GISTs) are mesenchymal tumors with a varying malignancy potential ranging from virtually indolent tumors to rapidly progressing cancers. There is no consensus about the role of surgical resection in the treatment of patients with metastatic GISTs.
Aims and Methods: We aim to evaluate the impact of operative management on survival outcomes in patients with metastatic-GIST based on US-population. Patients with GISTs were identified from the Surveillance Epidemiology and End Results (SEER) registry between 2001 to 2014. Kaplan-Meier analysis and Cox regression were performed to identify the influence of surgery on overall survival (OS) and GISTs-specific survival (GSS).
Results: A total 5773 patients diagnosed with GISTs, including 1392 metastatic-GISTs patients and 4381 non-metastatic GISTs patients. Compared with the non-metastatic GIST patients, patients with stomach GISTs had a smaller proportion among metastatic GISTs patients (621[44.6%] vs. 2611[59.6%], p < 0.001) and much less metastatic patients were managed operatively (728[52.3%] vs. 4068[92.8%], p < 0.001). Among patients with metastatic GISTs, Kaplan-Meier analysis indicated that surgical management was associated with improved survival. The five-year OS rates for metastatic patients with and without operative management were 55.3% and 27.9%, with median survival time of 85.6 and 46.5 months, respectively (p < 0.001). The five-year GSS rates were 59.5% and 32.1%, with median survival time of 94.2 and 53.0 months, respectively

($p < 0.001$). Cox regression multivariate analysis of metastatic patients showed that non-surgical management was associated with a more than 2-fold increased risk death form GISTs (RR: 2.25; 95% CI, 1.88–2.69; $p < 0.001$).
Conclusion: Surgical resection is associated with improved OS and GSS in metastatic GISTs patients.

Contact E-Mail Address: drp_desai@hotmail.com
Introduction: We have analysed our data or managing bile duct injury and have put forth a new classification more relevant in our clinical practice.
Aims and Methods: From October 2010 to May 2017, total 178 patients of mean age 51 (range 30–74) years were referred to our unit with bile duct injury following or during laparoscopic cholecystectomy. Laparoscopic cholecystectomy was described as 'uneventful' in 45% and 'difficult' in 55% patients; 19 injuries were recognized at operation. Rest patients were transferred on 7th post operative day on an average. Exploration and complete diversion of bile was done in initial 12 patients along with feeding jejunostomy (for bile refeeding) of type II & III. Later on all patients were internally drained irrespective of type II / type III, and feeding jejunostomy was not done. Average time for hepatico jejunostomy – day 62 following initial surgery. Out of 74 patients of type II and III only 39 patient required Hepatico jejunostomy (52.7%), one needing surgery was lost to follow up, rest 34 (45.9%) were managed successfully with endobiliary repeat/multiple stenting. All patient with type I injury were subjected to ERC-papillotomy and stenting of common bile duct was done successfully. Out of 102, 91 patients had drains kept during surgery and was draining bile, 11 patients had Biloma which was drained with pigtail catheter percutaneously. Two patients died, one was referred on day 11, after redo laparoscopy which was done on post of day 6, patient was in sepsis, ARDS & MODS. Was operated for biliary peritonitis but could not be saved. Another patient was referred on post operative day 12 with biliary fistula from drain and peritonitis with liver failure. On exploration found to have type 3B Bile duct injury with portal vein clipping and complete thrombosis with ischemic liver. This patient died of liver failure with sepsis post operatively.
Results: We propose new classification for bile duct injury according to its prevalence in our region and our management recommendations.
TYPE I: Cystic duct stump blow out.
TYPE II: Partial clip on CBD with or without cystic duct stump blow out or lateral injury.
TYPE III: a. Segment loss of CBD < 2cm.
b. CBD / CHD > 2 cm extending upto hilum.
c. Hilar injury with separate sectoral ducts. T
d. Any of above with ligation of right hepatic artery.
TYPE IV: Isolated sectoral duct injury.
Distribution of our cases according to types.
Number of patients: Type I – 102, Type II – 34, Type IIIA – 19, Type IIIB – 15, Type IIIC – 4, Type IIID – 2, Type IV – 2
Conclusion: Bile duct injury following laparoscopic cholecystectomy is a complex management problem and results in significant postoperative morbidity.
Bile duct injury recognized intraoperatively always does better irrespective of severity of injury.
More complex injuries are better drained first and then later date reconstruction is advisable.
We propose use of endobiliary plastic stents (routinely used following ERC) for internal drainage and repair of bile duct over stent without use of conventional T tube and if required later date hepatico jejunostomy can be done.
ERC is used in type I and II injury and use of multiple stents after a salvage surgery and placing intra operative stents in 45.9% cases.
In presence of biliary sepsis and peritonitis, surgical lavage and endobiliary stenting is advisable before subjecting patients to ERC.

P0887 BRAUN ENTEROENTEROSTOMY AFTER PARTIAL PANCREATICODUODENECTOMY AND CHILD RECONSTRUCTION DECREASES MORBIDITY, CLINICALLY RELEVANT PANCREATIC FISTULA, CLINICALLY RELEVANT DELAYED GASTRIC EMPTYING AND BILE LEAKS – A SYSTEMATIC REVIEW WITH META-ANALYSIS

S. Schorn, E.I. Demir, T. Vogel, R. Schirren, D. Reim, D. Wilhelm, H. Friess, G.O. Ceyhan
Klinikum rechts der Isar, Technical University of Munich, Department of Surgery, Munich, Germany

Contact E-Mail Address: stephan.schorn@tum.de
Introduction: Due to its high rates of postoperative mortality and morbidity, resections of the pancreas remain a high-risk operation. Since its first description by Kausch et al. and Whipple et al., several surgical reconstruction techniques have been introduced to minimize the risk for postoperative mortality and morbidity after pancreaticoduodenectomy/PD. These reconstruction techniques include the standard Child reconstruction defined as pancreatojejunostomy/PJ followed by hepaticojejunostomy/HJ and the gastrojejunostomy/GJ (s-Child), the s-Child reconstruction with an additional Braun enteroenterostomy (BE-Child) and the Isolated-Roux-En-Y-pancreaticojejunostomy (ISRY), in which the pancreas anastomosis is reconstructed in a separate loop after the GJ. Yet, no comparative systematic review with meta-analysis has been performed to assess the impact of these most commonly used reconstruction techniques on the postoperative course of patients undergoing PD.
Aims and Methods: This systematic review with meta-analysis aims to compare the effect of different reconstruction techniques on the postoperative course of patients after PD.
For this purpose, the Preferred-Reporting-Items-for-Systematic-review-and-Meta-Analysis/PRISMA-guidelines were used to conduct a systematic review with meta-analysis. Databases of Pubmed/Medline, Scopus, Cochrane Library and Web-of-Science were screened for relevant articles meeting predefined inclusion and exclusion criteria. Afterwards, data were extracted and pooled in meta-analysis calculating risk ratios/RR for postoperative complication rates between s-Child vs. BE-Child and s-Child vs. ISRY.
Results: Thereby, a total of 18 studies comparing the postoperative outcome of BE-Child or ISRY against s-Child could be identified. Neither BE-Child ($p = 0.47$) nor ISRY ($p = 0.95$) displayed any impact on postoperative mortality. Accordingly, the meta-analyses of ISRY could not reveal any relevant effect on postoperative morbidity ($p = 0.73$), postoperative pancreatic fistula/POPF Grade A/B/C ($p = 0.61$), clinically relevant POPF ($p = 0.79$), delayed gastric emptying/DGE Grade A/B/C ($p = 0.36$), clinically relevant DGE ($p = 0.16$) or bile leaks ($p = 0.56$) compared to s-Child. However, although the meta-analyses of BE-Child vs. s-Child could also not detect any differences in POPF ($p = 0.27$) and DGE ($p = 0.06$) in general, BE-Child was strongly associated with a decreased risk for overall morbidity ($p = 0.0002$), clinically relevant POPF ($p < 0.00001$), clinically relevant DGE ($p = 0.004$) and bile leaks ($p < 0.01$). In line with these results, BE-Child showed a decreased hospital stay ($p = 0.05$) but also an increased operation time ($p = 0.0002$) with no impact on haemorrhage ($p = 0.52$), surgical site infections ($p = 0.97$) and pulmonary complications ($p = 0.85$) compared to s-Child.
Conclusion: BE-Child favorably affects the outcome of patients after PD by decreasing the risk for morbidity, clinically relevant POPF, clinically relevant DGE and bile leaks. In contrast, no effect was visible for ISRY compared to s-Child. However, because of the low evidence of the included studies caused by the low number of participants of the randomized controlled trials and the retrospective character fo the studies, a randomized controlled trial is planned to confirm these results of the recent meta-analysis.
Disclosure: Nothing to disclose

P0888 PREVENTION OF POSTOPERATIVE BILE-LEAKAGE BY A NEWLY DESIGNED TISSUE SEALANT PATCH

A. Heumann[1], A. Bahar[1], M. Tooren[2], H. de Vries[2], J.R. Izbicki[1], M. Bockhorn[1]
[1]*Dept of General -, Visceral- and Thoracic Surgery, University Medical Center Hamburg, Hamburg, Germany*
[2]*Polygancis BV, Groningen, Netherlands*

Contact E-Mail Address: aheumann@uke.de
Introduction: Up to 10–15% of patients develop a bile-leakage after liver surgery, which increases the length of hospital stay as well as overall mortality and morbidity. However, with no effective preventive measure at hand, the surgical community is forced to accept bile-leakage as an unavoidable post-surgery complication.
Aims and Methods: To overcome the clinical challenge of post-operative bile leakage we developed a new tissue sealant patch to prevent this complication. The tissue sealant patch was designed in a multi angle approach including *in-vitro* comparison on tensile, burst pressure measurements and testing in a liver perfusion model with clinically relevant competitors. For *in-vivo* evaluation a porcine bile-leakage model was established and the tissue sealant patch was investigated in a prospective randomized animal trial with a suturing group and Veriset® group as controls.
Results: More than 30 different prototypes were screened *in-vitro*. The final selected sealant prototype showed superiority compared to clinical used competitors Tachosil®, Hemopatch® and Veriset® in tensile and burst pressure testing ($p < 0.05$ each). Moreover, the newly developed patch reduced the leakage rate in the liver perfusion model ($p < 0.05$). The pre-clinical performance of the sealant patch was confirmed in a porcine bile-leakage model. 21 animals were included in the study and randomized for treatment with the sealant, Veriset® or suturing ($n = 7$ each). After 7 days incidence of bile leakage was significantly lower in the sealant group compared to the Veriset® group ($p < 0.05$) and comparable to the suturing control group. These promising results were supported by strong bile containment and the formation of a smooth fibrous capsule by the sealant within one week. This was paralleled by the formation of neo bile ducts. Furthermore, no systemic or local side effects (e.g. bilioma) were seen.
Conclusion: The new designed sealant was as effective as suturing in preventing bile-leakage in our animal model. This was due to strong bile containment and formation of a fibrous capsule by the sealant within one week. The efficacy of the sealant was also histologically proven, as formation of neo bile ducts – which indicates a biliary obstruction – was detected. More importantly, no clinical relevant side effect of the sealant became evident. To our knowledge, this is the first report of a randomized trial showing the efficacy of a tissue sealant device for preventing postoperative bile leakage.

[2]*American University of Beirut Medical Center, Clinical Research Institute, Beirut, Lebanon*
[3]*American University of Beirut Medical Center, Department of Surgery, Beirut, Lebanon*

Contact E-Mail Address: fd21@aub.edu.lb

Introduction: Distal pancreatectomy (DP) accounts for 25% of all pancreatic resections. Complications following DP occur in around 40% of the cases.

Aims and Methods: Few studies compared the clinical outcomes of distal pancreatectomy in benign versus malignant diseases.

We studied all patients undergoing DP from the National Surgery Quality Improvement Program (NSQIP) pancreatectomy participant use data specific file from 2014–2016. NSQIP includes prospective validated outcomes and anonymized data for patients' demographics, functional statuses, preoperative risk factors, laboratory data, and 30-day postoperative outcomes for patients undergoing major surgery in more than 500 hospitals. The primary outcome in this study was short term surgical morbidity and mortality. The patients were divided into 2 groups, those who underwent DP for benign diseases (DP-B) and those who underwent DP for malignant diseases (DP-M). We used the chi square test or Fisher's exact (when one or more cells had an expected frequency lower than 5) to compare categorical variables between the 2 groups. We used the independent t-test for continuous variables. We performed multivariate logistic regression to evaluate the association between benign or malignant distal pancreatectomies and 30-day postoperative outcomes. We included confounders into the models based on both clinical and statistical significance.

Results: Over the specified period, 1685 (47%) patients underwent DP-B and 1894 (53%) patients underwent DP-M. DP-M patients were significantly older, had significant longer operation time and hospital stay. The most common indications of DP-B and DP-M were mucinous cystic neoplasm (26.4%) and pancreatic adenocarcinoma (75%), respectively. Open DP was the most performed type of surgery for both benign (39%) and malignant (60%) lesions while laparoscopic DP was performed at a higher rate for benign indications (29%) compared to malignant ones (15%). Thirty-day mortality occurred in 0.4% of DP-B compared to 1.3% DP-M. Pancreatic fistula occurred in 20% of DP-B compared to 18% of DP-M. Moreover, composite morbidity (including thromboembolism, sepsis, wound infection, cardiac, respiratory, and urinary complications) were significantly higher in DP-M. On multivariate analysis, after adjusting for clinically relevant confounding factors, no significant difference was found in mortality or in developing a pancreatic fistula between the 2 groups. Bleeding ($p = 0.002$) and composite morbidity ($p = 0.01$) were significantly higher in the DP-M group. Among composite morbidities, thromboembolism was shown to be significantly associated with DP-M (OR = 2.1, $p = 0.0004$).

Conclusion: Our study showed that DP-M is significantly associated with higher composite morbidity, sepsis, and thromboembolism. However, no significant difference in mortality was found between DP-B and DP-M groups.

[2]*American University of Beirut Medical Center, Clinical Research Institute, Beirut, Lebanon*
[3]*American University of Beirut Medical Center, Department of Surgery, Beirut, Lebanon*

Contact E-Mail Address: fd21@aub.edu.lb

Introduction: In a previous multicenter study, post-operative day 1 drain fluid amylase level (DFA-1) level of 2000 was found to be most predictive of the development of clinically relevant post-operative pancreatic fistula (CRPOPF).

Aims and Methods: We aimed to validate the previously established cut-off level for DFA-1 after distal pancreatectomy using the NSQIP database.

Methods: Patients undergoing distal pancreatectomy from the National Surgery Quality Improvement Program (NSQIP) pancreatectomy specific PUF file from 2014–2016 were studied. We applied the DFA-1 of 2000 cut off to compare clinical outcomes in both groups. In order to validate the previously defined DFA-1 level, we performed a receiving operating characteristic (ROC) curve to independently determine the optimal cut-off value of DFA1.

Results: 1012 patients underwent DP. CRPOPF occurred in 206 (20.4%). Patients with DFA1 levels $\geq$ 2000 U/L were more likely to develop CR-POPF (32.5% vs 11.3%, $p < 0.0001$), to have a higher mean number of days before drain removal (8.86 versus 5.59, $p < 0.0001$), to have a drain 30-days post-operatively (12.7% versus 3.6%, $p < 0.0001$) and to undergo percutaneous drainage (13.8% vs. 9.7%, $p = 0.04$). Application of maximal Youden index calculated the DFA-1 level value at 2000 U/L with a sensitivity of 68.45% and a specificity of 63.65% for CR-POPF, with PPV and NPV of 32.49% and 88.75%, respectively and a Youden index of 0.32.

Conclusion: Using a different population of patients and a different data set as well as an independent analysis, we successfully validated a DFA1 of 2000 as striking the best balance of sensitivity and specificity for the detection of CR-POPF. The identified cut-off might be employed in the design of a trial of early drain removal in patients undergoing distal pancreatectomy.

Amylase cutoff	Sensitivity	Specificity	Youden's Index	Positive Predictive Value	Negative Predictive Value
500	84.95	34.86	0.20	25.00	90.06
1000	76.21	47.27	0.23	26.98	88.60
1500	71.84	55.96	0.28	29.42	88.61
2000	68.45	63.65	0.32	32.49	88.75
2500	61.17	70.10	0.31	34.33	87.60
3000	57.77	73.70	0.32	35.95	87.22
3500	55.83	75.43	0.31	36.74	86.98
4000	52.91	78.78	0.32	38.93	86.75
4500	49.03	81.51	0.30	40.40	86.22
5000	46.60	83.00	0.30	41.20	85.88

[Table comparing outcomes between benign and malignant distal pancreatectomies, before and after adjusting for clinically confounding variables]

Surgical resection is generally accepted in patients with advanced neoplasia (AN) (high-grade dysplasia (HGD) or malignancy). Currently, the main challenge is to determine the risk of progression to AN in patients with PCNs. It is unclear whether the revised 2018 European guideline is more accurate for predicting AN than the 2013 European guideline. Therefore, the aim of this study was to evaluate the clinical usefulness of the predictors of malignancy listed in the 2018 European guideline and to validate the diagnostic accuracy of the 2018 European guideline with reference to the 2013 European guideline and to the revised 2017 IAP guideline.
Aims and Methods: Patients who underwent pancreatic resection were extracted from our prospective pancreatic cyst database (2006-present). The final histopathological diagnosis was compared with the initial indication for surgery stated by the 2013 European, 2017 IAP and 2018 European guidelines. We considered surgery in retrospect justified for AN, solid pseudopapillary neoplasms, cystic neuroendocrine tumors, and symptom improvement. Furthermore, we evaluated the patients with IPMN separately: receiver operating characteristics (ROC) curves were calculated and compared to measure diagnostic value.
Results: Overall, 172 underwent surgical resection. In hindsight, based on the histopathological outcomes and symptom improvement, surgery was indicated in 72/172 patients (41.9%). Ninety-two patients with IPMN (11 MD-IPMN, 55 MT-IPMN, 26 SB-IPMN) were included in the analysis to identify the value of the 2018 European guideline in identifying AN preoperatively. Of these, 44 were diagnosed with AN pathologically. The sensitivity, specificity, positive predictive value, negative predictive value, and accuracy of the 2018 European criteria were 94.7%, 29.6%, 48.7%, 88.9%, 56.5%, respectively. Sensitivity, specificity, positive predictive value, negative predictive value, and accuracy of the 2013 European guideline and 2017 IAP guideline were 100.0%, 9.3%, 43.7%, 100.0%, 46.7% and 94.7%, 22.2%, 46.2%, 85.7%, 52.2%, respectively. ROC comparison analysis showed that the 2018 European guideline criteria were superior to the 2013 European guideline criteria ($p = 0.02$) and to the 2017 IAP guideline ($p = 0.04$) in identifying AN in IPMN.
Conclusion: The revised 2018 European guideline criteria were superior to the 2013 European guideline criteria and 2017 IAP guideline criteria in identifying AN in IPMN in this retrospective analysis.

Introduction: The balance between host and microbes in the gut drives the intestinal homeostasis and prevents inflammatory situations such as inflammatory bowel disease (IBD). However, interactions between different microbial kingdoms, bacteria and fungi for example, and their effects on the intestinal homeostasis remain poorly understood. Here, we studied specific bacteria – fungi interactions and their implications in intestinal inflammation.
Aims and Methods: Female C57BL/6 mice were treated for 7 days with 1g/L vancomycin in drinking or 1g/L colistin (oral gavage) in order to deplete Gram positive and *Enterobacteriaceae* respectively. In addition, the effect of oral gavage with either the probiotic yeast *Saccharomyces boulardii* CNCM I-745 (Biocodex-Gentilly) or the pathogenic yeast *Candida albicans* were evaluated. After 7 days of antibiotic treatment and fungi supplementation, colitis was induced with 2% Dextran Sodium Sulphate (DSS) in drinking water for 7 days followed by a recovery period of 5 days with water. Mice were sacrificed at day 0, day 7 and day 12 post-DSS. The development of colitis and its recovery were assessed by monitoring daily weight loss and disease activity index from day 0 to day 12. Lipocalin levels, histological analysis as well as bacterial (16S sequencing) and fungi (ITS2 sequencing) microbiota compositions and diversity were monitored after antibiotic exposure and during colitis.
Results: In wild-type conventional mice, administration of *Saccharomyces boulardii* reduced DSS-induced colitis severity while administration of *Candida albicans* had the opposite effect. Antibiotics treatments strongly modified the observed phenotype. Vancomycin-treated mice were fully protected from colitis. Colistin treated-mice had a conserved colitis phenotype but were not affected anymore by administration of beneficial (*S. boulardii*) or pathogenic (*C. albicans*) fungi. 16S and ITS2 sequencing analysis showed that both fungal and bacterial microbiota were altered in colistin-treated mice. Bacteria-fungi abundance correlations were dramatically decreased in colistin-treated mice compared to vancomycin-treated and control mice suggesting that colistin-sensitive bacteria are involved in interactions with fungi. As expected, microbiota composition analysis showed that *Enterobacteriaceae* were depleted in colistin treated-mice. To test whether *Enterobacteriaceae* are required for positive or negative effects of fungi in colitis setting, colistin-resistant *Escherichia coli* (a major *Enterobacteriaceae* member) were administered in colistin-treated mice and then submitted to colitis. Restoring an *Enterobacteriaceae* population by administrating colistin-resistant *E. coli* reestablished both the beneficial effects of *S. boulardii* and the pathogenic effects of *C. albicans* on colitis severity. The mechanisms are not fully identified but involve an improved gut colonization of fungi in presence of *Enterobacteriaceae*.
Conclusion: The probiotic yeast *Saccharomyces boulardii* CNCM I-745 reduces colitis severity whereas the pathogenic yeast *Candida albicans* worsens it. These effects are influenced by *Enterobacteriaceae*, at least partly through an improved gut colonization of fungi. These results provide new insights into the role of interkingdom functional interactions in intestinal physiopathology and in IBD pathogenesis.

P0893GUT INFLAMMATION DEMONSTRATES A CIRCADIAN RHYTHM AND THE CLOCK IS DISRUPTED IN A MURINE MODEL OF COLITIS

T. Butler, S. Dickson, L. Hand, J. Gibbs
University of Manchester, Division of Diabetes, Endocrinology and Gastroenterology, Manchester, United Kingdom

Contact E-Mail Address: tom.butler@doctors.org.uk
Introduction: The circadian clock oscillates over a 24-hour (or circadian) cycle and is entrained to external stimuli such as light and food availability. At the molecular level, these circadian oscillations are generated by transcriptional-translational feedback loops. Immune cells show circadian rhythms in their function and consequently the symptoms of many inflammatory diseases are diurnal. Phenotypically, patients with IBD do not have diurnal symptoms, but there is emerging evidence of circadian dysrhythmia at a cellular level in the gut and gastrointestinal conditions are more prevalent in shift workers.[1,2] The interplay between gut inflammation and circadian biology requires further investigation.
Aims and Methods: The aim of this study was to examine circadian variation in inflammation within the colonic lamina propria, using a mouse model of colitis. To achieve our aims, C57BL/6 mice were given 2% (w/v) DSS in drinking water *ad libitum* for 4 days, followed by 4 days of water. Control mice drank water throughout. Mice were sacrificed at 4 different times across the circadian day: Zeitgeber Time (ZT)0 (lights on); ZT6 (mid-light); ZT12 (lights off) or ZT18 (mid-dark). Samples of colon were taken for histological staining and analysis of clock and inflammatory gene expression. Faeces were isolated for calprotectin assessment by ELISA. Colonic lamina propria immune cells were isolated from inflamed and naïve mice by enzymatic digestion and immune cell populations were quantified using flow cytometry.
Results: Mice administered DSS developed colitis, demonstrated by an average weight loss of −15% body weight (compared with +5% weight gain in controls), significantly greater spleen weight and reduced colon length. Furthermore, histological analysis confirmed inflammation within the colon. Flow cytometry revealed increased populations of neutrophils, monocytes, macrophages and dendritic cells within the lamina propria following DSS treatment.
Gene expression of pro-inflammatory cytokines (*il-1b*, *il-6*, *ccl2, cxcl1* and *cxcl5)* was significantly elevated in mice with DSS compared with controls at all time points. However, a subset of cytokines (*ccl2* and *cxcl1*) showed dramatically enhanced expression during the night (ZT18) compared to the day (ZT6), with up to a 40-fold increase in *ccl2*.
This localised inflammation was accompanied by dampening of the diurnal variation of clock gene expression, most notably *rev-erbα*, in the colon. Of interest, attenuated expression of *rev-erbα* was also noted in the liver of DSS treated mice.
Conclusion: We have demonstrated circadian variation in pro-inflammatory responses in a murine model of colitis, which coincides with dampening of rhythms in clock gene expression. This early work suggests colitis is a circadian disease and opens the possibility of identifying the circadian clock mechanism as a potential therapeutic target.

Introduction: Inflammatory bowel disease (IBD) is accompanied by lesions in the epithelial barrier, which allow translocation of bacterial products from the gut lumen to the host's circulation. Systemic exposure to certain bacterial products, including lipopolysaccharide (LPS) elicits strong immune responses, and thereby contributes to the pathogenesis and perpetuation of IBD. LPS exposure in

particular, promotes production of pro-inflammatory cytokines, and affects immune cell activation. Colostrum contains high levels of immunglobulins (Ig), which neutralize bacteria-derived antigens in the intestine, and thereby prevent systemic translocation of bacterial products. IMM-124E is a colostrum-based product, containing high levels of anti-LPS IgG, and therefore prevents systemic exposure to LPS. Since LPS is involved in IBD pathogenesis, we here investigated whether IMM-124E can ameliorate symptoms of intestinal inflammation.
Aims and Methods: Acute colitis was induced in WT C57B6 mice by administration of 2% DSS in the drinking water for 7 days. T cell transfer colitis was induced via transfer of 0.25x10^6 naïve T cells into $RAG2^{-/-}$ C57B6 mice. IMM-124E was administered daily by oral gavages throughout the experiment (acute DSS colitis) or upon onset of colitis symptoms, namely weight loss and macroscopically inflamed colon as visible by colonoscopy (T cell transfer colitis).
Results: In acute DSS-induced colitis, treatment with IMM-124E significantly ameliorated colitis, as observed by reduced weight loss ($p < 0.01$), lower endoscopic colitis score (MEICS score; $p < 0.05$), decreased myeloperoxidase levels ($p < 0.01$), and reduced shortening of the colon ($p < 0.05$). Histology of the terminal and proximal colon confirmed reduced colitis ($p < 0.05$). In the T cell transfer colitis model, therapeutic IMM-124E administration had similar effects and resulted in significant alleviation of colitis symptoms, including reduced disease activity scores and reduced levels of macroscopically detectable colitis in mouse endoscopy ($p < 0.05$ for both). Maximum anti-inflammatory effects were detected by an IMM-124E concentration of 100 mg/kg body weight. At 25 and 500 mg/kg IMM-124E, the anti-inflammatory effects were also detectable, but clearly less pronounced. Further, histology revealed reduced levels of infiltrating immune cells, and less pronounced mucosal damage ($p < 0.05$). In line with these findings, levels of IFN-g+ T cells and IL-17+ T cells were clearly reduced in mesenteric lymph nodes ($p < 0.01$) and the lamina propria ($p < 0.05$), while levels of FoxP3+ regulatory T cells were enhanced ($p < 0.01$) in mice treated with IMM-124E, when compared to control mice that received BSA.
Conclusion: Our results demonstrate that treatment with IMM-124E significantly reduces intestinal inflammation via reducing the accumulation and differentiation of pathogenic T cells, while concomitantly enhancing the induction of regulatory cells. This may suggest that inhibiting LPS-mediated effects on the mucosal immune system ameliorates colitis. Summarized, our findings indicate that IMM-124E administration might represent a novel therapeutic strategy to induce or maintain remission in IBD patients.

Introduction: Ferroptosis is an iron-dependent cell death mechanism which is defined by increased lipid peroxidation (LPO) and the inability of inhibitors for other cell death mechanisms to interfere with the ongoing process of cellular demise. Glutathione peroxidase 4 (GPx4) regulates this non-apoptotic cell death mechanism [1, 2]. A genome-wide association study identified GPx4 as a risk gene for the development of Crohn's disease (CD) [3]. However, CD has not been linked to ferroptosis or LPO in the intestine.
Aims and Methods: In this study we analysed ferroptosis and LPO in intestinal epithelial cells from patients with inflammatory bowel disease and analyzed the impact of GPX4-deficiency on intestinal-epithelial-cell (IEC)-derived inflammation.
Biopsies were obtained from lesional and non lesional mucosa of CD patients and healthy controls undergoing routine colonoscopy. One biopsy was paraffin embedded and used for IHC analysis. From a second biopsy an epithelial cells enriched single cell suspension was isolated and used for protein and RNA expression measurements. For in vitro experiments MODE-K cells, a murine small intestinal cell line, were used. Silencing for GPx4 was done for 24 hours prior to stimulating cells. ACSL4 knockout was obtained by CrisprCas9 editing of MODE-K cells. LPO was measured by staining for 4-HNE (human samples), BodipyC11 assessed lipid peroxidation by flow cytometry.
Results: In IEC enriched fractions from biopsies derived from the lesional mucosa of CD patients GPx4 activity and expression is diminished, compared to healthy controls. In line with this, CD patients exhibited increased LPO indicated by increased 4-HNE immunoreactivity. To further investigate the effect of diminished GPx4 in IECs we silenced MODE-K cells for GPx4 (siGPx4). SiGPx4 cells underwent ferroptosis, shown by increased LPO and increased cell death which could be prevented by vitamin e and ferrostatin, but not by inhibitors of necrotic or apoptotic cell death. SiGPx4 cells showed a markedly increased pro-inflammatory response to stimulation with arachidonic acid (AA), a polyunsaturated fatty acid largely contained within a westernised diet. Similar to ferroptosis, AA-induced inflammation was controlled by ACSL4 and lipoxygenases.
Conclusion: Reduced GPx4 activity in intestinal epithelial cells, as observed in Crohn's disease, leads to ferroptosis and promotes inflammation induced by arachidonic acid. This inflammatory response is controlled by ACSL4 and lipoxygenase-mediated LPO within intestinal epithelial cells. We suggest that ferroptosis is a feature of Crohn's disease which could be triggered by dietary-derived compounds such as long-chain fatty acids.

Introduction: Patients with inflammatory bowel disease (IBD) mainly present with ulcerative colitis (UC) or Crohn's disease (CD). Recently, it has been recommended that mucosal healing is therapeutic goal of IBD because dysfunction of epithelial cells might cause frequent relapse. However, the pathogenesis of epithelial cells in IBD remains unknown. Especially, although skip lesions in small intestine are often shown in the patients with CD, the mechanism to develop ulcer and stenosis at a certain part in entire small intestine remains unknown. We have previously identified the lesion-specific epithelial cell function in UC to compare the gene expression between organoids generated from active and inactive lesion of colon in the same patient with UC (DDW 2018).
Aims and Methods: We therefore aimed to identify lesion-specific genes to compare the gene expression between the organoids generated from active and inactive lesion of small intestine in same patient with CD.
Human small intestinal organoids were generated from both active and inactive lesion of the small intestinal tissue surgically resected from an identical patient with CD. Both organoids were cultured for a month to remove the effect of inflammation in tissue before the resection. Comprehensive gene expression profiles in the organoids were assessed by microarray analysis. The expression of genes upregulated or downregulated (>2 fold change) between active and inactive lesion-derived organoids were selected. The expression of selected genes was confirmed by RT-PCR using three pairs of small intestinal organoids in addition to another two patients with CD. This study was approved by the ethics committee.
Results: We have established both small intestinal organoids generated from active and inactive lesion of same CD patient. The configuration and growth patterns of the organoids from active lesion were the same as the organoids from no-active lesion. There was no significant difference of phenotypes such as stem cell and differentiation markers in the organoids. In spite of no significant difference of phenotypes, microarray analysis identified 7 upregulated genes in the organoids from active lesion more than 2 times compared to the organoids from inactive lesion. 3 downregulated genes in the organoids from active lesion less than half were also identified. 3 of 7 upregulated genes and all downregulated genes were preserved in the organoids from another patient but not all three patients.
Conclusion: Comparison of gene expression between organoids from active and inactive lesion of same patient might reveal the fundamental pathogenesis in intestinal epithelial cells of CD. The identification of lesion specific genes might also be useful for the elucidation of molecular mechanism and therapeutic target for mucosal healing in CD.

Introduction: *Bojanggunbi-tang* (BGT) is one of the most frequently used herbal prescription in Korea for colon diseases and the pharmacological activities of BGT on digestive system are also well-documented. However, BGT consists of 16 herbs, which makes it difficult to standardize and quality-control due to high cost in industrial manufacture.
Aims and Methods: The purpose of the current study is to develop a new simple and effective prescription derived from original prescription. We developed the essence of BGT (BGT-E) by mixing three herbs of BGT. Two herbs are *Lonicera japonica* Thunb. and *Alisma orientalis*, known as the most effective herbs in BGT. The other herb is *Atractylodes macrocephala* selected by literature review and screening test of total 16 kinds of components in BGT. Colitis mouse model was induced by 5% Dextran Sulfate Sodium (DSS) and body weight, histological damage, clinical score, gross anatomy and colon length were investigated to compare the effects between BGT and BGT-E. The mechanisms of action were analyzed by production of cytokines in colon tissue.
Results: We found that 300 mg/kg of BGT-E showed similar effect with same dose of BGT on colon shortening, clinical score, gross anatomical score and histological damage in the model. In addition, BGT-E showed dose-dependent decrease of pro-inflammatory cytokines including IL-1β, TNF-α, and IL-17.
Conclusion: Therefore, BGT-E could be a substitute prescription of BGT in clinical practice and a new candidate for alternative medicine for inflammatory bowel disease.

[3]*CHU Clermont-Ferrand, Department of Bacteriology, Clermont-Ferrand, France*

Contact E-Mail Address: anais.larabi@uca.fr
Introduction: The intestinal mucosa of CD patients is abnormally colonized with adherent-invasive *E. coli* (AIEC) strains, which are able to adhere to and to invade intestinal epithelial cells, to survive and replicate within macrophages and to induce a strong pro-inflammatory response. Exosomes, small extracellular vesicles of 30–100 nm, play a role in cell-to-cell communication by transferring their content from a donor cell to a recipient cell. We recently reported that upon AIEC infection, human macrophages secrete exosomes that induce a pro-inflammatory response and enhance the intracellular replication of AIEC bacteria in recipient cells.
Aims and Methods: This study aimed at investigating whether exosomes can transfer the microRNA (miRNA, miR) content between human macrophages during AIEC infection, and whether these miRNAs may contribute to the increased inflammation and AIEC replication observed in exosome-receiving cells. Exosomes released by human THP-1 macrophages uninfected (Exo-uninfected) or infected with the AIEC LF82 strain (Exo-AIEC) or the commensal *E. coli* HS strain (Exo-HS) were purified using the ExoQuick reagent and used to incubate with naïve THP-1 macrophages. The levels of the previously reported CD-associated circulating miRNAs in the purified exosomes and in exosome-receiving THP-1 macrophages were analyzed by qRT-PCR. *In silico* analysis was performed to predict the biological processes in which these miRNAs are potentially involved.
Results: Most of the CD-associated circulating miRNAs were detected in the purified exosomes. The levels of some miRNAs were increased in Exo-AIEC compared to Exo-uninfected or Exo-HS. The levels of these dysregulated exosomal miRNAs were also increased in THP-1 macrophages incubated with Exo-AIEC compared to those incubated with Exo-uninfected or Exo-HS. This suggests an efficient miRNA transfer *via* exosomes. *In silico* analysis revealed that the dysregulated exosomal miRNAs might be implicated in inflammatory responses and autophagy, which is required to restraint AIEC intracellular replication, among other biological processes.
Conclusion: Although functional studies are required to investigate the role of the exosomal miRNAs, our study suggests that during AIEC infection, miRNAs can be transferred between human macrophages *via* the exosomal shuttle to mediate their role as regulators of innate immune responses.

P0900 CYR61 EXPRESSION IN INFLAMMATORY BOWEL DISEASE

H. Kim, S.-Y. Park, J.H. Yoon, S. Lee
Chonnam National University Hospital and Medical School, Gwang Ju, Korea (Republic of)

Contact E-Mail Address: seekfory@naver.com
Introduction: The pro-angiogenic cysteine-rich protein 61 (Cyr61) is a novel proinflammatory factor. Whether Cyr61 is involved in the development of inflammatory bowel disease (IBD) remains unknown. The purpose of this study is to investigate the expression of Cyr61 in patients with IBD.
Aims and Methods: We achieved the colonic mucosae from 23 patients with IBD who had undergone colonoscopy. We measured the expression of Cyr61 and inflammatory markers in the biopsy specimens using the real-time PCR. And, we determined the expression of Cyr61 in LPS (Lipopolysaccharide) -treated colonic epithelial cells (Caco-2 and HCT 116).
Results: Expression of Cyr61 in the inflamed mucosae was 2.5 times higher than that of the non-inflammed mucosae ($p = 0.002$). Expression of TNF(tumor necrosis factor)-a, IL(interleukin)-6 and TLR(toll-like receptor)-4 increased significantly in inflamed mucosae than that of the non-inflamed mucosae (all $p < 0.05$). Time-dependent increase in Cyr-61 expression was observed in Caco-2 and HCT 116 after the treatment with LPS.
Conclusion: Our results reveal a novel mechanism suggesting the role of Cyr61 and therapies targeting Cyr61 in patients with IBD.

Introduction: Epithelial-to-mesenquimal transition (EMT) is a process which allows a switch of the phenotype from epithelial cells towards a fibrotic behavior. This process has been widely associated with the development of fistulas, a complication in IBD patients associated with an activation of the inflammation. Under inflammatory conditions, the metabolite succinate is accumulated and its receptor, called SUCNR1, mediates profibrotic responses in hepatic stellate cells; however, there is no study analyzing its role specifically in epithelial cells and in EMT.
Aims and Methods: We aim to analyze the role of succinate and its receptor in EMT.
HT-29 intestinal epithelial cells were treated with different concentrations of succinate (0, 0.1, 0.5, 1, 5mM) or TGF-β (5ng/ml) during 48 hours. In some experiments, HT-29 cells were transfected with a specific SUCNR1 siRNA or with a negative control siRNA using Lipofectamine. The expression of EMT markers (Snail1, Snail2, Vimentin and E-Cadherin) was analyzed by qPCR and Western Blot. Intestinal fibrosis was induced *in vivo* using the heterotopic transplant model. Briefly, one intestinal graft from WT or KO mice was transplanted into the neck of a receptor mice for 7 days. The expression of EMT markers was analyzed by qPCR. Intestinal resections from CD patients were obtained and the expression of SUCNR1, Snail1, Snail2 and E-Cadherin was analyzed by qPCR. Results are expressed by mean ± SEM ($n \geq 5$). Statistical analysis was performed with one-way ANOVA followed by Newman-Keuls test. Correlations were analyzed with the Spearman coefficient.
Results: In HT-29 cells, succinate induces in a dose-dependent manner: a) a significant increase in both mRNA and protein levels of SUCNR1; b) a significant increase in the mRNA expression of Vimentin, Snail1 and Snail2 and c) a significant reduction in the mRNA and protein expression of E-Cadherin. In HT-29 cells transfected with SUCNR1-specific siRNAs, the mRNA expression of Vimentin, Snail1 and Snail2 induced by succinate was significantly lower than that detected in HT-29 transfected with negative control siRNA (1.12 ± 0.12 vs 1.87 ± 0.09, 0.90 ± 0.09 vs 1.85 ± 0.18, 1.07 ± 0.26 vs 2.57 ± 0.19, respectively). In murine intestinal fibrotic tissue from WT mice we detected, seven days after transplantation a significant increase in the mRNA expression of Vimentin (3.50 ± 0.48), Snail1 (4.87 ± 0.79) and Snail2 (2.45 ± 0.25) and a significant reduction in the expression of E-Cadherin (0.60 ± 0.06) compared with that detected at day 0 (1.01 ± 0.07, 1.06 ± 0.13, 1.04 ± 0.10, 1.00 ± 0.04 respectively). In intestinal tissue from SUCNR1-/- mice, 7 days after transplantation we detected no significant changes in the expression of Vimentin, Snail1, Snail2 and E-cadherin vs KO-grafts at day 0 and levels of these markers were significantly lower than those detected in WT mice at day 7. Finally, SUCNR1 expression positively and significantly correlates with the expression of Snail1 ($r_{Spearman} = 0.6925$, $p < 0.0001$, $n = 36$) and Snail2 ($r_{Spearman} = 0.6305$, $p < 0.0001$, $n = 36$) in intestinal resections from CD patients.
Conclusion: Succinate activates EMT in intestinal epithelial cells through its receptor SUCNR1, which identifies a new molecular mechanism involved in EMT and points to a new possible target for fistula-treatment.

P0902 ECTOPIC EXPRESSION OF REG3A IN THE MICE DISTAL COLON IS MEDIATED BY INTERACTIONS BETWEEN NOTCH AND IL-22 SIGNALING PATHWAYS, AND PROMOTES TISSUE REPAIR BY THE AUGMENTATION OF EGFR SIGNALING

Introduction: Members of the Reg gene family share common upstream regulation pathway mediated by the IL-22-STAT3 axis, and encode multifunctional secretory proteins. Each Reg gene shows a distinct region-specific expression pattern in the colon. For example, REG3A is exclusively expressed in the intestinal epithelial cells (IECs) of the mouse proximal colon. In contrast, disease-active ulcerative colitis or Crohn's disease patients show ectopic expression of REG3A in rectal IECs. Those ectopically expressed REG3A may contribute to initiating tissue repair partly through its ROS scavenger activity. In our previous study, we have demonstrated the importance of Notch signaling in colonic tissue repair, and also its dominant role in IL-22-induced Reg gene family expression. However, the precise role of Notch signaling in "ectopic" expression of REG3A, or the comprehensive functional role of REG3A in the inflamed colonic environment is poorly understood.
Aims and Methods: The role of Notch signaling in REG3A expression was examined by immunohistochemical analysis of REG3A and HES1 in Villin-cre^{ER}; RBP-J$^{fl/fl}$ (RBP-J$^{\Delta IEC}$) mice and wild-type (WT) mice, under homeostatic and DSS-induced colitic conditions. Organoid culture system was used to analyze colonic region-specific regulation of REG3A expression, in regard to extrinsic IL-22 stimulation or intrinsic Notch signaling activity. To evaluate the direct effect of REG3A on IECs, organoid re-construction assay was performed under the presence of recombinant mouse REG3A. Those REG3A-treated organoids were also subjected to microarray analysis and immunoblotting to identify the IEC-intrinsic molecular pathway (s) regulated by REG3A.
Results: Under homeostatic condition, REG3A was specifically expressed in the proximal colon of WT mice. However in RBP-J$^{\Delta IEC}$ mice, IEC-specific deletion of RBPJ resulted in complete loss of both Hes1 and REG3A expression in the proximal colon. In DSS-colitis mice, REG3A was ectopically expressed by rectal IECs during the mucosal regeneration phase. In vitro analysis using distal colon-derived organoids confirmed IL-22-induced REG3A expression via STAT3 phosphorylation, which was completely cancelled by DBZ-mediated blockade of Notch signaling. Immunoprecipitation assay further revealed the direct interaction between STAT3 and HES1 in distal colon-derived organoid IECs. Furthermore, addition of recombinant mouse REG3A clearly promoted the organoid re-construction efficiency of single isolated distal colon-derived IECs. Microarray analysis of REG3A-treated distal colon-derived organoids revealed enhancement of EGF signaling pathway by REG3A, which was confirmed by immunoblotting analysis demonstrating REG3A-induced phosphorylation of EGFR and AKT. Consistently, addition of REG3A efficiently rescued the organoid re-construction ability of distal colon-derived IECs under a EGF-depleted environment.
Conclusion: Ectopic expression of REG3A in the inflamed distal colon is mediated by the interaction between IL22-STAT3 and Notch-Hes1 pathways. Ectopically secreted REG3A functions as a positive regulator of IEC-intrinsic EGF signaling, and thereby contribute to the repair of the inflamed colonic epithelium.

P0903 3,25-$(OH)_2D_3$ STIMULATES NHE8 EXPRESSION *VIA* ERK1/2 SIGNALING PATHWAY IN DSS COLITIS MICE

X. Li, C. Geng, X. Lei, C. Wang
West China Hospital of Sichuan University, Department of Gastroenterology, Chengdu, China

Contact E-Mail Address: lixiao5166@hotmail.com
Introduction: Vitamin D (VitD) and vitamin D receptor (VDR) have been regarded as protective factors for colonic mucosa in ulcerative colitis (UC) patients. Recent epidemiological studies have suggested that UC patients commonly suffered from VitD deficiency. However, the potential molecular mechanisms by which VitD/VDR protects colonic mucosa in UC remain poorly understand. Sodium/hydrogen exchanger 8 (NHE8) is reported to play a protective role in colitis, and we have previously found that stimulating NHE8 expression could ameliorate mucosal injury in dextran sulphate sodium salt (DSS) colitis mice. However, whether NHE8 involves in VitD/VDR-mediated mucosa protection is still unclear.
Aims and Methods: The main objective of this study is to test whether VitD/VDR protects colonic mucosa through mediating NHE8 expression. VitD-deficient mice were established by feeding VitD-deficient chow for 8 weeks. VitD supplementary mice were gavaged with 1,25-$(OH)_2D_3$ (0.2ug/25g/d) daily for 7 days in the eighth week. DSS colitis mice were induced by drinking 3% DSS containing water *ad libitum* for 7 days; treatment mice received 1,25$(OH)_2D_3$ (0.2ug/25g/d) daily intragastrically three days prior to DSS administration. The histological score and disease activity index (DAI) score were assessed, respectively. For mechanism study, caco-2 cells were incubated with TNF-α (100ng/ml) for 18 hours to induce inflammation and followed by incubating with ERK1/2 specific inhibitor PD98059 (25μM) for 1 hour.
Results: NHE8 protein expression was significantly decreased in VitD-deficient mice compared with the control (1.74 ± 0.06 vs. 2.02 ± 0.06, $n = 6$, $p < 0.05$). However, 1,25-$(OH)_2D_3$ supplementation effectively recovered NHE8 expression compared with VitD-deficient mice (2.12 ± 0.09 vs. 1.74 ± 0.06, $n = 6$, $p < 0.05$). In DSS colitis mice, the colonic histological score and DAI score were dramatically increased compared with the control ($n = 16$, $p < 0.05$), respectively. Whereas, 1,25$(OH)_2D_3$ treatment obviously declined the histological score and DAI score compared with DSS colitis mice ($n = 22$, $p < 0.05$). Moreover, DSS administration remarkably compromised NHE8 expression compared with the control (1.24 ± 0.11 vs. 1.73 ± 0.11, $n = 16$, $p < 0.05$), but that 1,25$(OH)_2D_3$ treatment partly restored NHE8 expression from 1.24 ± 0.11 to 1.65 ± 0.19 ($n = 22$, $p < 0.05$). Of note, Pearson correlation analysis showed that colonic NHE8 protein expression was positively associated with VDR ($R = 0.628$, $p < 0.0001$, $n = 28$). Furthermore, 1,25$(OH)_2D_3$ treatment significantly suppressed DSS induced ERK1/2 phosphorylation levels (0.42 ± 0.03 vs. 0.54 ± 0.02, $n = 22$, $p < 0.05$). In caco-2 cells, TNF-α intervention significantly downregulated NHE8 (0.43 ± 0.03 vs. 0.94 ± 0.12, $n = 3$, $p < 0.05$) and VDR (0.46 ± 0.03 vs. 0.63 ± 0.06, $n = 3$, $p < 0.05$) proteins expression compared with the control cells. Consistently, 1,25$(OH)_2D_3$ treatment dramatically upregulated NHE8 (0.78 ± 0.09 vs. 0.43 ± 0.03, $n = 3$, $p < 0.05$) and VDR (0.76 ± 0.05 vs. 0.46 ± 0.03, $n = 3$, $p < 0.05$) proteins expression compared with TNF-α treated cells. In addition, in TNF-α pretreated cells, PD98058 dramatically upregulated NHE8 expression from 0.21 ± 0.02 to 0.44 ± 0.04 ($n = 3$, $p < 0.05$).
Conclusion: The present study suggested that NHE8 decrease is responsible for colonic mucosa injury caused by VitD deficiency. 1,25$(OH)_2D_3$ supplementation could ameliorate DSS colitis via VDR-ERK1/2-NHE8 pathway.

P0904 ASSESSMENT OF AUTONOMIC FUNCTION IN INFLAMMATORY BOWEL DISEASE BY HEART RATE SPECTRAL ANALYSIS

J. Ma, X. Zhao, H. Zhang
The first Affiliated Hospital of Nanjing Medical University, Gastroenterology, Nanjing, China

Contact E-Mail Address: mjj7698@126.com
Introduction: Heart rate variability (HRV) are used to evaluate of autonomic dysfunction in various clinical disorders. In this study, we examined HRV in patients with inflammatory bowel disease (IBD) to evaluate autonomic nerve function.
Aims and Methods: A total of 136 IBD patients (98 Crohn's disease and 38 ulcerative colitis) from the First Affiliated Hospital of Nanjing Medical University were evaluated. Demographic data and clinical characteristics were collected. HRV in IBD patients were compared with those in the healthy controls. HRV parameters the power of high-frequency (HF) and the ratio of HF and low frequency (LF), reflects vagal/sympathetic balance were assessed.
Results: The power of HF component was significantly decreased in CD ($n = 98$), UC ($n = 38$) and IBD ($n = 136$) patients respectively, compared with health controls ($n = 16$) ($p < 0.001$). Patients with CD or UC in state of different disease activity had significantly lower levels of HF compared with health control. However, there was no significant differences of HF levels in mild CD, moderate and severe CD patients. UC patients also had the same alterations at stage of different disease activity.
Conclusion: Altered HRV were found in both CD and UC patients, implicated impaired autonomic function in patients with IBD.

P0905 CLASS-1-HISTONE DESACETYLASES AS A NEW THERAPEUTIC TARGET FOR THE CONTROL OF ADHERENT-INVASIVE E. COLI-INDUCED INTESTINAL INFLAMMATION

E. Gimier, **N. Barnich**, J. Denizot
Université Clermont Auvergne, Inserm U1071, INRA USC2018, M2iSH, Clermont-Ferrand, France

Contact E-Mail Address: nicolas.barnich@u-clermont1.fr
Introduction: Crohn's disease (CD) is a chronic inflammatory bowel disease with a complex etiology including genetic, environmental, infectious and also epigenetics factors. Adherent-invasive *E. coli* (AIEC) are clearly involved in triggering and maintaining ileal CD. AIEC bacteria adhere to the enterocytes through high affinity interaction between their variant type one pili and abnormally expressed CEACAM6 receptor on host cells. Once internalized, AIEC bacteria replicate within host cell (macrophages and intestinal epithelial cells). Intestinal mucosa colonization by AIEC alters intestinal barrier function, inducing chronic inflammation in CD patients. Controlling the invasion, intra-cellular replication and inflammatory response induces by AIEC could be a new promising strategy for CD patients. To date, no specific therapeutic targets were identified for AIEC positive CD patients.
Aims and Methods: The aim of this work are to (1) identify histone post-translational modifications altered during the course of AIEC colonization using intestinal epithelial cells (IECs) in culture infected by AIEC reference strain LF82 and non-pathogenic *E. coli* through immunofluorescence and western-blot approaches; (2) to assess the role of HDAC during infection using specific inhibitors (MS 275 and SAHA) on AIEC-intracellular replication in IECs cells and

during the course of colonization in humanized CEACAM6-expressing mice (CEABAC10 mice). These mice received SAHA intra-peritoneally for two weeks and were challenged with AIEC by oral gavage. Colonization was monitored for 3 days after infection (AIEC numbering in feces). AIEC associated to intestinal tissues were numbered at the time of sacrifice and inflammatory response was analyzed by ELISA.
Results: AIEC infection leads to an important increase in acetylated and crotonylated form of histone H3 in three different IECs lines. H3K9ac (acetylation) and H3K18cr (crotonylation) marks were significantly increased six hours after infection, in comparison to non-infected and non-pathogenic *E. coli*-infected cells. These observations suggest that AIEC infection could interplay with histone ''eraser''/''writer'' pathways leading to changes in genome organization in host cell. We focused the analysis on the erasers HDAC using pharmacological inhibition of HDAC. HDAC inhibitors pre-treatment of IECs led to a significant reduction of invasion and multiplication capacity of AIEC within IECs. Finally, in vivo approach using CEABAC10 mice treated with HDAC inhibitors revealed a decrease in AIEC colonization ability and decreased inflammatory response in the group treated with HDAC inhibitor compared to the untreated mice.
Conclusion: This work shows that AIEC infection alters the epigenetic landscape of host cell which could modify gene expression favoring the infection process. We reveal that pharmacological inhibition of HDAC limits AIEC colonization in vitro and in vivo in CEABAC10 mice and prevents intestinal inflammation, suggesting that HDAC could be an interesting target for controlling AIEC-induced intestinal inflammation in Crohn's disease patients.

Introduction: Long-term Inflammatory Bowel Disease (IBD) patients have a higher risk of developing colorectal cancer (CRC), namely, colitis-associated carcinoma (CAC). However, its tumorigenesis occurs differently from the model described for CRC tumorigenesis due to the active participation of inflammatory signaling pathways [1]. It is known that in CAC, cytokines such as TNF, PEG2, IL-6 and IL-1 can activate signaling pathways such as ERK, NFκB, PI3K-Akt and STAT3, promoting transformation and tumor progression [2,3]. However, most of the knowledge about CAC pathogenesis comes from mouse models, indicating the need for studies in human samples. Thus in this study we performed a comparative gene-expression analysis in surgical samples of IBD patients, and we intend to contribute to a better understanding of the carcinogenesis of CAC
Aims and Methods: Colon samples were collected from 60 patients divided in 6 groups: Control, Ulcerative Colitis (UC), Crohn's Disease-colitis (CD), UC- or CD-related CAC and CRC. Gene expression analysis was performed on RNA extracted from paraffin-embedded samples using the Nanostring amplification-free technique. A set of 624 genes related to immunology or epithelial barrier function and cell polarization was analyzed. Statistics and preliminary analyses were performed using the nSolver software and Pathway analysis was performed using the free platform ConsensusPathDB (http://ConsensusPathDB.org).
Results: The analysis of differentially expressed genes between CD-CAC and CD as well as UC-CAC and UC rendered 203 and 271 differentially expressed genes, respectively. Among the major up-regulated genes in both comparisons were genes related to inflammation and cell cycle progression, such as SPP1, DUSP4 and CCND1. Among the most down-regulated genes were cytokines, genes related to T-cell activation and to NFκB activation such as CXCL13, CD45RA, TNFRSF13B and TNFRSF17. The enrichment analysis of up-regulated genes resulted in 49 enriched pathway-based sets for UC-CAC and UC as well as 213 enriched pathway-based sets for CD-CAC and CD. Among the statistically significant pathways present in both analyses were pathways related to cancer, JAK STAT signaling pathway and cytokine-cytokine receptor interaction.
Conclusion: The customized gene expression panel offered a comprehensive analysis of the differences in expression between CAC and the underlying inflammatory diseases UC and CD. Identified upregulated or downregulated genes indicate signal transduction pathways that are crucial for CAC tumorigenesis, corroborating to the existing knowledge about CAC progression.
Disclosure: Nothing to disclose

Introduction: Accumulating data from animal models and clinical data from our group and others suggest beneficial effects of cannabis in the treatment of patients with inflammatory bowel diseases (IBD). Cannabinoid receptors are expressed on epithelial and immune cells throughout the gastrointestinal (GI) tract and CB2 immunoreactivityis specifically found in epithelium area of inflamed colonic tissue, thus suggesting a role for the endocannabinoid system inmodulating IBD disease activity. However, the mechanisms by which cannabis affects the inflammatory processes and/or the clinical presentation of IBD is not yet clear. Experimental mouse models of IBD have limited use in predicting the clinical relevance of therapeutic targets in relation to human IBD. Therefore, in the current study we used human-originated tissuemodelsto evaluate mechanisms for the beneficial effects of cannabis inpatients with IBD.
Aims and Methods: To investigate the effects of CB2 activation on colon epithelial cells, which are exposed to IBD microenvironment.
In the current study weused 2 biological systems: 1. mucosal samples were collected during endoscopy from inflamed and non-inflamed areas ofIBD patients. Samples were cultured for 7 hours with medium or CB2 agonist (JW-133, 10mM) or ethanol (the solvent). Samples (time 0, after 7hr) were analyzed for epithelial cells Ki67 (proliferation) and fragmented caspase 3 (apoptosis) expression by immunohistochemistry and quantified by ImageJ software. The secretomes of the explants were collected and analyzed for MMP9 activity (zymogram), which is known to impair colonic epithelial permeability.2) The effect of soluble IBD microenvironment and CB2 agonist directly on the epithelial cells was evaluated by culturing CaCO-2 (colon carcinoma cells) for 48hr with secretomes collected from the biopsies (treated with JW-133 or ethanol) and analyzing their effects on the cells' viability (alamar-blue), number (automatic cell counter), death (trypan blue) and migration (scratch assay). All experiments were done at least 3 times.
Results: We found: I. Higher epithelial cell proliferation in biopsies obtained from healthy areas of the colon compared to biopsies from inflamed areas (Ki67 expression: 64 vs 32%, $p < 0.05$). No difference was found in apoptosis (expression of caspase 3) between the two areas (both at time 0 and 7hr). II. Higher level of MMP9 activity was found in secretomes collected from inflamed biopsies in comparison to non-inflamed areas (79%↑, $p < 0.05$). III. Treatment with CB2 agonist (JW-133) returned epithelial Ki67 and MMP9 activity levels of the inflamed area to the level of the non-inflamed areas. IV. Secretomes collected from the inflamed biopsies, significantly ($p < 0.05$) reduced CaCO-2 cell viability (30%↓), number (40%↓) and migration (45%↓), while secretomes collected from CB2 agonist treated biopsies reversed these cell characteristics to the control levels (all $p < 0.05$). Direct addition of CB2 agonist (in the same concentration) to the CaCO-2 cells had no effect on theirviability and number, yet it facilitated cell migration (40%, $p < 0.05$).
Conclusion: Our study demonstrated in a human *ex-vivo* and *in-vitro* human models that cannabinoids alter epithelial cells phenotype in a way that may facilitate mucosal healing.

Introduction: Interleukin 10 (IL-10), representing the anti-inflammatory mechanisms of the human body, is a well-known marker used to characterise the course of ulcerative colitis (UC). Although many mechanisms of UC are well understood, some of them still remain unclear, including the exact factors that could attribute to better prognosis and more favourable outcome of the disease.
Aims and Methods: The aim of the study was to determine the association between the systemic anti-inflammatory state of the body and UC disease length and analyse the possible factors attributing to that. A cross-sectional

study was conducted analysing all patients with clinically, endoscopically and histologically confirmed UC diagnosis previously hospitalized in two largest tertiary medical care centres in Riga, Latvia during a 6-year period (2012–2017). Patients participated in out-patient interviews, blood samples were obtained and analysed for IL-10 using ELISA, UC disease activity was evaluated according to the full Mayo score.
Results: Out 65 UC patients – 34 (52.3%) male and 31 (47.7%) female patients with the mean age of 41.95 (SD = 15.1) years, who enrolled in the study – only one (1.5%) had increased IL-10 levels (more than 20 pg/ml). The levels of IL-10 in the study group ranged from 0 pg/ml to 55 pg/ml with a mean of 3.4 (SD = 7.9) pg/ml. Statistically significant negative correlation (RS = −0.35; p = 0.004) was found between IL-10 levels and the number of years since the patient experienced their first UC symptoms, showing that the longer the patient had UC, the lower their IL-10 levels were. The mean age when the first UC symptoms appeared in the study group was 32.1 (SD = 14.6) years, ranging from 2 to 48 years. The possible confounding factors that could influence the IL-10 levels in these patients, including UC disease activity, UC treatment, UC complications, the number of UC exacerbations, patient's BMI, smoking history, concomitant diseases, previous hospitalizations and CRP levels did not show any statistically significant effect. The only exception was systemic corticosteroid use, were IL-10 levels were significantly higher – 8.93 (SD = 13.84) in patients who had received Methylprednisolon therapy in the past 12 months, comparing to the patients who did not receive Methylprednisolon in the last 12 months – 1.65 (SD = 3.8) (p = 0.004). This finding is well known and described in the literature before. 81.5% (n = 53) of the study group had received conservative UC treatment in the last 12 months and 23% (n = 15) of the patients had received systemic corticosteroids in the last 12 months.
Conclusion: Patients with shorter UC disease history may still have well working anti-inflammatory defence mechanisms (elevated IL-10 levels), which however decline over the course of the disease. This could be valuable knowledge, when recommending to diagnose and treat UC patients as soon as possible, so that the course of the disease is not getting worse and more advanced treatment options have to be used.

Introduction: Inflammatory Bowel Disease (IBD) with colonic involvement has been associated to an increased colorectal cancer (CRC) risk – several guidelines recommend screening/surveillance strategies based on the early detection of dysplasia in colorectal mucosa. However, agreement in the definitions of IBD associated dysplasia or sporadic dysplasia in IBD patients is far from ideal. IBD associated carcinogenesis has distinctive features – some data favors the importance of abnormal DNA methylation.
Aims and Methods: This study aims to define methylation patterns of several genes presumably implicated in colorectal carcinogenesis, in patients with a CRC or colonic dysplasia diagnosis following an IBD diagnosis.
In the pilot phase, 25 samples from colonic mucosa with and without dysplasia from 3 patients with IBD associated dysplasia (multifocal/on random biopsies/lesions with ill-defined limits) and 3 patients with IBD and sporadic dysplasia were studied. The Cpg islands methylation patterns of 70 genes' promoter regions were analyzed by the MS-MLPA (methylation-specific multiplex ligation-dependent probe amplification) technique, using commercial kits (ME001, ME002, ME004, ME011, ME042) and Coffalyser.NET (MRC-Holland®) software.
Results: *NEUROG1, IGF2, CDKN2B, CDH13, ESR1, WT1, GATA5, GATA4, SFRP1* and *TERT* genes' promoters were frequently methylated. Regarding *ESR1* and *SFRP1* genes, dysplasia/CRC samples showed more frequent methylation (6/10 *vs.* 3/15); all high-grade dysplasia and CRC samples showed *SFRP1* gene methylation. The same tendency was seen for the *IGF2* gene (7/10 *vs.* 2/15); the 2 samples without dysplasia that showed methylation were active disease samples. No methylation pattern differences were seen between CRC/dysplasia samples and the remainder in any other genes.
Conclusion: Methylation analysis, particularly in the *ESR1*, *SFRP1* and *IGF2* genes, may contribute to the prediction of CRC risk in IBD – to be further tested in a larger number of patients/lesions.

Introduction: The dextran sulfate sodium (DSS)-induced model of colitis is frequently used as a preclinical model of inflammatory bowel disease (IBD). The chronic phase of DSS-induced colitis shares pathophysiological aspects of human ulcerative colitis (UC). Therefore, DSS-induced colitis is suitable for evaluating the therapeutic potential of treatments for UC. However, some treatments for IBD, such as prednisolone (PSL), show poor efficacy or even worsen colitis in the rodent model. Differences in inflammatory/immune mechanisms between humans and rodents are potential sources of this issue. Nonhuman primates are phylogenetically closer to humans than rodents and useful in investigating mucosal immunity.
Aims and Methods: In the current study, a nonhuman primate model of chronic colitis was created and the effect of PSL was assessed in this model. Eight male cynomolgus macaques were used. Macaques were allowed free access to 0.25% DSS in distilled water. Daily total intake of DDS-water was 100 mL/kg. One treatment cycle consisted of DSS-water for 2 weeks followed by 2 weeks without DSS-water. Macaques underwent a total of three treatment cycles. A modified Mayo score (0–12) was used to quantify the extent of colitis. The sum of the following parameters was calculated: stool consistency (0–3), gross bleeding in stool (0–3), colonoscopy examination (0–3), and general symptoms (0–3). Endoscopic findings were also classified according to the Rachmilewitz Endoscopic Index (EI, 0–12). Fecal calprotectin was measured using an ELISA kit. Macaques received either vehicle (control, N = 4) or PSL (treatment, N = 4). Prednisolone (1 mg/body, BID) was administered for 14 days during the third DSS-water treatment cycle.
Results: In the control group, during all three cycles of DSS treatment, increased feces scores (stool consistency and fecal bleeding) were observed. Colonoscopy revealed reduced vascularization and mucosal erythema, edema, and erosion in the mucosa of the rectosigmoid colon in three macaques. Ulceration of colonic mucosa was observed in one macaque. Similar modified Mayo scores (mean ± SEM), indicating moderate severity, were observed during all three cycles (Cycle 1, 4.0 ± 0.0; Cycle 2, 3.5 ± 0.6; Cycle 3, 4.2 ± 0.6). The EI indicated consistent and moderate colitis severity during all three DSS treatment cycles (Cycle 1, 4.3 ± 0.5; Cycle 2, 4.5 ± 0.6; Cycle 3, 5.5 ± 1.3). In between DSS treatments, Mayo scores recovered to the remission level. In the PSL-treated macaques, mean Mayo scores during the first and second DSS-treatment cycle were similar to that of the control group. However, a significantly lower score was obtained in the third DSS-treatment cycle (1.8 ± 0.5). The mean EI for PSL-treated macaques was also lower (1.8 ± 0.6) than of the control-treated macaques. Mean fecal calprotectin was higher in the control group compared to that of naïve macaques. By contrast, fecal calprotectin values of the PSL-treated animals indicated remission (< 70 μg/g).
Conclusion: A chronic DSS-induced colitis model was developed in macaques that showed similar symptomatic and endoscopic features to those seen in clinical UC, including repeated relapse and remission. In this model, PSL clearly inhibited disease relapse. Therefore, the macaque model, compared to the rodent model, could show better predictiveness of clinical outcome of compounds that are currently under evaluation for the treatment of UC.

Introduction: Among extraintestinal complications of inflammatory bowel diseases, pulmonary manifestations are rarely recognized in clinical practice. Exhaled nitric oxide (eNO) is an established biological marker of airway inflammation, one that can be potentially used to identify these manifestations.
Aims and Methods: Fractional eNO (FeNO) was measured in multiple flows, allowing us to assess alveolar concentration (C_ANO) and bronchial flux (JawNO) of nitric oxide in 27 patients with inflammatory bowel disease (17 with Crohn's Disease and 10 with Ulcerative Colitis) and in 39 healthy controls. Patients or healthy controls exhibiting factors that have been correlated in past studies with eNO measurements were excluded from the study. In patients with Crohn's Disease, Crohn's Disease Activity Index (CDAI) was used to define clinical disease activity, while Partial Mayo Score was used in patients with Ulcerative Colitis.
Results: Patients with inflammatory bowel disease had significantly higher C_ANO, compared to the control group (p < 0.0001). FeNO was significantly increased in patients with inflammatory bowel disease (p = 0.023), while there was no statistical significance found regarding levels of JawNO in patients with inflammatory bowel disease (p = 0.106), both compared to controls. Patients with Crohn's disease in clinical remission (CDAI < 150, n = 12) or patients

with UC that had inactive or mild disease (Partial Mayo Ranking of 0 or 1, n = 8), had significantly higher C_ANO levels compared to the control group (p = 0.024 and p = 0.005 respectively). None of the eNO components was correlated with markers of disease activity (CDAI, Partial Mayo score, CRP, ESR).
Conclusion: There seems to be a significant elevation of the alveolar concentration of nitric oxide in patients with inflammatory bowel disease, regardless of disease activity. Alveolar concentration of nitric oxide has been shown to be a marker of small airway inflammation. This may suggest that subclinical small airway inflammation is present in patients with inflammatory bowel disease, even those with mild or inactive disease.

Introduction: Vitamin D signals through the vitamin D receptor (VDR) which is a member of the nuclear receptor family of transcription factors that play an immunoregulatory role in the gut. Vitamin D deficiency is associated to Crohn's disease (CD).
Aims and Methods: The aim was to analyse the levels of VDR in murine and human intestinal fibrosis. We used intestinal tissue from CD patients as well as epithelial cells and fibroblasts isolated from intestinal tissue. Control tissue and control cells were obtained from the non-damaged intestine of patients with colorectal cancer. Fibroblasts were treated with 1,25 Vitamin D_3 (100nM) for 24 hours. A murine model of intestinal fibrosis was established by the transplant of one intestinal graft from C57BL/6 mice into the neck of receptor mice for 7 days. VDR, pSTAT3, STAT3 protein levels were determined by Western Blot and VDR and CYP24A1 gene expression by qPCR. Statistical significance was measured by t-test.
Results: VDR protein levels were significantly lower in intestinal tissue, epithelial cells and fibroblasts obtained from CD patients than that the obtained from controls (18.7 ± 9.1 vs 100 ± 35.1, 48.5 ± 23.9 vs 100 ± 3.7, 57.2 ± 13.2 vs 100 ± 16.7, respectively). Vitamin D_3 significantly increased the mRNA and protein expression of VDR and CYP24A1 (a VDR gene target) in human isolated fibroblasts. In the murine model of intestinal fibrosis, compared with control, we detected reduced VDR protein levels (18.5 ± 9.8 vs 100.3 ± 25.9) and increased levels of the ratio pSTAT3/STAT3 (149 ± 10 vs 100 ± 1).
Conclusion: Our study indicates reduced VDR protein levels in murine intestinal fibrosis and intestinal tissue from CD patients. Diminished VDR protein levels were also detected in isolated epithelial cells and fibroblasts from human intestine in which exogenous administration of Vitamin D_3 increases the VDR signaling pathway.

P0913 CLINICAL ASPECTS AND PROGNOSES OF PATIENTS WITH INFLAMMATORY BOWEL DISEASE AND AUTOIMMUNE LIVER DISEASE

H.C. Rocha, E.G. Vilela
Faculdade de Medicina da Universidade Federal de Minas Gerais, Instituto Alfa de Gastroenterologia, Belo Horizonte, Brazil

Contact E-Mail Address: henriquecarocha@gmail.com
Introduction: Inflammatory bowel diseases (IBD) are associated with autoimmune liver diseases (AILD) and numerous studies have been published, however, almost all of them have focused on Primary Sclerosing Colangitis (PSC).
Aims and Methods: This is a retrospective, observational, case-control study aimed to evaluate the clinical features of PSC and non-PSC autoimmune diseases in patients with IBD and compare the course of both groups. Distribution of data was assessed for normality test (Shapiro-Wilk), chi-square test was used to assess the association between variables and variables with $p < 0.2$ were included in regression binary logistic model. p values < 0.05 were considered statistically significant.
Results: Fifty-four patients were included. The median age was 34 years (17–74) and 31 were males (53.4%). Ulcerative colitis was present in 48 patients (88.8%) and Crohn's disease in six (11.2%). The follow-up time median was 8 years (1–28 years). PSC was present in 35 patients (64.8%). Non-PSC in 19 (35.2%), and it was: autoimmune hepatitis in seven patients; five patients had autoimmune hepatitis with PSC; variant type of autoimmune hepatitis with cholestasis was present in two; autoimmune cholangiopathy and primary biliary cholangitis were present in two patients each and one patient had autoimmune hepatitis with PSC small duct. The median IBD diagnosis time was 5 years (1–30). The median of liver disease diagnosis time was 7 years (1–26). Thirty-three patients underwent liver biopsy and of these, 19 (57.5%) were staged as F0 or F1 of Metavir Classification and 14 (42.5%) were F2-F4. Portal hypertension was observed in 19 patients at diagnosis. Twenty-two patients were submitted to liver transplant. Colon adenocarcinoma was detected in one patient and there were six deaths of all patients. There was no difference between two groups in regard diagnosis time, drug therapy, liver disease staging, liver transplantation and need for proctocolectomy and death. When multiple logistic regression was performed to evaluate factors associated with liver transplant it was observed that only the liver disease diagnosis time persisted with $p < 0.05$ (p = 0.001). The value of Odds Ratio was 1.792 (95% CI 1.689–1.911). Regarding the need for surgery to approach IBD, the time of diagnosis of IBD remained in the final model (p = 0.041; Odds Ratio 1.861 – 95% CI 1.745–1.994). Other variable that was analyzed was the recurrence of IBD after liver transplantation: the diagnosis of autoimmune hepatitis remained in the final model (p = 0.012; Odds Ratio 7.1 (95% CI 1.215–42.43).
Conclusion: Clinical features and evolution of both groups were the same, but this population had liver transplant chance increased by 20.1% for each year of diagnosis of liver disease. Besides, how longer was the time of IBD diagnosis, the chance of needing surgical treatment is greater and patients with previous diagnosis of autoimmune hepatitis have increased in 7 times the chance of *de novo* IBD

Introduction: Despite uncertain pathogenesis of IBD, deregulation of the mechanisms of adaptive immunity, including excessive T-cell responses towards gut microbiota as well as lymphocyte resistance to desensitization signals, is paramount for the initiation and perpetuation of inflammatory response. Essential role in the resolution of inflammation is played by apoptosis, which is strictly regulated by among others transcription factor p53 and the members of Bcl-2 family. An increased level of anti-apoptotic mediators as well as an aberrant response to pro-apoptotic signals have been previously observed in lymphocytes isolated from intestine in IBD whereas little is known about the susceptibility to apoptosis of peripheral lymphocytes (PBLs).
Aims and Methods: Study was performed to evaluate the concentrations of p53, cytochrome c and Bcl-2 in PBLs in healthy volunteers and IBD patients with respect to the disease type and activity. Diagnostic utility of apoptosis mediators using ROC analysis was assessed as well.
A group of 64 individuals was enrolled: 42 IBD patients (25 ulcerative colitis (UC) and 17 Crohn's disease (CD)) from the Department of Gastroenterology and Hepatology, Wroclaw Medical University and 22 apparently healthy volunteers. Cytochrome c, Bcl-2 and p53 were quantified immunoenzymatically in lysates of peripheral lymphocytes.
Results: The concentrations of Bcl-2 in PBLs from IBD patients were significantly lower as compared to healthy volunteers (17 vs.35 ng/ml, $p < 0.001$) without significant difference between CD and UC (p = 0.063) or disease activity in CD. However, patients with active UC had significantly lower Bcl-2 as compared to patients with inactive UC (18 vs. 28 ng/ml, p = 0.044). Also cytochrome c was lower in IBD than controls (294 vs. 406 ng/ml, p = 0.003) without significant difference between CD and UC (p = 0.060). Patients with active CD, but not UC, had significantly higher cytochrome c than these with inactive disease (213 *vs.* 75.5 ng/ml, p = 0.039). Yet, cytochrome c tended (p = 0.070) to increase along with increased Truelove and Witts severity index with 244, 339, and 349 ng/ml in mild, moderate and severe UC. In turn, p53 did not differ significantly between IBD patients and controls (p = 0.080) but was significantly lower in CD than UC (3.1 vs. 8.5 ng/ml, p = 0.039). There was no difference in p53 concentrations with respect to CD (p = 0.477) or UC (p = 0.351) activity. None of the apoptosis mediators correlated with CDAI or MDAI. In a whole cohort, there were positive correlations between Bcl-2 and p53 ($r = 0.56$, $p < 0.0001$) and cytochrome c and p53 ($r = 0.25$, p = 0.049). In subgroups, Bcl-2 and p53 were positively correlated in healthy controls ($r = 0.69$, $p < 0.001$) as well as CD ($r = 0.50$, p = 0.041) but not UC patients. Bcl-2 was characterized by good accuracy as an IBD marker (86% at ≤25 ng/ml) and p53 by moderate accuracy as a CD/UC differentiating marker (70% at ≤6.8 ng/ml).
Conclusion: IBD is associated with decreased concentrations of apoptosis modulators in peripheral lymphocytes and the deregulation seems to be more pronounced in CD. Bcl-2 has a good overall accuracy as an IBD marker while p53 is moderately accurate in differentiating CD from UC.

Introduction: The PRO-MC Collaboration is a European prospective registry for incident cases of Microscopic colitis (MC)[1]. Follow-up data from patients at 15 different European centres are accured to provide real life data on disease activity, treatment response, and long-term prognosis. One-year follow-up data on the first 71 patients are reported.

Aims and Methods: Incident cases of MC prospectively followed for 12 months were eligible for inclusion. Patient characteristics and data on pathology, medical history and performed diagnostics were registered at baseline. Disease activity, quality of life and treatment strategies were registered at baseline and after 3, 6 and 12 months. Data are reported numerically and as percentages. Non-parametric statistics were used

Results: By March 2018, 71 of 318 patients included in the registry had been followed for 12 months. Mean age 64 years, 70% females. In total, 52% had collagenous colitis (CC), 39% lymphocytic colitis (LC) and 8% incomplete MC (MCi).

At baseline 42 (59%) presented with active disease according to Hjortswang criteria[2]. Twenty (28%) were in remission due to budesonide initiated before baseline visit in the study, 9 (12%) were in spontaneous remission.

Treatment in patients with active disease at baseline was initiated in 29 patients, of which 19 were treated with budesonide. Ten patients were treated with bulging agents (cholestyramine, loperamide, fibres). Thirteen patients received no medical treatment. Patients were classified according to disease behaviour during the first year in four groups, see Table.

Patients with chronic active or chronic relapsing disease did not differ from patients with mild or quiescent disease concerning smoking habits or subtype of MC ($p > 0.05$, Chi-square). Quality of life (Short Health Score) improved significantly from baseline visit to week 52 in patients with mild/quiescent disease ($p = 0.02$, Wilcoxon). No improvement in quality of life was detected in patients with chronic relapsing disease.

Conclusion: The prognosis for MC after one year appears good. The majority of patients (63%) have a quiescent or mild disease course. Bulging agents and on-demand use of budesonide are frequently applied. The PRO-MC cohort will provide further information on long term prognosis, identify predictive factors for disease activity and generate proposals for new treatment algorithms.

Disease behaviour	Total N = 71	n CC / LC / MCi
Quiescent	Only one flare at onset of disease subsided spontaneously or after one course of budesonide, N = 19	12 / 6 / 1
Mild	Treatment with bulging agents or occasional use of budesonide on demand), N = 26	12 / 11 / 3
Chronic relapsing	Disease activity or budesonide treatment at ≥ two visits, N = 24	11 / 11 / 2
Chronic active	Disease activity or in budesonide treatment at every visit, N = 2	2 / 0 / 0

[Microscopic colitis disease behaviour during the first year after diagnosis]

P0916 OPPORTUNISTIC INFECTIONS ARE MORE PREVALENT IN PATIENTS WITH CROHN'S DISEASE AND ULCERATIVE COLITIS: A LARGE POPULATION-BASED STUDY

M.Z. Sheriff[1], E. Mansoor[1], **M. Dave**[1]
[1]*Case Western Reserve University School of Medicine, Internal Medicine/Gastroenterology, Cleveland, United States*

Contact E-Mail Address: maneeshdave@gmail.com

Introduction: Inflammatory bowel diseases (IBD) comprising of Crohn's disease (CD) and Ulcerative Colitis (UC) are chronic inflammatory disorders that have been associated with an increased risk of opportunistic infections (OIs)[1,2]. While OIs like Clostridium difficile have been extensively studied, there is limited data on the prevalence of other OIs in a large cohort of IBD patients.

Aims and Methods: The aim of this study was to investigate the epidemiology of seventeen OIs in IBD in a large, population-based database. Data was collected from a commercial database (Explorys Inc, Cleveland, OH, USA) that provided electronic health records (inpatients and outpatients) from 26 major integrated United States healthcare systems from March 2013- March 2018. We identified a cohort of patients with CD, UC, and OIs based on Systemized Nomenclature of Medicine – Clinical Terms. We compared the prevalence of seventeen OIs in this cohort of CD and UC patients to controls without IBD[2] and characterized the distribution of these OIs with age.

Results: Of the 35,420,110 individuals in the database, we identified 153,290 patients with CD and 128,540 patients with UC. The overall prevalence rate of CD and UC was 432.8/100,000 persons and 362.9/100,000 persons respectively. Both UC and CD patients had significantly increased odds for OIs compared to controls (OR, 2.87 in CD; $p < 0.0001$, and OR, 3.15 in UC; $p < 0.0001$). The OIs with the highest odds ratios (OR) in IBD patients were *Clostridium difficile* followed by cytomegalovirus and tuberculosis (Table 1 for ORs). The most prevalent opportunistic infections in IBD patients by numbers were candidiasis followed by *Clostridium difficile*, human papilloma virus, influenza, and herpes simplex virus (Table 1). Viral infections i.e influenza (OR, 2.56 in CD; $p < 0.0001$ and OR, 1.75 in UC, $p = 0.0001$) and Epstein-Barr virus [EBV] (OR 2.69 in CD; $p < 0.0001$, and OR, 2.82 for UC; $p < 0.0001$) were more common in children (< 18 years of age). On the other hand, fungal and bacterial infections i.e aspergillosis (OR, 2.93 in CD; $p < 0.0001$, and OR, 3.21 in UC; $p < 0.0001$), histoplasmosis (OR, 1.60 in CD; $p = 0.003$, and OR, 2.14 in UC; $p < 0.0001$) and pneumococcal disease (OR, 3.36; $p < 0.0001$, and OR, 3.09 in UC; $p < 0.0001$) were more prevalent in the elderly (> 65 years). Tuberculosis was more common in CD and *Clostridium difficile* and cytomegalovirus infections were more common in UC.

Conclusion: OIs are more prevalent in patients with CD and UC. Children with UC and CD tend to have a higher prevalence of viral OIs and older adults with UC and CD tend to have a higher prevalence of fungal and bacterial OIs.

Introduction: Diet may be involved in the pathogenesis of inflammatory bowel disease (IBD) but this is controversial, as is an association between IBD with celiac disease (1). Wheat sensitivity has been reported in Crohn's disease, and associated with more severe disease (2). A diet which excludes gluten (along with other dietary components) has been shown to induce clinical remission in 79% of treated patients with Crohn's disease (3). These findings suggest gluten may aggravate IBD.

Aims and Methods: The aims of this study were to evaluate if wheat sensitivity and celiac disease are risk factors for physician-diagnosed IBD in a general community and determine which symptoms and factors are associated with wheat sensitivity in IBD. A total of 3542 people randomly selected from the Australian population returned a mail survey (Digestive Health & Wellbeing Survey, response rate = 43%) which contained questions on gastrointestinal (GI) symptoms (present in the last 3 months), medical and lifestyle factors including a self-reported physician diagnosis of celiac disease and IBD. Response bias was minimal. Wheat sensitivity was defined as people without celiac disease who reported GI symptoms on wheat ingestion. Associations between categorical variables were evaluated using the Pearson chi-square test.

Results: The prevalence of IBD by self-report in our cohort was 1.9% (95% CI 1.5–2.5). Of those with IBD, 13% reported celiac disease compared with 1.2% of those without IBD (unaffected cohort) (OR 12.9, 95% 6.0–27.7). In addition 26.7% of those with IBD reported wheat sensitivity, compared with 14.8% of the unaffected cohort (OR 2.1, 95% CI 1.2–3.7, Attributable Risk 11.9% 95% CI 0.7–23.2). There was no significant association between wheat sensitivity in IBD and age (p = 0.27), gender (p = 0.16) or psychological distress (p = 0.93). There was a significant association with modified Rome IV criteria for functional dyspepsia (OR 3.49, 95% CI 1.03–11.82), particularly epigastric pain syndrome subtype (OR 4.11, 95% CI 1.15–14.73), but not irritable bowel syndrome. Symptoms significantly associated with wheat sensitivity in the IBD cohort included epigastric pain and constipation (see Table 1).

Conclusion: In this cohort, celiac disease and wheat sensitivity are both significantly associated with a diagnosis of IBD, and wheat sensitivity is associated with constipation and epigastric pain in particular. This suggests exacerbation of symptoms in IBD may be related to wheat sensitivity. These results suggest that it is worth testing for celiac disease in IBD, and asking patients whether wheat sensitivity worsens symptoms if the present results are confirmed.

P0918 LONGITUDINAL IMPACT OF IBS-TYPE SYMPTOMS ON DISEASE ACTIVITY, HEALTHCARE UTILISATION, PSYCHOLOGICAL HEALTH, AND QUALITY OF LIFE IN INFLAMMATORY BOWEL DISEASE

Introduction: Irritable bowel syndrome (IBS)-type symptom reporting in quiescent inflammatory bowel disease (IBD) is associated with anxiety, depression and reduced quality of life when compared with patients who do not report these symptoms (1,2). However, the impact of IBS-type symptom reporting on disease activity, healthcare use and psychological well-being over protracted follow-up is uncertain. This was addressed in a longitudinal study of secondary care IBD patients.

Aims and Methods: Longitudinal disease activity was defined by glucocorticosteroid prescription or disease flare identified by physician's global assessment, escalation of medical therapy, hospitalisation, or intestinal resection. The number of investigations performed and clinics attended determined healthcare utilisation. Psychological well-being, including assessment for the presence of anxiety, depression or somatisation, and quality of life, was determined using

validated questionnaires. These outcomes were compared over a minimum period of 2 years between patients reporting IBS-type symptoms and patients with quiescent disease, occult inflammation, and active disease at baseline. A χ^2 test was used to compare categorical variables and an independent samples t-test to compare continuous data. Due to multiple comparisons, a 2-tailed p value of <0.01 was considered statistically significant for these analyses. Independent predictors of the occurrence of any of the objective disease activity outcomes of interest were determined by performing multivariate Cox regression analysis to control for baseline demographic, disease related and psychological characteristics. Results were expressed as hazard ratios (HR) with 95% confidence intervals (CI).
Results: In 360 IBD patients, there were no differences in longitudinal disease activity between patients reporting IBS-type symptoms and patients with quiescent disease or occult inflammation. Glucocorticosteroid prescription or disease flare identified by physician's global assessment, and escalation of medical therapy, was more common in patients with active disease than in patients reporting IBS-type symptoms (HR = 3.16; 95% CI 1.93–5.19 and HR = 3.24; 95% CI 1.98–5.31, respectively). A significantly greater mean number of investigations were performed in patients reporting IBS-type symptoms than those with quiescent disease (p = 0.008), but not compared with patients with occult inflammation or active disease. Anxiety, depression, and somatisation scores at follow-up were significantly higher, and quality of life scores significantly lower, in patients reporting IBS-type symptoms when compared with patients with quiescent disease, but were similar to patients with active disease.
Conclusion: The reporting of IBS-type symptoms in IBD was associated with increased healthcare utilisation, psychological co-morbidity, reduced quality of life, but not adverse objective disease activity outcomes during longitudinal follow-up.

P0919 EVIDENCE OF A BI-DIRECTIONAL EFFECT OF THE BRAIN-GUT AXIS IN INFLAMMATORY BOWEL DISEASE

D.J. Gracie[1,2], P.J. Hamlin[1,2], E.A. Guthrie[3], A.C. Ford[1,2]

Introduction: Evidence to support the existence of a bi-directional relationship between the presence of mood disorders and gastrointestinal symptom reporting has been previously described (1,2). Whether a similar bi-directional relationship exists between psychological co-morbidity and disease activity in inflammatory bowel disease (IBD) is uncertain. We aimed to resolve this issue during longitudinal follow-up in secondary care patients.
Aims and Methods: The hospital anxiety and depression scale (HADS) and clinical disease activity indices were administered at baseline and after ≥2 years. Faecal calprotectin (FC) was collected at baseline. Objective markers of disease activity during longitudinal follow-up were assessed via case note review. These included glucocorticosteroid prescription or flare of disease activity defined by physician's global assessment, escalation of medical therapy, hospitalisation and intestinal resection. Brain-to-gut interactions were defined as development of new-onset disease activity in patients with quiescent disease and abnormal baseline HADS scores. Gut-to-brain interactions were defined as *de novo* abnormal HADS scores in patients with active disease and normal HADS scores at baseline. Multivariate Cox regression analysis was performed to control for baseline characteristics and duration of follow-up, with results expressed as hazard ratios (HRs) with 95% confidence intervals (CI).
Results: 405 (50.7%) of 799 patients with baseline data were followed up. Baseline clinical disease activity was associated with an almost six-fold increase in subsequent development of abnormal anxiety scores (HR 5.77; 95% CI 1.89–17.7). In patients with clinically quiescent disease at baseline, abnormal anxiety scores were associated with need for glucocorticosteroid prescription or flare of disease activity (HR 2.08; 95% CI 1.31–3.30) and escalation of medical therapy (HR 1.82; 95% CI 1.19–2.80), but not hospitalisation (HR = 1.59; 95% CI 0.77–3.31) or intestinal resection (HR = 0.79; 95% CI 0.22–2.84). Abnormal baseline anxiety scores remained associated with subsequent flare of disease activity or escalation of medical therapy when both normal clinical disease activity indices and FC $<250\mu g/g$ were used to define quiescent disease at baseline (HR = 2.29; 95% CI 1.03–5.07 and HR = 2.43; 95% CI 1.13–5.20, respectively). There was no association between depression and disease activity during longitudinal follow-up.
Conclusion: We provide evidence of a bi-directional relationship between psychological co-morbidity and disease activity in IBD, suggesting that brain-gut axis activity may have a significant effect on the natural history of IBD. These findings underline the need for the development of novel approaches towards IBD management, away from one that focuses solely on the management of inflammatory activity, to one that integrates this with the need for proactive management of psychological well-being. Novel therapeutic interventions are much needed.

Introduction: Inflammatory Bowel Disease (IBD) is a chronic disease with a significant burden of healthcare utilization and hospitalizations.
Aims and Methods: The aim of this study was to evaluate the causes of hospitalization and readmission, therapeutic intensification and surgery rates, in patients with Inflammatory Bowel Disease admitted to our department.
This was a retrospective study of all patients with acute exacerbation of Inflammatory Bowel Disease admitted in our department from January 2011 to December 2016.
Results: We included 446 admissions from 278 patients, 51% male, with mean age of 38.3 ± 14.3 years, 338 with Crohn's disease (CD) (47 newly diagnosis) and 108 with ulcerative colitis (UC) (21 newly diagnosis). The median time of hospitalization was 7 [5–10] days.
The large proportion of the patients (67.6%) with UC presented pancolitis, and in CD 46.5% had ileal involvement and 46.3% had penetrant disease. Twenty four percent took oral corticosteroids in the previous 3 months, 43.9% were under azathioprine and 20% under infliximab. The vast majority (95%) had had one clinic appointment in the previous 3 months.
The main causes of admission were acute exacerbation of CD (39.9%) e UC (24.2%), being 3 patients admitted to an intermediate care unit. The most common symptoms were abdominal pain (83%), diarrhea (54%), nausea (44%) and reduction in bowel movements (26%).
During the hospital stay, 65.2% were treated with intravenous corticosteroids, 41% with antibiotics, 14.8% with infliximab and one patient was submitted to surgery.
After discharge, more than an half needed to intensify therapy and 21.5% were submitted to surgery.
The readmission rate at 30, 90, 180 and 360 days were, respectively, 9.4%, 20%, 27.1% and 34.5%. The factors associated with readmission at 180-days were therapy with intravenous corticosteroids ($p < 0.05$) and reduction in bowel movements ($p < 0.05$).
Conclusion: Patients with Inflammatory Bowel Disease present with multiple exacerbations of the disease, needing multiple admissions and therapeutic intensification.
The readmission rate in patients with IBD is high and intravenous corticosteroids use during hospitalization ($p < 0.05$) and reduction in bowel movements ($p < 0.05$) were statically associated with 180-days readmission.

P0921 IS FATIGUE COMMON IN INFLAMMATORY BOWEL DISEASE AND IS IT A SEPARATE ENTITY?

K.R. Morrison[1], N. Reynolds[2], J. Todd[2], J. Paterson[2], C. Mowat[2], M. Groome[2]

Introduction: Fatigue in inflammatory bowel disease (IBD) is a significant problem, reported to affect between 44–86% of patients with active disease [1,2] and 22–54% of patients in remission [1–5]. Fatigue has been demonstrated to have a substantial effect on quality of life [4] with IBD patients reporting fatigue as one of their main concerns [6,7].
However, the aetiology and pathogenesis of fatigue in IBD is unknown. Proposed mechanisms frequently centre around inflammation but this does not fully explain the persistence of fatigue in quiescent disease.
Little consideration has been given to the idea that fatigue may be a separate entity: could it be possible that it is actually a result of chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME)?
Through our study, we wished to assess the burden of fatigue in a cohort of patients with IBD in Tayside and gain a better understanding of it by evaluating whether those reporting fatigue fulfilled criteria for CFS/ME.
Aims and Methods: We designed a questionnaire to assess the prevalence of fatigue in patients attending IBD clinics in Tayside and whether they met the diagnostic criteria for CFS/ME.
Given numerous guidelines for the diagnosis of CFS/ME exist we followed the recommendations from BMJ Best Practice and based our questionnaire on the following four criteria: Centres of Disease Control (CDC) which was the most widely used, International Consensus Criteria (ICC) which is the most widely accepted, Institute of Medicine (IOM) and the National Institute for Health and Care Excellence (NICE) guidance.
NICE guidelines, whilst suggested to be less clinically appropriate, were included as, in the UK, these may be the guidelines with which practitioners are most familiar.
All guidelines required specific patterns of fatigue in addition to associated symptoms; the biggest differences are in requirements for post exertional malaise and numbers of associated symptoms.
All patients attending the IBD clinics between 3rd−24th November 2017 were given the anonymous questionnaire to complete. Exclusion criteria were age < 16, incapacity and/or absence of an established diagnosis of IBD.

Questionnaire responses were analysed to determine whether the criteria for a diagnosis of CFS/ME in the context of each of the four guidelines had been reached.
Results: Of 130 patients approached, 113 met the inclusion criteria and 99 returned a completed questionnaire, forming the study group: 52 female; 47 male, median age 41 (range 18–84 years). 46 had Crohn's disease (CD), 38 ulcerative colitis (UC) and 12 IBD unclassified (3 did not state IBD type).
Fatigue was experienced by 65% (n = 64) and was more prevalent in CD than UC (74% vs 52%) and in females than males (77% vs 51%). 64% of those experiencing fatigue reported fatigue persisting in the absence of gastrointestinal symptoms.
Of these patients with fatigue, 26 patients (41%) with IBD fulfilled the NICE CFS/ME diagnostic criteria, 13 (20%) the ICC, 6 (9%) the IOM criteria and 13 (20%) the CDC criteria.
Conclusion: Fatigue is commonly reported in this population even when disease is reportedly in remission. Although there may be other confounding factors contributing to fatigue in our cohort, such as concurrent medication or co-morbidity, a small proportion nevertheless meet recognised diagnostic criteria for CFS/ME and this should not be overlooked when managing fatigue in IBD.

Introduction: Inflammatory Bowel Diseases (IBD) are associated with the variety of Extra-intestinal Manifestations (EIM), axial involvement is common. Sacroiliitis on different imaging modalities is detected in 20–50% of patients with IBD (both in ulcerative colitis (UC) and Crohn's Disease (CD)). Ankylosing spondylitis (AS) occurs in 1–10% of patients [1].
Aims and Methods: The aim of the study is to determine the prevalence of Spondyloarthritis (SpA), AS and incidence of Inflammatory Back Pain (IBP) according to ASAS criteria in patients with IBD and to analyze the clinical features in patients with SpA and IBD compared to patients with IBD alone.
The single-center observational cross-sectional study included 91 patients with IBD: 52 (57.1%) with UC, 39 (42.9%) with CD, males – 47 (51.6%), mean age – 40.2 years (95% CI 39.0 to 41.0), duration of IBD – 7.7 years (95% CI 5.9 to 8.1). Seven (7.7%) patients had an established diagnosis of AS. Inflammatory Back Pain (IBP) was determined according to ASAS criteria (2009), which include five clinical signs. If suspected with SpA, patients underwent X-ray and/or MRI of sacroiliac joints. Secondary SpA was diagnosed in compliance with ECCO recommendations, AS was defined according to the modified New-York Criteria (1984). Mann-Whitney test and Fisher's Exact Test were performed for group comparisons between patients with SpA and IBD and IBD alone, with $p < 0.05$ considered statistically significant. Univariate binary logistic regression models were constructed to assess the ORs.
Results: Chronic Back Pain was observed in 58 patients (63.7%), IBP was detected in 39 (42.9%) patients with IBD. Diagnosis of SpA was established in 26 (28.6%) patients. Significant sacroiliitis, sufficient for the diagnosis of AS according to modified New York criteria was found in 14 (15.4%) patients. Patients with CD had higher chance of being diagnosed with SpA compared to patients with UC (41.0% vs. 19.2%, OR 2.92 (CI 1.14–7.48)). In patients with a combination of IBD and SpA, the incidence of chronic back pain (41.3% and 0%, p = 0,00), arthralgia (45.7% and 15.4%, p = 0.29), arthritis (75% and 20%, p = 0.00) and inflammatory back pain (51.3% and 11.5%, p = 0.00) was higher compared to patients with IBD alone. Clinical and laboratory signs of IBD, such as frequency of bowel movement, abdominal pain, ESR, CRP and hemoglobin values, were similar between the groups. There was also no difference between the patients with SpA and IBD and with IBD alone in the duration of IBD, disease activity and smoking.
Conclusion: Almost half of the patients with IBD had signs of inflammatory back pain according to ASAS criteria; one-third of them was classified as SpA. Patients with CD had higher chance of having of SpA compared to UC. Performing of pelvis X-ray in patients with IBD increased the number of diagnosed cases of AS by twofold.

P0923 FACTORS ASSOCIATED WITH GUT COLONIZATION AND DECOLONIZATION WITH EXTENDED SPECTRUM BETA-LACTAMASE PRODUCING ENTEROBACTERIA IN ULCERATIVE COLITIS PATIENTS: PRELIMINARY STUDY RESULTS

V. Skuja[1,2], F. Bossmeyer[1], J. Malina – Bambite[1,2], L. Putnina[1], E. Tropina[1], D. Rudzite[2], E. Lavrinovica[2], A. Oscepkova[1], A. Krumina[1,2], A. Derovs[1,2], A. Lejnieks[1,2]

Introduction: Extended spectrum beta-lactamase producing Enterobacteria (ESBL-E) are the most frequently found multi-drug resistant bacteria colonizing the gut of ulcerative colitis (UC) patients.[1] Changes in the microbiome may act as a trigger in UC inflammation process. Previous studies have shown that gut colonization with ESBL-E might increase UC disease severity.[2]
Aims and Methods: The aim of the study was to analyze whether gut colonization with ESBL-E in UC patients is a constant state or changing over time and what are the factors attributing to that. A prospective study was conducted analysing patients with clinically, endoscopically and histologically confirmed UC diagnosis previously hospitalized in two largest tertiary medical care centres in Riga, Latvia. During the two study visits (2015 and 2017) the same patients participated in out-patient interviews regarding factors for gut colonization and decolonization with ESBL-E, UC disease activity was evaluated according to the full Mayo score (FMS), faecal samples were obtained and analyzed for ESBL-E presence according to EUCAST guidelines.
Results: 102 patients with UC participated in the fist study visit in 2015 and gut colonization with ESBL-E was found in 12% (n = 12) of the patients. 29 patients participated in the second study visit in 2017 and gut colonization with ESBL-E was found in 7% (n = 2) of the patients. The analyzed reasons for not participating in the second study visit showed that patients with previous gut colonization with ESBL-E were feeling bad (8 vs 1 patient) or had traveled abroad (17 vs 8 patients) more often at the time of the visit, comparing to the patients which were not previously colonized with ESBL-E. In between the two study years, two patients had become newly colonized with ESBL-E, whereas two other patients became decolonized. Patients who became newly colonized with ESBL-E were only women and were 11 years older in comparison to the patients who became decolonized. Both patients who become decolonized, had not used any antibiotics during the study period, while all the patients who became newly colonized with ESBL-E had used antibiotics during the study period. Patients newly colonized with ESBL-E had more exacerbations – 11, in comparison to decolonized patients, who only had 1 exacerbation during the study period. All patients who became colonized with ESBL-E had severe UC disease activity, while patients who became decolonized had either mild or moderate UC disease activity, according to the FMS. Also the mean FMS in patients who became colonized with ESBL-E was much higher – 11 (severe disease), comparing to the patients who became decolonized – 6 (moderate disease). There were no differences found in patients who became colonized and decolonized with ESBL-E regarding hospitalization times, UC conservative treatment and surgical interventions.
Conclusion: Gut colonization with ESBL-E in UC patients is not a constant state and is changing over time. Older age, female gender, previous antibiotic use, patients with more UC exacerbations and higher UC disease activity may act as risk factors for gut colonization with ESBL-E in UC patients. Inversely – younger age, male gender, abstention from antibiotic use, less UC exacerbations and lower UC disease activity may act as factors for gut decolonization from ESBL-E in UC patients.

Introduction: Previous reports have indicated that the clinical presentation and initial treatment of patients with elderly-onset inflammatory bowel disease (IBD), defined as patients diagnosed ≥60 years, differs from that of younger patients.

Aims and Methods: To assess the age-specific incidence, initial presentation and treatment of elderly-onset IBD, compared with IBD diagnosed in patients aged 15–39 and 40–59, in a European population-based inception cohort.

The EPI-IBD cohort is a prospective, population-based inception cohort of patients diagnosed 2010 and 2011 in 36 European and 1 Australian centres. Background population was available for 35 centres representing 14,119,004 person-years; incidence was calculated considering only the patients diagnosed in those centres. For this study, data regarding disease characteristics and medical or surgical treatment during the first three months from diagnosis were analysed. All data were entered in a secure web-based database, www.epi-com-ecco.eu. Early, intensive treatment was defined as the need of immunomodulators (IMM), biologicals or surgery. Patients were classified according to age at diagnosis into 15–39y, 40–59y and ≥60y, and the results are presented in this sequence.

Results: In total, 2000 IBD patients (53.6% males) were included in the cohort, 747 (37.4%) CD, 1106 (55.3%) UC and 147 (7.4%) IBDU. The CD incidence was 7.18, 3.95 and 2.70 cases/10^5, in each age group respectively ($p < 0.001$). The UC incidence rate was 9.58, 6.30 and 5.68, respectively (40–59y vs ≥60y, $p = 0.257$). In elderly-onset IBD, overall more patients were diagnosed with UC, and the frequency of proctitis at diagnosis was lower (Table). In CD patients, elderly-onset patients more often had colonic location, while no differences were observed in disease behaviour (Table). Within the first three months, elderly-onset CD patients were less likely to be treated with IMM or biologicals. Elderly-onset UC patients received more frequently topical steroids and were less frequently treated with 5-ASA or IMM. No difference was observed between the age groups in the need of abdominal surgery, in CD or UC (Table). In CD patients, a regression analysis found that the need of early, intensive treatment was inversely associated to elderly-onset (OR 0.29, 95% CI 0.16–0.51) and inflammatory behaviour (OR 0.24, 95% CI 0.1–0.35). In UC patients, it was associated to extensive disease (OR 12.03, 95% CI 3.71–39.05) and inversely associated to elderly-onset (OR 0.35, 95% CI 0.16–0.75).

Conclusion: In this large population-based inception cohort, the age-specific incidence of CD decreases with age, while UC incidence shows a peak in young ages and it decreases to a plateau in adult and elderly individuals. Elderly-onset IBD shows a different phenotype from that of young patients: elderly patients are more likely to be diagnosed from UC, and in case of CD it is more frequently associated to colonic localisation. At diagnosis, elderly-onset IBD patients were less aggressively treated than other age groups; this differences in the management might be due to differences in severity but this should be confirmed with the analysis of the long-term follow-up of the cohort.

Introduction: PSC associated to IBD drastically increases the risk of liver and colonic complications. However, no specific screening is recommended. The local IBD unit proposed to perform systematic screening by liver biopsy during surgery.

Aims and Methods: The aims of the study were to assess the frequency, characteristics and outcomes of inflammatory bowel disease (IBD) patients diagnosed with primary sclerosing cholangitis (PSC) on systematic liver biopsy during a surgery for IBD.

In a retrospective monocentric study, all patients who underwent a major abdominal surgery related to IBD were included. IBD phenotype and outcomes were assessed according to the presence of PSC.

Abstract No: P0924

	15-39 years	40-59 years	≥60 years	p
IBD (CD -UC – IBDU)	40.5%–52.6%–6.9%	35.4%–56.3%–8.3%	29.7%–62.9%–7.4%	0.006
CD behaviour (B1 – B2 – B3 – B1+p – B2+p – B3+p)	64.8%–16.8%–8.3%–7.2% –1.7%–1.1%	63.6%–19.8%–9.1%–5.3% –1.1%–1.1%	66.0%–22.0%–6.0%–4.0% –1.0%–1.0%	0.912
CD location (L1 – L2 – L3 – L4–1+4 – L2+4 – L3+4)	30.4%–22.6%–23.3%–5.1% –5.1%–5.5%–7.7%	26.3%–29.0%–22.0%–7.5% –7.5%–1.6%–5.9%	22.7%–38.1%–19.6%–5.2% –9.3%–3.1%–2.1%	0.022
UC extent (E1 – E2 – E3)	23.2%–38.0% -38.7%	24.0%–42.5%–33.6%	16.2%–45.7%–38.1%	0.087
CD TREATMENT (5ASA – Systemic STEROIDS/Topic STEROIDS – IMM – BIOLOGICALS – ABDOMINAL SURGERY)	50.2%–46.5%/16.1%–37.6% –8.3%–7.4%	50.3%–38.3%/17.6%–27.8% –5.3%–8.6%	53.3%–37.0%/16.6%–14.0% (*)–1.0% (**)–10%	(*): $p < 0.001$ ///—/// (**): $p = 0.022$
UC TREATMENT (5ASA – Systemic STEROIDS/Topic STEROIDS – IMM – BIOLOGICALS – ABDOMINAL SURGERY)	89.9%–34.0%/8.9%–7.7% –2.2%–1.2%	90.2%–26.3%/7.4%–4.4% –1.3%–0.7%	83.5% (*)–29.2%/12.7% (**)–3.3% (***)–0.9%–0.5%	(*) $p = 0.025$ ///—/// (**) $p = 0.026$ ///—/// (***) $p = 0.027$

[Phenotype at diagnosis and initial (first 3 months) treatment]

Results: Between 1998 and 2011, 390 IBD patients were operated and followed-up for 68 months [14; 118], 255 systematic peroperative liver biopsies were performed. The incidence of PSC was 12.8%. Twenty-two patients with PSC on 29 (75.9%) had normal liver biochemistry at the time of surgery, and 18 PSC patients on 41 (43.9%) presented no abnormality during the follow-up. Hepatic pejorative outcomes were infrequent, no patient underwent liver transplantation. Demographic, IBD phenotype and IBD outcomes were broadly comparable according to PSC status except for disease location. Among the IBD population, 27 (6.9%) colorectal neoplasia occurred, including 8 (29.6%) in patients with PSC. The cumulative risk of developing colorectal neoplasia from IBD diagnosis were 1.1%, 3.5%, 10.6%, 19.6% at 5, 10, 20, 30 years respectively. Neoplasia was mostly multifocal (40.7%). By multivariate analysis, PSC strongly increased the risk of developing neoplasia, with an HR = 2.51 [1.01; 5.8]. Extensive colitis also increased the risk of neoplasia (HR = 2.71 [1.004; 9.49]). The use of immunosuppressant drugs and/or biotherapy trended to be independently associated with colorectal neoplasia (HR = 0.46 [0.21; 1.02], p = 0.05).
Conclusion: Asymptomatic forms of PSC are frequently associated to IBD and alter the prognosis of patients with colitis through colorectal neoplastic complications, favouring a systematic screening of PSC in these patients, including peroperative liver biopsy.

Introduction: MaRIA index is the most well-characterized MRI index to measure activity in Crohn's Disease (CD). This index was validated with ileocolonoscopy as a reference. However, there are no data on its applicability as a predictor of disease course.
Aims and Methods: A retrospective study that included patients with ileal/ileocolic CD with initial diagnosis between 2013 and 2014 who underwent MRI prior to initiating treatment. MaRIA index was calculated in the worst affected segment taking into account the formula: 1.5x wall thickness (mm) + 0.02x relative enhancement + 5x edema + 10x ulceration. Disabling DC was defined as ≥1 of the following: ≥2 cycles of corticoid therapy/year, cortico-dependence or cortico-refractoriness; immunomodulatory/anti-TNF modulation or dose escalation; ≥2 hospitalizations; new events (perianal, penetrating and / or stenosis); ≥1 surgery. The aim of this study was to evaluate MaRIA index at diagnosis as a predictor of disabling CD.
Results: Included 26 patients – mean age 37 ± 13 years; 58% female; 62% inflammatory, 30% penetrating, 8% stenosing; 46% ileal, 54% ileocolic. At follow-up (mean 31 ± 9months), 65% of the patients had disabling CD- corticosteroid therapy in 31% (n = 8), immunomodulator / anti-TNF modification or dose escalation in 46% (n = 12), hospital admission in 27% (n = 7), new events in 27% (n = 27) and surgery in 15% (n = 4).
The MaRIA score was a predictor of disabling CD (12 vs 21; p = 0.001). From the formula, wall thickness (3,8mm vs 6,7mm; p = 0.02) and ulceration (0% vs 21%; p = 0.02) were predictors of disabling CD.
Conclusion: The MaRIA score at diagnosis in this group of patients was a predictor of disabling DC during the course of the disease.

Introduction: Patients with inflammatory bowel disease (IBD) are at increased risk for developing colorectal cancer (CRC) – this risk is modulated by several factors. Currently, surveillance colonoscopy is recommended to detect and treat neoplastic lesions.
Aims and Methods: A cohort study was conducted in order to determine clinical and endoscopic variables associated with dysplasia in IBD patients who were part of a colonoscopy surveillance program between 2011–2016.
Statistic tests: Chi-square, Fisher's Exact Test, Mann-Whitney U test, Multivariate Logistic Regression.
Results: A total of 162 patients (51.2% men, mean age at diagnosis 36.8 ± 13.5 years, mean duration of IBD at the start of the program: 11.0 ± 8.9 years) were included.
105 patients had Ulcerative Colitis (UC) (70.5% having extensive colitis) and 57 patients had Crohn's Disease (CD), 82.5% of which with > 50% surface of the colon affected. Only 6 patients had concurrent primary sclerosing cholangitis, 18 had a family history of CRC and 6 had personal history of colorectal dysplastic lesions.
The majority of patients (95.7%) were or had been under 5-ASA; half (55.6%) of the patients received thiopurines and 24.1% were or had been under anti-TNF alpha.
A total of 342 colonoscopies were performed during the 5 years period (2.1 ± 1.2 colonoscopies/patient). Random biopsies were performed at least once in 81.5% of patients with a mean 27.5 ± 6.4 biopsy samples per colonoscopy and 33.3% of the patients underwent chromoendoscopy (CE) at least once.
During the surveillance period, endoscopically resectable lesions were detected in 55 patients (34%) and visible lesions deemed unfit for endoscopic resection were found in 5 patients (3.1%). Overall, 61 dysplastic visible lesions (58 with low grade dysplasia and 3 with high grade dysplasia) and 1 adenocarcinoma were found in 34 patients.
Dysplasia in random biopsies was present in 3 patients, the yield of random biopsies for dysplasia being 1.85% per-patient (3/162), 1.75% per-colonoscopy (6/342) and 0.25% per-biopsy (9/3637). Dysplasia detected in random biopsies was associated with a personal history of visible dysplasia (p = 0.006).
The presence of dysplasia, either in targeted samples or random biopsies, was significantly associated, on univariate analysis, with type of IBD (26.7% in UC vs 10.5% in CD) (p = 0.016), with the performance of random biopsies (p = 0.009), and CE (p = 0.05) and with previous ileo-colonic surgeries (p = 0.002). On multivariate analysis, dysplasia was associated with type of IBD (p = 0,034), with the performance of random biopsies (p = 0.09) and with previous ileo-colonic surgeries (p = 0.001). Median disease duration was superior in patients with dysplasia compared with those without dysplasia (14.0 (IQR 5.75–21.0) vs 9.0 (IQR 3.25–15.0) years, p = 0.03). There was no significant association between the presence of dysplasia and family history of CCR or personal history of PSC.
The presence of endoscopically resectable lesions was associated, on multivariate analysis, with duration of disease (p = 0.03), with the presence of histologic inflammation (p = 0.017) and with the performance of random biopsies (p = 0.02).
Conclusion: Our data confirm that patients with longstanding IBD, in particular UC, should be enrolled in dysplasia surveillance programs and that perfoming CE and random biopsies helps in the detection of colonic neoplastic lesions.
Disclosure: Nothing to disclose

Introduction: Aphthous or small ulcerations in terminal ileum are infrequently observed in patients with ulcerative colitis (UC) without evidence of backwash ileitis. However, clinical significance and natural course of terminal ileal (TI) ulcers in UC are unclear.
Aims and Methods: This study was conducted to demonstrate the frequency and prognostic implication of UC patients with TI ulcer. We retrospectively reviewed 1,585 UC patients with successful TI intubation among 2,211 UC patients, excluding 626 patients with no available images. To evaluate the frequency, we compared with those of historic healthy cohort (n = 26,735)[1] who had no gastrointestinal symptom and history of NSAIDs use at the same center. Regarding the clinical characteristics, we compared the 87 UC patients with TI ulcer (group A) and the 1,498 UC patients without TI ulcer (group B). The natural courses of TI ulcers were also investigated during the follow-up periods.
Results: Of 1,585 UC patients**,** 87 patients (5.5%) showed TI ulcer without the evidence of inflammation in the cecum and right colon, which was higher than the frequency of healthy cohort (106/26,735, 0.4%), (p < 0.001). There was not any difference in age, sex, smoking history, family history, and the incidence of extraintestinal manifestations between the group A and group B. The group A had more proctitis and left-sided colitis than the group B (p = 0.001). However, disease activity and maximal disease extent during follow-up periods were not different between the two groups. The histories of medication use including corticosteroids, azathiopurine, and anti-tumor necrotizing factor and the colectomy showed also no significant differences. Of the 55 patients who underwent follow-up colonoscopy, 36 patients (65.5%) showed a resolution of TI ulcer.

Conclusion: Discrete TI ulcers are more common in UC patients, compared with healthy control. Two third of them, lesions were resolved. Clinical impact on disease extension and severity seems not to be significant.
Disclosure: Nothing to disclose

Introduction: Radiologic imaging is used as a method to monitor Crohn's disease (CD) activity in clinical practice. Magnetic resonance enterography (MREn) depicts the transmural extent of disease, and can be performed on equipment commonly available at most hospitals and many outpatient clinics globally. There is a growing interest in implementing MREn in clinical trials and in research. The magnetic resonance index of activity (MaRIA) score requires quantitative assessment of MREn imaging sequences before and after intravenous gadolinium. To date, assessment of MREn in the research setting has been largely restricted to single centre studies, and use of MREn in a prospective multicentre trial has not previously been reported.
Aims and Methods: The aim of this report was to evaluate the deployment of a standardised MREn protocol execution in a clinical trial setting in CD. VERSIFY (NCT02425111) was an international, multicentre, phase 3b, open-label study of mucosal healing with vedolizumab (VDZ) in a difficult-to-treat population (n = 101) with moderate-severe CD (≥3 months; CD Activity Index 220–450; Simple Endoscopic Score for CD ≥7; ≥1 mucosal ulceration on central endoscopy; prior failure with corticosteroid, immunomodulatory and/or ≥1 tumour necrosis factor antagonist). In the MREn substudy (n = 37), scanner and protocols were qualified and expert-to-site technologist training was delivered, either face-to-face or via conference call. Sites were qualified after submitting a test scan from a healthy volunteer. All MREns from Weeks 0 (baseline) and 26 (follow up) were consensus reviewed by two radiologists. Missing sequences were counted. Exam-adequacy was measured as critical sequences that allowed calculation of MaRIA score present (including T2 with/without fat saturation and T1 coronal pre-/post- gadolinium), sequence order correct and full anatomy covered. Image quality (5-point scale: 1–2 = failure; 3–5 = success) and artefact frequency were assessed. Per patient and per sequence analyses were performed for each visit. Data were summarised descriptively by time point (compared using McNemar's test).
Results: All MREns (37 patients with 302 sequences at baseline, 30 patients with 255 sequences at follow up) were reviewed. At baseline and follow up, 92% and 83% of patients had all critical sequences present, 97% and 93% had execution order that matched prescribed order, and 100% and 97% had full anatomy. The majority of sequences (98%; 98%) were rated as 3–5 on the quality scale. At baseline and follow up, artefacts were observed in 152 and 132 sequences (36 and 30 patients, respectively), most frequently: breath-motion (13%; 15% of sequences); low signal:noise ratio (15%; 15%); segmental signal loss (15%; 19%); and faeces/gas (6%; 9%).
Overall, 89% of patients at baseline and 83% at follow up had MREns suitable for assessing activity. In patients evaluated at both time points (n = 30), no significant change in the proportion of patients with inadequate examinations was observed (p = 0.51 missing sequences, p = 0.13 missing critical sequences, p = 1.00 acquisition order, p = 1.00 full anatomy, p = 0.73 complete readability; no patient had a quality score of 1 or 2 for any critical sequence at either time point).
Conclusion: MREn is considered an accurate, minimally invasive tool for monitoring CD activity in clinical practice and in research. In our study, MREn was technically feasible, indicating it also has the potential to be successfully deployed in an international multicentre clinical research setting.

Introduction: It can be difficult to differentiate the various forms of inflammatory bowel disease (IBD) endoscopically. There is a need for a single endoscopic score for all IBD patients to simplify and unify mucosal assessment for Crohn's disease (CD), ulcerative colitis (UC) and inflammatory bowel disease – unclassified (IBDU). Although the Mayo score for UC is relatively simple to use, it does not account for the entire colonic burden of disease as it is not scored by segment and there is no agreement on how IBDU should be assessed and with which score.
Aims and Methods: The aim of this study was to develop an endoscopic scoring tool for all IBD patients and to compare it with existing endoscopic scoring tools for UC and CD.
The TIGER score was developed as a modified endoscopic mucosal scoring tool using renewed parameters and specifications (mucosal appearance, ulcer/erosion size, percent ulcerated/erosion mucosal surface, segmental involvement and presence of luminal narrowing) that can be applied during ileocolonoscopy to any IBD patient. A unique property of the TIGER score is that it adds extra points for segments showing moderate to severe mucosal involvement thereby allowing a global assessment of the total endoscopic severity. Three blinded IBD experts reviewed and scored anonymized ileocolonoscopy videos for 200 intestinal segments in 40 IBD patients (20 CD and 20 UC). In addition to the TIGER score, the Mayo score and the SES-CD were simultaneously determined for UC and CD subjects respectively. Reviewers' inter-rater reliability for the TIGER score was explored using the interclass correlation coefficient (ICC) with 95% confidence intervals (CI) for all 200 ileocolonic segments (5 segments per patient X 40 patients). The TIGER score was categorized into two distinct levels: a score of 0–4 represented a mild/inactive disease segment and ≥5 represented a moderate to severely active segment. Agreement in the categorized score was estimated using Cohen's kappa coefficient as well as the overall agreement percentage. Clinical application of the scores were determined a priori as follows: TIGER score >4, Mayo >1 and SES-CD > 5 per segment were all considered to be consistent with moderate to severe mucosal disease. The agreement between the TIGER score and the conventional scores was estimated using Cohen's kappa coefficient as well as by reporting the overall agreement with 95% confidence intervals (CI).
Results: The ICC per segment between reviewers was excellent (ICC = 0.94; 95% CI: 0.92–0.96). In the categorized TIGER score the lowest overall agreement was 96.9% [95% CI: 93.5%−98.6%] and the lowest kappa was 0.91 [95% CI: 0.84–0.98], reflecting excellent agreement. The overall agreement per segment between the SES-CD and TIGER was 91% [95% CI: 84%−95%] with a kappa coefficient of 0.74 [95% CI: 0.59–0.90]. The overall agreement between the Mayo and the TIGER scores was 84% with a kappa coefficient of 0.61 [95% CI: 0.42–0.80], indicating moderate to good agreement. Per patient analysis for the 3 total scores included all 40 patients and yielded overall agreement of 88% [95% CI: 74%−94%] and kappa coefficient 0.66 [95% CI: 0.39–0.93]. McNemar's test (p = 0.1797) reflected no significant difference in clinical application between the TIGER score and the conventional scoring methods.
Conclusion: The TIGER endoscopic score is comparable to existing endoscopic scoring tools for ileocolonoscopy in terms of assessing disease severity and was shown to be reproducible and easy to use for both CD and UC patients.

Introduction: The incidence of *Clostridium difficile* infection (CDI) is increasing both in general population and in patients with ulcerative colitis (UC). Available studies provide contradictory results: several studies demonstrated higher mortality and surgery rate following a CDI diagnosis [1] while another showed negative association between CDI and colectomy [2].
Aims and Methods: The aim of the study was to evaluate the impact of CDI in non-surgical patients with ulcerative colitis (UC), to estimate association between CDI and disease severity in patients with UC, to examine histologic features suggestive of CDI in patients with UC.
A cross-sectional study included 70 consecutive inpatients or outpatients with UC (37 males, 33 females, aged 19 to 65 years, mean age 37.97 ± 1.53 years) with disease duration of 1 to 10 years. Patients received no antibiotic medications for at least 6 months prior to the study. None of the patients was operated or died during hospital admission or was operated previously. No patents were diagnosed to have pseudomembranous colitis. Patients were enrolled after history and clinical examination, stool samples and were evaluated for the presence of C. difficile toxins A and B (CDT) by ELISA. UC severity was assessed according to Mayo Score/disease activity index (DAI): mild in 24 cases (34.3%), moderate — in 26 (37.1), severe — in 20 (28.6%). All patients underwent hi-resolution colonoscopy in white and NBI modes with mucosa biopsies (1 per each segment of the colon and terminal ileum). Colonic biopsies were scored 0 through 3 for lymphocytic, neutrophilic infiltration and atrophy. Slides were also reviewed for evidence of pseudomembranes, ischemic-like changes and *lamina propria* hemorrhage. Bacterial overgrowth syndrome (BOS) was diagnosed by hydrogen breath test with lactulose.
Results: Thirty one UC patients (44.3%) had no CD toxins, 33 (47.1%) —toxin B only, 6 (8.6%) — both A and B toxins. Demographic data and laboratory values upon admission did not differ between subgroups of patients with and without CDT. BOS was revealed in 17 of 30 cases (56.7%). Colon histology revealed no signs consistent with pseudomembranous colitis. As determined by Kruskal-Wallis one-way ANOVA and chi-square test there was no statistically significant difference in gender, age, education level, duration of UC history, stool frequency, type of immunesuppressive therapy, other clinical, endoscopic or histological features of UC or in the presence of BOS in patients with and without CDT. No difference was found in UC severity according to DAI: mild/moderate/severe distribution was 9/12/10 for CDT-negative and 15/14/10 for CDT-positive patients respectively ($\chi^2 = 0.749$, $p = 0.688$).
Conclusion: CDT may play important role for the outcomes of severe UC patients undergoing surgery, who receive potent broad-spectrum antibiotics. However, no significant differences in severity of UC in our group of patients in relation to the presence of CDT were found.
Disclosure: Nothing to disclose

Introduction: Cross-sectional imaging techniques, including bowel ultrasonography (BUSG) and magnetic resonance enterography (MRE) are increasingly used for evaluation of Crohn's Disease (CD). Various clinical, laboratory and imaging indices have been derived to evaluate disease activity in CD.
Aims and Methods: The aim of the present study was to compare the diagnostic accuracy of BUSG and MRE for detecting disease activity in CD using simple endoscopic score for CD (SES-CD) as reference standard. A total of 71 consecutive adult patients with known CD underwent ileocolonoscopy, BUSG and MRE within one month prospectively, and comparisons were made as per-patient. The SES-CD > 6 was accepted as active disease. Sensitivity of BUSG and MRE for detection of disease activity was compared with the McNemar test, with results of SES-CD > 6.
Results: The sensitivity and specificity of BUSG lesions in detecting patients with SES-CD > 6 were as follows; bowel wall thickening 62.3/50, loss of wall stratification 66.7/34, color Doppler USG signal (Limberg 3–4) 78.6/36.8, rigidity 81/40, mesenteric fibro-fatty proliferation 76.9/40, and fistula 66.7/33.8, respectively. Noteworthy MRE lesions in detecting patients with SES-CD > 6 were as follows; bowel wall thickening 70.2/50, loss of wall stratification 69.6/40, bowel wall edema 74.4/43.8, ulcers 65.3/31.8, total hyperenhancement 67.9/37.9, layered enhangement 64.3/32.6, homogenous enhangement 70/36.6, comb sign 69.2/35.6, mesenteric fibro-fatty proliferation 79.4/45.9, and lymphadenopathy 69.6/35.4, respectively.
Regarding the fallowing uniform parameters, there was a significant correlation between BUSG and MRE in detecting endoscopically active CD (SES-CD > 6): bowel wall thickening ($p = 0.727$), prestenotic dilatation ($p = 0.210$), mesenteric fibro-fatty proliferation ($p = 0.167$), mesenteric lymphadenopathy ($p = 0.815$), and fistula ($p = 1.000$). Compared to BUSG, the diagnostic accuracy of MRE was significantly higher in detecting loss of wall stratification and strictures ($p = 0.000$). On the other hand, diagnostic accuracy of BUSG color Doppler signal (Limberg 3–4) was significantly higher than MRE comb sign in detecting hyper vascularity ($p = 0.030$).
Conclusion: BUSG and MRE are equally accurate to detect disease activity in CD. MRE was more sensitive than BUSG for detection of loss of wall stratification and strictures. BUSG was significantly more sensitive than MRE in detecting hyper vascularity. In this study, bowel wall thickening, loss of wall stratification, rigidity, increased color Doppler signal, fistula and mesenteric fibro-fatty proliferation come into prominence on the BUSG examination in active CD. BUSG may denote an alternative technique to MRE in evaluating disease activity and follow-up of CD.

P0933 PLATELET INDICES IN THE COURSE OF INFLIXIMAB INDUCTION REGIMEN IN ULCERATIVE COLITIS PATIENTS – EXPERIENCE OF A SINGLE CENTRE – A PILOT STUDY

A. Michalak, H. Cichoż-Lach, B. Kasztelan-Szczerbińska, K. Laskowska, P. Radwan
Medical University of Lublin, Department of Gastroenterology with Endoscopy Unit, Lublin, Poland

Contact E-Mail Address: lady.agatamichalak@gmail.com
Introduction: Platelet (PLT) abnormalities are known to participate in the pathological appearance of inflammatory bowel disease (IBD). Chronic inflammatory process in patients with IBD is connected with elevated PLT count and changes in PLT activation.
Aims and Methods: The aim of the study was to assess the correlation between PLT indices: MPV (mean platelet volume), PCT (plateletcrit), PDW (platelet distribution width), C-reactive protein (CRP) and endoscopic picture in the course of infliximab (IFX) induction regimen in ulcerative colitis (UC) patients. 46 patients with UC, 32 men and 16 women, were enrolled to the study. They were administered IFX (standard induction therapy). Laboratory tests (CRP and PLT indices) and colonoscopy were performed in all patients during induction regimen – at 0, 2, and 6 weeks and in follow-up six weeks after finished induction therapy.
Results: The study revealed statistically significant ($p < 0.01$) decrease in mean CRP level (from 32.35 to 7.05 mg/L) and mean PLT count (from 398 to 315 x 10^9/L) together with improvement of endoscopic picture (MAYO score; $p < 0{,}01$) in all patients. Mean MAYO score prior to BT and after finished induction therapy were 9.78 and 2.76 points, respectively; mean MAYO endoscopic subscore decreased from 2.8 to 1.84 points ($p < 0.01$). Mean PCT values were too high prior to BT (0.46%) and normalized after induction therapy (0.22%) ($p < 0.01$). On the other hand, mean MPV measurements were under normal range during qualification to BT (6.8 fl) and obtained adequate values after BT (8.08 fl) ($p = 0.01$). Subsequently, CRP and PCT levels correlated positively with each other before the introduction of BT ($p = 0.02$). Negative correlations between PDW level and PLT count and positive correlations between PCT level and PLT count were noticed before IFX induction regimen and in follow-up after finished therapy, too ($p < 0.01$).
Conclusion: Chronic inflammatory process in patients with IBD is connected with elevated PLT count and changes in PLT activation and morphological parameters. Our data suggest that PLT indices might be useful biomarkers for determining active UC and for assessing the efficacy of BT. However, further studies are required to establish a correlation between platelet functions and BT in IBD patients.
Disclosure: The work was presented as a poster at one international meeting – Falk Symposium 209 October 6–7, Berlin, Germany IX GASTRO-CONFERENCE (Part II) IBD 2017 – Therapeutic and Biological Barriers

Introduction: Patients with inflammatory bowel disease (IBD), i.e. Crohn's disease (CD) and ulcerative colitis (UC), may be at increased risk for cardiovascular disease (CVD) even in the absence of documented risk factors. Data linking the severity of IBD to coexisting CVD are rather scarce.
Aims and Methods: This is a retrospective analysis from IBD patients with concurrent CVD derived from 3 participating IBD Centers. Patient demographic and clinical characteristics, routine laboratory tests including serum biomarkers, disease activity scored by the Harvey-Bradshaw Index (HBI) for CD and the Simple Colitis Activity Index (SCCAI) for UC, quality of life scores based on the short inflammatory bowel disease questionnaire (SIBDQ), and health care resources utilization were compared to those of IBD patients without CVD. Statistical analysis was performed with the SPSS 24.
Results: Overall, 321 IBD patients (167 CD, 154 UC, 192 males, median [IQR] age 55[42–65] years) with a mean (±SD) follow-up of 12.6 ± 9.3 years were included. Of these, 82(35.5%) patients, mainly with UC (59.8% vs 43.8%, $p = 0.015$) had a history of CVD. CVD followed IBD diagnosis in 51.2% of cases. Among patients with CVD, 53 (64.6%) reported coronary artery disease (4/53 had at least another one CVD comorbidity), 22 (26.8%) were diagnosed with stroke, 10 (12.2%) with heart failure, and 2 (2.4%) with peripheral artery disease. Patients with CVD were smoking more frequently (75.6% vs 66.5%, $p < 0.001$), had hypertension (65.9% vs 18%, $p < 0.001$) and diabetes mellitus (34.1% vs 6.3%, $p < 0.001$) as well as older age at diagnosis (53.6 ± 15.2 vs 38.2 ± 14 years, $p < 0.001$) and elevated body mass index (28.8 ± 0.6 vs 26.7 ± 0.4, $p = 0.04$). Patients without CVD were receiving more often anti-TNFa (53.6% vs 26.8%, $p < 0.001$), steroids (81.2% vs 59.8%, $p < 0.001$), immunomodulators (61.1% vs 36.6%, $p < 0.001$) but no 5-ASA ($p = 0.285$). HBI, SCCAI, or SIBDQ scores did not differ between the two groups. Rates of hospitalization and/or surgery after diagnosis were not different between the two groups. Endoscopic activity was milder when CVD was present ($p = 0.018$ and $p = 0.002$ respectively for UC and CD).
Conclusion: The results of this study did not confirm the hypothesis that IBD patients with CVD have a more severe disease. Inflammatory burden possibly plays a less important role in the development of CVD in IBD patients. Data from larger prospective studies are essential to confirm our findings.
Disclosure: Nothing to disclose

P0935 THE ROLE OF SERUM IL-17 AND IL-23 IN ASSESSING INFLAMMATORY BOWEL DISEASE SEVERITY

Introduction: Interleukin-17 (IL-17) and Interleukin-23 (IL-23) play a critical role in inflammatory bowel disease (IBD) immune response and are currently being targeted by therapeutic agents in clinical trials. High serum levels of IL-17 and IL-23 in IBD patients with active disease has been reported before, but the relationship between these cytokines and disease severity has not been thoroughly assessed.
Aims and Methods: We aimed to investigate if the levels of IL-17 and IL23 in the serum of patients with Crohn's disease (CD) and ulcerative colitis (UC) reflect disease severity and if they correlate with standard inflammatory biomarkers, such as C-reactive protein (CRP) and fecal calprotectin (FC).
We prospectively included in the study 62 IBD patients and 15 healthy controls. Using disease activity scores, disease pattern, serum and fecal inflammatory biomarkers we further classified the patients into severe and mild or moderate disease. Serum levels of IL-17 and IL-23 were determined using sandwich enzyme-linked immunosorbent assays (ELISA). Mann Whitney U test was used to assess distribution among groups, and Spearman's rank correlation for describing relationship among variables. Numerical data was presented with median and interquartile range.
Results: In Crohn's disease, IL-17 had with 930.48pg/mL lower serum levels in mild/moderate disease group vs severe disease group, $p = 0.119$. As for IL-23, mild/moderate group had with 699.86pg/mL lower serum levels than severe disease group, $p = < 0.001$. In UC, mild/moderate group had with 1328.13pg/mL lower levels of IL-17 ($p = 0.003$) and with 723.62pg/mL lower levels of IL-23 ($p = < 0.001$) comparatively to the severe group. Spearman's rank correlation test between IL-17, IL-23 and Fcal showed a correlation coeficient of 0.52 for IL-17 ($p = 0.003$) and 0.67 for IL-23 ($p = < 0.001$). The median distribution of IL-23 serum levels among patients with intestinal complications showed with 622.1pg/mL higher values in fistula group ($p = 0.035$) vs other types of complications.
Conclusion: IL-17 and IL-23 serum level can differentiate between IBD patients with severe and non-severe disease and can assess disease severity in the clinical practice. Further monitorization of these cytokins in larger IBD groups might be a promissing tool in assessing disease progression.

Introduction: Treatment of Crohn's Disease (CD) and Ulcerative Colitis (UC) is usually directed at organic aspects of the disease, often disregarding psychosocial factors. A comprehensive strategy including identification of anxiety and depression are possible therapeutic targets to increase quality of life in inflammatory bowel disease (IBD).
Aims and Methods: The present study aims to test the association between anxious and depressive symptoms with IBD activity and course.
Of 221 patients followed in outpatient setting in October and November of 2017, 64 patients with confirmed IBD who accepted to participate in the study were selected. Patients with known mental illness followed by Psychiatry were excluded. Anxiety symptoms were quantified by Spielberg's Anxious State Inventory (STAI) and symptoms of depression by the Beck II Depression Scale (BDI-II).
Results: Sixty-four patients were included, of which 75% with CD and 25% with UC. The mean age was 40 ± 13.99 years and 53.1% were female. Clinical remission rate was 87.5% in CU and 75% in CD, with an endoscopic remission rate of 25% in CU and 50% in CD. The correlation between anxiety and depression symptoms was significant ($p < 0.001$, $r = 0.73$). There was no statistically significant difference in anxiety and depression scores between patients with CD and CU. The correlation of number of disease flairs with STAI and BDI-II scores was significant (STAI $p = 0.023$; BDI-II $p = 0.017$). In IBD patients, there was also a statistically significant association between STAI score (anxiety) and clinical remission, endoscopic remission and need for therapy step-up ($p < 0.05$). In CD patients there was a significant association between anxiety and the presence of perianal disease ($p = 0.035$). In UC patients, there was a significant association between anxiety and recent flair ($p = 0.021$), use of emergency room ($p = 0.029$), hospitalization ($p = 0.029$) and therapy step-up ($p = 0.013$). In this group of patients a significant association between depressive symptoms and immunosuppressant or anti-TNF therapy was seen ($p = 0.009$).
Conclusion: In the analyzed patients there was an association of anxious and/or depressive symptoms with frequency of disease flairs and disease activity. Screening for anxious and depressive symptoms may have a significant impact on the quality of life of patients with IBD.

Contact E-Mail Address: lorantgonczi@gmail.com

Introduction: IBD is associated with substantial disability and impairs quality of life. Optimal management of IBD requires harmonized monitoring processes and treatment pathways. We aimed to retrospectively analyze quality of care indicators (QIs) including patient assessment strategy, monitoring, treatment decisions and outcomes at referral and during follow-up in the McGill University Health Center (MUHC) IBD Center.
Aims and Methods: We reviewed out- and inpatient records of consecutive patients seen at the MUHC IBD center between June and December 2016. Demographic variables, outpatient visits, inpatient stays including IBD related surgery, laboratory, imaging and endoscopy data, current medications and/or changes in medications, and vaccination profile were captured.
Results: 1357 patients (46.8% male, 64.4% Crohn's disease (CD), age at diagnosis: 29.8 years, age at referral: 39.3 years, duration of disease: 14.1 years) were included. At referral 49.5% of CD patients had ileocolonic, 45% complicated behavior (B2 or B3) and 23.7% perianal disease. 47.2% and 41.7% of UC patients had extensive and moderate to severe disease, respectively. Patients

were objectively re-evaluated at referral: 68.4% underwent ileocolonoscopy, 15.7% upper GI endoscopy, 15.6% of CD patients had abdomino-pelvic MRI or CT and 23.6% abdominal US. CBC, CRP and FCAL were measured in 89.9%, 81.9% and 16.5%, respectively. Medical therapy was changed in 53.6% (active disease: 75.6%, remission: 24.4%), and 22.5% of patients started biological therapy at around referral. 12.4% of patients required hospitalization while 6% surgery at referral. During follow-up, in June-December 2016, 41.1% of patients were receiving biological therapy and 15.1% of patients were steroid dependent. An objective patient monitoring strategy was applied at the IBD center: ileocolonoscopy/colonoscopy was performed in 79% within 2 years before, and in 32% within 6 months from index visit. Biomarkers (CRP: 78%, FCAL: 37.6%) *C. difficile* or stool culture (18% and 17.9%) and therapeutic drug monitoring (16.3%) were performed frequently. Treatment was changed in 18%. Need for surgery (4%) and hospitalization (8%) were low, while 16.8% of patients required an IBD-related ER visit within 6 months after index visit.
Conclusion: Our data support that tight monitoring was applied at the MUHC IBD center with a high emphasis on objective patient (re) evaluation, and accelerated treatment strategy at referral or during follow-up.

Introduction: IBD impacts on a patient's physical health, social functioning and quality of life, contributing to the health-economic burden associated with the disease, especially in emergency situations. We aimed to prospectively measure the impact of the implementation of a rapid access clinic (RAC) at a tertiary IBD center.
Aims and Methods: Consecutive patients from the McGill University Health Center who accessed the RAC via email were prospectively included, between June 2017 and January 2018. Time to medical appointment, resource utilization (laboratory, imaging and endoscopy), need for change in medical therapy, unplanned emergency (ER) visits or admissions 30 to 90 days after consulting the RAC were collected.
Results: 173 patients (61% female, mean age: 38 years, CD: 64%, L3: 50.9%, B2-3: 34.6%, UCE3: 53.8%, biological therapy: 67.3%, previous surgery: 21%) were included. 85% of requests were considered appropriate for a RAC appointment. 65.9% of patients presented with a clinical flare. Patients were seen at the IBD clinic a median of 3 days (mean 4.7) after the request. Laboratory assessment including FCAL (52%) and CRP (80%) was performed as appropriate. Fast-track endoscopy (colonoscopy or sigmoideoscopy) was performed in 32 and 11 patients (19.8% and 6.6%), and 13 patients (7.8%) had abdominal/pelvic CT. Treatment was modified in 78 patients (48.8%). Admission was initiated in 5 patients during RAC visit. A total of 8 (4.6%) and 3 (1.7%) patients required an ER visit within 30 and 90 days after the RAC appointment, of which 2 and 1 patients had non-IBD reason for presenting at ER.
Conclusion: Implementation of a RAC improved healthcare delivery by avoiding unnecessary ER visits and optimizing resource utilization.

Introduction: The clinical course of ulcerative colitis (UC) is featured by remission and relapse, which remains unpredictable. Recent research revealed that fecal calprotectin (FC) could predict clinical relapse for UC in patients with remission, but this role of FC has not been applied to clinical practice.
Aims and Methods: We carried out a comprehensive electronic search of PUBMED, WEB OF SCIENCE, EMBASE and the Cochrane Library to identify all eligible studies. Diagnostic accuracy including pooled sensitivity, specificity, positive likelihood ratio (PLR), negative likelihood ratio (NLR), diagnostic odds ratio (DOR) and pooled area under the receiver operating characteristic (AUROC) was calculated using a random effects model. Sources of heterogeneity were detected by subgroup analysis. Potential factors correlated to DOR were tested by meta regression.
Results: 14 articles enrolling a total of 1043 participants were finally included for final calculation. Pooled sensitivity, specificity, PLR, NLR were 0.73 (95% CI: 0.67–0.77), 0.77(95% CI: 0.74–0.80), 3.32 (95% CI: 2.30–4.79) and 0.40(95% CI: 0.32–0.51) respectively. The area under the summary receiver-operating characteristic (sROC) curve was 0.81 and the diagnostic odds ratio was 9.29 (95% CI: 5.71–15.12). FC was more diagnostically accurate in studies using Bühlmann as FC assay (DOR = 15.08; 95% CI: 6.84–33.25) and studies with longer follow-up time (DOR = 9.61; 95% CI: 5.52–16.72) or a lager cut-off value (DOR = 11.64; 95% CI: 4.93–16.72). There was no significant correlation between any of the covariates and the DOR in the univariate meta-regression analysis.
Conclusion: Our study confirms the diagnostic utility of FC for the detection of UC relapse in adults. Due to its simplicity and noninvasiveness, measuring FC levels at clinical remission appears to be a reliable and reproducible indicator to predict UC relapse.
Disclosure: Nothing to disclose

P0940 GASTROINTESTINAL SYMPTOMS ARE COMMON IN U.S. PATIENTS WITH MODERATE-SEVERE PSORIASIS

S. Feldman[1], S. Fakharzadeh[2], J. Abell[2], **T. Hoops**[2], B. Srivastava[2], E. Muser[3], D. Dungee[2], S. Quinn[2], M. Leone-Perkins[4], M. Kappelman[5]

Introduction: Patients with moderate-to-severe plaque psoriasis (PsO) are at increased risk of developing inflammatory bowel disease (IBD). A survey was conducted to evaluate the prevalence of gastrointestinal symptoms in PsO patients.
Aims and Methods: An electronic survey was available to U.S. PsO patients with data collected from Jan-Feb. 2017. Patients with moderate-to-severe plaque PsO and healthy controls (HC), with common co-morbidities allowed in both groups qualified for inclusion in the survey. Psoriasis patients were further categorized as those without recent exposure to biologic therapy (PsO-) vs those with recent (within 4 months) biologic exposure (PsO+). GI symptoms and signs, including frequency and severity, were compared across groups. CalproQuest (CPQ) scores, which have recently been proposed as a tool to identify patients with elevated fecal calprotectin levels and increased risk for IBD, were also calculated. Patients with inflammatory bowel disease (IBD), inflammatory bowel syndrome (IBS), or other gastrointestinal (GI) diagnoses with symptoms that overlap with IBD were excluded.
Results: Overall, 915 patients with self-reported moderate-severe PsO and 1,411 healthy controls participated. Demographics were generally comparable between

Abstract No: P0940

	Psoriasis patients (PsO-)	Psoriasis patients + recent treatment* (PsO+)	Healthy controls (HC)
Number of pts	465	450	1411
GI signs & symptoms			
Belly Pain	20.6% (96) p = 0.002 vs HC p = 0.002 vs PsO+	36.9%(166) p = 0.002 vs HC	10.5%(148)
Full/Bloated	37.2% (173) p = 0.002 vs HC p = 0.002 vs PsO+	48.4% (218) p = 0.002 vs HC	25.3% (357)
Diarrhea	16.3% (76) p = 0.023 vs HC p = 0.002 vs PsO+	29.3% (132) p = 0.002 vs HC	12.2% (172)
Mucous in stool	4.5% (21) p = 0.020 vs HC p = 0.317 vs PsO+	6.0% (27) p = 0.002 vs HC	2.4% (34)
Blood in stool	4.3% (20) p = 0.004 vs HC p = 0.390 vs PsO+	5.6% (25) p = 0.002 vs HC	1.9% (27)

Data reported in % (n), *recent treatment = within 4 months of biologic, p-values are comparisons between psoriasis groups and healthy controls.

[Table 1]

groups. GI symptoms and signs were significantly more prevalent in the PsO- and PsO+ groups vs the HC group. Pain, fullness/bloating, and diarrhea were more frequent in PsO+ vs PsO- groups (Table 1). A significantly greater percentage of PsO- and PsO+ patients had positive CPQ scores vs HCs, with the greatest percentage of positive CPQ scores in the PsO+ group: 9.5% in PsO-, 20.2% in PsO+ vs 5.7% in HC, p = 0.005.

Conclusion: GI symptoms and signs are common in patients with moderate-to-severe PsO, more so than in healthy controls. This suggests that physicians caring for patients with PsO may consider assessing for GI symptoms and signs, and monitoring for their progression with treatment of PsO to identify patients potentially at risk for developing IBD.

Contact E-Mail Address: terezadrskova@gmail.com

Introduction: Endoscopic examination is a golden standard in evaluation of mucosal healing, which should be the main goal in the treatment of paediatric patients with inflammatory bowel disease (IBD). However, due to clear invasiveness, biomarkers, especially faecal calprotectin (FC), have become standard part of remission assessment.

Aims and Methods: The aim of the study was to compare accuracy for detection of endoscopic activity using a recently developed FC home test to standard ELISA assay (FC-ELISA). Finally, 102 consecutive observations from 89 paediatric patients with IBD (62 Crohn's disease (CD) and 27 Ulcerative colitis (UC)) were included in prospective observation study. We parallelly performed home FC test based on a smartphone image evaluation from lateral flow device (FC-IBDoc, Buhlmann Laboratories AG, Switzerland) analysed by physician and FC-ELISA in IBD patients indicated for endoscopic evaluation. We defined mucosal healing by endoscopic scores, in patients witch CD by SES-CD $<=2$ (n = 44), in patients with UC by UCEIS $<=4$ (n = 27) and in patients with CD after ileocecal resection (ICR) by Rutgeert's score i0 and i1 without signs of colon involvement (n = 19). Due to multiple observations from one subject the associations between mucosal healing and FC were assessed using generalized linear mixed model and linear mixed model. The sensitivity and specificity of FC-IBDoc and FC-ELISA for respective scores were analysed using ROC curve with cross-validated area under curve (AUC), optimal cut-off values were found. The AUCs were compared using DeLong test and regression models were compared using ANOVA.

Results: We found an association of the mucosal healing scores of the entire group both with FC-ELISA (p = 0.002) and FC-IBDoc (p = 0.012). The AUC for FC-ELISA was 0.883 (95% CI 0.807–0.960) with optimal cut-off at 136.5 ug/g, the AUC for FC-IBDoc was 0.792 (95% CI 0.688–0.895) with optimal cut-off at 48 ug/g. The accuracy of FC-ELISA was better than FC-IBDoc when tested by Delong test (p = 0.033). Similarly, the regression mix-model constructed using FC-ELISA as predictor was significantly better than the model using FC-IBDoc. We did not find any association with FC, neither tested by FC-ELISA nor by FC-IBDoc, and mucosal healing among subset of patients assessed by SES-CD, UCEIS nor Rutgeert's score. When assessing inflammation intensity using linear mix-model for subsets of observations evaluated by SES-CD we found association with FC-ELISA ($\beta = 2.35$,95% CI 0.98–3.81), but not with FC-IBDoc. We found association of UCEIS both with FC-ELISA and FC-IBDoc ($\beta = 0.62$, 95% CI 0.37–0.85, resp. $\beta = 0.46$,95% CI 0.19–0.74). FC-ELISA and FC-IBDoc was associated with Rutgeert's score in subgroup of CD patients after ICR ($\beta = 0.46$, 95% CI 0.21–0.70, resp. $\beta = 0.30$, 95% CI 0.10–0.53).

Conclusion: The standard ELISA assay for FC evaluation seems to be a more reliable predictor of mucosal healing than the FC home test in paediatric IBD patients. The cut-off values for both tests were highly incongruous. The FC-IBDoc could not be used for prediction of the inflammation intensity defined by SES-CD.

Introduction: Inflammatory bowel disease (IBD) which primarily consists of Crohn's disease (CD) and Ulcerative Colitis (UC) has a chronic relapsing nature. Therefore, it is of importance to detect, predict and treat a relapse as soon as possible in order to decrease the inflammation and avoid further intestinal damage. There is increasing evidence substantiating that intestinal microbial dysbiosis in IBD plays a role in the pathogenesis and progression hereof. Dysbiosis is poorly understood and therefore not yet considered in clinical use for optimizing treatment of IBD.

Aims and Methods: The aim was to characterize the microbiome in IBD in a consecutive cohort, and correlate dysbiosis index and other findings to conventional disease activity measures in understanding and interpreting the microbiome in IBD.

During 1 year, 120 consecutive IBD patients in any IBD therapy were enrolled in the web-outpatient clinic at North Zealand University Hospital, Capital Region of Denmark to monitor on Constant.care.dk. Patients were randomized to home-monitoring every 3rd month or on demand (monitoring after patients choice) on Constant care © and CalproSmart™ app. All home-monitoring data were visualized to the patients in a traffic light manner: Harvey-Bradshaw Index (HBI) for CD or Simple Clinical Colitis Activity Index (SCCAI) for UC and faecal calprotectin (FC) using CalproSmart™ Self Test Kit (Calpro AS, Norway).

The microbial dysbiosis index (DI); 1–5 normo-dysbiosis, GA-map™ (Genetic Analysis AS, Norway)[1] was correlated to disease activity indices and FC. Polymerase chain reaction (PCR) of faecal bacteria's 16S rRNA, Illumina was additionally analysed and subsequent bioinformatic analyses were performed.

Patients were asked to send faecal samples for both microbiome analyses longitudinally every time they were scoring themselves on the apps.

Results: Eighty four IBD patients consented to send faecal samples for microbiome analysis. 64 (76%) send longitudinal samples, 14 (17%) handed in only one sample each and 6 (7%) did not send any samples at all. Out of the 78 patients that sent faecal samples – 11 (14%) were diagnosed with CD (n = 36 samples), 63 (81%) with UC (n = 230) and 4 (5%) with IBDU (n = 22). Median (IQR) for the following variables FC, SCCAI, HBI and DI were respectively: 82 (28–455), 1 (0–2), 3 (1–9), 3 (2–4). Spearman correlations between FC and DI: 0.24 ($p < 0.01$), DI and SCCAI: 0.17 (p = 0.01), DI and HBI: 0.25 (p = 0.17). Based on Illumina microbial data 3 clusters (PCoA) according to FC values categorized as; remission (0–200 mg/kg), moderate activity (200–600 mg/kg) and severe activity (>600mg/kg) showed a trend towards separation in these 3 groups, ANOSIM R = 0.15, p = 0.001. No clear clusters were observed in regards to HBI and SCCAI.

Conclusion: Disease activity measures FC and SCCAI showed relatively small but significant correlations with DI-Dysbiosis Index. Illumina microbial data showed a trend in separating FC in mild, moderate and severe inflammation. Further bioinformatic analyses are awaiting on the individual longitudinal data in relation to disease course and changes in disease activity.

Introduction: Capsule endoscopy (CE) allows a complete, painless and noninvasive exploration of the small bowel (SB), eliminates insufflation inconveniences and the need of sedation permitting the patient the possibility to return to daily activities after its intake. During the last years, endoscopy nurses have gained autonomy and acquired new roles for diagnostic purposes that were previously only reserved to the medical field. The implementation of CE has given nurses a broad field to develop in an autonomous and secure way.

Aims and Methods: We aimed to compare the diagnostic precision of a nurse with a specific endoscopic training to a gastroenterologist trained in visualization of the small bowel by capsule endoscopy.

Validation and reliability study of diagnostic procedures in witch were included all patients that were evaluated in a clinical setting at the Hospital Clínic of Barcelona with a CE for the study of the SB, for the period of June 2016 to October 2017.

Capsules were visualized blindly by a capsule endoscopy trained gastroenterologist and a nurse.

Results: 103 patients were included, average age of 54.28% ± 18.5. 44.7% was male, and 55.3% female. The most common indication for CE was anemia in 52.4% of cases. SB cleansing was excellent, good of fair in a 6.8%, 76.7% and 16.5% respectively.

The average time for visualization for the gastroenterologist and the nurse was 15.54 ± 7.05 y 16.12 ± 6.77 min, respectively with no significant differences.

The gastroenterologist and the nurse detected a total of 532 and 644 lesions respectively, which were significant in 129 (24.25%) and 135 (20.96%) (p = ns), and no significant were 403 (75.75%) y 509 (79.04%) ($p < 0.001$), respectively.

There was a good and statistical significant correlation between both explorers for the detection of significant and no significant findings ($R = 1$; $p < 0.001$).
The sensibility for a nurse was of 96.62% for any lesions, 100% for significant lesions and 95.53% for non-significant lesions.
This nurse, acquires sensibility and a positive predictive value (PPV) for the detection of lesions in the SB by CE, being of 100% for significant lesions, and uses a similar amount of time as a CE trained gastroenterologist.
Conclusion: A specialized nurse, trained and familiarized with the pathology of the small bowel, can detect the same amount of significant lesions as a trained gastroenterologist for the exploration of CE. The nurse can also detect more non-significant lesions that usually lack of clinical relevance.

Introduction: Contrast-enhanced ultrasonography (CEUS) in Crohn's Disease (CD) allows the detection and quantification of transmural vascularization.
Aims and Methods: The aim of this study was to evaluate the CEUS as a predictor of response to immunosuppressive treatment in CD.
A retrospective study was carried out with inclusion of patients with ileal CD, undergoing ileocolonoscopy and start immunosuppressive therapy, both with an interval < 8 days in relation to the CEUS. Demographic, endoscopic, clinical and analytical data were analyzed at the time of CEUS evaluation.
After assessing an area of interest in the bowel wall, the time-intensity curve was determined and quantitative parameters were recorded. Subsequent therapeutic changes, complications of the disease, surgery and need for hospitalization in the first 6 months were considered as failure to therapy.
Results: Twenty-eight CD patients were included. Significant endoscopic inflammatory activity (SES-CD≥7) was identified in 14 patients (50%).
The increase in brightness intensity, in relation to baseline, in patients with significant endoscopic activity was higher than in patients without significant endoscopic activity, 14.2x vs 4.7x, $p = 0.002$.
Ten patients did not respond to the therapy (35.7%). In relation to the increase in brightness intensity, a median was higher in the group of non-responders compared to the group of responders, 15.9x vs 4.8x, $p < 0.001$.
The area on the ROC curve of the increase in brightness intensity for prediction of therapeutic failure was 0.939. For values > 7.68x the baseline, the sensitivity, specificity, positive and negative predictive value was 100%, 83.3%, 76.9% and 100%, respectively.
There was no association between median C-reactive protein or fecal calprotectin and endoscopic activity ($p = 0.301$ and $p = 0.237$) and therapeutic response ($p = 0.065$ and $p = 0.440$).
Conclusion: The CEUS proved to be a useful, non-invasive, superior to the analytical parameters in detection of ileal inflammatory activity and prediction, with an excellent accuracy the treatment failure in CD.

Introduction: The need for therapeutic drug monitoring (TDM) in the treatment of inflammatory bowel disease (IBD) patients under biologics, namely adalimumab (ADA), is unquestionable. Several ELISA-based methodologies are already available in the market. A new point-of-care device (POC-ADA) was recently launched for monitoring serum ADA levels.
Aims and Methods: The aim of this study was to validate the first point of care for TDM of serum ADA levels available in the market by comparing it with three well- established methods. Sera from 199 IBD patients undergoing ADA therapy were quantified by two commercial ELISA, one in-house ELISA and a point of care rapid test. Moreover, donor's serum samples were spiked with known concentrations of ADA and the percentage of recovery of each assay was evaluated.
Results: Regarding the clinical samples, the Intraclass Correlation Coefficients (ICC) of the POC-ADA assay vs. the three ELISA-based established methods was 0.530, 0.761 and 0.864, respectively POC_ADA/ELISA A, POC_ADA/in-house ELISA and POC-ADA/Elisa B. When using different cutoffs for a qualitative comparison, POC_ADA showed an accuracy between 73–89% and the kappa statistics revealed mostly a good agreement (0.492 and 0.682). Spiked samples showed an excellent ICC between theoretical and measured concentrations for all the assays 0.927, 0.984, 0.982 and 0.989 and a good recovery 111%, 113%, 86%, 110%, respectively ELISA A, ELISA B, POC-ADA and in-house ELISA.
Conclusion: The new and first POC-ADA rapid test, which is able to deliver results within 15 min, can be safely used to replace the commonly used ELISA-based ADA quantification kits. This new assay is perfect for immediate concentration adjusted dosing avoiding delays cause by ELISA assays with a turnaround time of approximately 8h.

Introduction: Fecal calprotectin (Fcal) and fecal immunochemical test (FIT) are known to be a useful predictor of endoscopic activity in ulcerative colitis (UC). The aim of this study is to confirm the correlation between ulcerative colitis endoscopic index of severity (UCEIS) and the two tests in addition to the existing Mayo endoscopic subscore (MES).
Aims and Methods: A total of 130 results, obtained in simultaneous examination with endoscopy and two tests, were retrospectively evaluated for 110 patients with UC. The efficacy of two tests for evaluation of endoscopic activity was compared. Endoscopic activity were assessed using the MES and UCEIS.
Results: Both Fcal and FIT results were significantly correlated with MES and UCEIS ($p < 0.001$ and $p < 0.001$). But Fcal showed a more accurate statistical correlation than FIT in both MES ($r = 0.688$ versus 0.662) and UCEIS ($r = 708$ versus 0.683). In the mucosal healing state, the sensitivity of FIT was more accurate than that of Fcal (sensitivity to MES 0; FIT 97% versus Fcal 71%, sensitivity to UCEIS 0 or 1; FIT 93% versus Fcal 64%).
Conclusion: Both Fcal and FIT were well correlated with endoscopic activity in UC. Fcal was more accurate than FIT in endoscopic activity and FIT was more sensitive to mucosal healing.

Introduction: Suppressor of Tumorigenicity 2 (ST2) is an IL33 receptor detected in mucosa and serum of IBD patients and associated with inflammatory burden[1]. Golimumab (GLM) is effective for induction and maintenance of response in patients with moderate to severe ulcerative colitis (UC)[2]. Non-invasive serum biomarkers to assess intestinal inflammation and predict clinical response to therapeutic regimens are needed and may assist current IBD patient care.
Aims and Methods: This was an open-label uncontrolled multicenter prospective study. Primary objective was to evaluate the correlation of serum soluble ST2 levels with endoscopic and histological activity in subjects with moderate to severe active UC treated with GLM. All subjects were evaluated for clinical, endoscopic and histologic activity at screening, week 6 (W6) and week 16 (W16). Endoscopic and histologic activity were scored with the Mayo endoscopy score and Geboes score, respectively. Biomarker samples (ST2 and fecal calprotectin, FC) were collected at baseline and subsequent visits. All study data were analyzed using descriptive statistics. Statistical tests were two-tailed and considering a significance level of 0.05.
Results: A total of 38 patients were treated with GLM, 34 (89.5%) completed through W6 (full analysis set, FAS), and 29 (76.3%) completed through W16. Mean age (range) was 34.6 (19–65) years; 15 (44.1%) were male. At baseline, 94.1% had moderately active disease (Mayo score 6–10) and 5.9% (N = 2) severe disease; 27 (79.4%) were treated with immunosuppressants and 16 (47.1%) were taking glucocorticoids. At W6, 47.1% of patients were in clinical response and 14.7% in clinical remission; 62.1% and 37.9% at W16, respectively. At W6, ST2 levels were significantly correlated with endoscopic activity ($r_s = 0.451$, 95% CI: 0.133–0.685, $p = 0.0074$) but not with histological activity ($r_s = 0.252$, 95% CI: −0.094–0.544, $p = 0.1506$). At W16 no correlations were significant. For patients with endoscopically active (n = 20) *vs.* inactive (n = 14) UC at W6, ST2 levels were different at baseline: mean (SD) levels were 25.0 ± 12.5 *vs.* 17.2 ± 6.8 ng/mL ($p = 0.0259$). Changes from baseline to W6 were also different between patients with endoscopically active *vs.* inactive UC at W6: ST2 increase of 2.4 ± 7.8 *vs.* decrease of −3.5 ± 6.9 ng/mL ($p = 0.0290$), respectively. The best cut-off for ST2 level at W6 to discriminate between endoscopically active *vs.* inactive UC at W6 was 16.9 ng/mL, with specificity = 71% and sensitivity = 85% (AUC = 0.800, $p = 0.0001$). ST2 did not correlate with FC at any timepoint (baseline, W6, W16).
Conclusion: This exploratory study shows that ST2 may be a surrogate biomarker of UC disease activity and therapeutic response.
Disclosure: Patrícia Machado is an employee of MSD Portugal and George Philip of Merck & Co., Inc., Kenilworth, NJ, USA. Isabel Redondo was an employee of MSD Portugal at the time the study was conducted.

Introduction: Ulcerative colitis (UC) is a chronic inflammatory disease of the bowel that necessitates thorough disease activity monitoring to provide an optimal treatment strategy. Colonoscopy is considered to be a gold standard method for mucosal healing assessment, although the method is invasive and not the most comfortable for a patient. Contrast-enhanced ultrasound (CEUS) is a promising non-invasive method of bowel wall evaluation.
Aims and Methods: Our aim was to estimate relation between endoscopic activity of UC and quantitative CEUS parameters. During a period from November 2016 to March 2018 45 patients with known UC were recruited into our study. Abdominal CEUS of the bowel (contrast agent – sulfur hexafluoride) with a linear transducer was performed in each patient. The acquired video-loops were processed on a computer work-station with an application Philips QLab. Region of interest including all the layers of the bowel was chosen. The application delivered a time-intensity-curve (TIC) as well as a fitted curve and TIC parameters. The latter were compared with endoscopic activity (Schroeder score) in a bowel segment examined with CEUS. Statistical analysis was carried out using Statistica 8.0 software.
Results: 39 patients were taken for the final analysis, in 7 patients the quality of CEUS data turned out to be inappropriate for quantitative analysis. 4 patients had endoscopic remission (Schroeder 0), 13 had mild disease (Schroeder 1), 15 – moderate disease (Schroeder 2), 7 – severe disease (Schroeder 3). Statistical analysis revealed a significant correlation between volume parameters (area under TIC, peak intensity) and endoscopic activity (Pearson correlation coefficient – 0.6 for AUC and 0.531 for PI, $p < 0.05$).
Conclusion: Quantitative parameters of bowel wall contrast enhancement significantly correlate with endoscopic activity in UC, therefore CEUS is a promising non-invasive tool for disease activity monitoring in patients with UC. Although further large studies are needed to recommend the method for a routine use.
Disclosure: Nothing to disclose

P0949 CUTTING EDGE TECHNOLOGIES TO PREDICT TREATMENT RESPONDER AND NON-RESPONDER IN IBD PATIENTS

M. Breidert[1], P. Eftekhari[2]
[1]*Gastroenterology/Hepatology, Zurich, Switzerland*
[2]*Inoviem, Illkirch-Graffenstaden, France*

Contact E-Mail Address: matthias.breidert@waid.zuerich.ch
Introduction: As it has been shown so far, ''-omics'' alone cannot help solving the dilemma of IBD. Physiological intermolecular modulation spectroscopy (PIMS), a cutting-edge technology is able to reconcile these data with the clinic. PIMS is a label free technology through which dynamic molecular resonance of entire proteins and macromolecular assemblies in a given organ of an individual is recorded, on real time, as the temperature within the sample rises from −37 to 37°C. It discriminates the responders from non-responders to a given treatment.
Aims and Methods: In a transversal clinical study, protein extracts of peripheral blood mononuclear cells (PBMC) of 47 outpatients (female = 16, mean age = 40.8 ± 16.4 years & men = 31, mean age = 41.5 ± 18.6) diagnosed with UC or CD (UC = 20, CD = 27) and treated with anti-TNFα, were subjected to PIMS analysis. Patient's data were blinded. One µg of total protein from each patient's PBMC was challenged with 10ng of infliximab. After determination of base line the samples were frozen at −37°C. Dynamic changes in macromolecular interaction were registered from −37 to 37°C. Three CD patients from each group of responder and non-responder were subjected to Nematic protein Organization technique (NPOT) technology in order to identify the pharmacologically active interactome behind.
Results: PIMS discriminated responder from non-responder profiles as follow: responder to infliximab CD 58% (n = 15) versus 42% (n = 12) non-responder as well as in UC, 65% (n = 13) versus 35% (n = 7) non-responder. This prediction matched with 98% accuracy with corresponding clinical results with only two miss matches in CD. NPOT revealed the presence of proteins ITGA2B, TLN1, FLNA, HSN and SAMHD1 beside the TNF alpha receptor in responder groups whereas only FLNA and SAMHD1 were found in non-responder group.
Conclusion:
1. PIMS in a blinded transversal study is able to stratify patients into two distinct groups of responders and non-responders to infliximab.
2. NPOT revealed the candidate protein interactors needed for benefic effects of infliximab. This could be of a high value for development of biomarkers.

Introduction: Activity in chronic inflammatory bowel disease (IBD), (Crohn's disease and ulcerative colitis) is monitored endoscopically to adjust ongoing pharmacologic treatment in order to achieve defined therapeutic targets such

as mucosal healing. However, many patients opt out of endoscopic evaluation. Bowel preparation, pain, anxiety, embarrassment, and logistics are factors affecting adherence.
Aims and Methods: The aim of this study was to investigate the influence of deep sedation on the attitude towards colonoscopic monitoring in patients with IBD. A prospective, randomized clinical trial of deep nurse administered propofol sedation (NAPS) versus moderate midazolam and fentanyl sedation. Patients provided a satisfaction score prior to discharge. Patient aged > 17 years with a strong suspicion or established diagnosis of IBD and scheduled colonoscopy were eligible for the study. Exclusion criteria: ASA class > II, pregnancy, non-compliant with fasting, a history of complicated anaesthesia or inability to complete satisfaction survey.
Results: A total of 126 patients were randomized to deep (n = 62) or moderate sedation (n = 64). The deep sedation group was sedated significantly more to their liking (p = 0.001), experienced less pain (5 = no pain, 1 worst pain) (4.97 vs 3.42, p = < 0.001), and rated the current experience better than prior sedations and higher than the moderate sedation group, (4.30 vs 3.65, p = < 0.001). Of note, the deep sedation group were more likely to accept frequent endoscopies (4.33 vs 3.55, p = < 0.001), and scored higher on Overall Satisfaction score (4.94 vs 4.04, p = < 0.001) than the moderate sedation group. The results were consistent within a week after the procedure.
Conclusion: Patients with IBD significantly favor deep sedation over moderate sedation. Pain and previous experience with moderate or deep sedation are important contributing factors. Availability of deep propofol sedation may facilitate patient adherence to endoscopy-based monitoring programmes, including drug adjustment and cancer surveillance.

Introduction: In the absence of a feasible, non-invasive gold standard, iron deficiency anaemia (IDA) is best measured by the use of multiple indicators. However, the choice of an appropriate single iron biomarker to replace the multiple-criteria model for IDA screening at the population level continues to be debated. Recently, low haemoglobin density (LHD%) from Coulter counters has been suggested as a useful tool to detect iron deficiency.[1] Its diagnostic performance in a population of patients with inflammatory bowel disease (IBD) has not yet been evaluated. Using the mathematical sigmoid transformation LHD% = $100\times\sqrt{}$(1-(1/(1 + e (1.8 (30-MCHC))))), this study investigated the reliability of LHD% for the assessment of iron status in iron deficiency anaemia (IDA), anaemia of chronic inflammation (ACI) and mixed IDA/ACI.
Aims and Methods: The study population consisted of 88 patients with IBD (mean age 39.09 ±13.12 years, 78.4% female) who consecutively attended the Interdisciplinary Crohn Colitis Centre Rhein-Main, Frankfurt/Main for routine evaluation between October 2014 and September 2016. In addition to LHD%, blood count, transferrin saturation (TSAT), serum ferritin (SF), and C-reactive protein (CRP) were determined by routine assays. Patients with anaemia were classified as having IDA if active inflammation (CRp < 5mg/L) was absent, TSAT < 20% and ferritin level < 30μg/L; patients were classified as having ACI if active inflammation was present (CRP ≥5mg/L), TSAT < 20% and ferritin level ≥100μg/L; patients were classified as having IDA/ACI if active inflammation was present, TSAT < 20% and ferritin level >100μg/L.[2] Receiver operator characteristic (ROC) curves were constructed to evaluate the diagnostic performance of LHD%.
Results: In ferropoenic IBD patients, applying a cut-off of 3.7%, LHD% values were not statistically different in patients with IDA compared to the IDA/ACI group (17.80 vs. 23.52%; p = 0.834). Significant differences were not observed between patients with ACI (LHD 12.52%) compared with the IDA/ACI group (LHD 23.55%, p = 0.268). ROC analysis for LHD% in the detection of iron deficiency showed the following: Area under the curve 0.927; cut off 3.7%, sensitivity 86%, specificity 85%. Haematological and biochemical parameters of the patients are shown in Table 1.
Conclusion: These results clearly demonstrate that LHD% is a reliable biomarker for the detection of iron deficiency in IBD patients with anaemia regardless of whether inflammation is present. Our findings indicate that LHD can provide added value in diagnosing iron deficiency in anaemic IBD patients.

Introduction: Recent epidemiological studies report an increased risk of ischemic vascular disease in patients with inflammatory bowel disease (IBD). In a previous study (1) we have shown increased expression of surrogate markers of early atherosclerosis (ATS), such as aortic stiffness and intima media thickness (IMT) in a homogeneous cohort of IBD patients, in spite of absence of traditional risk factors for ATS, suggesting a role for chronic inflammation.
Aims and Methods: The aim of this study was to assess prospectively modifications of IMT and arterial stiffness in a longitudinal study on the same cohort, in relation to therapy and disease characteristics. A total of 39 patients with IBD (14 ulcerative colitis and 25 Crohn's disease) underwent a second clinical, biohumoral and instrumental assessment after a mean period of 4.8 ± 0.3 years. Carotid IMT was evaluated by using high resolution B-mode ultrasonography. Arterial stiffness was assessed by measurement of carotid-femoral Pulse Wave Velocity (cf-PWV) and Augmentation Index (AIx).
Results: We found a statistically significant increase in body mass index (22.44 kg/ m^2 at baseline vs 23.39 kg/ m^2 at last follow-up visit, p = 0.043), white blood cell count (7339.05/mmc at baseline vs 8291.28 mmc at follow-up, p = 0.015) and total cholesterol (160.79 mg/dl at baseline vs 172.08 mg/dl at follow-up, p = 0.028); while a statistically significant reduction in glycemia (88.69 mg/dl at baseline vs 83.90 mg/dl at follow-up, p = 0.019 was observed. No statistically significant variation was observed with respect to the values of the AIx and carotid IMT; while an average increase in cf-PWV values was observed (8.67 m/s at baseline vs. 9.19 m/s at follow-up, p = 0.129), but without reaching statistical significance. As far as concerns the other hemodynamic parameters, we found a trend in improvement of PAD (diastolic arterial pressure) and PAM (mean arterial pressure): respectively 75.31 mmHg at baseline vs 71.15 mmHg at follow-up, p = 0.064; 89.51 mmHg at baseline vs 85.13 at follow-up, p = 0.062). No statistically significant difference was found for PAS (systolic blood pressure). On logistic regression analysis, the only variable that was able to influence the worsening of cf-PWV is the duration disease (p = 0.048).
Conclusion: In our prospective cohort of IBD patients there was no significant increase in the expression of surrogate markers of ATS, except cf-PWV which did increase over time. Disease duration was the only variable, among those evaluated, able to predict the worsening of cf-PWV. ATS in IBD is a progressive complication, however progression is slow and the timing of surveillance measures is yet to be established.

P0953 LONG-TERM OUTCOME OF TRANSMURAL HEALING VERSUS MUCOSAL HEALING IN CROHN'S DISEASE: THE TIME FOR A NEW TARGET

F. Castiglione, **N. Imperatore**, A. Testa, O.M. Nardone, M. Schettino, A. Opramolla, L. Pellegrini, F. Crispino, N. Caporaso, A. Rispo
Federico II University, Naples, Italy

Contact E-Mail Address: nicola.imperatore@alice.it
Introduction: While mucosal healing (MH) has been proved to predict clinical outcomes in Crohn's disease (CD), little is known about the long-term outcome of transmural healing (TH).
Aims and Methods: The aim of this study was to prospectively assess the one-year clinical outcomes of CD patients achieving TH after 2 years of treatment with biologics, comparing to patients reaching MH alone or no healing (NH). We performed a 1-year observational longitudinal study, evaluating steroid-free clinical remission (CR), clinical relapse, rate of hospitalization and surgery in all CD patients treated with biologics for 2 years, who were classified in accordance with clinical, endoscopic and sonographic findings in 3 groups: TH, MH and NH.
Results: Among 218 patients who completed a 2-year treatment period with biologics, 68 subjects (31.2%) presented TH, 60 patients (27.5%) MH alone, while 90 patients (41.3%) did not achieve any healing (NH). At the end of the study, TH was associated with higher rate of steroid-free CR, lower rates of clinical relapse, hospitalizations and surgeries at 1-year respect to MH and NH ($p < 0.001$). Furthermore, TH was associated with a longer time until clinical relapse (HR 0.87, $p = 0.01$), hospitalization (HR 0.88, $p = 0.002$) and surgery (HR 0.94, $p = 0.008$) than MH. Also among patients withdrawing biologics, TH predicted better clinical outcomes at 1-year than MH ($p < 0.01$).
Conclusion: TH is the most ambitious and powerful endpoint associated with complete improvement of all clinical outcomes, even more than MH. Additionally, TH was associated with better long-term clinical outcomes than MH also after biologic withdrawal.

P0954 ADVANCED ENDOSCOPY FOR SURVEILLANCE OF COLONIC INFLAMMATORY BOWEL DISEASE: SYSTEMATIC REVIEW WITH META-ANALYSIS

N. Imperatore, F. Castiglione, A. Testa, G.D. De Palma, N. Caporaso, A. Rispo
Federico II University, Naples, Italy

Contact E-Mail Address: nicola.imperatore@alice.it
Introduction: Considering the high risk of dysplasia and cancer in inflammatory bowel disease (IBD), surveillance is advocated. However, international guidelines do not reach a uniform recommendation on how to perform surveillance.
Aims and Methods: We performed a systematic review with meta-analysis to assess the best endoscopic surveillance strategy in colonic IBD. The systematic review was performed in PubMed/MEDLINE, EMBASE, SCOPUS and Cochrane databases to identify studies comparing white light endoscopy (WLE) and advanced endoscopy (AdvE) in the detection of dysplasia or neoplasia in colonic IBD. A sub-analysis between dye-spray chromoendoscopy (DCE), narrow-band imaging (NBI), I-SCAN, full-spectrum endoscopy (FUSE) and auto-fluorescence imaging (AFI) was also performed. Another sub-analysis explored the role of random vs targeted biopsies in the detection of dysplastic lesions in IBD. Pooling was performed using diagnostic fixed or random-effect model according with heterogeneity.
Results: Twenty-seven studies (6167 IBD patients with 2024 dysplastic lesions) met the inclusion criteria. There was no publication bias. AdvE showed a higher likelihood of detecting dysplastic lesions than WLE (19.3% vs 8.5%, OR = 2.036), with an incremental yield (IY) of 10.8%. DCE (OR = 2.605) and AFI (OR = 3.055) had higher likelihood of detecting adenomas than WLE; otherwise, I-SCAN (OR = 1.096), NBI (OR = 0.650) and FUSE (OR = 1.118) were not superior to WLE. Dysplasia was found in 1256/7267 targeted biopsies (17.3%) and in 363/110040 random biopsies (0.33%) (OR = 66.559, IY = 16.9%).
Conclusion: AdvE, especially DCE and AFI, was associated with higher likelihood of discovering dysplastic lesions than WLE. Chromoendoscopy with targeted biopsies should be the preferred endoscopic technique for IBD surveillance.

Introduction: Serum procalcitonin (PCT) is an excellent marker of infectious conditions. We evaluated serum PCT as diagnostic marker for CMV reactivation in exacerbation of ulcerative colitis patients.
Aims and Methods: We retrospectively analyzed clinical data from 47 patients with exacerbation in UC for whom serum procalcitonin and CMV study were measured between January 2017 and December 2017. Diagnosis of CMV reactivation was either CMV IgM, CMV antigenemia, blood CMV PCR, tissue CMV PCR or CMV immunohistochemical stain were positive. Other infectious conditions were excluded.
Results: Positive CMV reactivation among them were observed in 28 patients (59.6%). There was no difference in the sex, steroid, immunomodulator, anti-TNF agents, and disease extension between the two groups. The mean serum PCT levels in positive CMV reactivation and negative CMV reactivation were 0.127 ± 0.29 mg/mL and 1.510 ± 3.53 ng/mL, respectively ($p = 0.10$). Also, there was no difference in the white blood cell, neutrophil, lymphocyte, hemoglobin, platelet, ESR, CRP, albumin and Fecal calprotectin between two groups.
Conclusion: Serum PCT was not correlated with CMV reactivation in exacerbation of ulcerative colitis patients.

P0956 SYSTEMATIC REVIEW: PREDICTING THE DEVELOPMENT OF PSYCHOLOGICAL MORBIDITY IN INFLAMMATORY BOWEL DISEASE

A.B. Hoogkamer[1], A. Brooks[2], A.J. Lobo[2], G. Rowse[3]
[1]*University of Sheffield, Medical School, Sheffield, United Kingdom*
[2]*Royal Hallamshire Hospital, Academic Department of Gastroenterology, Sheffield, United Kingdom*
[3]*University of Sheffield, Department of Psychology, Sheffield, United Kingdom*

Contact E-Mail Address: abhoogkamer1@sheffield.ac.uk
Introduction: Psychological morbidity (anxiety and/or depression) in inflammatory bowel disease (IBD) is common (reported prevalence of up to 50% in patients with IBD) and has significant personal and economic costs to society. Prediction of psychological morbidity in IBD may allow for early intervention, but predictive factors are unclear.
Aims and Methods: To undertake a systematic literature review to determine predictors of the development of psychological morbidity in patients with IBD. Electronic searches for English-language articles were performed using keywords for "psychological morbidity" according to DMS-IV, "prediction" and "IBD" in the MEDLINE, PsychInfo and Web of Science databases for studied published from 1997 to February 2018. Studies were included if they had both baseline data (T1) and follow data (T2) to allow differentiation between factors *associated with* and those *predictive of* psychological morbidity.
Results: 1129 studies were identified, of which seven met the inclusion criteria. Five of these focused on predicting depression with only two studies additionally examining anxiety. The median age of patients was 37 years (range 11.8–48) and on average 59% of participants were female (SD 18.2). Longitudinal follow-up periods varied considerably (median 12 months (range 6–60)). Statistical methods were inconsistent across studies and included regression models, cross-lagged panel models and ANCOVAs. Physical factors predicting psychological morbidity included: female gender (OR 1.7; 95% CI 1.61–2.71); additional comorbidity (≥1 chronic illness alongside IBD) (OR 4.31; 95% CI 2.28–6.57); surgical intervention (OR 1.9; 95% CI 1.15–3.13) and immunosuppressant use (OR 1.56; 95% CI 1.03–2.38). Predictive psychological factors included: parental stress (r-change = 0.03, $F(1,58) = 35.6$, $p < 0.05$); attachment anxiety ($r = 0.61$, $P \leq 0.001$); psychological thriving ($r = -0.37$, $p < 0.01$) and gratitude ($r = -0.43$, $p < 0.01$). Factors with an inverse relationship to the development of morbidity were protective, for example higher levels of gratitude reduced the likelihood of developing psychological morbidity.
Conclusion: Psychological morbidity in IBD may be predicted by disease-related and psychological factors, potentially allowing earlier intervention and reducing personal and economic costs. Further longitudinal data from large IBD cohorts are required to determine additional predictive factors rather than associations. Development and validation of a predictive tool for the development of psychological morbidity in IBD would benefit patients and health care professionals.

Introduction: In Stricturing Crohn's Disease (SCD) strictures have traditionally been classified as inflammatory or fibrotic: the first have been thought to respond to medical treatment and the latter have usually been associated with the need for surgery[1]. Recent papers establish that in most cases these strictures appear to have mixed characteristics[2], and that even in inflammatory strictures medical treatment doesn't always avoid the risk of critical stenosis of the bowel lumen, thus resulting in surgery too. In our study we tried to identify ultrasonographic findings in SCD that may associate with a higher risk of surgery and allow us to make early choices regarding treatment election in this specific cohort of patients.
Aims and Methods: We conducted a case-control study at our institution, selecting 70 patients diagnosed with SCD that underwent ultrasonography (US) during follow up from 2013 to 2017 and then divided them into groups depending

on the need for surgery: surgery group and control group. Main target was evaluating ultranosographic findings associated with a higher risk of surgery, US features analyzed are described in results. We used Student's T and Chi^2 tests for quantitative and qualitative variables comparison respectively, and performed multivariable analysis using logistic regression. We considered statistical significance a p value of <0.05.

Results: Out of 70 patients, 24 needed surgery because of obstructive symptoms (34.29%), while 46 remained surgery-free at the time of the analysis (65.71%). Baseline characteristics of both groups can be found in table 1. Median time from US to surgery was 71.5 days (IQ range [12–300]). Ileocolic resection was performed in 16 patients (66.6%) while the rest underwent ileocolic plus other kind of bowel resection (8 patients, 33.3%). When comparing US findings, the following ones reached statistical significance: stricture doppler activity (control group: mean 0.86 SD 0.34 vs surgery group: mean 2.08 SD 0.88, $p < 0.001$), presence of fistulas (enteromesenteric: $chi^2 = 4.23$, $p = 0.04$; enteroenteric: $chi^2 = 9.13$, $p = 0.003$) and presence of abscess ($chi^2 = 8.46$, $p = 0.004$). When performing multivariable analysis, these data appear to have clinical significance regarding risk of subsequent surgery but they didn't reach statistical significance probably due to lack of sample size. Data obtained applying logistic regression are: doppler activity (OR = 1.14 IC95% [0.79–1.64], $p = 0.46$), enteroenteric fistula (OR = 5.43, IC95% [0.7–40] $p = 0.09$), associated abscess (OR = 7.9, IC95% [0.5–112], $p = 0.69$). Bowel wall thickness, presence of pre-stenotic dilation and involvement of mesenteric fat did not show clinical or statistical significant association with the risk of surgery ($p = 0.20$, $p = 0.517$ and $p = 0.25$, respectively).

Conclusion: In our experience, transmural complications detected in a follow-up US of patients with SCD are associated with a higher risk of surgery and should be taken into account when deciding the best choice of treatment, wether it is a possible therapeutic escalation of medical therapy or early surgical resection. These data must be validated in prospective studies that confirm our findings.

Characteristic	Surgery group (n = 24)	Control group (n = 46)
Sex, n: male (%), female (%)	10 (41.7%), 14 (58.3%)	26 (56.5%), 20 (43.5%)
Age at diagnosis of CD: mean (SD)	34.33 (15.1)	37,09 (16.2)
Smoking, n: smokers (%), non smokers (%), ex smokers (%)	12 (50%), 8 (33.3%), 4 (16.7%)	4 (8.8%), 39 (84.7%), 3 (6.5%)
Stricture location according to Montreal, L: n (%)	L1: 15 (62.6%), L3: 8 (33.3%), L4: 1 (4.1%)	L1: 33 (71.7%), L2: 3 (6.5%), L3: 7 (15.2%), L4: 1 (2.1%)
Number of strictures (n, %)	1 (11, 45.83%), 2 (9, 37.5%), 3 (3, 12.5%), 4 (1, 4.1%)	1 (22, 47.82%), 2 (19, 41.3%), 3 (5, 6.5%)
Associated fistula (n, %)	17 (70.8%)	9 (19.56%)
Associated abscess (n, %)	6 (25%)	3 (6.5 %)
AntiTNF treatment: n (%)	17 (70.83%)	8 (17.39%)

[Baseline characteristics of the study group.]

Introduction: Microscopic colitis (MC) is an important cause of chronic diarrhoea in adults. Histopathology is the gold standard for diagnosis but colonic biopsy has a variable yield. Endoscopically, the mucosa is normal, often leading to delayed diagnosis As the mucosa appear normal on endoscopy in most cases, there is no specific area to target for biopsy.

Aims and Methods: The aim of the current study was to evaluate the ileocolonic mucosa in patients with suspected MC with narrow band imaging (NBI) and to describe the narrow band imaging findings (NBI), in patients with microscopic colitis. We also aimed to study the utility of NBI guided biopsy for improving the diagnostic yield of colonic biopsies by comparing yield of NBI-guided biopsy with the yield of white light colonoscopy-guided biopsy for the diagnosis of microscopic colitis.

Materials and methods: We prospectively recruited patients aged more than 18 years with suspected microscopic colitis during the period July 2016 to December 2017. Patients with malignancy, coeliac disease, small intestinal bacterial overgrowth, inflammatory bowel disease, gastrointestinal tuberculosis and severe comorbidities were excluded. Patients underwent blood investigations, imaging including contrast enhanced computed tomography abdomen (if indicated), stool analysis and hydrogen breath tests using glucose,lactose and lactulose. All patients underwent colonoscopy with ileal intubation if possible. Patients underwent both HDWLE and NBI during the same setting by the same observer. NBI finding were recorded in a predefined format. Four pieces of biopsies were taken during white light examination (WLE) from caecum/ascending colon and four pieces from descending colon/sigmoid colon. Additional four pieces of biopsies were taken during NBI examination from same colonic segments during NBI examination Each set of biopsies was collected in separate containers and labelled for further histopathological processing and examination by an expert gastrointestinal histopathologist. The diagnosis of MC was made using statements of the European Microscopic Colitis Group 2012.

Results: A total of 53 patients suspected to have microscopic colitis were enrolled in the study, and a final diagnosis of MC was established in 43 [mean age – 45.83(±15.92), males – 27]. Out of 43 cases with MC, 25(58.1%) patients had collagenous colitis (CC), 14 (32.5%) had lymphocytic colitis (LC) and 4(9.4%) had mixed picture fulfilling criteria for both. The WLE findings were normal mucosa in all patients. NBI showed type 1 pit pattern in all patients with MC. Vascular pattern was regular pattern in all patients. Mucosal pattern was honey comb type in all patients. A patternof focal area of abnormal vascularity with focally obscure pit pattern was found to be more common in cases than controls [35(81.39%); 5(12.5%) ($p = 0.052$). In the group of CC, NBI guided biopsy yielded the diagnosis in 88% (22 out of 25 patients) whereas white light guided biopsy yielded the diagnosis in all 25 cases (100%) ($p = 0.24$). In the group of lymphocytic colitis, NBI guided biopsy yielded the diagnosis in 92% (13 out of 14 patients) whereas white light guided biopsy yielded the diagnosis in all 14 cases (100%) ($p = 0.89$).

Conclusion: This prospective studydescribes the NBI findings of colon in patients with MC and describes a unique sign of focal area of abnormal vascularity with focally obscure pit pattern to be more common in MC. However, there was no significant difference in yield of NBI-guided biopsy compared to white light colonoscopy-guided biopsy for the diagnosis of MC.

P0960 THE PREVALENCE OF INFLAMMATORY BOWEL DISEASE IN PATIENTS WITH HIDRADENITIS SUPPURATIVA

S. Lovas[1], K. Gáspár[2], A. Jenei[2], S. Kacska[1], F.I. Altorjay[1], A. Szegedi[2], É. Remenyik[2], **K. Palatka**[1]

[2]*University of Debrecen, Dermatology, Debrecen, Hungary*

Contact E-Mail Address: palatka@med.unideb.hu

Introduction: Hidradenitis suppurativa (HS) is an inflammatory, recurrent skin disease of hair follicle, that mainly presents in axillary, inguinal and anogenital regions. Clinically, the condition can imitate the cutaneous Crohn's disease and it can co-exist with inflammatory bowel diseases (IBD). HS and IBD have many similarities in clinical appearance, pathogenesis and etiology.

Aims and Methods: The purpose of our study was to determine the prevalence and characteristics of inflammatory bowel disease in patients diagnosed with hidradenitis suppurativa by comparing clinical signs, endoscopy, histology and laboratory results.

Thirty-nine patients (64% male; mean age: 35,77; median: 34) were seen with diagnosed hidradenitis suppurativa, whom underwent screening colonoscopy. By the endoscopic and histological results, we made two patient-groups (HS and HS+IBD) and compare the epidemiological, clinical, laboratory data.

Results: The prevalence of IBD was 17,9% among HS patients (n = 7; Crohn's disease: 6; colitis ulcerosa:1). The average time between HS and CD diagnosis was one year. In 'HS+IBD' group, CRP levels were not significantly higher (mean: 36,37 mg/l; median: 27) but we found higher ASCA IgG levels (mean: 15,48; median:10). In HS group, body mass index (BMI) was higher than 30kg/m^2 in all cases. In 'HS+IDB' group, all patients have lower BMI. In the two patient-groups, we could not find any difference in smoking habits and NOD2 polymorphism.

Conclusion: Based on our data, the appearance of IBD correlated with younger age, lower body mass index, severe HS activity, penetrating form. In the future, it may be justified to screen HS patients for IBD.

Introduction: Serum albumin concentration has been shown to be inversely related to drug clearance for biologic therapies used to treat inflammatory bowel disease.[1–3] Lower albumin levels may be linked to higher drug clearance rates and poorer clinical outcomes for some biologics.[4] Albumin levels as a predictor of efficacy in patients (pts) receiving tofacitinib is uncertain.

Aims and Methods: Tofacitinib is an oral, small molecule JAK inhibitor that is being investigated for ulcerative colitis (UC). We evaluated the effect of baseline albumin (BALB) on tofacitinib pharmacokinetics (PK) and efficacy. Four randomised placebo-controlled studies of tofacitinib in pts with moderate to severe UC were included in PK analyses: one Phase (P) 2 study (A3921063, NCT00787202)[5] and three P3 studies (OCTAVE Induction 1 & 2, NCT01465763 & NCT01458951; and OCTAVE Sustain, NCT01458574).[6] The base PK model was one-compartmental disposition with covariates for BALB, evaluated as a potential predictor for apparent oral clearance (CL/F). The effect of BALB related to efficacy endpoints in P3 induction and maintenance studies was evaluated in a multivariate analysis.

Results: 1096 pts were included in the PK analysis: 641 males and 455 females; the majority (81.3%) were white; median age: 40 years. Mean (standard deviation) BALB was 4.18 g/dL (0.39), range 2.1–5.4 g/dL. In the population PK (popPK) model, BALB was evaluated as a predictor of individual CL/F, showing no statistically significant correlation, so was not included in the final popPK model. BALB concentration was evaluated as a covariate in exposure-response (ER) efficacy analyses, and was shown by stepwise covariate modelling to be non-significant, so was not included in the final ER model. Primary endpoints for induction and maintenance studies were remission based on central read at Weeks 8 and 52, respectively. Multivariate analysis showed no statistically significant correlation between BALB and efficacy endpoints in ER analysis after accounting for other significant predictors of efficacy such as baseline Mayo score.

Conclusion: In contrast to biologic therapies,[1–3] tofacitinib clearance was not related to albumin concentration. As shown in multivariate analyses, BALB had no effect on induction or maintenance efficacy endpoints, and therefore may not be informative to tofacitinib dosing decisions.

Introduction: Preceding PCG 2 was a prospective, double-blind, randomised, phase 3 induction study to compare the efficacy and safety of two different dosing regimen of LT-02 (LT-02 0.8 g QID, LT-02 1.6 g BID) with placebo for 12 weeks for induction of remission in patients with mild-to-moderately active ulcerative colitis refractory to 5-ASA. Present PCG-4 was aimed to investigate the maintenance profile of LT-02.

Aims and Methods: This was a prospective, double-blind, double-dummy multicenter trial to compare the efficacy and safety over 48 weeks of LT-02 1.6 g BID versus placebo and mesalazine 0.5 g TID in a randomization ratio of 2:1:1 for maintenance of remission in patients with UC who had achieved either deep remission (total mDAI score $\leq$1, with 0 points in rectal bleeding and stool frequency-subscores) or remission (total mDAI score $\leq$2, no subscore $>$1) during PCG-2. Primary endpoint was the

Abstract No: P0962

	LT-02 1.6 g BID (N = 75)	Placebo (N = 37)	Mesalazine 0,5 g TID (N = 38)
Primary Endpoint			
Number (%) of patients relapse-free and not a treatment failure after 48 weeks	37(49.3%)	16 (43.2%)	19 (50.0%)
Subgroup analyses: Number (%) of patients relapse-free and not a treatment failure after 48 weeks:			
by Criterion of Deep Remission at baseline of PCG-4 fulfilled [n/N (%)]:			
Yes	24/43 (55.8%)	9/24 (45.8%)	12/22 (54.8%)
No	13/32 (40.6%)	5/13 (38.5%)	7/16 (43.8)
by Localization of disease at baseline of PCG-2 [n/N (%)]:			
Left-sided	22/43 (51.2%)	9/20 (45.0%)	14/25 (56.0%)
Extended	15/32 (46.9%)	7/17 (41.2%)	5/13 (38.5%)
Secondary endpoints:			
Time in Study, in days: Mean (SD)	231.7 (134.7)	183.4 (144.2)	214.4 (136.8)
Time to Clinical Relapse or Discontinuation, in days: Median [95% CI] ; HR [95% CI (LT-02 vs PCO)]	338 [172; —] ; 1.371	167 [52; —]	343 [101; —]
Change from baseline of Histological Index: Mean (SD)	0.5 (0.85)	0.5 (1.01)	0.6 (1.04)

[Primary & secondary efficacy endpoints]

percentage of patients being relapse-free with relapse defined as a rectal bleeding score of ≥1 and a mucosal appearance score of ≥2 of the mDAI scores and not a treatment failure defined as premature withdrawal (whatever the reason) after 48 weeks.
Results: Due to premature recruitment stop of PCG-2 only 150 patients of 400 targeted patients were included (Table). Both the primary and secondary efficacy endpoints showed no significant differences across treatment groups (Full Analysis Set).
Numbers of AEs, SAEs and ADRs were comparable for patients in the three treatment groups. Tolerability of LT-02 was assessed as very good or good by the majority of patients.
Conclusion: Although the study failed to prove superiority of LT-02 treatment vs. placebo for maintenance of remission in UC, there was a numerical trend towards superior efficacy of LT-02 compared to placebo and a marked prolongation of the time to clinical relapse.

P0963 REFLECT: A FRENCH NATIONWIDE PROSPECTIVE STUDY OF CT-P13 -INFLIXIMAB BIOSIMILAR USE IN REAL LIFE

Y. Bouhnik[1], **S. Nancey**[2]
[1]*CHU Beaujon Dept. of IBD and Nutrition, Dept. of Gastroenterology, Clichy, France*
[2]*CH Lyon Sud, Dept. de Gastroenterologie, Pierre Benite, France*

Contact E-Mail Address: snancey@gmail.com
Introduction: CT-P13 is the first monoclonal antibody biosimilar to infliximab (IFX) approved in France. Reflect trial has been set up to evaluate in real life the use of the CT-P13 biosimilar after its introduction in a French sanitary cooperation group (UNIHA) created at the initiative of university hospitals which support the generation of real-world data.
Aims and Methods: Reflect is a multicenter, prospective, observational study, which aimed to describe in real-life the treatment effectiveness and the characteristics of patient (pts) treated with CT-P13. Inclusion criteria were pts (≥ 6 yrs-old) with Crohn's Disease (CD), Ulcerative Colitis (UC), rheumatoid arthritis, ankylosing spondylitis and psoriatic arthritis, treated with CT-P13. Both IFX naive pts (IFXn) and pts having switched from IFX originator to CT-P13 (IFXs) were enrolled. Preliminary results in pts suffering from CD or UC using descriptive statistical analyses from inclusion are reported here. Descriptive analyses were performed.
Results: Between October 2016 and December 2017, among the 627 pts included in the study, 282 pts had an inflammatory bowel disease (IBD) and were analyzed. At baseline, they were 176 CD (51.1% males; mean age: 37.0 ± 13.9 years; median time since diagnosis: 5.7 years) and 106 UC (55.7%; 40.7 ± 17.8 years; 5.5 years). For CD patients colonic/ileocolonic localization was noted in 23.6%/ 45.3%, and 37.3% had perianal disease. For UC patients, left-sided colitis/extensive colitis was noted in 27.7%/57.4%. Almost all pts have been already treated with CT-P13 before inclusion (90.8% of CD and 90.0% of UC); the median treatment duration was 5.6 and 7.4 months, respectively. Previous treatments with biotherapies other than infliximab were taken by 42.9%of CD and 45.5% of UC pts. A minority of pts (12.4% of CD and 9.1% of UC) switched from the originator infliximab to CT-P13. At inclusion, the median Mayo Score for UC were 2 and 1 in IFXn and IFXs pts respectively and the median Harvey-Bradshaw Index (HBI) for CD were 2 and 1 in IFXn and IFXs pts respectively. At 6 and 12 month follow-up, 59.8% and 77.8% of CD pts and 48.7% and 69.2% of UC pts were in remission. In IFXn pts the median change from baseline to 6 and 12 months were 0 and – 2 for mayo score and 0 and -1 for the HBI respectively. Except for the HBI at 6 months, there was no change in the IFXs pts in both UC and CD scores at 6 and 12 months. The safety results are showed in table 1.

	Safety population (N)	n (%)	Number of AE(s)
Pts with at least one adverse event (AE)			
UC pts	106	16 (15.1%)	33
CD pts	176	33 (18.8%)	69
Pts with at least one serious AE			
UC pts	106	4 (3.8%)	7
CD pts	176	10 (5.7%)	14
Pts with at least one allergic infusion reaction†			
UC pts	106	1 (0.9%)	1
CD pts	176	3 (1.7%)	4
Pts with at least one infection‡			
UC pts	106	–	–
CD pts	176	1 (0.6%)	1

[Safety results]
† Including acute and delayed hypersensitivity reactions.
‡ Including severe infections, tuberculosis, opportunistic infections, hepatitis.
Conclusion: Preliminary results from this prospective cohort suggest that patients treated with CT-P13 maintained elevated rates of remission in CD and UC pts at 12 months. No new safety concerns were identified.

Introduction: Vedolizumab (VDZ) is a gut-selective monoclonal antibody blocking α4β7 integrin, which can be effective for patients with inflammatory bowel disease (IBD). Although several studies have reported the real-world experiences of VDZ in Western patients, no study has been reported in Asian IBD patients.
Aims and Methods: We aimed to investigate the clinical effectiveness and safety of VDZ as an induction therapy for Korean patients with Crohn's disease (CD) or ulcerative colitis (UC), who were previously failed to anti-tumor necrosis factor (TNF) therapy. Between August 2017 and April 2018, a total of 34 patients with CD (n = 21) or UC (n = 13) received an induction therapy with VDZ at the Asan Medical Center, Seoul, Korea and were prospectively enrolled in the ASAN VDZ registry. Of those, patients who received three doses of VDZ (week 0, 2, and 6) and were evaluated at week 14 were analyzed. The co-primary outcomes were corticosteroid-free clinical remission (both for CD and UC) and endoscopic remission/ response (for UC) at week 14. The secondary outcomes were corticosteroid-free clinical response, clinical remission/ response, and safety (both for CD and UC).
Results: A total of 23 patients were enrolled (CD, 13 [56.5%]; male, 16 [69.6%]; median age, 38 years [range, 19–52]; median disease duration, 8.5 years [range, 0.7–23.3]). Thirteen patients (56.5%) previously had experienced failures to one anti-TNF agent and 10 patients to two anti-TNF agents (43.5%). Corticosteroid-free clinical remission rates in CD and UC patients were 22.2% and 10%, respectively (Table 1). In patients with UC, endoscopic remission and response rates were 10% and 20%, respectively (Table 1). Corticosteroid-free clinical response rates were 44.4% for CD patients and 30% for UC patients, respectively (Table 1). Clinical remission/ response rates were 33.3%/ 55.6% for CD patients and 10%/ 40% for UC patients, respectively (Table 1). In patients with CD, median Harvey-Bradshaw index, leukocyte count, C-reactive protein level, and fecal calprotectin level were not significantly decreased at week 14 compared with the baseline values (p=0.28, P=0.17, P=0.79, and P=0.43, respectively). In patients with UC, median partial Mayo score was significantly decreased (p = 0.003). However, median leukocyte count, C-reactive protein level, and fecal calprotectin level were not significantly decreased (p=0.38, P = 0.75, and p=0.08, respectively). Nasopharyngitis (30.4%) was the most common adverse events. IBD exacerbation was observed in 4 patients (17.4%) with IBD-related admissions in 2 patients (8.7%).
Conclusion: In Korean IBD patients with prior failures to anti-TNF therapy, VDZ induction therapy may be effective with acceptable safety profile. Further long-term follow-up studies with larger number of patients are required to prove the effectiveness and safety of VDZ.

Introduction: Tofacitinib is an oral, small molecule Janus kinase inhibitor that is being investigated for ulcerative colitis (UC). OCTAVE Induction 1 & 2 (NCT01465763 & NCT01458951) were identical, randomised, double-blind, placebo-controlled Phase 3 trials in adult patients with moderately to severely active UC who had failed, or were intolerant to, steroids, immunomodulators or tumour necrosis factor inhibitors.[1] Rapid onset of tofacitinib efficacy with

significant improvements in patient-reported symptoms (Mayo stool frequency and rectal bleeding subscores) was observed within 3 days.[2]

Aims and Methods: The Mayo score is a combination of four subscores including the Physician's Global Assessment (PGA), which comprises the daily record of abdominal discomfort, and other observations such as physical findings and the patient's performance status. Here, we evaluate the time course of improvement in PGA in patients with UC following induction therapy with tofacitinib. PGA subscores of patients who received placebo or tofacitinib 10 mg twice daily (BID) for 8 weeks in the OCTAVE Induction 1 & 2 trials were collected at baseline, and at Weeks 2, 4 and 8 of the blinded treatment period. Comparisons between groups were made using stratified Cochran-Mantel-Haenszel chi-square test.

Results: A total of 905 patients received tofacitinib 10 mg BID (mean age 41.2 years; 59.2% male) and 234 patients received placebo (mean age 41.1 years; 56.4% male). At baseline, the mean total Mayo score in both placebo and tofacitinib groups was 9.0; the mean partial Mayo score (total Mayo score excluding endoscopic subscore) in both treatment groups was 6.4. By Week 2, 10.3% of patients treated with tofacitinib, compared with 3.4% of placebo-treated patients, achieved a PGA subscore of 0 ($p < 0.01$). Similarly, by Week 2, significantly more patients treated with tofacitinib vs placebo achieved a PGA subscore of 0 or 1 (41.3% vs 27.4%; $p < 0.0001$). A greater proportion of tofacitinib-treated patients had a reduction of $\geq$1 PGA point from baseline compared with placebo patients at Week 2 (52% vs 37.6%; $p < 0.0001$). From Week 2 to Week 8, differences between tofacitinib-treated and placebo-treated patients increased for all three PGA subscores analysed ($p < 0.01$ for all comparisons).

Conclusion: In these two randomised trials in patients with UC, treatment with tofacitinib was associated with a significant improvement in the PGA subscores within 2 weeks and continuing through to Week 8. This coincided with an improvement in patient-related outcomes (stool frequency and bleeding).

Table. Summary of PGA subscores in OCTAVE Induction 1 & 2

	Placebo N = 234	Tofacitinib 10 mg BID N = 905	Difference from placebo, % (95% CI)
PGA subscore of 0, n (%)			
Week 2	8 (3.4)	93 (10.3)	6.9 (3.8, 9.9)**
Week 4	18 (7.7)	149 (16.5)	8.8 (4.6, 13.0)**
Week 8	20 (8.5)	188 (20.8)	12.2 (7.8, 16.7)***
PGA subscore of 0 or 1, n (%)			
Week 2	64 (27.4)	374 (41.3)	14.0 (7.4, 20.5)***
Week 4	87 (37.2)	511 (56.5)	19.3 (12.3, 26.3)***
Week 8	73 (31.2)	507 (56.0)	24.8 (18.1, 31.6)***
Reduction of $\geq$1 point from baseline PGA, n (%)			
Week 2	88 (37.6)	471 (52.0)	14.4 (7.4, 21.4)***
Week 4	121 (51.7)	615 (68.0)	16.2 (9.2, 23.3)***
Week 8	95 (40.6)	575 (63.5)	22.9 (15.9, 30.0)***

**$p < 0.01$; ***$p < 0.0001$ vs placebo based on Cochran-Mantel-Haenszel chi-square test; Data are full *analysis* set.

Introduction: ABP 501 (AMGEVITA®; adalimumab) is an approved biosimilar to adalimumab (Humira®), a fully human recombinant monoclonal antibody. Amgen validated separate assays to independently detect ADAs against ABP 501 and adalimumab; this testing strategy was applied to both binding and neutralizing ADA detection to evaluate immunogenicity of ABP 501 compared to adalimumab. The goal of the present analyses is to assess the extent of ADA cross-reactivity between the biosimilar and reference product (RP) among patients with rheumatoid arthritis and psoriasis in two pivotal Phase 3 studies.

Aims and Methods: All protocol-defined antibody samples collected from drug-exposed subjects, irrespective of treatment group, were tested for binding antibodies against ABP 501 and adalimumab RP using a validated electrochemiluminescence-based assay. Binding ADA magnitude was expressed as signal-to-noise (S/N), defined as the mean signal of the study sample divided by the mean signal of the negative control analysed on the same plate. Samples positive for binding ADAs were then tested in a TNFα-target binding assay for neutralizing activity. Neutralizing antibody titre was reported as the highest dilution that tested positive in the assay. Validated assay parameters for both binding and neutralizing assays such as assay cut point, sensitivity, precision, and drug tolerance for each assay were highly similar. Correlation of binding and neutralizing antibody results (S/N or titre) between ABP 501 or and adalimumab RP assays was evaluated using the Pearson's correlation coefficient. Concordance of antibody results (positive/negative) was evaluated using the kappa statistic.

Results: Irrespective of treatment group, the binding ADA results for ABP 501 and adalimumab RP assays correlated well, with a Pearson correlation coefficient >0.950 and concordance measure of (kappa $>$ 0.860). In a small subset of samples that were not concordant, the distribution of sample reactivity was detected equally across assays. The magnitude of ADAs was at or near the assay cut point, indicating low probability of clinical impact. Furthermore, neutralizing antibody titre results correlated well between ABP 501 and adalimumab RP assays with a Pearson correlation coefficient $>$ 0.780 and strong concordance (kappa $>$ 0.884).

Conclusion: No meaningful differences were observed in the detection of binding and neutralizing ADAs in the different ADA assays, providing evidence of high similarity between ABP 501 and adalimumab RP.

Introduction: Mucosal healing and deep remission (DR) are therapeutic targets in inflammatory bowel disease (IBD).

Aims and Methods: We aimed to characterize DR in patients with Crohn's Disease (CD) and Ulcerative Colitis (UC) under monotherapy with immunomodulators.

Out of a total of 432 patients observed in 2017–2018, 45 were under azathioprine or 6-mercaptopurine monotherapy for a period $\geq$3–6 months. Patients who underwent surgery, patients previously treated with anti-TNF and patients who started anti-TNF were excluded. DR was defined by: clinical remission (CR) in patients without endoscopically documented ulcers / erosions. Imaging activity was also evaluated in patients with CD.

Results: Mean age was 37.9 ± 12.4 years and 53.3% were men. Of the 45 studied patients, 33 had CD (76.8%) and 12 UC (23.2%). In the group with CD Montreal Classification was evaluated (A2-90.9%, L1-39.4%, B1-78.8%), and in this group the prevalence of perianal disease and penetrating phenotype was 27.3% and 12.1%, respectively. In UC 75.0% had extensive colitis-E3. The mean age of diagnosis was 28.9 ± 11.0 years and the mean duration of the disease was 8.9 ± 6.8 years. The majority of patients were under azathioprine (93.3%). Mean duration of treatment was 5.15 ± 3.98 years.

CR was obtained in 37 patients (CD-89.7%, CU-66.7%) and DR in 25 (DC-57.6%, CU-50.0%). Age of diagnosis, early onset and duration of immunomodulatory treatment were not associated with DR. In CD, ileal disease, penetrating phenotype, and perianal disease showed no significant association with DR. The need for topical/oral corticosteroids after initiation of treatment was significantly associated with lower mucosal healing rates ($p = 0.033$).

Conclusion: Despite the high rate of clinical remission under immunomodulator in monotherapy, about half of the patients did not achieved deep remission. The need for corticoid was associated with a lower probability of mucosal healing.

Introduction: Vitamin D deficiency is common in Crohn's disease (CD). Preclinical experiments and one clinical trial suggested anti-inflammatory effects of vitamin D in CD. We studied the anti-inflammatory effect of vitamin D in a prospective placebo controlled clinical trial in patients with CD undergoing an ileocolonic resection with ileocolonic anastomosis.

Aims and Methods: This was a prospective randomized, placebo-controlled trial in 17 centres in Belgium and the Netherlands. CD patients were randomized to receive weekly 25.000 IU vitamin D or placebo for 6 months following their first or second ileocolonic resection. All other CD medication was stopped. The primary endpoint was endoscopic recurrence defined as a modified Rutgeerts score $\geq$i2b at 26 weeks (>5 aphthous ulcerations in the neoterminal ileum, with or without anastomotic lesions); secondary endpoints included clinical recurrence (Crohn's disease activity index (CDAI) $\geq$ 220), quality of life (SF-36, IBD-Q and EQ-5D), safety and differential outcomes by baseline vitamin D serum concentrations. All endoscopies were centrally read and adjudicated by 2 expert blinded endoscopists (GD and PB).

Results: 143 patients were randomized (72 to vitamin D and 71 to placebo); baseline patient characteristics were comparable between the two groups (mean age (±SD) 34 (±12) vs 37 (±15) years, and 38% vs 40% male, respectively). Serum 25-OHvitamin D levels increased from median (IQR) 42 (27–56) nmol/L to 87 (73–105) nmol/L in the intervention group at week 26 ($p = <0.00001$), and remained unchanged at 43 (29–64) nmol/L in patients on placebo throughout the whole study. No difference was seen in the incidence of endoscopic recurrence at 26 weeks between the two groups (Table 1). In addition, the cumulative clinical recurrence rates at week 26 were comparable (Table 1). Quality of life as measured by SF-36, IBD-Q and EQ-5D improved slightly over time in both groups but was not significantly different between the two groups. Adverse events were uncommon in either group; adverse events with an incidence >5% included abscess formation in both groups and wound infection in the placebo group, and were related to the prior surgery. Outcome was not affected by baseline serum vitamin D level, season of inclusion, or ethnicity.

Conclusion: High-dose vitamin D treatment did not reduce the incidence of postoperative endoscopic and clinical recurrence in Crohn's disease patients, despite normalization of serum 25(OH)D concentrations. Hence vitamin D deficiency might merely be a consequence of disease activity rather than a causal explanation in the pathophysiology of Crohn's disease.

	Vitamin D	Placebo	p-value
Rutgeerts $\geq$ i2b	58%	66%	0.37
Rutgeerts $\geq$ i2a	87%	82%	0.22
CDAI $\geq$ 220	18%	18%	0.93

[Table 1. Endoscopic and clinical recurrence rates at week 26]

Introduction: Stenosing lesions in Crohn's disease respond poorly to medical treatments alone. In the face of this problem, bowel-sparing techniques have been developed, including endoscopic dilation, as an alternative to definitive surgery. There is still insufficient evidence regarding the long term success rate, for all phenotypes taken together, and insufficient knowledge of the predictive factors for the success of endoscopic dilation. The aim of our study was to assess efficacy and safety in strictures in Crohn's disease. The secondary objective was to highlight factors predicting the success of this procedure.

Aims and Methods: We conducted a single-centre retrospective cohort study including all patients managed endoscopically, between January 2000 and November 2016, with dilation of digestive strictures in the context of Crohn's disease (all phenotypes taken together). The technical and clinical success was assessed, as was the complication rate. Surgical management after endoscopic management was considered as a failure

Results: 104 patients were included in the course of this study, of whom 56 (53.8%) were men. Of the total number of patients, 43% presented a phenotype considered to be severe (fistulising lesions, ano-perineal lesions...). Median follow-up was of 61 months, or a little over 5 years. A total of 145 dilations were performed on 104 strictures, and 113 concerned secondary anastomotic strictures (77.9%). Technical success was obtained in 117 dilations (92.9%), and only one immediate complication, of the haemorrhagic type, was identified in the course of the endoscopy. There were 10 delayed complications (6.9%), represented by 6 perforations, 2 haemorrhagic events and 2 cases of bacteriaemia with febrile episodes. During our follow-up, 71 patients (68.2%) were treated only endoscopically. Of these patients, 52 (71.2%) required only one dilation session. The remaining 33 patients (31.7%) had surgery within a median delay of 13 months in relation to the first dilation. The presence of another stricture ($p = 0.03$) or a long stricture ($p = 0.02$) were factors predicting the need for surgery in a multivariate analysis. Early clinical success was a protective factor ($p = 0.0005$).

Conclusion: Endoscopic dilation appears to be an effective long term alternative in the management of Crohn's strictures, whether they are primary or secondary in nature and this, for all phenotypes taken together. This procedure allowed two thirds of the patients with stenosing lesions to avoid the need for surgery.

Disclosure: Nothing to disclose

P0970 ESTABLISHING PK EQUIVALENCE BETWEEN ADALIMUMAB AND ABP 501 IN THE PRESENCE OF ANTI-DRUG ANTIBODIES USING POPULATION PK MODELLING

S. Doshi[1], E. Krishnan[2], H. Wang[2], N. Zhang[2], **V. Chow**[1]

Introduction: Adalimumab (HUMIRA®) and its approved biosimilar ABP 501 (AMGEVITA® ; adalimumab) exhibit nonlinear pharmacokinetics (PK) following a single subcutaneous (SC) dose in healthy volunteers possibly due to target mediated disposition or development of anti-drug antibodies (ADAs). The presence of nonlinear PK leads to low and variable drug levels posing a challenge in assessing PK equivalence of these two agents. To address this we used a population PK modeling approach to assess PK equivalence.

Aims and Methods: A one-compartment linear PK model with first-order absorption was selected to characterize the ABP 501 and adalimumab PK in healthy subjects. The model was parameterized in terms of apparent systemic clearance and apparent central volume of distribution for subjects with or without ADAs. Body weight, albumin and ADA status were evaluated for their potential impact on adalimumab or ABP 501 PK. For subjects who developed ADAs, the model evaluated the inclusion of additional antibody mitigated clearance mechanisms using Michaelis-Menten (MM) type of saturable clearance or time-dependent changes in linear clearance. The effect of treatment on PK parameters was evaluated by comparisons of the empirical Bayes' estimates of the individual PK model parameters.

Results: In healthy subjects without ADAs, the ABP 501 and adalimumab PK after SC administration was linear and adequately described by a one-compartment model with first order absorption and linear clearance from the central compartment. Inclusion of an additive time dependent linear clearance for subjects with ADAs was superior to a model incorporating an additive MM saturable clearance for subjects with ADAs. Graphical and statistical comparisons of empirical Bayes' estimates by treatment demonstrated no difference in any PK model parameters by treatment. The population and inter-individual variability estimates of clearance and volume were 0.399 (33.6%) L/d and 8.94 (23.5%) L, for a 72.7 kg subject (median body weight). The time to onset and magnitude of the additive ADA-related linear clearance was 33.7 (54.4%) days and 1.15 (52.6%) L/d. Diagnostic plots demonstrated good concordance between observed and population or individual predicted concentrations without any bias. Visual predictive checks demonstrated the model described well the variable PK following a single dose of ABP 501 or adalimumab. The model described the PK of each individual well and was used to estimate accurately each individual's area under the concentration curve (time 0 to infinity) for all 203 subjects who completed the study.

Conclusion: The present population PK modeling confirms PK similarity of ABP 501 to adalimumab.

Introduction: Immunomodulatory therapy with agents such as methotrexate and corticosteroids can impact the development of anti-drug antibodies (ADAs) to monoclonal antibodies such as adalimumab used to treat inflammatory bowel disease. ABP 501 (AMJEVITA®; adalimumab) is an approved biosimilar to adalimumab. Here we report results from a Phase 3 study in patients with rheumatoid arthritis (RA) comparing the incidence of ADAs and the relative magnitude of the ADA response between ABP 501 and adalimumab reference product (RP) on background methotrexate (MTX).
Aims and Methods: We analysed data from a randomized, double-blind, 26 week, 1:1 active-controlled study designed to show clinical equivalence between ABP 501 40 mg and adalimumab 40 mg subcutaneously every two weeks among adalimumab-naive adult patients with moderate to severe RA who had an inadequate response to MTX. Patients were required to receive a stable dose of MTX (range 7.5 to 25 mg/week) for the duration of the study. Patients were also allowed to remain on oral corticosteroids at a dose of ≤10 mg/day of prednisone, or equivalent. Validated electrochemiluminescent assays were developed and used for detection of binding ADAs. ADA magnitude was expressed as signal-to-noise (S/N), defined as the mean signal of the study sample divided by the mean signal of the negative control analysed on the same plate. Samples positive for binding ADAs were then tested in a TNFα-target binding assay for neutralizing activity. Neutralizing antibody titre was reported as the highest dilution that tested positive in the assay.
Results: For the ABP 501 and adalimumab (RP) groups, 5 (1.9%) and 6 (2.3%) patients, respectively, tested positive for pre-existing binding antibodies and no patients tested positive for pre-existing neutralizing antibodies. Overall, 201 (38.2%) of all patients tested positive for binding antibodies at weeks 4, 12, or 26, with similar percentages in each treatment group (ABP 501, n = 101, 38.3%; adalimumab, n = 100, 38.2%) across all time points. A total of 53 (10.1%) of all randomized patients tested positive for neutralizing antibodies at weeks 4, 12, or 26, which was also similar in each treatment group (ABP 501, n = 24, 9.1%; adalimumab, n = 29, 11.1%). The rate of seroconversion over time for both treatment groups was similar, progressively increasing throughout the study. For subjects testing ADA positive, the magnitude of both the binding and neutralizing ADAs across the treatment groups were evenly distributed, with similar median S/N or titre values at each time point.
Conclusion: Similar immunogenicity rates were observed and relative magnitude of the ADAs was similar between the ABP 501 and adalimumab RP treated patients.
Disclosure: Authors have been or continue to be employees and stockholders of AMGEN.

P0972 INJECTION SITE REACTIONS AND INJECTION SITE PAIN FOR THE ADALIMUMAB BIOSIMILAR ABP 501: RESULTS FROM TWO DOUBLE-BLIND RANDOMIZED CONTROLLED STUDIES

E. Krishnan, N. Zhang, **H. Wang**
Amgen, Biosimilars, Thousand Oaks, United States

Contact E-Mail Address: hwang01@amgen.com
Introduction: Adalimumab (40 mg/0.8 mL strength) is a commonly used, subcutaneously administered anti-TNF therapy for inflammatory bowel disease. Clinical studies of adalimumab in rheumatoid arthritis (RA) have documented that the injection site reactions (erythema, itching, haemorrhage, pain or swelling) were the most common adverse events and that the immediate post administration pain from the injection to be 3.7 cm on a 10 cm visual analogue scale (VAS). ABP 501 (AMGEVITA®; adalimumab) was recently approved in the EU as the first biosimilar to adalimumab, a fully human recombinant monoclonal antibody. Formulation excipients of a biosimilar can differ provided there is no impact to product quality. ABP 501 is therefore formulated with different set of excipients that do not include citrate as that is known to cause pain or stinging.
Aims and Methods: To compare injection site pain and injection site reactions between ABP 501 and adalimumab, two randomized, double-blind, active-controlled clinical trials were conducted; one in patients with moderate to severe RA (n = 526) and the other in patients with moderate to severe plaque psoriasis (PsO; n = 350). The details of the two study designs and their efficacy, safety, and immunogenicity results have been previously reported. In both studies, injection site pain perception was assessed at baseline and at weeks 4, 8, and 12 using a 100 mm horizontal VAS measured within 5 minutes after injection.
Results: In the RA study 9 injection site reactions treatment-emergent adverse events (TEAEs) occurred in 6 of 264 subjects (2.3%) in the ABP 501 group and 39 events occurred in 13 of 262 subjects (5.0%) in the adalimumab reference product (RP) group. In the PsO study 4 injection site reactions TEAEs occurred in 3 of 174 subjects (1.7%) in the ABP 501 group and 26 events occurred in 9 of 173 subjects (5.2%) in the adalimumab RP group through week 16. In the RA study, mean injection site pain perception scores were lower in the ABP 501 group (range: 10.0–10.7 mm) vs. the adalimumab RP group (range: 16.1–21.4 mm) at each evaluated visit. In the PsO study, mean injection site pain perception scores were also lower in the ABP 501 group (range: 3.3–4.5 mm) compared with the adalimumab RP group (range: 12.4–19.3 mm) at each of the four time-points.
Conclusion: These results confirm that in addition to having clinically equivalent efficacy, the frequency of injection site reactions and perception of injection site pain were lower with ABP 501 compared with adalimumab RP. Results are attributed to the different excipients in the ABP 501 formulation.

Introduction: Sustained clinical response to biologic therapies is predicated on adequate drug exposure, which can, in turn, be impacted by development of binding anti-drug antibodies (ADAs).
Aims and Methods: To compare serum trough concentrations of adalimumab and ABP 501, an approved biosimilar and correlate them with incidence of immunogenicity. We descriptively analyzed serum drug trough concentration data and the binding anti-drug antibodies from baseline to primary analysis time point in two randomized controlled trials comparing ABP 501 with adalimumab. The first was a 52-week study among patients with moderate-to-severe plaque psoriasis (PsO); the second was a 26-week study among patients with moderate-to-severe rheumatoid arthritis (RA) on background therapy with methotrexate.
Results: The proportion of subjects with binding ADA positive results increased from 29.0% to 57.0% from week 4 to week 16 (time of primary analysis in the plaque psoriasis study) and 18.1% to 33.5% from week 4 to week 24 (time of primary analysis) in the RA study. Mean serum trough concentrations of ABP 501 and adalimumab was lower among those who tested positive for binding in all time points. However, trough concentration over the duration of the study remained similar between the two treatment arms in binding ADA negative and binding ADA positive subgroups in both studies.

	Mean (standard deviation) trough serum drug concentration (ug/mL)				
	Rheumatoid Arthritis			Plaque Psoriasis	
Treatment group	Week 4	Week 12	Week 24	Week 4	Week 16
ADA negative subgroup					
ABP 501	4.13 (1.48)	7.28 (2.75)	8.18 (3.41)	6.67 (2.23)	8.21 (3.11)
Adalimumab	4.07 (1.45)	7.05 (2.80)	7.92 (3.06)	6.85 (2.14)	8.62 (3.31)
ADA positive subgroup					
ABP 501	2.90 (1.77)	3.75 (3.18)	3.81 (3.79)	4.62 (2.16)	5.04 (2.25)
Adalimumab	2.82 (1.70)	3.45 (3.07)	3.59 (3.50)	3.03 (3.05)	3.59 (3.59)

[Serum trough concentrations of ABP 501 and adalimumab in ADA negative and positive subgroups]
Conclusion: The formation of binding ADAs in both studies impacted the exposure of both ABP 501 and adalimumab over time. The degree of decline in drug exposure over time was similar between ABP 501 and adalimumab arms in both studies regardless of the ADA status.

Introduction: In the PURSUIT-M study, ulcerative colitis (UC) patients who were nonresponders to golimumab (GLM) induction treatment at Wk6 (by full Mayo score) were given GLM 100mg q4wk from Wk6 through Wk60. We previously showed that, compared with Wk6-Responders, Wk6-Nonresponders have lower GLM trough levels (TLs) at Wk6, and that Wk6-Nonresponders on the 100mg maintenance dose (at Wk6 and Wk10) achieved TLs at Wk14 that were similar to the TLs at Wk14 in Wk6-Responders on the 50mg dose (1). At Wk14, 28% of the Wk6-Nonresponders became responders (by partial Mayo score) after receiving 100mg at Wk6 and Wk10 (2). Here, we report on GLM TLs in the PURSUIT-M trial, in responders and nonresponders to induction treatment, through Wk50.
Aims and Methods: GLM TLs were measured at Wk 6, 10, 14, 18, 26, 34, 42 and 50. To eliminate artefactual changes in median values due to dropouts/missing data, only patients with TLs available at all the timepoints were included in this post-hoc analysis. Also, subgroups based on body weight (BW) < 80kg and

≥80kg were examined: Wk6-Responders with BW < 80kg on 50mg (n = 42), Wk6-Responders with BW < 80kg on 100mg (n = 42), Wk6-Responders with BW≥80kg on 100mg (n = 18), and Wk6-Nonresponders with BW < 80kg on 100mg (n = 62). The 80kg cutpoint was selected based on the maintenance doses currently approved in the EU: either 50mg for BW < 80kg, or 100mg for BW≥80kg.
Results: At Wk14 (steady-state), Wk6-Nonresponders with BW < 80kg on 100mg and Wk6-Responders with BW < 80kg on 50mg had the same median TL (0.98 μg/mL). At Wk26, 42, and 50, the IQ ranges of GLM TL were largely overlapping in these same two subgroups (Table). At each time point, the highest median TLs were observed in Wk6-Responders with BW < 80kg on 100mg, a posology that is not approved in the EU label of GLM for UC.
Conclusion: Based on TLs observed at steady state then followed over 1 year, these data suggest that patients with initial nonresponse to GLM induction who weigh < 80kg may require the GLM 100mg maintenance dose to achieve TLs similar to the TLs in induction responders receiving the maintenance doses currently approved in EU (either 50mg for BW < 80kg, or 100mg for BW≥80kg).

Serum golimumab trough concentrations (μg/ml) at selected timepoints during 1 year of maintenance, based on Clinical Response status, body weight and maintenance dose: Subjects with TLs at all timepoints

	Week-6 Responders,[a] BW < 80 kg, on 50 mg maintenance N = 42	Week-6 Responders,[a] BW < 80 kg, on 100 mg maintenance N = 42	Week-6 Responders,[a] BW ≥80 kg, on 100 mg maintenance N = 18	Week-6 Nonresponders,[a] BW < 80 kg, on 100 mg maintenance N = 62
Week 6 (post-induction)

Contact E-Mail Address: b_helmy_2000@hotmail.com

Introduction: Historical studies showed 5ASAs to be effective in Crohn's disease. However, more recently, several meta-analysis of trial data have now shown no improvement over placebo. The latest ECCO guidelines published in 2016 advises against the use of 5ASA in Crohn's disease.
Aims and Methods: Our retrospective study aims to assess our current practice. Using the IBD registry, we identified every patient diagnosed with Crohn's disease between 2009 and 2017. We included patients with L1/L2/L3 B1 Montreal classification as these patients are more likely to be treated with 5ASAs. Our patients are then subdivided into Group I: small bowel Crohn's (L1/L3 B1) and Group II: colonic Crohn's (L2 B1).
Results: Between 2009 and 2017, we had 453 patients diagnosed with Crohn's disease, 139 were in Group I and 49 in Group II.
In our Group I, 35% were prescribed 5ASA within first year of diagnosis (n = 49). 27 patients were L1 B1 and 22 patients were L3 B1. 18 patients were given 5ASAs as monotherapy. When looking at the prescriber, 16 were consultants, 14 were registrars and there was no documentation for the rest. In 24 patients, the prescriber clearly documented awareness of diagnosis of ileal/ileocolonic Crohn's disease. 13 patients are still on 5ASAs today. Only 2 were discontinued after a discussion about the lack of evidence in CD.
In Group II, 76% were prescribed 5ASAs (n = 19); 10 as monotherapy. In 14 patients, the prescriber documented awareness of diagnosis of colonic Crohn's. 6 patients remain on 5ASAs today, 3 were lost to follow-up and 10 stopped 5ASAs for various reasons including 1 for nephrotoxicity
Conclusion: This retrospective study assess current practice in an IBD tertiary centre. 5ASAs are still being used in this unit. There is awareness of the lack of evidence for using it but there remain patients on it. We recommend a discussion on the potential side effects and the lack of evidence for its use with every patient who remain on 5ASAs. It should be an alternative option in patients where steroids are contraindicated or intolerant.

Introduction: Biologic therapy has revolutionised the treatment of IBD in the last 20 years. There is limited data on the patient journey through multiple lines of biologics and mapping this to outcomes. We aimed to establish the prevalence of biologic use in a single tertiary IBD centre and assess outcomes defined by biologic persistence.
Aims and Methods: Retrospective review of electronic health records (TrakCare) was performed on all patients who have received infliximab (IFX), adalimumab (ADA), vedolizumab (VEDO) or ustekinumab (UST) in Edinburgh from January 1999 to October 2017. We collected data for demographics, phenotyping details and duration of treatment. Kaplan-Meier survival curves and log-rank analyses were used to compare time to either discontinuation or resectional surgery.
Results: 841 patients were identified who have had biologic therapy for IBD. Median interval from diagnosis to biologic was 4.9 years (IQR 1.3–11.0). The multiple combinations of biologics used is displayed in Figure 1. 665 CD patients (79.7% of total) were treated with biologics; 486 received IFX (73.1%), 169 ADA (25.4%) and 10 VEDO (1.6%) as first line therapy. Second-line therapy was required in 238 patients and consisted of ADA 189 (79.4%), IFX 25 (10.9%), VEDO 18 (7.6%) and UST 6 (2.5%). Third-line therapy was required in 57 patients, VEDO 41 (74.5%) and UST 14 (25.5%). 3 (0.5%) patients received fourth-line therapy with UST. In the CD cohort persistence of treatment on ADA was longer than IFX when used as first-line treatment; median 2373 vs 1430 days (p = 0.0189).
Conclusion: Multiple sequential biologic use is becoming increasingly common and this will accelerate with the increasing use of anti-integrin and anti-IL12/IL23 therapies. Mapping the sequence of biologic use and linking this to outcomes is a priority for IBD research.

Introduction: Faecal loss of antibodies against anti-tumor necrosis factor (TNF) is a possible cause for primary non-response to anti-TNF agents in patients with severe ulcerative colitis (UC) ADDIN EN.CITE ADDIN EN.CITE.DATA [1]. For the intravenously administered infliximab, faecal loss has been demonstrated in the first days after start of treatment. The highest faecal infliximab concentrations were approximately 50-fold lower compared to infliximab serum concentrations. Evidence is lacking about faecal antibody loss with other anti-TNF agents.
Aims and Methods: The aim of this study was to investigate faecal loss of golimumab (GLM), a subcutaneously (sc) administered anti-TNF agent, in patients with moderate to severe UC. GLM concentrations were measured in serum and faeces using an ELISA developed by Sanquin Laboratories (lower limit of quantification (LLOQ) 0.005 μg/mL). First, this ELISA developed for GLM serum measurements was validated for the measurement of GLM in faeces. Homogenized faecal samples (0.95–1.05 g) of moderate to severe UC patients naive to biological therapy were spiked with GLM to obtain three different concentrations (QC-1: 5 μg/ml, QC-2: 0.5 μg/ml and QC-3: 0.05 μg/ml) and stored at −80 °C immediately. Second, faecal samples of patients with moderate to severe UC (endoscopic Mayo score ≥2) starting GLM treatment, (200 mg (day 1) and 100 mg (day 14) sc) followed by maintenance treatment according to the registered label, were prospectively collected at day 1 and 4–6 days after the first GLM injection and stored at −20 °C. Simultaneously, serum samples for the measurement of GLM serum concentrations were collected.
Results: For the assay validation, faecal samples of three anti-TNF naive patients with moderate-to-severe colitis were collected. The median [interquartile range (IQR)] faecal GLM concentrations of samples spiked with QC-1, QC-2 and QC-3 were 3.5 μg/ml [IQR 3.4–3.6 μg/ml], 0.3 μg/ml [IQR 0.3–0.4 μg/ml] and 0.05 μg/ml [IQR 0.04–0.05] respectively. For the clinical validation of faecal loss of GLM, faecal and serum samples of 12 UC patients were collected. The median serum GLM concentrations at day 1 and day 4–6 were 4.9 μg/ml [IQR 2.8–10.3 μg/ml] and 11.5 μg/ml [IQR 8.9–12.8], respectively. In all faecal samples collected at these time points, faecal GLM concentrations were below the LLOQ.
Conclusion: We validated the assay for measurement of GLM in a homogenized fecal matrix. With a hypothetical serum/faeces ratio of 50 for infliximab, faecal GLM concentrations should have been above the LLOQ in a real-life clinical setting. However, no GLM could be detected in faeces of treated UC patients. This may be explained by the fact that maximum serum drug concentrations after sc administration are much lower compared to intravenous administration. Moreover, the variation in bioavailability after sc administration is significantly greater than for iv agents. Furthermore, degradation of GLM in the gut may also play a role. Additional studies are needed to explore these phenomena.
Disclosure: Nothing to disclose

Introduction: Switching from Remicade® to CT-P13 could be cost-saving strategy in inflammatory bowel disease (IBD) patients
Aims and Methods: We aimed to evaluate the clinical outcomes in patients with IBD after switching from Remicade® to CT-P13 in comparison with patients who maintain Remicade®.
Adult patients under Remicade® (as first biologic treatment) due to active IBD that were in clinical remission [defined by Harvey-Bradshaw index (HBI) in CD or Partial Mayo score (PMS) in UC] with standard dosage at study entry were included. The switch cohort (SC) was comprised with patients that made the switch from Remicade® to CT-P13 and the "non-switch" cohort (NC) was comprised with patients kept under Remicade®. SC came from centres that made the switch in a generalized way to all their patients, and the NC from centres that did not switch any patient from Remicade® to CT-P13. The follow-up started when the switch was made, in the SC, and in March 2015 (when the switch strategy started in most of the centres) in the NC.
Results: 476 patients were included: 199 (42%) in the SC and 277(58%) in the NS (table 1). The switch to CT-P13 was volunteered in only 25% of cases. Median follow-up was 18 months in the SC and 23 months in the NC ($p < 0.01$). 24 out of 277 patients relapsed in the NC after a median follow-up of 23 months; the incidence of relapse was 5% per patient-years. The cumulative incidence of relapse was 2% at 6 months and 10% at 24 months in this group. 38 out of 199 patients relapsed in the SC after a median of 18 months; the incidence rate of relapse was 14% per patient-years. The cumulative incidence of relapse was 5% at 6 months and 28% at 24 months. In the multivariate analysis, to have been switched to CT-P13, adjusted by duration of Remicade® treatment before entry, was associated with a higher risk of relapse ($HR = 3.5$, 95% CI = 2–6).13% of patients had adverse events in the NS and 6% in the SC ($p < 0.05$).
Conclusion: In this large real-life population of IBD patients in remission, switching from Remicade®to CT-P13 was associated with a higher risk of relapse (in comparison with those maintaining the infliximab originator). Nocebo effect might have influenced this result. Switching fromRemicade®to CT-P13 was safe.

Introduction: During treatment with adalimumab (ADA), a variable proportion of Crohn's disease (CD) and ulcerative colitis (UC) patients with loss of efficacy need dose optimization to regain response. A meta-analysis showed that the mean percentage of CD patients who needed ADA dose optimization was 24.4% per patient-year.[1] Conversely, real-life need for ADA optimization in UC is not well known. No studies have directly compared the need for ADA dose optimization in CD and UC in the same real-life clinical setting.

Aims and Methods: The aim of the study was to compare the need for and timing of ADA dose optimization in two cohorts of patients with luminal CD or UC. In this single centre, observational, cohort study, dose optimization was determined by two senior staff specialized in IBD. CD patients with active perianal disease were excluded. We compared the rates of patients-months on ADA who needed dose optimization in the cohorts of CD or UC patients. We also compared the interval between ADA first induction dose and the first escalated ADA dose. Escalation-free survival was estimated by the Kaplan-Meier method. We also evaluated the rate of de-escalation.

Results: We included 43 patients with CD (mean age 43 years; 56% female) and 43 patients with UC (mean age 50 years; 42% female). Forty-eight% CD patients vs 51% UC patients ($p = 0.92$) were receiving an immunomodulator at baseline. After a median follow-up of 22.8 months (interquartile range [IQR] 9–49 months) and 13.9 months (IQR 5–31 months) for CD or UC patients, respectively ($p = 0.14$), 24 CD patients (56%) vs 28 UC patients (65%) required ADA optimization. In 88% of cases, ADA was escalated to 40 mg weekly. The rate of patient-month who needed ADA dose optimization was 2.5% vs 8.1% ($p < 0.001$) for CD and UC, respectively. In patients who underwent ADA optimization, median time between the first ADA induction dose and the first escalated dose was 11.8 (IQR 6–33) months vs 3.3 (IQR 2–10) months ($p = 0.001$) for CD and UC, respectively. Survival curves showed that patients with UC had an increased probability of needing ADA dose optimization when compared with CD (hazard ratio [HR] 2.51; 95% confidence interval [CI] 1.37–4.61; $p < 0.001$). Twelve CD patients (50%) vs 9 UC patients (32%) were able to de-escalate dose. Survival curves showed that patients with CD had an increased probability of ADA de-escalation when compared with UC patients (HR 2.32; 95% CI 1.10–5.59; $p = 0.030$). Median time to de-escalation was 3.8 months (IQR 3–13) vs 8.9 months (IQR 3–30) for CD and UC patients, respectively ($p = 0.12$). In the multivariate analysis, UC patients (HR 1.84; 95% CI 1.04–3.52; $p = 0.04$) and short-term non-response (HR 3.92; 95% CI 1.79–8.59; $p = 0.001$) were associated with a higher rate of ADA optimization.

Conclusion: In clinical practice, the rate of patient-month who needed ADA dose optimization is higher in UC when compared with luminal CD. Patients with UC required optimization of ADA dosing earlier and also had lower ADA escalation-free survival. The probability of dose de-escalation was also significantly higher in CD patients.

Introduction: Tofacitinib is an oral, small-molecule JAK inhibitor that is being investigated for ulcerative colitis (UC). We present an integrated analysis of non-melanoma skin cancer (NMSC) events in the tofacitinib Phase (P) 3 programme for patients (pts) with moderate to severe UC.

Aims and Methods: NMSC events were evaluated from 3 randomised placebo (PBO)-controlled studies (2 identical 8-week induction studies [OCTAVE Induction 1 & 2; NCT01465763, NCT01458951], a 52-week maintenance study [OCTAVE Sustain, NCT01458574]) and an ongoing, open-label extension study (OCTAVE Open, NCT01470612).[1,2] Pts were analysed as 3 cohorts: Induction (P3 induction studies); Maintenance (P3 maintenance study); Overall (pts receiving >1 dose of tofacitinib 5 or 10 mg twice daily [BID] in the P3 programme). An independent, blinded adjudication committee reviewed all potential NMSC. Proportions and incidence rates (IRs; unique pts with events per 100 pt-years [PY] of exposure) for NMSC were evaluated. Cox proportional hazards model was used for risk factor analysis. Data shown are as of 16 December 2016.

Results: 1124 pts were evaluated for NMSC, with 1648 PY of tofacitinib exposure and up to 4.4 years of treatment. NMSC was reported in 2 Induction pts receiving 10 mg BID, 1 PBO Maintenance pt (IR 0.97) and 3 Maintenance pts receiving 10 mg BID (IR 1.91) (Table). In the Overall Cohort, NMSC was reported in 11 pts (IR 0.67), including 7 pts with squamous cell carcinoma (SCC) and 6 pts with basal cell carcinoma (BCC); 2 pts had both SCC and BCC. No NMSC was metastatic or led to study discontinuation. Of all tofacitinib-treated pts with NMSC, 6 had prior NMSC history, 10 had prior use of thiopurines and 10 had prior tumour necrosis factor inhibitor (TNFi) failure. In the Overall Cohort, higher IRs were observed for subgroups aged ≥ 65 years vs < 65 years, and for subgroups with prior TNFi failure or prior immunosuppressant treatment, vs those without. Cox regression selected prior NMSC (hazard ratio [HR] [95% CI] 64.07 [19.27, 213.03]; $p < 0.0001$) and prior TNFi failure (HR [95% CI] 9.56 [1.21, 75.22]; $p = 0.0320$) as significant risk factors.

Conclusion: NMSC occurred infrequently with tofacitinib treatment in the UC clinical programme. NMSC IRs were similar to those reported for tofacitinib in other indications, including rheumatoid arthritis[3] and for biologic UC treatments.[4] Cox regression analysis selected prior NMSC diagnosis and TNFi failure

Abstract No: P0980

Table. Incidence rates for all NMSC events for Induction, Maintenance and Overall Cohorts, and univariate subgroup analyses for the Overall Cohort

Introduction: Brazikumab (MEDI2070), a human monoclonal antibody that is an anti-p19 subunit inhibitor of interleukin-23, was shown to be effective over 8 weeks of treatment for patients with moderate-to-severe active Crohn's disease.[1] Here, we report the long-term safety and tolerability of brazikumab.

Aims and Methods: The Phase 2a study (NCT01714726) consisted of a 12-week double-blind induction period with randomisation to intravenous brazikumab (700 mg) or placebo, followed by the open-label (OL) period where all patients were administered subcutaneous brazikumab (210 mg) every 4 weeks. Patients were aged 18–65 years, had a ≥6-month history of moderate-to-severe active Crohn's disease, had failed or were intolerant to ≥1 anti-TNFα agent, successfully completed the double-blind period and signed consent for inclusion in the OL period. Adverse events (AEs) and vital signs were recorded every 4 weeks until patients discontinued or completed the study at 100 weeks.

Results: 104 patients entered (n = 52 from placebo to brazikumab and n = 52 from brazikumab to brazikumab) and 57 (54.8%) patients completed the OL period. 87 (83.7%) patients experienced ≥1 treatment-emergent AE (TEAE); 12 (11.5%) experienced ≥1 TEAE leading to permanent discontinuation of study drug and 20 (19.2%) experienced ≥1 serious AE (SAE). The most common TEAEs were headache (22.1%), nasopharyngitis (22.1%), abdominal pain (18.3%) and Crohn's disease (16.3%) [Table]. Half of the SAEs observed were gastrointestinal disorders associated with Crohn's disease. Five SAEs of infection were reported, none of which were opportunistic, such as herpes zoster or tuberculosis; all resolved and the investigational product was permanently discontinued for only one patient. No cases of cancer were reported. The AE profile was similar between patients who completed a previous 12-week course of either placebo or brazikumab treatment.

Conclusion: In this 100-week OL period, brazikumab was well tolerated in patients with moderate-to-severe active Crohn's disease, warranting future studies in larger patient populations.

Treatment-emergent adverse events occurring in ≥5% of patients, n (%)	Total (N = 104)
Headache	23 (22.1)
Nasopharyngitis	23 (22.1)
Abdominal pain	19 (18.3)
Crohn's disease	17 (16.3)
Diarrhoea	14 (13.5)
Influenza	13 (12.5)
Nausea	11 (10.6)
Vomiting	11 (10.6)
Anaemia	10 (9.6)
Arthralgia	10 (9.6)
Pyrexia	9 (8.7)
Upper respiratory tract infection	9 (8.7)
Urinary tract infection	8 (7.7)
Bronchitis	7 (6.7)
Gastroenteritis	7 (6.7)

Introduction: The growing burden of inflammatory bowel diseases (IBD) has the potential to have a negative impact on the delivery of quality health care. Decision support tools (DST) may facilitate shared decision making (SDM) and improve quality of care by increasing patients' participation in their management.

Aims and Methods: This study aimed to assess the effectiveness of a clinical DST on improving quality of care in ulcerative colitis (UC).

A prospective quality improvement intervention was conducted at two metropolitan hospitals in two states (Victoria and Queensland) in Australia using a DST on a tablet-based app to assess UC symptoms, psychological wellbeing and IBD preventive care. Participants included adult patients aged ≥18 years with mild-to-moderate UC (Simple Clinical Colitis Activity Index ≤15), attending IBD outpatient clinics. Patient management was compared using an interrupted time-series study design to assess the effectiveness of a DST in improving clinical quality indicators pre- and post- use of the DST. The primary outcome was the percentage of process indicators used for UC care. The thirteen process indicators assessed were derived from ECCO guidelines and incorporated management of: disease activity; psychological wellbeing, and; preventive care. Secondary outcomes included: usability [based on the systems usability scale (SUS)] and acceptability of the DST and SDM (based on the decisional conflict scale) following clinic review.

Results: 100 patients with mild-to-moderate UC were invited to and agreed to participate. 50 patients were managed pre-intervention in outpatient clinics using standard care [median age 54 (range 23–81); 48% male)] and 50 patients used the DST for clinical management [median age 45 (range 19–78); 54% female] over an 18-week period. ***Primary outcome:*** A significant increase in the use of process indicators overall was observed following use of the DST [27% vs 94% ($p < 0.001$)], as well as specifically those for psychological wellbeing (15% vs 91%; $p < 0.001$), preventive care (22% vs 94%; $p < 0.001$) and disease activity management (52% vs 94%; $p < 0.001$). ***Secondary outcomes:*** The DST was found to be usable (SUS score = 82). The majority of patients deemed the DST to be acceptable with 91% of patients demonstrated interest in using the DST for outpatient management. SDM was greater in the post-intervention group, with a mean decision conflict score of 18.0, compared to a mean decision conflict score

of 33.5 in the pre-intervention group (p = 0.002), indicating less decisional conflict (and greater SDM) by patients in management decisions in the post-intervention group.
Conclusion: Implementing an evidence-based DST in the outpatient setting significantly improves quality of care, as measured by an increased use of process indicators. The DST improved the quality of the delivery of the psychological and preventive health aspects of care which may be neglected during routine IBD care. DSTs therefore have the potential to minimize errors of omission via a standardized approach to care.

Introduction: UNITI-1 & 2 and IM-UNITI are Phase 3 multicenter, randomized, double-blind, placebo-controlled studies to evaluate the safety and efficacy of ustekinumab (UST) in adults with moderately to severely active Crohn's disease (CD).
Aims and Methods: To assess the effect of UST on improving work productivity with 8 weeks of induction therapy and maintaining improvement over the next 44-week period in patients with active CD. Patients with moderately to severely active CD [defined by a CD Activity Index (CDAI) score of 220–450] who had an inadequate response or intolerance to TNF inhibitors (UNITI-1, N = 741) or conventional therapy (UNITI-2, N = 639) were randomized in a 1:1:1 ratio to receive placebo or UST 6mg/kg intravenously (IV) or UST 130mg subcutaneously (SC) at week 0. Patients who had a clinical response to UST at week 8 (defined as having a reduction in CDAI score ≥100 points, or CDAI score < 150 if baseline CDAI score ≤248) were re-randomized to receive placebo or UST (SC) 90mg q12w or q8w through week 44 (IM-UNITI, N = 388). The impact of CD on productivity at work, school or home was measured using a visual analog scale (VAS) ranging from 0–10 (0 = no impact at all and 10 = very much impact). Of patients who were working two weeks prior to each visit, presenteeism (productivity loss on the job) was assessed using the Work Limitation Questionnaire (WLQ). The WLQ has 4 domains (time management, and physical, mental-interpersonal and output demands) with each domain score ranging from 0–100 and higher scores indicating greater work limitations. Productivity VAS and WLQ outcomes were collected and compared between treatment groups at baseline, week 8 (induction), and 22 and 44 weeks after induction (maintenance).
Results: At induction baseline, mean productivity VAS values ranged from 6.3–6.8, indicating significant impact of CD on productivity, and were comparable across treatment groups. At Week 8, patients in both UST dose groups had statistically significantly greater improvement in productivity VAS score vs. the placebo group in both UNITI-1 and UNITI-2 (all comparisons, $p < 0.05$). The reduction in productivity VAS score from baseline in the UST dose groups combined was −1.6 (23.2% improvement) in UNITI-1 and -2.1 (33.3% improvement) in UNITI-2, compared to placebo (−0.8 [11.9% improvement] in UNITI-1 and -1.1 [17.7% improvement] in UNITI-2, p-values < 0.01). Overall, percent improvement from baseline was numerically greater for UST-treated vs. placebo patients in 3 out of 4 WLQ domain scores at Week 8: time management (24.1% vs. 17.6% in UNIT-1, and 35.1% vs. 27.3% in UNIT-2), physical demand (21.2% vs. 11.9% in UNIT-1, and 25.6% vs. 21.9% in UNIT-2), output demand (21.4% vs. 20.1% in UNIT-1, and 38.3% vs. 21.0% in UNIT-2) and mental-interpersonal demand (19.5% vs. 20.3%in UNIT-1, and 33.7% vs. 24.5% in UNIT-2). Improvements in productivity VAS and WLQ scores were better maintained in the UST groups vs. the placebo group in the IM-UNITI study through Week 44.
Conclusion: UST treatment improves productivity and reduces work limitations in patients with moderate to severe CD.

Introduction: The infliximab biosimilar CT-P13 has been approved by the EMA for the treatment of ulcerative colitis (UC) and Crohn's disease (CD) based on extrapolation of data from rheumatology trials. Since then, several un-controlled and controlled studies have later-on shown that CT-P13 could be safe and effective for IBD patients who switched from originator to biosimilar or who received CT-P13 as first infliximab, although in the pivotal trial (1) a trend to disease worsening after swichting was observed in CD patients. In addition, no randomized long-term data from single-centre cohorts were presented that prospectively analysed efficacy and safety in IBD-patients who switched from originator to biosimilar infliximab.
Aims and Methods: We performed an independent, prospective and randomized, double-blinded trial in patients of the IBD center Munich with CD and UC who had responded to originator infliximab for at least 3 months. We provided each elegible patient with individualized information about biosimilars and the possibility of switching from originator infliximab to CT-P13. Between June and September 2015, 200 (68%) of the elegible patients consented to the blinded switch. After randomization, patients were either switched to CT-P13 or maintained on originator infliximab and prospectively observed.
Primary endpoint was a combination of clinical remission at 52 weeks and the ability to continue the study drug throughout 52 weeks.
Clinical remission was evaluated at weeks 0, 24 and 52 for UC using the modified Rachmilewitz Clinical Activity Index (CAI) and CD using the Crohn's disease activity score (CDAI). Study infliximab was discontinued, if loss of response or side effects occurred.
Results: Of 200 patients participating, 111 (55.5%) patients were switched to CT-P13 and 89 (44.5%) were maintained on the originator in a double-blinded mode (uneven numbers are due to the simplified randomization process). Mean age, sex, type of IBD and remission rates at study start were equally distributed in both study groups: 46.8% vs. 47.2% women, mean age 37 vs. 40 years, 62.2% vs. 58.4% patients with CD, and 82.9% vs. 80.9% remission rates at start in the CT-P13 group vs. the originator group, respectively. Discontinuation of the study due to loss of response or side effects occurred in 25.2% (n = 28) of patients in the CT-P13 group and 18.0% (n = 16) in the originator group (p = 0.219). Among those patients who could continue study therapy throughout 52 weeks, remissions was achieved in 83.1% of the patients (n = 69) in the CT-P13 group and 89.0% (n = 65) in the originator group (p = 0.290). Hence, the primary endpoint (clinical remission and continuation of study drug at 52 weeks) was achieved in 62.2% of the patients (n = 69) in the CT-P13 group and 73.0% (n = 65) in the originator group (p = 0.104).
Conclusion: After switching from the originator infliximab to the biosimilar CT-P13, 11% more patients lost response or had to stop therapy due to side effects as compared to those patients who remained on the originator infliximab. Although this difference did not reach significance level, our finding is in accordance with the results of the other double blinded switch-trial, the NOR-SWITCH study, in which a similar outcome was observed in IBD without reaching significance level. In both studies larger numbers might have shown significant differences. We conclude that switching from the originator infliximab should not be enforced, until results of larger long-term switch-trials in CD and UC are available, especially since in most European countries all infliximab products are sold at the same price, now.

Introduction: Bone marrow-derived myeloid antigen presenting cells, such as macrophages (Mø) and myeloid dendritic cells (mDCs) have been increasingly linked to pathogenesis of Crohn's disease (CD). Monocytes (Mo) recruited to the intestinal lamina propria differentiate into an inflammatory Mø/mDC phenotype, which then expresses high levels of TNFα, IL-12 and IL-23 upon activation by enteric bacteria, inducing proliferation of Th1 T cells. Colony stimulating factor (CSF-1) is prominent among the several factors that support Mo/Mø/mDC survival, proliferation, and differentiation. PRV-6527, also known as JNJ-40346527, is an oral small molecule inhibitor of CSF-1R, in development by Provention Bio to target inflammatory Mo/Mø/mDC for the interception and treatment of CD.
Aims and Methods: To demonstrate that preclinical and biomarker data support the clinical study of PRV-6527, whose objectives are to assess the safety, tolerability and clinical efficacy of the CSF-1R inhibitor PRV-6527 in Crohn's disease, as well as to determine blood and tissue pharmacodynamics and pathway gene signatures in biopsy tissue. Colitis was induced in C.B-17 SCID mice by i.p. injection of $4x10^5$ $CD45^+RB^{high}$ T cells harvested from Balb/C donor spleens.

Mice were treated orally with 15 mg/kg PRV-6527, a selective inhibitor of CSF-1 receptor kinase, either prophylactically or therapeutically through termination on day 42. Murine anti-TNFα monoclonal antibody (CNTO5048) was administered therapeutically at 3 mg/kg i.p. as positive control. RNAseq analysis of murine colonic mucosa was performed, and gene expression profiles were compared to publicly available profiles from healthy and CD mucosal biopsies (Rutgeerts GSE16879). The PRINCE (PRovention INvestigation in Crohn's DiseasE) Phase 2 study (EudraCT Number: 2017-003017-25) is a randomized, double-blind, placebo-controlled, parallel-group, multicenter study in adult subjects with moderately to severely active CD. The study hypothesis is that PRV-6527, a CSF-1R inhibitor, will be superior to placebo in treating subjects with moderate to severe active CD over 12 weeks, as measured by the change from baseline in the Crohn's Disease Activity Index (CDAI) score. Approximately 80 subjects are planned to be enrolled. Proof of mechanism will be assessed in secondary endpoints, including mucosal changes on endoscopy and histology and the presence of inflammatory myeloid cells by immunohistochemistry and gene signature in mucosal biopsies.

Results: A CSF-1 gene signature was elevated in the inflamed mucosa in CD and remained elevated in anti-TNF-non-responder patients. Inhibition of the CSF-1 receptor by PRV-6527 significantly reduced histological disease scores by ~60% in established murine colitis. Recruitment of $CD3^+$ T cells was reduced and $F4/80^+$ mononuclear cells were decreased to levels similar to control. RNAseq analysis demonstrated significant concordance of disease pathways between human CD and the mouse model. Treatment of mice with either PRV-6527 or CNTO5048 impacted those pathways in a manner comparable to patients who respond to infliximab.

Conclusion: Pre-clinical and human biomarker data support the study of PRV-6527, a CSF-1R inhibitor, in CD and the promise for an oral therapy with the potential for benefit in anti-TNF non-responders. Furthermore, these PD and biomarker data could be useful for patient stratification for future clinical studies or for tailored therapy in CD patients.

Introduction: Vedolizumab is an anti-integrin monoclonal antibody approved for use in moderate to severe ulcerative colitis (UC). However, concurrent use of calcineurin inhibitors was not studied in the original clinical trials. We have previously described the 10 and 26 week outcomes of the first prospective study bridging cyclosporine to vedolizumab in patients with severe, steroid-resistant UC (ECCO and DDW 2018). Here we present the longer term follow-up on these patients.

Aims and Methods: This is follow-up of a prospective study of 17 UC patients treated with cyclosporine in conjunction with vedolizumab at the Military Medical Academy in Belgrade, Serbia. UC patients, not responding to IV steroids for 3 days were treated with IV cyclosporine at doses of 2 mg/kg titrated to goal trough level of 300–400. At day 8 after IV cyclosporine was started (defined as week 0), those who responded were prescribed vedolizumab 300 mg IV. After vedolizumab was administered, cyclosporine was continued orally at double the IV dose and discontinued after 8 weeks of cyclosporine use. Vedolizumab was additionally dosed at 300 mg at weeks 2 and 6, followed by 300 mg IV every 8 weeks. Patients were followed up to 52 weeks. Demographics and disease information were reviewed. Clinical and endoscopic response and remission were the primary endpoints.

Results: Seventeen patients (mean age 40 (range 20–67 yrs)); mean disease duration 4.9 ± 4 yrs with severe, steroid-resistant UC were treated with cyclosporine. Fifteen (79%) patients (9/15 male) initially responded to IV cyclosporine (median cyclosporine dose 200 mg (100–300) IV and 400 mg (200–600) oral. At initial follow-up at week 10, ten (67%) patients achieved a Mayo score of ≤1 (decrease from 3 at admission). At week 26, 14/15 patients were in clinical remission. One patient was referred to surgery due to recurrence of symptoms. At week 52 of follow-up, eleven of 14 (79%) patients continued to be in clinical and endoscopic remission. The remaining 3 patients (21%) had a clinical response to treatment but continued to have endoscopically active disease. No adverse effects were reported from either cyclosporine or vedolizumab during the duration of the study.

Conclusion: In the first prospective study bridging cyclosporine to vedolizumab in steroid-refractory severe UC patients, the clinical outcomes at 10 weeks were predictive of those at 52 weeks. At one year follow-up, patients continued to be responsive to treatment, with the majority maintaining clinical and endoscopic remission.

P0987 PROBIOTICS CAN IMPROVE THE INFLIXIMAB RESPONSE FOR PATIENTS WITH CROHN'S DISEASE

S.-X. Dai[1], W. Sha[2]

Introduction: Even though the biological agents (BAs) are used, there are still not less CD cases who are not responsive to BAs. Thus we hypothesize that "can probiotics benefit CD patients who are not responsive to BAs"?

Aims and Methods: To distinguish the gut microbiota differences between response and non-response to infliximab (IFX), and observe the effect of probiotics on improving the response rates, for patients with CD. The faeces and peripheral blood from 38 cases of CD treated with IFX were collected. According to the response to IFX, they were divided into Response Group (Group 1, $n = 29$) and Non-response Group (Group 2, $n = 9$; cases have been exclusive when opportunistic infections or IFX doses deficiency were merged). The gut microbiota was sequenced by 16SrDNA, and the concentrations of fecal calprotectin (FCP) were detected by ELISA. The peripheral blood antibodies (ATI) and trough level (TLI) of IFX were detected, and the frequencies of $CD8^+CD28^+$T and $CD8^+CD28^-$T cells were detected through flow cytometry (FCM). A triplet live bacteria tablet, consisting of *Streptococcus faecalis*, *Clostridium butyricum*, and *Bacillus mesentericus* (SCB), was prescribed for the patients of non-response for 16 weeks. All the above-mentioned factors were compared between the two groups, as well as between pre-treatment and post-treatment for the non-response group.

Results: I. Gut microbiota: The species of bacteria in Response Group and Non-response group were 659 and 560, respectively. Surprisingly, a novel bacteria, the *Alistipes*, was found to be the most dominant bacterial between the two groups.
II. FCP, TLI and ATI: The concentrations of FCP in Non-response Group were significantly higher than those of the Response Group. Nine patients (100%) in the Non-response Group were ATI-positive whereas only 2 (6.90%) were positive in the Response Group. The TLIs of the Response Group were significantly higher than those of the Non-response Group.
III. $CD8^+$T lymphocyte subsets: The percentages of peripheral blood $CD8^+CD28^+$T lymphocytes of non-response group were significantly lower than those of Response Group. The frequencies of $CD8^+CD28^-$T cells in the Non-response group were significantly higher than those of the response group.
IV. Probiotics treatment: Five of 9 (55.56%) non-responders expressed *Alistipes*, and FCP decreased but TLIs increased for the non-responders after SCB treatment. Seven of the 9 (77.78%) non-responders were transferred to clinical response, and 6 (66.67%) were ATI-negative. The frequencies of $CD8^+CD28^+$T lymphocytes increased and $CD8^+CD28^-$T lymphocytes decreased for the non-responders. The overall response rate increased from 76.32% (29/38) to 94.74% (36/38) ($p = 0.047$).
V. Predicting efficiency of *Alistipes*: *Alistipes* significantly correlated with anyone of IFX response, clinical response, FCP, TLI, ATI, $CD8^+CD28^+$T and $CD8^+CD28^-$T lymphocytes *Alistipes* was proved to be powerful to predict the IFX non-response, with an area under curve (AUC) of 0.914, 100% in specificity, and 82.8% in sensitivity.

Conclusion: Decrease in diversity, especially in *Bacillus* and *Clostridium*, is the vital characteristic of CD patients with IFX non-response. Lower *Alistipes*, TLI, and $CD8^+CD28^+$T lymphocytes, as well as higher $CD8^+CD28^-$T lymphocytes and surveillance factors (FCP and ATI), are associated with IFX non-response. The triplet live bacteria tablet, SCB, is brilliant to equilibrate the general immunity balance ($CD8^+CD28^+/CD8^+CD28^-$T lymphocytes) and thus to improve the IFX response rates. The novel bacteria, *Alistipes*, can predict the IFX non-response with high efficiency.

Disclosure: Nothing to disclose

Introduction: Etrolizumab, a monoclonal antibody to the β7 integrin, inhibits both α4β7:mucosal addressin cell adhesion molecule 1 (MAdCAM-1)-mediated lymphocyte trafficking to the gut mucosa and αEβ7:E-cadherin-mediated lymphocyte retention. In patients with ulcerative colitis (UC) from the Phase 2 EUCALYPTUS trial (NCT01336465), treatment with etrolizumab resulted in a reduction in serum levels of soluble (s) MAdCAM-1 compared with placebo; this reduction in sMAdCAM-1 paralleled a reduction in free β7 receptors in the peripheral blood, with complete receptor occupancy (RO) observed at day 5 after the first dose in both dose cohorts (100 mg and 300 mg).[1,2] Pharmacodynamic (PD) activity in patients with Crohn's disease has yet to be evaluated.

Aims and Methods: The effect of etrolizumab treatment on serum levels of sMAdCAM-1 (PD biomarker) and β7 RO in patients with moderate to severe Crohn's disease were evaluated in a substudy of cohort 1 of the Phase 3 BERGAMOT trial (NCT02394028). Patients were randomly assigned to receive subcutaneously administered etrolizumab 105 mg once every 4 weeks, etrolizumab 210 mg at weeks 0, 2, 4, 8, and 12 or placebo during a 14-week induction period. Biomarker and pharmacokinetic (PK)/PD analysis was conducted using serum and whole blood samples obtained at baseline and weeks 1 (days 3, 4 or 5), 2, 4, 10 and 14 from patients who enrolled in the PK/PD substudy. Measurements of serum sMAdCAM-1 were performed using a validated assay on the Gyrolab xP immunoassay platform. Whole blood samples were evaluated by flow cytometry within 24-48 hours of collection to assess β7 expression, β7 occupancy and enumeration of peripheral blood lymphocyte subsets using previously established methods.
Results: This preliminary analysis included 64 patients with Crohn's disease (etrolizumab 105 mg, n = 29; etrolizumab 210 mg, n = 24; placebo, n = 11). Patients treated with etrolizumab showed a sustained decline in sMAdCAM-1 from baseline (week 1: group median decline of ~40%, weeks 4 through 14: group median decline of ~80%) with minimal (< 10%) changes from baseline observed in the placebo arm (**Table**). β7 integrin receptors on "$\beta7^{high}$ intestinal homing" $CD3^+$ T cells were rapidly and completely occupied in etrolizumab-treated patients as indicated by a near 100% decrease in $CD3^+$ T cells with "available" β7 receptors. Similar RO results were observed with CD4 T, CD8 T and CD19 B lymphocytes. There were no dose-related differences observed in sMAdCAM-1 reduction and RO.

	sMAdCAM-1 (median % change ± MAD from baseline)	Intestinal homing CD3+ T cells with "available" β7 (median % change ± MAD from baseline)
Etrolizumab 105 mg		
Week 1	−37.2 ± 7.5	−100.0 ± 0.0
Week 4	−78.5 ± 4.1	−99.8 ± 0.2
Etrolizumab 210 mg		
Week 1	−38.0 ± 8.1	−100.0 ± 0.0
Week 4	−78.1 ± 2.0	−100.0 ± 0.0
Placebo		
Week 1	−7.8 ± 6.2	23.5 ± 25.6
Week 4	−4.9 ± 10.1	24.7 ± 32.8

Week 1 = days 3, 4 or 5 after first dose. MAD, median absolute deviation.

[Table 1. Absolute Change From Baseline of Serum sMAdCAM-1 and β7 "Available" Intestinal Homing $CD3^+$ T Cells After Etrolizumab Treatment]
Conclusion: In this preliminary analysis, sMAdCAM-1 was reduced following etrolizumab treatment in patients with Crohn's disease. Full β7 RO was achieved with both doses of etrolizumab. Overall, results were similar to those reported in UC[1] and confirm the expected pharmacologic profile of etrolizumab.

Introduction: A sizable proportion of patients with Crohn's disease (CD) will undergo intestinal resection. Most will experience early post-operative endoscopic and clinical disease recurrence. The superiority of anti-TNF agents over both placebo and immunomodulators in the prevention of post-operative recurrence using a risk-stratified strategy was previously demonstrated.
Aims and Methods: To evaluate the efficacy of an early unstratified approach comparing anti-TNF (adalimumab) with thiopurine (6-mercaptopurine, 6MP) therapy on post-operative CD recurrence, as demonstrated by endoscopy at 24 weeks.
All CD patients undergoing a first ileocecectomy for inflammatory complications were prospectively recruited to the Post Operative Adalimumab Recurrence Trial (POPART). Patients were randomized within 45 days to receive either adalimumab or 6MP. All patients underwent ileocolonoscopy at 24 weeks post operation to asses for endoscopic recurrence as defined by the Rutgeerts score. Endoscopic recurrence was defined as a Rutgeerts score of i2-i4.
Results: Fourty-one patients were recruited to the study. Four patients were lost to follow-up, and two who did not adhere to treatment were excluded from the final analysis. A total of 35 patients completed the study protocol −16 were treated with 6MP and 19 with adalimumab. Mean age 32.2 ± 21.6, 62.9% males, 54.3% non-smokers. Follow-up endoscopy was performed at week 24. Baseline clinical parameters and smoking status were comparable between treatment arms (43.8% vs. 38.9% respectively, p = 0.774).
Endoscopic recurrence at week 24 was significantly lower in the adalimumab vs. the 6MP arm: 21.1% vs 56.2%, p = 0.03. Other clinical and biologic indices at week 12 and 24 were comparable (Table 1).
Table 1. Clinical and endoscopic parameters of Crohn's disease patients at post ileocecectomy weeks 12 and 24 according to medical therapy
Conclusion: Early treatment of post-operative CD patients with adalimumab is significantly superior to 6MP, regardless of risk stratification. Endoscopy is superior to clinical and biochemical indices, in early risk stratification of patients.

Introduction: The use of infliximab (IFX) biosimilar CT-P13 has dramatically increased in patients with Crohn's disease (CD) and ulcerative colitis (UC), but doubts about the efficacy and safety of switching from IFX originator to biosimilar still exist with patients and health care professionals.

Aims and Methods: We investigated pharmacokinetics as well as efficacy and safety of a mandatory switch from IFX originator to CT-P13.

In our tertiary referral center, CT-P13 was initiated in a 2 step procedure, with initiation of CT-P13 in IFX naïve patients from November 2015 onwards (controls). In March 2017, all patients receiving IFX originator were electively switched to CT-P13 (cases). Patient reported outcome (PRO2), C-reactive protein (CRP), IFX trough levels (TL, ELISA apDia) and anti-drug-antibodies (ADA, drug sensitive assay apDia) were measured at switch (T0), the next infusion of CT-P13 (T1) and 6 months after switch (T2).

The primary endpoint was IFX discontinuation within 6 months after switch. Secondary endpoints included loss of clinical remission, need for treatment optimization, adverse events, as well as evolution of PRO2, CRP and IFX TL. Clinical remission was defined as a rectal bleeding score of 0 and a stool frequency $\leq$1 for UC, or an abdominal pain score $\leq$1 and liquid stool frequency $\leq$1.5 for CD. Treatment optimization was defined as the need for changes in IFX dosage or introduction of additional disease-modifying drugs.

Results: A total of 401 patients (53% male, median age 25 years, 71% CD, 61% in clinical remission) were enrolled, including 361 cases and 40 controls. Both groups were comparable except for median disease duration (7.0 vs. 1.5 years, $p=0.011$), median duration of IFX treatment (6.0 vs. 0.9 years, $p<0.0001$), concomitant immunosuppressive therapy (6% vs. 20%, $p=0.002$), and median CRP (1.5 vs. 2.3 mg/L, $p=0.032$). IFX discontinuation within 6 months of switch was observed in 4% of cases and 13% of controls ($p=0.04$). The percentage of patients developing loss of clinical remission (22% vs. 29%, $p=0.91$), adverse events (2% vs. 8%, $p=0.052$) and ADA (0.6% vs. 2.5%, $p=0.18$) were similar between both groups. In addition, cases less frequently needed treatment optimization (24.9% vs. 42.5%, $p=0.02$). Table 1 shows the evolution of median PRO2, CRP and IFX TL over time. Although PRO2 increased significantly in cases between T0 and T2, this difference was not statistically different compared to the increase in PRO2 in controls ($p=0.61$). In both groups, CRP and IFX TL remained stable over time.

Conclusion: Compared to continued therapy with biosimilar CT-P13, switching from IFX originator to CT-P13 was not associated with an increased risk of treatment discontinuation, loss of response or adverse events. In addition, no differences in IFX TL or immunogenicity could be identified.

Introduction: The BioColitis Registry (Biological Registry with Ulcerative Colitis-Patients in Germany) of the Competence-Network IBD is a five-year prospective registry of Ulcerative Colitis (UC)-patients with an early disease and/or a newly introduced biological-therapy in Germany. In this sub-analysis of the BioColitis Registry we are showing the 6-months clinical efficacy of anti-TNFs in biologics-naïve UC-patients.

Aims and Methods: Within the framework of this five-year prospective non-interventional study with an every 6-months online documentation and assessment of the clinical course of disease, medication, psychosocial burden and health economics as well as the patient's genetic profile were separately examined. At the end of 2016, nearly 900 UC-patients from 52 gastroenterology practices and hospitals in Germany had been included prospectively into the "BioColitis-Study" with a 5-years follow-up until the end of 2021. The following subgroup-analysis of 183 biologics-naïve UC-patients of 439 newly introduced anti-TNF therapies in UC-patients reports the clinical efficacy at 6-months in the 183 biologics-naïve UC-patients with a newly introduced anti-TNF-therapy as an induction and maintenance therapy. The selection of the respective anti-TNF therapy was made in the IBD-experienced centers on the basis of clinical requirements taking patient's request into account. The primary objective was the steroid-free remission (pMayo <2) at months 6.

Results: 183 anti-TNF-naïve UC-patients with a 6-months follow-up were available for the sub-analysis (average age: 42 years; female: 47%; pancolitis 52%; course of disease: 9.7 years). 76/183 UC-patients were in steroid-free remission at months 6 (41.5%). Along with the steroid-free remission, there are significantly fewer signs of sub-depression/ depression than in the group without a remission (EQ-5D) at months 6 (12.7% vs. 39.6%; $p=0.0001$). The analysis of steroid-free remission at months 6 with the different anti-TNF-antibodies showed the following remission-rates: Adalimumab 28/60 (46.7%), Infliximab 24/74 (32.4%), Golimumab 16/31 (51.6%) and Vedolizumab 8/18 (44.4%) (n.s.). In addition, the patients received 5-ASA in 40.4%, and immunosuppressants in 27.3% at months 6.

Conclusion: About 40% of the investigated anti-TNF-naïve UC-patients were in clinical remission at months 6. These anti-TNF UC-patients, even in steroid-free remission showed an unexpectedly high (co) morbidity with unmet needs e.g. regarding depression, indicating a reduced health state already in these UC-patients without a remission at months 6.

Introduction: ABP 501 (AMGEVITA®; adalimumab) is the first approved biosimilar to adalimumab (HUMIRA®). Here we report immunogenicity results from a Phase 3 study in patients with moderate to severe plaque psoriasis without concomitant immunosuppressive therapy that undergo a single transition from adalimumab reference product (RP) to ABP 501. In this report we have examined the incidence of anti-drug antibodies (ADAs) and the relative magnitude of the ADA response among patients that transitioned from adalimumab RP to ABP 501.

Aims and Methods: Patients were randomized 1:1 (ABP 501: n = 175; adalimumab RP: n = 175) to receive ABP 501 or adalimumab every 2 weeks for 16 weeks. Eligible subjects who continued treatment beyond week 16 were re-randomized in a blinded fashion such that all subjects initially randomized to ABP 501 continued treatment with ABP 501, and subjects initially randomized to adalimumab RP either continued treatment with adalimumab RP or underwent a single transition to ABP 501 in a 1:1 ratio. The last dose was at week 48; end of study at week 52.

After re-randomization, ADAs were assessed on weeks 20, 32 and 52. A validated electrochemiluminescent assay was used for detection of binding ADAs. Samples positive for binding ADAs were then tested in a TNFα-target binding assay for neutralizing activity. Neutralizing antibody titre was reported as the highest dilution that tested positive in the assay.

Results: The proportion of subjects positive for binding and neutralizing antibodies was comparable from baseline through week 52, regardless of the transition (adalimumab RP/adalimumab RP 74.7% (59/79) binding and 20.3% (16/79) neutralizing; adalimumab RP/ABP 501 74.0% (57/77) binding and 24.7% (19/77) neutralizing). The overall incidence of binding antibodies that formed after the re-randomization at week 16 was comparable from week 16 through end of study [adalimumab RP/adalimumab RP 72.2% (57/79) vs. adalimumab RP/ABP 501 72.7% (56/77)]. To determine the true effect of transition from adalimumab RP to ABP 501, the rate of ADA development was assessed in subjects who were binding ADA negative through week 16. In this subset, the incidence of binding ADA was similar between the transition group [28.6% (8/28)] and those who remained on adalimumab RP [35.5% (11/31)]. None of these subjects that tested ADA negative through week 16 developed neutralizing antibodies after transition through week 52.

Conclusion: Transition from adalimumab RP to ABP 501 was not associated with higher immunogenicity.

Introduction: Adalimumab therapy is associated with appearance of anti-drug antibodies (ADAs). ABP 501 (AMGEVITA®; adalimumab) is an approved biosimilar to adalimumab (HUMIRA®). The goal of the present analysis was to compare the time course of incidence and magnitude of ADAs among patients who are not on immunomodulatory medication.

Aims and Methods: We analysed data from a Phase 3 randomized double blind study by comparing the incidence of ADAs and relative magnitude of the ADA response between ABP 501 and adalimumab reference product (RP) in patients with moderate-to-severe plaque psoriasis. Patients were randomised (1:1) to receive ABP 501 or adalimumab every 2 weeks for 16 weeks. ABP 501 and adalimumab RP were administered at an initial loading dose of 80 mg subcutaneous on Week 1/Day 1, followed by 40 mg subcutaneous every other week (starting at Week 2) for 16 weeks.

ADAs were assessed at baseline, week 4 and week 16. A validated electrochemiluminescent assay was used to detect binding ADAs. Assays were developed for both ABP 501 and adalimumab RP, and each serum sample was tested using both assays irrespective of treatment group. Binding ADA magnitude was expressed as signal-to-noise (S/N), defined as the mean signal of the study sample divided by the mean signal of the negative control analysed on the same plate. Samples positive for binding ADAs were then tested in a TNFα-target binding assay for neutralizing activity. Neutralizing antibody titre was reported as the highest dilution that tested positive in the assay.

Results: For the ABP 501 and adalimumab RP groups, 1/171 (0.6%) and 2/168 (1.2%) patients tested positive for pre-existing binding antibodies and no patients tested positive for pre-existing neutralizing antibodies. Overall, 206 of 347 (59.4%) patients developed positive binding antibodies through week 16 post-baseline, which was similar to the percentages in each treatment group (ABP 501, 55.2% (96/174); adalimumab RP, 63.6% (110/173)). A total of 41/347 (11.8%) of all randomized patients developed positive neutralizing antibodies through week 16 post-baseline, which was also similar to the percentages in each treatment group (ABP 501, 9.8% (17/174); adalimumab RP, 13.9% (24/173)). The rate of seroconversion over time for both treatment groups was similar with exposure. For subjects testing ADA positive, the magnitude of both the binding and neutralizing ADAs across the treatment groups are reported as median S/N or titre values between groups per time point.

Conclusion: No clinically meaningful differences were observed in the incidence and magnitude of binding and neutralizing ADAs between ABP 501 and adalimumab RP-treated patients with plaque psoriasis.

Disclosure: Authors have been or continue to be employees and stockholders of AMGEN.

P0994 GUT COLONIZATION WITH EXTENDED SPECTRUM BETA-LACTAMASE PRODUCING ENTEROBACTERIA MIGHT BE ASSOCIATED WITH CIPROFLOXACIN RESISTANCE IN INFLAMMATORY BOWEL DISEASE PATIENTS: PRELIMINARY STUDY RESULTS

Introduction: Inflammatory bowel disease (IBD) patients are a risk group for antibiotic resistance because of the frequent hospitalizations, immunosuppressive therapy and treatment with antibiotics [1]. Extended spectrum beta-lactamase producing Enterobacteria (ESBL-E) are the most frequently found multidrug resistant microorganisms colonizing the gut of IBD patients. Also previous studies have shown that Ciprofloxacin use in IBD patients is higher comparing to non-IBD patients (27% vs 1%) [2]. There might be a link between these findings.

Aims and Methods: The aim of the study was to determine if there is an association between gut colonization with ESBL-E and Ciprofloxacin resistance in IBD out-patients. A cross-sectional study was conducted analysing all patients with confirmed ulcerative colitis (UC) or Crohn's disease (CD) diagnosis previously hospitalized in two largest tertiary medical care centres in Riga, Latvia during a 5-year period (2013–2017). Patients participated in out-patient interviews, faecal biomaterial was obtained, Enterobacteria were cultured and analyzed for ESBL presence and Ciprofloxacin resistance according to EUCAST guidelines.

Results: A total of 54 patients with confirmed IBD diagnosis – 83.3% (n = 45) UC patients and 16.7% (N = 9) CD patients were enrolled in the study. Patients included 55.6% (n = 30) male and 44.4% (n = 24) female patients with the mean age of 44.74 (SD = 15.82) years. ESBL-E was found in 7.4% (n = 4) of the IBD cases. Ciprofloxacin resistance was found in 14.3% (n = 8) of the IBD cases. More patients with Ciprofloxacin resistance had also gut colonization with ESBL-E (75%; n = 3), whereas most patients without Ciprofloxacin resistance did not have gut colonization with ESBL-E (90%; n = 45) (p = 0.008). ESBL-E strains colonizing the gut included *E. coli* (n = 2), *E. faecium* (n = 1) and *Kl. pneumonia*e (n = 1). Enterobacteria strains resistant to Ciprofloxacin included *E. coli* (n = 6), *E. coli* in combination with *Kl. pneumoniae* (n = 1) and *Vancomycin-resistant enterococcus* (n = 1). The severity of the Ciprofloxacin resistance in 2 cases showed high resistance (MIC > 32) and was found in *E. coli*.

Conclusion: Gut colonization with ESBL-E might be associated with Ciprofloxacin resistance in IBD out-patients, E. coli being the most commonly found and the most resistant strain linking the cases. Ciprofloxacin use should be avoided in IBD patients colonized with ESBL-E, especially ESBL producing E. coli.

P0995 PREDICTIVE ROLE OF ANTI-TNF TROUGH LEVELS IN THE OUTCOME OF PATIENTS WITH INFLAMMATORY BOWEL DISEASE IN REMISSION

M.J. Casanova[1], M. Chaparro[1], J.P. Gisbert[1]
[1]*Hospital Universitario de La Princesa, IIS-IP and CIBERehd, Gastroenterology Unit, Madrid, Spain*

Contact E-Mail Address: mjcasanova.g@gmail.com

Introduction: It has been suggested that the knowledge of serum concentration of the anti-TNF drug could be relevant in the management of inflammatory bowel disease (IBD) patients. However, a consistent clinical benefit of the adjustment of treatment based on drug levels in patients at remission has not been established.

Aims and Methods: The aim was to evaluate whether anti-TNF drug levels in IBD patients in clinical remission may predict their outcome (that is, the risk of disease relapse during the following months).

Unicentre, observational, prospective study. All consecutive Crohn's disease (CD) and ulcerative colitis patients on maintenance therapy with infliximab (IFX) or adalimumab (ADA) and being in clinical remission, were included. At inclusion, anti-TNF drug trough level was measured and, during a 6 months follow-up period from this measurement, the clinical outcome of the patients was evaluated. During the follow-up period, all therapeutic decisions (treatment withdrawal, anti-TNF dose escalation, switch to another anti-TNF or to another biologic,), were based exclusively on standard clinical, analytical and endoscopic parameters. The cut-off to consider therapeutic anti-TNF trough levels, based on our previous study[1], was above 3.4 for IFX and 7.2 μg/mL for ADA.

Results: 102 patients in remission while receiving anti-TNF therapy were included (54% men, mean age at diagnosis 33 years, 80% CD, 65% were on ADA and 34% were on IFX). 45% received concomitant immunosuppressive therapy. 33% were exposed to a previous anti-TNF drug. Sub-therapeutic anti-TNF trough levels were found in 53% of the patients in clinical remission at the inclusion. During the 6 months follow-up period, 11% of the patients relapsed. From the patients with therapeutic drug levels, 6% relapsed, whereas 14% of the patients with sub-therapeutic anti-TNF levels relapsed at the end of follow-up ($P > 0.2$). Also, there were not differences between CD or UC patients, and between patients who received ADA or IFX. Anti-TNF dose was escalated empirically in 13 patients with loss or response, and 8 (61%) of them regain remission: 5/10 patients with sub-therapeutic anti-TNF trough levels (measured just previously to dose escalation) but also 3/3 with therapeutic levels before intensification.

Conclusion: Anti-TNF drug levels in IBD patients in clinical remission do not predict the risk of relapse during the following months. The majority of patients with sub-therapeutic anti-TNF levels remain in remission during follow-up. Therefore, therapeutic strategies based on anti-TNF trough levels in IBD patients in remission need further research.

P0996 CIPROFLOXACIN RESISTANCE IS HIGHER IN ULCERATIVE COLITIS PATIENTS WITH MORE SEVERE DISEASE ACTIVITY AND MORE EXACERBATIONS: PRELIMINARY STUDY RESULTS

V. Skuja[1,2], A. Rosberg[1], J. Malina – Bambite[1,2], L. Putnina[1], E. Tropina[1], D. Rudzite[2], E. Lavrinovica[2], A. Oscepkova[1], A. Krumina[2], A. Derovs[2], A. Lejnieks[1]

Introduction: Ulcerative colitis (UC) patients are a risk group for antibiotic resistance because of the frequent hospitalizations, immunosuppressive therapy and treatment with antibiotics [1]. Previous studies have shown that Ciprofloxacin use in UC patients is higher comparing to non-UC patients (27% vs 1%) [2]. In many cases Ciprofloxacin is given as empiric treatment by non-gastroenterologists to UC patients with exacerbations and higher disease activity. This could lead to higher antibiotic resistance and worse outcome in this particular UC phenotype.

Aims and Methods: The aim of the study was to determine if there is an association between Ciprofloxacin resistance and UC disease activity and what are the risk factors attributing to that. A cross-sectional study was conducted analysing all patients with clinically, endoscopically and histologically confirmed UC diagnosis previously hospitalized in two largest tertiary medical care centres in Riga, Latvia during a 5-year period (2013–2017). Patients participated in out-patient interviews regarding their risk factors for Ciprofloxacin resistance, faecal biomaterial was obtained and analysed for Ciprofloxacin resistance according to EUCAST guidelines Version 7.1 and UC disease activity was evaluated according to the full Mayo score (FMS).

Results: A total of 45 patients with confirmed UC diagnosis, 55.6% (n = 25) male and 44,4% (n = 20) female patients with the mean age of 44.74 (SD = 15.82) years, were enrolled in the study. Ciprofloxacin resistance in faecal biomaterial was found in 17,8% (N = 8) of the cases. *E. coli* was the most frequently found bacterial strain resistant to Ciprofloxacin, found in 6 cases alone and in 1 case in combination with *Kl. pneumonia*. In 1 case *Vancomycin-resistant enterococcus* resistant to Ciprofloxacin was found. The severity of the Ciprofloxacin resistance for *E. coli* in 2 cases showed high resistance (MIC > 32). Patients with Ciprofloxacin resistance had more severe disease – moderate or severe disease activity (FMS 6–12) compared to patients without Ciprofloxacin resistance – remission or mild disease activity (FMS 0–5) ($p < 0.001$). Also, the mean FMS was higher in patients with Ciprofloxacin resistance found in their faecal biomaterial – 2 (SD = 1.07), comparing to patients without Ciprofloxacin resistance – 1.1 (SD = 0.52) ($p = 0.001$). Differences in various factors that could attribute to Ciprofloxacin resistance were analysed in these UC patients and revealed no statistically significant differences between UC patients with and without Ciprofloxacin resistance regarding socio-demographic factors like age, gender and international travels; IBD-related factors like UC complications and treatment modalities; and risk factors for Ciprofloxacin resistance like previous hospitalizations, residence in a nursing home, antibiotic treatment, urinary tract infections and invasive manipulations in the past 12 months. The only factor that was different in UC patients with and without Ciprofloxacin resistance was the number of UC exacerbations in the past 12 months. UC patients with Ciprofloxacin resistance had higher number of exacerbations 4,25 (SD = 4.92) comparing to UC patients without Ciprofloxacin resistance 1.23 (SD = 2.46) ($p = 0.011$).

Conclusion: There is a high resistance to Ciprofloxacin in UC patients. More severe disease and more exacerbation in the past 12 months increase the resistance to Ciprofloxacin. Ciprofloxacin use should be avoided in these UC patients., because this may lead to a higher antibiotic resistance and worse outcome in these patients.

Disclosure: Nothing to disclose

Introduction: Real-world treatment of inflammatory bowel disease (IBD) remains challenging. High adverse event (AE) rates and limited effectiveness of treatments in some patients may lead to early therapy discontinuation. The aim of this study was to assess treatment persistence with immunosuppressant (IS), anti-tumor necrosis factor (aTNF) and anti-integrin (aI) agents in patients with IBD.

Aims and Methods: We conducted a retrospective cohort analysis of patients diagnosed with ulcerative colitis (UC) or Crohn's disease (CD) who were newly initiating treatment with IS, aTNF or aI from 01/01/2013-31/12/2015. Patients were identified from a German sickness fund (AOK PLUS), had continuous insurance coverage, and had no evidence of IS, aTNF or aI use for 12 months before the index date (date of newly initiating selected therapy during the study period). Treatment persistence was defined as percentage of patients still on index therapy after 12, 24 and 36 months, censoring for death and end of follow-up period. Patients were considered to have discontinued therapy if there was a drug coverage gap > 60 days. Cox regression analysis was used to identify differences in mean persistence between the 3 treatment groups, adjusting for baseline characteristics.

Results: A total of 1,126 (UC: 450; CD: 676) met the inclusion criteria and constituted the treatment-naïve IBD cohort used for the analysis. Mean age of UC and CD patients was 42.5 and 36.5 years; 47.6% and 60.5% were female. Among UC patients, IS was the most common (85.8%) index therapy, followed by aTNF (13.6%) and aI (0.7%). Among CD patients, IS was the most common (77.7%) index therapy, followed by aTNF (21.2%) and aI (1.2%).

By 12 months, 55.7% of UC and 57.7% of CD patients discontinued their index therapy. Of the 990 patients followed for 24 months (UC: 395; CD: 595), 66.2% of UC and 67.8% of CD discontinued their index therapy. Of the 802 patients followed for 36 months (UC: 325; CD: 477), 73.1% of UC and 74.4% of CD discontinued their index therapy.

Adjusting for baseline characteristics, aTNF was associated with later treatment discontinuation compared with IS (hazard ratio [HR]: 0.364, $p < 0.001$) in UC patients. In CD patients, both aTNF and aI were associated with later treatment discontinuation compared with IS (aTNF HR: 0.562, $p < 0.001$; aI HR: 0.187, $p = 0.018$).

Conclusion: Although some patients performed better than others, persistence with IBD treatment is far from ideal, with more than 50% of patients discontinuing their index therapy by 12 months in this dataset. It also needs to be noted that because of the requirement for 60 days' continuous therapy with the index agent, we could not report the rate of discontinuations occurring early in therapy. As demonstrated in previous studies, IBD treatment discontinuation mainly results from poor effectiveness and/or safety concerns. There is an urgent need for development of more effective and/or safe IBD therapies which should lead to better real-world treatment persistence.

Introduction: Crohn's disease (CD) is a chronic relapsing inflammatory bowel disease, characterised by severe transmural inflammation of the gastrointestinal tract. The aetiology of CD remains unclear and there is no known cure. Emu Oil (EO) is extracted from adipose tissue of the emu; a large flightless bird native to Australia. Previously, we demonstrated that orally-administered EO reduced inflammation and protected the intestine against experimentally-induced ulcerative colitis, colitis-associated colorectal cancer, NSAID-enteropathy and chemotherapy-induced mucositis.
Aims and Methods: To investigate whether orally-administered EO could attenuate disease severity in a trinitrobenzene sulfonic acid (TNBS) mouse model of CD. Female ARC(s) mice ($n = 10$/group) were intra-rectally administered 120µl water or TNBS (3mg). Mice were orally-administered water or EO (80µl or 160µl) daily for five days and were culled on day six. Bodyweight and disease activity index (DAI; four parameters including bodyweight loss, general condition, rectal bleeding and stool consistency) were recorded daily. Burrowing activity and facial grimace parameters were assessed as behavioural measures of disease progression. Colonoscopy was performed to assess disease severity based upon thickening of the colon, changes to vasculature pattern, presence of fibrin, granularity of mucosal surface and stool consistency. Additionally, proximal and distal colonic crypt depth, myeloperoxidase activity (indicative of acute inflammation) and fluorescein isothiocyanate dextran (indicative of intestinal permeability) uptake were quantified. $p < 0.05$ was considered statistically significant.
Results: Compared to normal controls, TNBS decreased bodyweight (days 1, 2 and 4; maximum 4.5% bodyweight reduction; $p < 0.05$) and increased DAI (days 1–6; maximum 11-fold increase; $p < 0.01$). In TNBS-treated mice, 80µl EO significantly reduced DAI scores on days 5 and 6 (maximum 55% reduction) compared to controls ($p < 0.05$), though bodyweight loss remained unchanged. TNBS administration increased mouse grimace scores (11.5-fold; indicative of pain and distress), compared to normal controls; an effect significantly attenuated by both 80µl (11.5-fold decrease) and 160µl (5.4-fold decrease) EO treatment ($p < 0.001$). Colonoscopically-assessed disease severity score was greater in TNBS controls (2.9 ± 0.3; [mean ± SEM]), compared to normal controls (0.1 ± 0.1; $p < 0.001$). Importantly, in TNBS-treated animals, both 80µl and 160µl volumes of EO significantly reduced colonoscopically-assessed disease severity (80µl: 1.7 ± 0.3; 160µl: 2.1 ± 0.3), compared to TNBS controls ($p < 0.01$). TNBS induced compensatory distal colonic crypt lengthening (190.9 ± 8.6) compared to normal controls (161.1 ± 3.9; $p < 0.05$), which remained unaffected following EO administration (80µl: 206.6 ± 10.7; 160µl: 202.4 ± 4.9), compared to TNBS controls ($p > 0.05$). Burrowing activity, proximal colonic crypt depth, myeloperoxidase activity and intestinal permeability remained unchanged across all treatment groups ($p > 0.05$). Moreover, in normal animals, EO treatment did not significantly impact any parameter compared to water-treated controls.
Conclusion: Emu Oil reduced clinical indicators of disease severity, including daily disease activity index, grimace pain scores and colonoscopically-assessed disease parameters in TNBS-treated mice. These findings suggest therapeutic efficacy for Emu Oil as an adjunct to conventional treatment approaches for Crohn's disease.

Introduction: Golimumab (GLM) is a fully human anti-TNF effective for induction and maintenance of response and remission in moderate to severe ulcerative colitis (UC) patients[1]. Measurement of anti-TNF serum trough levels (TL) is increasingly used to assist in physician decisions on dose (de) escalation or discontinuation to achieve the treatment target in IBD.
Aims and Methods: This study evaluated the association of GLM TL with clinical, endoscopic and histological disease activity measures and with fecal calprotectin (FC) levels in a multicenter, open label, nonrandomized, prospective study of Portuguese patients with moderate to severe active UC treated with GLM. Subjects were followed for a period of 16 weeks with clinical assessments and data collection at screening, week 6 (W6) and week 16 (W16). GLM TLs and FC were measured at both W6 and W16. GLM TLs were assayed with an ELISA kit[2]. All study data were summarized using descriptive statistics. Statistical tests were two-tailed and considering a significance level of 0.05.
Results: A total of 38 patients were treated, 34 (89.5%) completed through W6 (full analysis set, FAS) and 29 (76.3%) completed through W16. Nine patients (23.7%) discontinued the study. Mean (range) age was 34.6 years (19–65 years); 15 (44.1%) were male. At baseline, 94.1% had moderately active disease (Mayo score 6–10) and 5.9% ($N = 2$) had severe disease; 27 (79.4%) were treated with immunosuppressants and 16 (47.1%) were taking glucocorticoids. At W6, 16/34 (47.1%) patients were in clinical response and 5/34 (14.7%) in clinical remission; 18/29 (62.1%) and 11/29 (37.9%) at W16, respectively. At W6, GLM TL quartile values were significantly correlated with clinical response ($p = 0.0035$), with 1/8 (12%) and 9/11 (82%) responders in the lowest (<1.0 ug/mL) and highest GLM TL quartile (≥3.2 ug/mL), respectively. Median W6 GLM TL in clinical responders ($n = 16$) *vs.* nonresponders ($n = 18$) was 3.7 *vs.* 1.3 ug/mL ($p = 0.0013$); and 3.1 *vs.* 1.7 ug/mL in endoscopically inactive disease ($n = 14$) *vs.* active disease ($n = 20$) ($p = 0.021$). W6 GLM TL was negatively correlated with the total Mayo score ($p = 0.0008$); the endoscopic Mayo score ($p = 0.0262$), the histological activity score ($p = 0.0057$), and FC level ($p = 0.0044$).
Conclusion: Low GLM TLs are associated with poor clinical, endoscopic, histological, and fecal calprotectin outcomes at W6 in UC patients treated with GLM. Our data add further evidence for an early exposure-response relationship in UC patients treated with golimumab.

Contact E-Mail Address: sun.diana@gene.com
Introduction: Treating patients with inflammatory bowel disease (IBD) is challenging, as available therapies might be associated with substantial rates of adverse events (AEs). Our aim was to evaluate the rate of drug-related severe AEs and the associated health care costs among patients with IBD, who are receiving aminosalicylate (ASA), oral corticosteroid (OCS), immunosuppressant (IS), anti-tumor necrosis factor (aTNF) or anti-integrin (aI) agents in Germany.

Aims and Methods: We conducted a retrospective cohort study of patients diagnosed with ulcerative colitis (UC) or Crohn's disease (CD) who were newly initiating treatment with IS, aTNF or aI from 01/01/2013-31/12/2015; chronic ASA and OCS use was also observed. Patients were identified from a German sickness fund (AOK PLUS), had continuous insurance coverage, and had no evidence of IS, aTNF or aI use for 12 months before the index date (date of newly initiating therapy during the study period). The period after the index date was defined as follow-up. Rate of AEs, based on 28 different codes associated with inpatient encounters, and direct health care cost were reported separately for patients who experienced/did not experience AEs. Only treatment periods lasting ≥60 days were considered; patients could be assigned to >1 treatment during follow-up.

Results: A total of 1,126 (UC: 450; CD: 676) met the inclusion criteria. Mean age of UC and CD patients was 42.5 and 36.5 years; 47.6% and 60.5% were female. Among UC patients, 51.2% of observed follow-up time was covered by IS monotherapy index treatment, followed by aTNF mono (17.7%), ASA mono (15.0%), and OCS + IS (5.2%). Among CD patients, IS mono was the most common (45.3%) index treatment, followed by aTNF mono (27.3%), OCS + IS (9.0%), and OCS mono (5.3%).

A total of 157 patients (UC: 74; CD: 83) had at least 1 coded AE during follow-up, overall AE rate was 1,546 events per 10,000 patient years (TTPY). Most common AEs among patients with UC or CD were (rates per TTPY) severe infection (UC: 320; CD: 90), diabetes mellitus (UC: 460; CD: 73), perianal disease (UC: 153; CD: 169) and bone-related conditions (UC: 292; CD: 51). Among the 157 patients, 126 patients (80.3%) experienced at least 1 switch from 1 treatment to another during the whole follow-up period, respective number in the whole sample was 66.5%.

In a multivariate analysis adjusting for key confounders available in the database, a higher comorbidity was associated with a higher AE rate in UC patients. In CD patients, presence of a previous extraintestinal manifestation was associated with a higher AE rate. However, none of the treatments were significantly associated with a higher AE rate. Cost for patients with an AE were generally higher than for those without an AE (UC: 11,279 € vs 7,965 €; CD: 20,723 € vs 8,538 €).

Conclusion: Burden of severe AEs is substantial in IBD patients, with an event rate of 1,546/TTPY in this dataset. AE rates did not differ between IBD treatments in our study, which may also be due to low sample size. We observed that AEs are associated with higher health care cost. Our results show that there is urgent need for development of IBD treatments that are associated with lower rates of severe AEs.

Introduction: Inflammatory bowel disease (IBD) has a negative impact on work productivity, which is associated with indirect health care costs and lower quality of life.

Aims and Methods: The aim of this ongoing study is to determine treatment-related risk factors for IBD-related work productivity loss in a Dutch IBD cohort. A web-based follow-up study was initiated in two tertiary and two secondary referral hospitals in the Amsterdam region. IBD patients between 16 and 63 years old were invited to participate if they were (self-) employed. Patients received a baseline questionnaire, which included sociodemographic, work-related and disease-related questions. Patient-reported simple clinical colitis activity index (p-SCCAI) for ulcerative colitis (UC) and patient-reported Harvey Bradshaw Index (p-HBI) for Crohn's disease (CD) were used to determine clinical disease activity. IBD-related work productivity loss was measured using the WPAI questionnaire. Moderate to severe absenteeism was defined as > 20% work time missed, presenteeism as >20% reduced productivity while working, and overall work productivity loss as >20% overall work impairment due to IBD (including absenteeism and presenteeism). Risk factors were identified using logistic regression. Factors with a p-value < 0.1 in univariate analysis were entered into multivariate analysis with stepwise selection.

Results: In total, 1590 patients were invited of which 516 (32%) responded to the invitation so far: 368 agreed to participate and 148 patients were not eligible or refused to participate. Up to now, 321 patients completed the baseline questionnaire (61% female, 65% CD and 35% UC) with a mean age of 43 ± 12 years and median disease duration of 13 [IQR 7–23] years. Immunomodulators were used in 28% of patients, 29% received anti-TNF treatment (infliximab, adalimumab or golimumab), 5% received vedolizumab, 3% received ustekinumab, 8% had an ostomy and 4% had an ileal pouch-anal anastomosis. Moderate to severe absenteeism was reported in 49 (15%) and presenteeism in 138 (43%) patients. Moderate to severe overall work productivity loss was reported in 152 (47%) patients (107 (51%) CD and 45 (41%) UC). In multivariate analysis, the risk of moderate to severe overall work productivity loss was significantly greater in patients with prior anti-TNF use (OR 2.40 [95% CI 1.34–4.29]), in patients using anti-TNF agents at the time of this study (OR 1.89 [95% CI 1.04–3.46]), and in patients with clinical disease activity (OR 7.63 [95% CI 3.84–15.14]). Neither significant associations were found between work productivity loss and type of IBD (CD versus UC), immunomodulators (i.e. azathioprine, mercaptopurine and methotrexate) or other biologics such as vedolizumab or ustekinumab, nor between patients with an ostomy or ileal pouch-anal anastomosis and work productivity loss.

Conclusion: Prior and active anti-TNF use, as well as clinical disease activity are risk factors for work productivity loss in IBD patients. Anti-TNF use may be a marker for more severe IBD, however for vedolizumab and ustekinumab an association with work productivity loss was not (yet) found. These findings will be analyzed in more detail in a prospective follow-up study using this cohort.

Introduction: Vedolizumab (VDZ), an $\alpha_4\beta_7$ integrin antagonist, was approved in Germany in 2014 for the treatment (Tx) of moderately to severely active ulcerative colitis (UC). This study descriptively assessed the real-world effectiveness and safety of VDZ and anti-tumour necrosis factor-alpha (anti-TNFα) after VDZ was introduced in Germany.

Aims and Methods: A retrospective chart review (15 sites) investigated patients (pts) with UC who were biologic- (bio-) Tx naïve or had received one prior anti-TNFα at initiation of index Tx with VDZ or anti-TNFα between 15 July 2014 and 20 October 2015. Time to first chart-documented clinical remission (total Mayo or partial Mayo score ≤2 and no subscore >1), rectal bleeding (RB) resolution (score of 0) and stool frequency (SF) resolution (score of 0 or 1) were assessed using time-to-event Kaplan-Meier analyses over 26 weeks.

Abstract No: P1002

Follow-up Week	Outcome	Bio-naïve: Anti-TNFα	Bio-naïve: VDZ	Prior anti-TNFα: Anti-TNFα	Prior anti-TNFα: VDZ	Total: Anti-TNFα	Total: VDZ
Week 6	**Clinical remission**	10.6 (5.8)	29.4 (11.1)	0 (0)	17.2 (6.4)	7.4 (4.1)	21.2 (5.7
Week 6	**RB resolution**	17.0 (6.9)	46.4 (12.9)	7.7 (7.4)	22.5 (7.5)	14.2 (5.4)	30.4 (6.8)
Week 6	**SF resolution**	29.2 (8.2)	33.0 (12.1)	22.6 (11.5)	30.0 (8.4)	27.2 (6.7)	30.8 (6.9)
Week 14	**Clinical remission**	22.2 (8.1)	50.1 (12.8)	9.1 (8.7)	39.9 (8.7)	18.6 (6.4)	43.3 (7.2)
Week 14	**RB resolution**	27.4 (8.3)	68.8 (12.5)	7.7 (7.4)	48.5 (9.5)	21.5 (6.4)	55.2 (7.7)
Week 14	**SF resolution**	39.3 (8.9)	68.8 (12.5)	30.4 (12.7)	41.5 (9.3)	36.8 (7.3)	50.9 (7.8)
Week 26	**Clinical remission**	31.5 (9.4)	50.1 (12.8)	30.7 (15.0)	55.5 (9.4)	31.7 (8.1)	53.7 (7.6)
Week 26	**RB resolution**	57.0 (10.1)	68.8 (12.5)	52.0 (15.0)	65.7 (9.5)	55.8 (8.4)	66.8 (7.6)
Week 26	**SF resolution**	51.0 (9.4)	68.8 (12.5)	49.2 (14.8)	54.8 (9.9)	50.7 (8.0)	59.8 (7.9)

[Kaplan-Meier Estimates of Responders Over 26 Weeks, % (standard error)]

Results: The study investigated 76 VDZ (29% bio-naïve; 47% female) and 57 anti-TNFα (12 adalimumab, 14 golimumab, 31 infliximab; 70% bio-naïve; 58% female) pts. At baseline, pts' median age was 40 years (y; VDZ) vs 34 y (anti-TNFα); median disease duration was 6 y (VDZ) vs 5 y (anti-TNFα); and 43% (VDZ) vs 47% (anti-TNFα) received a corticosteroid. The outcomes of interest were available in the medical chart for a subset of pts: total or partial Mayo in 60 VDZ (18 bio-naïve) and 47 anti-TNFα (33 bio-naïve) pts; RB in 50 VDZ (16 bio-naïve) and 44 anti-TNFα (31 bio-naïve) pts; and SF in 50 VDZ (16 bio-naïve) and 46 anti-TNFα (32 bio-naïve) pts. A higher proportion of VDZ vs anti-TNFα pts achieved each outcome by Week 6 (clinical remission [21% vs 7%], RB [30% vs 14%], and SF [31% vs 27%]), Week 14 (clinical remission [43% vs 19%], RB [55% vs 22%], and SF [51% vs 37%]), and Week 26 (clinical remission [54% vs 32%], RB [67% vs 56%], and SF [60% vs 51%]; **Table**) although differences were not significant (log-rank test: clinical remission = 0.081; RB = 0.066; SF = 0.411). These trends in VDZ vs anti-TNFα outcomes were also seen in bio-naïve (Week 26: clinical remission [50% vs 32%], RB [69% vs 57%], and SF [69% vs 51%]) and one prior anti-TNFα (Week 26: clinical remission [56% vs 31%], RB [66% vs 52%], and SF [55% vs 49%]) pts (**Table**). Independent of index Tx, more bio-naïve vs one prior anti-TNFα pts achieved clinical remission and symptom resolution at Week 6 and Week 14 (**Table**). Differences between cohorts by prior Tx history were not significant (log-rank test: clinical remission = 0.374; RB = 0.193; SF = 0.489). Adverse events occurred in 39% of VDZ vs 44% of anti-TNFα pts.

Conclusion: In this descriptive analysis of Tx outcomes in bio-naïve and one prior anti-TNFα experienced German UC pts, VDZ and anti-TNFα achieved similar clinical remission and symptom resolution, assessed at Weeks 6, 14, and 26. Bio-naïve pts were consistently more likely to have responded than pts who had received one prior anti-TNFα. These data suggest VDZ is an effective biologic Tx option in UC for both bio-naïve pts and pts who have received a prior anti-TNFα.

Introduction: Small intestinal bacterial overgrowth (SIBO) is characterized by an abnormal bacterial proliferation in the small bowel. Crohn's disease (CD) and ulcerative colitis (UC) share many common features with SIBO-diarrhea, bloating, weight loss, abdominal pain. SIBO has not been studied in children with inflammatory bowel disease (IBD).

Aims and Methods: The aim of this study was to assess the prevalence of SIBO among children with IBD and the relationship between SIBO and disease phenotype, localization and activity. Methods: 43 children with IBD (29 CD and 14 UC) and 40 healthy controls were enrolled. 23 patients had active disease, whereas in 20 subjects the disease was in remission. SIBO was assessed using glucose hydrogen breath test (GHBT). Concentration of hydrogen was measured by LactoFAN analyser.

Results: 15 children with IBD (12 CD, 3 UC; 34.8%) and two control subjects (5%) were positive for GHBT. SIBO prevalence was significantly higher in IBD children as compared to controls ($p < 0.001$). The occurrence of SIBO in CD (41.3%) was higher compared to UC group (21.4%) ($p < 0.05$). Dysbiosis had a higher frequency among children with active disease (52.1%) compared to those in remission (15%) ($p < 0.05$). There was no correlation of SIBO with the Pediatric Crohn's Disease Activity Index in CD group. SIBO was significantly more frequent in CD children with stricturing pattern and ileum involvement.

Conclusion: SIBO is a frequent but underestimated condition in IBD, that might mimic acute flares. Stricturing phenotype in CD and active disease were associated with dysbiosis. SIBO diagnostic work-up followed by directed treatment is recommended in IBD children who present stricturing disease, especially in those with concurrent intestinal inflammation.

Introduction: During active ulcerative colitis (UC), myeloid lineage leucocytes are elevated with activation behaviour including the CD14+CD16+ monocytes, which are a major source of inflammatory cytokines including tumour necrosis factor-α (*J Immunol* 2002; 168: 3536–42). Therefore, selective depletion of elevated/activated myeloid leucocytes is expected to induce remission, or enhance drug efficacy.

Aims and Methods: We were interested to see if selective depletion of myeloid leucocytes by adsorptive granulocyte/monocyte apheresis (GMA) with an Adacolumn induces remission in children and adolescents who had active disease despite receiving first-line medications. In clinical practice setting, 31 consecutive patients with active UC, age 11–19 years, bodyweight 33–55.5kg were given mesalazine (n = 24) or sulphasalazine (n = 7) as the first-line medication. Twenty patients relapsed while receiving first-line medication or did not respond and received GMA, at 2 sessions in the first week, then weekly, up to 11 sessions. Patients who achieved ≥5 decrease in the clinical activity index (CAI) continued with GMA, while non-responders received GMA plus a low-dose prednisolone (0.5–1.0mg/kg). At entry and week 12, patients were clinically and endoscopically evaluated with each patient serving as her or his own control.

Results: Eleven patients achieved stable remission with the salicylates and did not receive GMA. Six patients did not respond well to the first 5 GMA sessions and received prednisolone together with GMA, 12 patients achieved stable remission with GMA and 2 withdrew to receive high dose prednisolone. Prednisolone was tapered to 0mg within 3 months in those who received to induce remission. Therefore, at week 12, all 31 patients were in remission.

Conclusion: GMA in young corticosteroid naïve patients with active UC refractory to the first-line salicylates induced remission and mucosal healing, while in non-responders to GMA monotherapy, addition of a low dose prednisolone enhanced the efficacy of GMA and tapering of the prednisolone dose was not associated with relapse. Additionally, GMA has a good safety profile, which is a very favourable feature in growing patients.

Introduction: Previous studies report that faecal calprotectin (FC) can be altered by factors like weight, Body Mass Index (BMI) and age (see references 1–9), but many of them have methodologic limitations.

Aims and Methods: Our primary aims were to (i) establish normal levels of FC in healthy children living in a Spanish urban environment; and (ii) analyse correlation of FC with age, gender and anthropometry.

A multicentre, cross-sectional and observational study from January 2015 to December 2016 enrolled healthy donors under 18 who attended the participating primary health centers for routine pediatric controls. The exclusion criteria were: (i) immunodeficiency; (ii) autoimmune disease; (iii) gastrointestinal disease; (iv) intake of drugs; (v) gastrointestinal symptoms; or (vi) any positive finding in the associated microbiological study. We determined the FC levels (Quantum Blue® test), and perfomed stool cultures, parasites, rotavirus and adenovirus detection. The statistical analysis (SPSS® software) considered a P value < 0.05 statistically significant.

Results: We included 395 subjects from 3 days to 16.9 years old (mean 4.2 years, standard deviation (SD) 4.7 years); 51.6% boys and 48.4% girls. Table 1 displays the results. FC values showed a non-normal distribution using the Kolmogorov-Smirnov test. The correlation between age (days) and FC (μg/g) was analyzed via Spearman correlation coefficient, with a bilateral significance of 0.00.

Weight was recorded in 389 subjects, mean 17.9 Kg (95% CI 16.4–19.6), and median 11.8 Kg (range 2.2–73 Kg). Height was measured in 383 children, mean 94.2 cm (95% CI 90.4–98 cm), and median 85.0 cm (range 46–185 cm). Using these data, we calculated the BMI of 382 subjects, mean 16.4 Kg/m2 (IC 95% of 16.1 a 16.6), and median 11.3 Kg/m2 (range 10.2- 25.4 Kg/m2).

Boys had a FC mean of 196.8 μg/g, and median 86.0 μg/g. Girls had a FC mean of 186.0 μg/g, and median 71.0 μg/g. The Mann-Whitney U test showed no significant differences ($p > 0.05$).

The association of weight, height (both absolute values and SD) and BMI with FC was analysed via Spearman, with a bilateral significance of 0.00 ($p < 0.05$), suggesting a negative correlation. However, no correlation of weight SD and BMI SD with FC was found (Spearman correlation coefficient $p > 0.05$).

Conclusion: FC values in healthy children were higher than those considered as pathological in adults. A negative correlation with age was observed, with no correlation with gender. Our results suggest that weight and BMI do not influence FC values, since the negative correlations of their absolute values and FC

were not confirmed when analysing their SDs. This may reflect the role of age as a confounding factor. We found a negative correlation between height (both absolute values and SD) and FC, that had not been previously described. Based on this, it seems necessary to reconsider the levels of FC deemed pathological in pediatric patients by age group and further investigate the role of anthropometric data.

Age group	No. of Subjects	Mean FC (μg/g)	10 th (μg/g)	50 thP (μg/g) (median)	90thP (μg/g)
<1 month	43	344.3	156	303	620
1–6 months	64	424	76	325.5	993
6–12 months	46	167.7	30	63	488
12–24 months	42	217.7	30	97	533
2–4 years	45	116.1	30	71	271
4–8 years	64	89.1	30	46	163
8–12 years	46	85.4	30	34.5	143
12–18 years	45	45.2	30	30	75
Total (0- 18 years)	395	191.6	30	77	508.4

[Table 1: FC levels in each age group. 10thP: 10th percentile. 50thP: 50th percentile. 90thP: 90th percentile.]

Introduction: Inflammatory bowel disease (IBD) seems to have a unique phenotype in patients with primary sclerosing cholangitis (PSC). However, in children with PSC there are few data on the clinical course of IBD [1,2].

Aims and Methods: The aim of this retrospective case-control population-based study was to investigate the outcome of IBD in a cohort of subjects with a paediatric-onset of IBD-PSC and in a matched group of patients with IBD only. Twenty-seven IBD-PSC cases diagnosed with a paediatric-onset of disease (male 18, mean age at IBD diagnosis 13 years, range: 6–18 years and mean age at PSC diagnosis: 14 years, range: 5–18) were identified. Diagnosis of IBD-PSC was done between 1993–2011. For each case three IBD controls matched for age and year of diagnosis were selected from IBD Register at Helsinki University Hospital (HUH). However, three of the controls developed PSC during the follow-up and were excluded. Thus, overall 78 IBD-controls were included (males 50; age at IBD diagnosis 12 years, range: 4–18). All data regarding patients' baseline characteristics and intestinal/liver diseases were collected at diagnosis and at the end of follow-up (median follow-up 13 years, range: 4–26). Mean age in IBD-PSC group was 26 years (range: 14–39) and in IBD control group 25 years (range 15–41) at the end of follow-up. Data are presented as number with percentage when categorical and as mean/median and range when continuous. Differences were tested by using Fisher's Exact Test for categorical variables and Mann-Whitney Test for continuous variable. The study was approved by the Ethics Committee of HUH (number 64/13/03/03/2012).

Results: At diagnosis, 20 IBD-PSC children (74%) had pure PSC and 7 (26%) PSC-AIH-overlap syndrome. Of these, 22/27 (82%), 3/27 (11%) and 2/27 (7%) had ulcerative colitis (UC), unclassified colitis (IBDU) and Crohn's disease (CD), respectively. Correspondingly, in the IBD-control group 32/78 (41%), 6/78 (8%) and 40/78 (51%) had UC, IBDU and CD, respectively. The difference in IBD subtype between IBD-PSC cases and IBD-controls was not statistically significant ($p = 0.2$).

At diagnosis no difference in disease extent/localisation and severity between IBD-PSC cases and IBD-controls was found. Colitis was histologically detected in 22/27% (81%) of IBD-PSC patients and in 67/78 (86%) of IBD-controls ($p =$ not significant). At last follow-up, IBD-PSC cases tended to be more frequently in remission (40% vs 21% of IBD-controls, $p =$ not significant) and they showed less active colitis (37% vs 63% of IBD-controls, $p = 0.002$). IBD-controls had used more frequently TNF-alfa-inhibitors (49% vs 7% of IBD-PSC cases, $p = 0.0001$). The number and type of surgery was similar between IBD-PSC cases and IBD-controls, but patients with IBD-PSC turned out to need more often proctocolectomy, with J-pouch (26% vs 18% of IBD-cases, $p =$ not significant). However, they tended to have less pouchitis (57% vs 86% of IBD-controls, $p =$ not significant). Low-grade dysplasia was detected in the colon in 1 IBD-PSC patient (age 24 years, 10 years from IBD diagnosis) and colon cancer in 1 IBD control (age 31, 17 years from IBD diagnosis). All patients in both group were alive at the end of follow-up.

Conclusion: The course of paediatric onset IBD in patients with IBD-PSC seems to be more benign than in those with pure IBD, in line with reports in adult population. Colon dysplasia/cancer may though occur in both.

Introduction: As a result of increasing incidence of pediatric-onset inflammatory bowel disease (IBD) growing number of adolescents need handover to adult care. Whereas transfer is essentially only an event, transition is a well-planned, coordinated process. Recent data support that structured transition programs in IBD may improve patient compliance and disease control.

Aims and Methods: We aimed to evaluate the effect of our current structured transition process on clinical outcomes in adolescent inflammatory bowel diseases (IBD) patients.

Two groups of IBD patients diagnosed in pediatric care were compared: Group A patients did not attend the transition process, whilst Group B patients entered the planned transition service. Outcomes at 1- year after transfer to adult care were evaluated.

Results: Forty-five IBD patients (18 males and 27 females) diagnosed under the age of 18 years were identified of whom 35 had Crohn's disease and 10 had ulcerative colitis. 24 patients were in Group A (without transition), and 21 patients in Group B (with at least one planned transition visit). Mean age at diagnosis was 15.1 ± 2.2 and 13.7 ± 3.0 years ($p = 0.086$), respectively. There were no significant differences in disease duration before transfer, Montreal classification at diagnosis, body mass index, anti-TNF therapy usage, and disease status at transfer between the two groups. Significantly higher number of Group B patients were in remission at 12-month after transfer when compared to patients in Group A (11 vs. 18, respectively, $p = 0.037$). There was a significant difference between groups regarding the number of elective admissions within the examined period (9 vs. 16, $p = 0.011$, respectively).

Conclusion: Planned transition visits resulted in higher disease remission rate at 1-year follow-up after transfer from pediatric to adult health care system in adolescent IBD patients. Well-established transition programs in IBD are needed.

P1008 EFFICACY AND SAFETY OF GRANULOMONOCYTAPHERESIS AS REMISSION INDUCTION THERAPY IN ULCERATIVE COLITIS PATIENTS INCLUDING ADOLESCENTS AND ELDERLY

T. Ohmori, S. Ohmori
Ohmori Toshihide GastroIntestinal Clinic, Ageo, Japan

Contact E-Mail Address: toshihideo@gmail.com

Introduction: At our gastroenterology clinic, we receive patients with ulcerative colitis (UC) who wish to avoid hospitalization, require treatment in an outpatient setting. Additionally, with the availability of granulomonocytapheresis (GMA, Adacolumn) therapy, most of our patients favour this non-pharmacologic option as the first-line therapy to avoid pharmacologicals. In fact, most elderly UC patient have multiple other complications as co-morbidities, which may include diabetes, hypertension, cardio-cerebral disease, and therefore, are likely to be on

other medications. Likewise, in younger UC patients, we like to avoid corticosteroids, which may adversely affect their overall growth and development.
Aims and Methods: Therefore, we have been applying GMA as a first-line therapy before any drug based medication hoping to spare our young and elderly patients from pharmacologicals. In a retrospective setting, we reviewed the treatment outcomes measures in patients with UC who had received granulomonocytapheresis (GMA) with the Adacolumn as remission induction therapy at our gastroenterology clinic over the past 11 years. The patients were divided into three groups, under 18 years of age (Group 1, n = 8), 18 to 64 years of age (Group 2, n = 130), and beyond 64 years of age (Group 3, n = 13). In each group, patients' age, gender, UC profile, location, duration, and past medications were factored for analysis to determine the clinical response GMA therapy. Clinical activity index (CAI) ≤4 meant remission.
Results: Each patient had received up to a maximum of 11 GMA sessions at 1 to 5 sessions per week. The clinical response together with remission rates were 87.5% in Group 1, 77.7% in Group 2, and 84.6% in Group 3. Similarly, the clinical remission rates were 87.5% in Group 1 (all 8 patients), 63.8% in Group 2, and 53.8% in Group 3. Further, in Group 1, younger patients showed pancolitis, while in Group 3, elderly patients had a short disease duration, most of them had developed UC around 60 years of age, the so-called elderly onset UC. In all 3 groups, GMA therapy was well tolerated and was without any severe adverse event.
Conclusion: The efficacy outcomes in our patients are very much higher than previous studies reported for GMA in patients with severe UC, refractory to pharmacologicals. However, in our patients, GMA is a very much favoured treatment option for young and elderly patients because of its good safety profile, as well as for being a non-pharmacologic treatment option. Provided patients can afford to make frequent visits to the treatment centre and the medical personnel can achieve a straightforward blood access, GMA should be a first-line therapy before corticosteroids or other pharmacologicals.

[2]*University "Federico II" of Naples, Department of Translational Medical Science, Section of Pediatrics, Naples, Italy*

Contact E-Mail Address: nicola.imperatore@alice.it
Introduction: The transitional process of young patients affected by inflammatory bowel disease (IBD) from pediatric to adult care is a crucial step. It should ensure continuity of care and the maintaining of a well-being condition in a critical and delicate phase of life. It has been suggested that patients who take part in a transitional program show greater compliance and fewer adverse events.
Aims and Methods: The aim of our study was to investigate the 1-year success outcome of the transitional process of IBD patients in terms of maintenance of the nutritional status, patients' compliance to the care in the adult setting and disease activity control, after the implementation of a specific transition programme in our center. From January 2013 to January 2018 we evaluated the transitional process of patients with childhood onset of Crohn's disease (CD) or ulcerative colitis (UC), from the Pediatric to the Adult IBD center, at School of Medicine "Federico II" of Naples, Italy. For each patient we compared the following parameters 12 months before and 12 months after the transition from pediatric to adult care: Body Mass Index (BMI), albumin and hemoglobin level, smoker status. We also compared the number of outpatient visits and the pharmacological therapy in the 12 months prior to the transition with the one in course one year after the transfer to the adult center, as well as the number of disease exacerbations, hospitalizations and surgical interventions.
Results: We enrolled a total of 106 patients with IBD (43 with CD and 63 with UC). We did not find a statistically significant difference between the patients' BMI before and after the transition, while there was a lower percentage of smokers seen in the post-transition period (11% vs. 13.2%; p = ns). Furthermore, there was a statistically significant reduction in the number of exacerbations and hospitalizations in the 12 months following the transition (pre-transition exacerbations: 0.74 ± 0.79, post-transition exacerbations: 0.35 ± 0.57, $p < 0.001$; pre-transition hospitalizations: 0.28 ± 0.44, post-transition hospitalizations: 0.1 ± 0.3, $p < 0.001$). In contrast, there was no statistically significant difference in the number of outpatient visits (3.40 ± 1.4 vs. 3.25 ± 1.2; p = ns) and in the percentage of patients undergoing surgery (0.9% vs. 1.8%, p = ns). We also evaluated pharmacological strategies and we showed a significant difference ($p < 0.01$) in the use of nutritional therapy between the pre-transition phase (18.8%) and the post-transition phase: in fact, no patient in post-transition phase used this therapeutic approach. Moreover, in post-transition period there was a reduction in immunosuppressant use (methotrexate: 9% vs. 2%, p = 0.0031; azathioprine: 36% vs. 23%, $p < 0.01$).
Conclusion: The parameters used as success indicators of the transition program confirm the achievement of a continuity of care from Pediatrics to adult Gastroenterology, such as the maintenance of a state of well-being, in a generally critical phase of the natural history of IBD patients.

P1010 EFFICACY AND DIAGNOSTIC ACCURACY OF FAECAL CALPROTECTIN IN CHILDREN IN PRIMARY CARE, A PROSPECTIVE PRIMARY CARE COHORT STUDY

G. Walker[1], **M. Abdelrahim**[1], L. Moore[1], N. Heerasing[1], P. Hendy[1], A. Thomas[1], B. Hamilton[1], C. Bewshea[1], J. Goodhand[1], C. Calvert[1], T. Ahmad[1], J. Hart[2], N.A. Kennedy[1]

[2]*Royal Devon and Exeter Foundation NHS Trust, Paediatrics, Exeter, United Kingdom*

Contact E-Mail Address: mohamed.abdelrahim@nhs.net
Introduction: Faecal calprotectin (FC) is recommended (NICE, DG11, 2013) as an option to support clinicians with the differential diagnosis of IBD and non-IBD (including IBS) in children who have been referred for specialist GI assessment, but data relating to its clinical utility in primary care as part of a referral pathway are limited. We hypothesised that FC would have clinically useful positive and negative predictive values in this setting and would perform better than existing clinical and blood biomarkers to guide appropriate referral.
Aims and Methods: GPs from all 49 local practices in the catchment area for the Royal Devon and Exeter Hospital were recommended to submit an FC test for children aged 4–18 yrs presenting with new GI symptoms where they suspected but were uncertain of an IBD diagnosis. We considered FC levels of ≥100μg/g as positive and recommended referral of positive tests and GP management for negative tests. Clinical symptoms and blood results were captured prospectively at the time of GP referral. Secondary care records after 12 months' follow-up were reviewed to ascertain diagnosis, with unreferred patients after this time assumed to have a non-IBD diagnosis. Mann-Whitney U, Students T-test and Chi-squared tests were used as appropriate. ROC curves and a stepwise backwards multivariable logistic regression were used to explore thresholds and fit models, respectively.
Results: 132 patients were included in the final analysis: 66 (54%) were female and median age was 15.1yrs [IQR 12.4–14.4].10 (8%) patients were diagnosed with IBD (7 CD, 1 UC, 2 IBD-U). The most frequent non-IBD (n = 122) diagnoses were: IBS/functional gut disorder 82%; anal fissure/haemorrhoids 3%; infective gastroenteritis 3% and coeliac disease 2%. FC ≥100μg/g had a sensitivity = 100% (95% CI 69–100%), specificity = 89% (82–94%), PPV = 43% (23–66%), NPV = 100% (97–100%). The AUROC for FC and CRP were 0.98 [0.96–1.00] and 0.94 (0.89–1.00) respectively (p = 0.22). The optimal threshold for distinguishing IBD from non-IBD was FC = 112μg/g and for CRp = 1.5mg/L. Patients with IBD had a higher FC ($p < 0.001$), CRP ($p < 0.001$), white cell count ($p < 0.001$), ferritin (p = 0.05) and platelet count (p = 0.023); lower albumin (p = 0.004) and haemoglobin (p = 0.004) and reported a shorter duration of symptoms (p = 0.037), looser motions (p = 0.007) and a change in stool appearance (p = 0.030) than non-IBD cases. In the multivariable model for every 10-fold increase in FC and CRP the odds of IBD increased by 4.90-fold (95% CI 1.9–2.6, p = 0.01) and 3.6-fold (95% CI 1.6–2.3, p = 0.02), respectively.
Conclusion: Calprotectin testing of paediatric patients in the primary care setting accurately distinguishes IBD from non-IBD conditions in situations of diagnostic uncertainty with clinically useful positive and negative predictive values. It is superior to other clinical and blood parameters except CRP. These data might inform patient care pathways and guide primary care clinicians.

Introduction: Functional gastrointestinal disorders (FGID), as defined by the Rome IV criteria, may appear in children of all ages and include a wide range of digestive related symptoms. Dietary intolerances to lactose, fructose, or intestinal dysbiosis might be related to FGID, but these conditions are often underdiagnosed and poorly managed.
Aims and Methods: The aim of this study was to assess the prevalence of lactose, fructose intolerance and small intestinal bacterial overgrowth (SIBO) by using hydrogen breath test (HBT) in children with recurrent abdominal pain. Methods:The authors enrolled 226 consecutive children admitted to our hospital with chronic abdominal pain between January 2017 and March 2018. After organic causes were ruled out, the remaining patients underwent lactose, fructose and glucose HBT. A standard dose of 1 g/kg of lactose, 1 g/kg fructose and 1 g/kg glucose were orally administered dissolved in 200 ml of water, with a maximum of 25 g for lactose and fructose, respectively 50 g for glucose. Exhaled hydrogen was measured at 20 minutes intervals for 3 hours. An increase with at least 15 parts per million (ppm) above baseline was considered suggestive for lactose and fructose malabsorption or indicative for SIBO after glucose intake. HBT were conducted in different days for each patient.
Results: Of 226 children analyzed, organic disorders were found in 82 children. The rest of 144 children with FGID (16 functional dyspepsia, 89 irritable bowel syndrome and 39 centrally mediated abdominal pain according to Rome IV criteria) underwent HBT. Lactose HBT was positive in 35 of 144 (24.3%), fructose HBT was positive in 14 of 144 (9.7%), while 29 (20.1%) had positive glucose HBT, indicating SIBO. 31 of 35 children (88.5%) improved on lactose-free diet, 12 of 14 children

(85.7%) improved after fructose exclusion and symptoms disappeared in 28 of 29 children with SIBO (96.5%) after oral rifaximin and probiotics.
Conclusion: Lactose and fructose malabsorption along with intestinal dysbiosis can contribute to recurrent functional abdominal pain in children. Symptoms improved after dietary changes and oral nonabsorbed antibiotic and probiotics.

Introduction: Current tests to measure gastrointestinal transit have limitations or use ionising radiation, making them undesirable, particularly for younger patients. We have previously developed and validated prototypes of magnetic resonance imaging (MRI) transit marker capsules (1), which detect differences in whole gut transit between constipation and health (2). Those prototypes are however quite large (20 mm x 7 mm) and large indigestible objects may not travel normally through the gut (3).
Aims and Methods: We aimed to develop an improved MRI alternative to the old x-ray radiopaque markers (ROM) methods to measure whole gut transit. Mini-capsules were manufactured by JEB Technologies (Suffolk, UK). They are small (8 mm × 4 mm), made of inert plastic material and filled with an oil-in-water emulsion that can be imaged uniquely by exploiting common water and fat selective MRI (4). Five healthy volunteers swallowed 24 mini-capsules for 3 consecutive days, for a total of 72 mini-capsules (a common X-ray ROM protocol). They were scanned on the 4th day using a 3.0 T MRI scanner.
Results: The new mini-capsules were easy to swallow and the protocol was accepted well by the volunteers. The mini-capsules were imaged successfully in the colon.
Conclusion: We have developed new MRI mini-capsule markers that can overcome limitations of previous whole gut transit tests. They are particularly well suited for younger patients and their production can be scaled up industrially.
This work was funded by a NIHR i4i award. The views expressed are those of the authors and not necessarily those of the NHS, the NIHR, or the Department of Health.

Introduction: Recurrent abdominal pain (RAP) is a common complaint during childhood, but the natural history of childhood RAP and pain-predominant functional gastrointestinal disorders (pFGID) in the general population remains poorly understood.
Aims and Methods: The aim of the current study was to describe the prevalence and turnover of childhood RAP during the first 16 years of life and explore the association between childhood RAP and Rome III defined pFGID in adolescence.
In this prospective Swedish population-based birth cohort study of 4089 children, parents and children answered questionnaires on gastrointestinal symptoms at 1, 2, 12, and 16 years and doctor's diagnosis of inflammatory bowel disease (IBD) and celiac disease (CD) at 12 and 16 years. RAP at 1 and 2 years was defined as repeated attacks of colic for the past 6 and 12 months respectively, and was pooled and called early childhood RAP. RAP at 12 and 16 years was defined as self-reported weekly abdominal pain with no parent-reported diagnosis of IBD and/or CD. pFGID at 16 years were defined according to the Rome III criteria and included irritable bowel syndrome (IBS), functional dyspepsia (FD) and functional abdominal pain (FAP). Sex-adjusted associations were examined using binominal generalized linear model and presented as relative risk (RR) with 95% confidence interval (CI).
Results: Any history of RAP between early childhood and 16 years was reported in 33.0% (890/2698) of children. The prevalence of RAP peaked at 16 years in both boys and girls. Prevalence rates were significantly higher for girls compared to boys at 12 ($p < 0.01$) and 16 years ($p < 0.01$), but not in early childhood. In the subgroup of children with RAP who had completed the detailed Rome III questionnaire at 16 years (498/609), 69.9% fulfilled the criteria for any pFGID. IBS was the most common phenotype in both boys and girls. The prevalence of pFGID was higher in girls than in boys ($p < 0.01$). See Table below.Early childhood: Total n = 3797; Boys n = 1925; Girls n = 1872. 12 years: Total n = 2764; Boys n = 1382; Girls n = 1382. 16 years RAP: Total n = 3039; Boys n = 1494; Girls n = 1545. 16 years pFGID: Total n = 2926; Boys n = 1451; Girls n = 1475. FAp = Functional abdominal pain; FD = Functional dyspepsia; IBS = Irritable bowel syndrome; pFGID = Pain-predominant functional gastrointestinal disorders; RAp = Recurrent abdominal pain.
Complaints of RAP over two assessment points was reported in 2.8% (70/2459) of the children (77.1% girls), and complaints over three assessment points was reported in four children (all girls). Children with RAP in early childhood and at 12 years reported persisting symptoms at the following assessment point in 6.8% (11/161) and 43.4% (43/99) of cases respectively. It was more common for girls than for boys to report persisting symptoms between early childhood and 12 years (10/81 vs 1/80, $p < 0.01$), but not between 12 years and 16 years (34/75 vs 9/24, $p = 0.50$).
Children with RAP at 12 years had an increased risk for RAP at 16 years (RR 2.4, 95% CI 1.9–3.0) for any pFGID at 16 years (RR 2.5, 1.8–3.4), and for IBS at 16 years (RR 3.2, 2.0–5.0). No association was found between early childhood RAP and RAP at 12 years or RAP, any pFGID, and IBS at 16 years.
Clinical follow-up of a subsample of children (87/175) fulfilling the Rome III criteria for IBS at the 16-year questionnaire, confirmed the diagnosis of IBS in 78.2% of cases.
Conclusion: RAP is common in childhood, but most children with RAP do not have persisting symptoms throughout childhood. However, reporting RAP at 12 years is an independent risk factor for RAP, any pFGID, and IBS at 16 years.

Introduction: Constipation is common and a nagging symptom around the world. Associated factors of childhood constipation have been reported, however, few research exist about the development. Our aim was to clarify the effect of dietary pattern and lifestyle on the development of childhood constipation.
Aims and Methods: Participants were aged 12–13 years and from the Toyama Birth Cohort Study in Japan, a prospective longitudinal study examining lifestyle and child's health. Children who completed questionnaires both in 1999 and 2002 were included. Children's dietary pattern, lifestyle factors such as sleep duration,

Abstract No: P1013

			16 years

physical activity, and psychological status at baseline were inquired. Children with bowel movements of less frequently than once every 2 days was defined as being constipated. Children who had already constipated at baseline were excluded.
Results: Out of 10438, 6662 children (63.8%) were included in our longitudinal study. In total, 317 (4.8%) developed constipation during the three years. Logistic regression analysis showed that the development of constipation was significantly associated with being girl (odds ratio [OR] = 2.33), infrequent intake of fruit (OR = 1.60). Physical activity, TV viewing, sleep duration, and psychological status at baseline was not associated.
Conclusion: Only dietary pattern of taking fruits infrequently predicted a constipation in school children. Lifestyles and psychological status at baseline might change and not effect on development of constipation during the period. A longitudinal study with shorter follow up interval will be needed to clarify the risk factors of childhood constipation.
Disclosure: Nothing to disclose

Contact E-Mail Address: bearinspring@hotmail.com
Introduction: Intussusception is one of the most emergent gastrointestinal disease in paediatric patients, which somtimes lead to the perforation, necrosis, and even death if the initial diagnosis is delayed.
Aims and Methods: The aim of this study was to identify the related factors of the recurrent intussusception in the paediatric patients. The medical record of the intussusception patients who were diagnosed and treated at Dongsan Medical Center from March 2015 to June 2017 was retrospectively reviewed. Baseline demographic findings, the time interval from the symptom onset to the treatment of reduction or operation, the reduction methods (barium enema vs. water enema), the presenting symptoms such as vomiting, bloody stool, abdominal pain or irritability, and lethargy, the history of previous or concurrent infection, the radiologic findings and laboratory findings were analyzed. The pathologic leading points and operation methods were investigated too.
Results: Among the total of 137 patients, the male to female ratio was 1.4 (male = 80, 56.7%, female = 57, 40.4%). The mean age was 2.17 ± 1.36 years with a range of 0.18 to 10.1 years. The mean interval time from the symptom onset to the reduction time was 24.39 ± 25.64 hours with a range of 2 to 168 hours. The mean age for recurrence group was 5.35 ± 2.72 years and the interval time from the initial reduction to recurrence was 50.96 ± 25.52 hours. The reduction methods were the water reduction (n = 69, 48.9%), the barium reduction (n = 64, 45.4%), operation (n = 1, 0.7%) and spontaneous reduction (n = 3, 2.1%). The type of intussusception was mostly ileocolic (n = 136, 96.5%) with one small bowel case (n = 1, 0.7%). The diagnosis age and the intussusception head size on ultrasonography were significantly related with the recurrence of intussusception ($p = 0.006$, $p = 0.028$, respectively). In laboratory analysis, CRP was significantly higher in the recurrence group (1.03 ± 1.49 vs.1.49 ± 2.68, $p = 0.024$). Bloody stool and history of infection were significantly more frequent in the non-recurrence group ($p = 0.001$, $p = 0.000$, respectively), and vomiting, abdominal pain or irritability, and lethargy did not show any significant difference between the two groups. No pathologic leading point except for enlarged lymph nodes was found.
Conclusion: The diagnosis age, CRP and the mass size in radiologic finding was significantly related with the recurrence of intussusception.
Disclosure: Nothing to disclose

P1016 PSYCHO-GASTROENTEROLOGICAL PROFILE IN PAEDIATRIC OUTPATIENTS AFFECTED BY DISORDERS OF GUT-BRAIN INTERACTION

Introduction: Disorders of Gut-Brain Interaction (DGBI), previously known as Functional Gastrointestinal disorders (FGIDs), are common among children. Nevertheless, their pathophysiology is still uncertain, an efficacious therapy is lacking, and valid tools to evaluate these disorders during childhood are not available. We have developed a multi-parametric questionnaire that evaluates the psycho-gastroenterological profile (PGP) and socio-demographic characteristics of the paediatric population and have tested its validity in children with and without DGBI.
Aims and Methods: We studied a population of 119 Caucasians, aged 11–18, consisting of 28 individuals diagnosed with DGBI using the Rome IV criteria at our Outpatient Clinic and 91 controls enrolled in secondary schools. All subjects were asked to fill our Psycho-Gastroenterological Questionnaire (PGQ), which takes into account the following parameters: number of medical examinations due to gastrointestinal symptoms, sensation of pain evaluated with the Faces Pain Scale Revised (FPS-R), form of the feces established with the Bristol Stool Chart (BSC), gastrointestinal symptoms assessed with the Gastrointestinal Symptoms Rating Scale (GSRS), anxiety with the State-trait anxiety inventory (STAI Y-1 and STAI Y-2), alexithymia with the Toronto Alexithymia Scale 20 (TAS 20), perceived Self-efficacy in the management of negative emotions and expression of positive emotions with APEN-G and APEP-G, Quality of life with the Irritable bowel syndrome-Quality of Life (IBS-QoL) Questionnaire, school performances, tobacco use, history of familial trauma, digitalization. Differences between the two groups were evaluated by Student's t-test and considered significant for $p < 0.05$.
Results: Compared to controls, patients with DGBI had significantly higher school performances ($p < 0.05$) and were significantly less frequently tobacco users (0% vs 16%, $p < 0.05$). A history of familial trauma was significantly more common in DGBI subjects than controls (28% vs 1%, $p < 0.05$). No differences between the two groups were found in terms of level of digitalization and BSC. Subjects with DGBI reported more frequent medical examinations due to gastrointestinal symptoms than controls. They also reported a significantly higher percentage of pain classified as 4 at the FPS-R (14% vs 7%, $p < 0.05$). Scores of GSRS and APEN-G were significantly higher in patients than controls (12.2 ± 8.1 vs 6.9 ± 4.0, $p < 0.05$ and 24.3 ± 6.8 vs 22.1 ± 5.0, $p < 0.05$, respectively). On the other hand, scores of STAI Y-1 (33.5 ± 12.1 vs 48.6 ± 10.9, $p < 0.05$), STAI Y-2 (39.3 ± 10.7 vs 47.4 ± 10.6, $p < 0.05$), TAS 20 (48.2 ± 8.0 vs 51.8 ± 11.4, $p < 0.05$), and IBS-QoL ($p < 0.05$ for dysphoria, interference with activity, body image, health worry, food avoidance, social reaction, relationships, overall) were significantly lower among DGBI patients than controls.
Conclusion: Our PCQ detected, among subjects with ≤ 18 years of age affected by DGBI compared to controls, higher prevalence of history of familial trauma, lower QoL, more medical examinations, lower anxiety levels (both STAI Y1 and STAI Y2), and higher perceived self-efficacy in the management of negative emotions. It also detected lower levels of alexithymia and tobacco use. The PGQ is a novel, easy-to-use, questionnaire deserving further investigation for its potential utility in the assessment of the psycho-gastroenterological profile of children and adolescents affected by DGBI.

Introduction: Recently, a number of studies have reported that gut microbiota could contribute to human condition including obesity, inflammation, cancer development and behavior. We hypothesized that the composition and distribution of gut microbiota are different according to the stool frequency. And we tried to identify the association between gut microbiota and stool frequency.
Aims and Methods: We collected faecal samples from healthy people who divided into three groups according to the stool frequency. Group 1, a small number of defecation (≤ 2 times/week); Group 2, normal defecation (1 time/day or 1 time/2 days); Group 3, a large number of defecation (≥ 2–3 times/day). The defecation patterns (number of defecation and associated Bristol stool scale (BSS) scores from 1-week diaries) were recorded. And we evaluated the composition and distribution of gut microbiota in each group by 16S rRNA-based taxonomic profiling of faecal samples.
Results: Faecal samples were collected from a total of sixty individuals (31 males and 29 females, aged 34.1 ± 5.88), and each group was 20 individuals. We identified microbial richness of Group 1 was significantly higher than that of Group 3, and tendency to decrease with increasing a number of defecation. The biological community composition was fairly different based on the number of defecation, and the ratio of Bacteroidetes/Firmicutes was higher in Group 1 than in other groups. And we found specific strains at family and genus level which exist in Group 1 and Group 3, respectively.
Conclusion: Stool frequency might be associated with richness and community composition of gut microbiota and these findings could be supported by the assessment in further metagenome-wide association studies of gut microbiota.

P1018 THE ROLE OF THE METABOLIC ACTIVITY OF THE INTESTINAL MICROFLORA IN CHILDREN WITH IMMUNE THROMBOCYTOPENIC PURPURA RESISTANT TO CORTICOSTEROID THERAPY

M. Abuzin, S. Belmer, E. Donyush, Z. Kondrashova, O. Malkova
Pirogov Russian National Research Medical University, Russian Children's Clinical Hospital, Health Ministry of Russian Federation, Moscow, Russian Federation

Contact E-Mail Address: mdabuzinmn@yandex.ru

Introduction: Immune thrombocytopenic purpura (ITP) is a disease characterized by isolated thrombocytopenia of less than $150x10^9$/l with a normal or increased amount of megakaryocytes in the bone marrow and the presence of autoantibodies on the surface of platelets causing their increased destruction. Gastrointestinal disorders in ITP directly related to the underlying diseases cause the development of intestinal microbiota disorders in children.

Aims and Methods: To evaluate the metabolic activity of the intestinal microflora based on the assessment of the spectrum of stool short chain fatty acids in children with ITP resistant to corticosteroid therapy.

The study included 41 patients (19 girls and 22 boys) aged from 2 to 17 years (mean age – 10.27 years, median age – 10 years) with ITP resistant to corticosteroid therapy. All patients were observed in the department of the hematology and oncology of the Russian Children's Clinical Hospital (Moscow).

All patients underwent conventional clinical-instrumental and an assessment of the metabolic activity of the intestinal microflora based on the stool short chain fatty acids levels assessment by gas-liquid chromatography.

Results: In children with ITP resistant to corticosteroid therapy a wide range of gastroenterological symptomps were identified, including abdominal pain (14/41, 34.15%) belching (8/41, 19.5%), heartburn (7/41, 17.1%), stool disorders (8/41, 19.5%), indirect signs of intestinal digestion (4/41, 9.76%) and absorption abnormalities (41/41, 100%). The revealed disturbances in the metabolic activity of the intestinal microflora were characterized by an increased production of the acetic, propionic, butyric, valeric acids and also isovanoic acid. A significant increase in the isocyanates production and a slightly increased ratio of EiC/EC (10/16, 62.5%), indicating a predominance of iso-acids over non-isoforms, a significant predominance of isovaleric acid (an increase in the ratio of iC5/C5 in 68.75% of patients with ITP) were observed. Additionally, the anaerobic index was increased.

Conclusion: In children with ITP resistant to corticosteroid therapy, a wide range of gastroenterological complaints were identified, as well as changes in intestinal microbiota expressed in disturbance of short chain fatty acids production, indicating an increase in the activity of the saccharolytic flora, accompanied by an increase in the activity of proteolytic microorganisms uncharacteristic for normal microbiota with an increase in the fraction anaerobes.

Introduction: *Clostridium difficile* infection (CDI) is a public threat due to its recurrences and severity. Faecal transplantation is more effective than antibiotics in reducing recurrences, but with some unknown risks. Bile acids (BA) are known to influence germination and growth of *C.difficile*: taurocholate acid (TCA), a primary BA, promotes germination and growth of *C. difficile* (1). Secondary BA inhibit germination and growth (2). Ursodeoxycholic acid (UDCA), a tertiary BA minor in human, inhibits germination and growth of *C. difficile in vitro* (2,3), but was never tested *in vivo* with an infectious challenge. We hypothesized that we could use UDCA for prevention of CDI. We evaluated the effects of UDCA on *C.difficile in vitro* on germination and growth and *in vivo* in an animal model, with pharmacokinetics study and prevention of CDI. We then studied the infection incidence in UDCA-treated patients.

Aims and Methods: *In vitro* trials evaluated germination and growth of several strains of *C.difficile* by optical density measurements and colony count, with 0.01%, 0.05% and 0.1% UDCA, in competition with 0.1% TCA. We analysed faecal BA of hamsters receiving antibiotics and UDCA (50mg/kg/day), antibiotics alone, or UDCA alone. Then, we challenged with spores of *C.difficile* at D6 hamsters treated with UDCA (50 mg/kg/day) from D1 to D13, versus control. Their survival, colonization and BA were evaluated. In human, we analysed the database of a cohort that studied CDI in acute flares of inflammatory bowel disease (IBD) from September 2012 to May 2014 (4). As PSC-IBD patients were under UDCA treatment, we compared PSC-IBD patients to IBD patients without PSC.

Results: *In vitro*, UDCA strongly inhibited germination and growth of *C.difficile* at 0.05% and 0.1%, competing with 0.1% TCA (0.05% $\pm$0.05% colony forming unit versus 100% $\pm$0%, $p<0.0001$). UDCA reached high proportions of faecal BA pool only in hamsters that received UDCA with antibiotics, with a 43.5% UDCA peak at D5. Without antibiotics, we didn't observe any similar UDCA peak in faeces of hamsters (max. 4.28% UDCA), probably because of UDCA transformation into lithocholate by gut microbiota. During infectious challenge, mortality was high (62.5%, n = 5/8) and similar in animals treated or not with UDCA ($p=0.78$). UDCA percentage in group A was high, similar and with the same kinetics in dead and surviving hamsters (the day of infection: 46.03% UDCA versus 40.82%, respectively, $p=0.14$). However, dead hamsters had a higher ratio of primary over secondary BA compared to surviving hamsters: first hamsters to die had the highest ratios of primary over secondary BA. 9% (n = 41/445) of patients with IBD without PSC (not treated with UDCA) had a CDI at the time of admission for an IBD flare, versus 25% (n = 4/16) of patients with PSC-IBD treated with UDCA.

Conclusion: We confirmed the strong inhibitory effect of UDCA on growth and germination of *C.difficile in vitro*, with 0.05% or 0.1% UDCA competing with 0.1% TCA. However, in our hamster model, UDCA was inefficient to prevent CDI, despite high levels of UDCA in faeces (41–46%). Patients with PSC-IBD treated with UDCA did not have less CDI than IBD patients.

Introduction: Alterations in the gut microbiome have been implicated in the pathogenesis of several immune-mediated inflammatory diseases such as in patients with psoriatic arthritis. Psoriasis is a chronic, inflammatory, multi-organ disease characterized by papulosquamous lesions with varying morphology, distribution, severity and course.

Aims and Methods: To characterize the gut microbial signature of patients with active psoriasis as compared to matched non psoriatic control participants and to determine whether these changes translate to differences in expression of significant metabolic pathways.

This observational prospective multicenter study was conducted at the Tel Aviv Medical Center (TLVMC) and Maccabi healthcare services (MHS). Patients' clinical details were recorded and stool was collected and stored at −80 °C. In parallel matched controls were recruited. Fecal samples were processed and 16S rRNA was sequenced using the Illumina platform. This data as well as clinical data of the patients and healthy cohorts were compared. A false discovery rate (FDR)≤0.1 was considered statistically significant. A multivariate analysis was performed to correct for confounding variables. PICRUSt was used to determine whether there were differences in genes encoding various metabolic pathways between the cohorts.

Results: Forty-six participants were recruited to the study of whom 52% (n = 24) suffered from psoriasis. Psoriatic patients were older (52.7 ± 11.6 vs. 43.9 ± 12.7, $p=0.02$) and had a lower body mass index (BMI) (25 ± 2.9 vs. 27 ± 3.4 kg/m^2, $p=0.05$) compared to control patients, respectively. There was a significant difference in beta-diversity between the two patient groups. Psoriatic patients had a significant increase in the Firmicutes and Actinobacteria phyla, while Bacteroidetes and Proteobacteria were decreased compared to the control cohort. At the genus level, significant differences were detected between the 2 patient groups, using the LEfSe analysis (Table 1). At the species level, there were significant increases (FDR < 0.05) in *Ruminoccocus gnavus, Dorea formicigenerans*, and *Collinsella aerofaciens,* in the psoriasis group, while *Prevotella copri,* and *Parabacteroides distasonis* were significantly increased in the control group. A metabolic gene analysis (PICRUSt) revealed increases in metabolic pathways related to lipopolysaccharide function in the psoriatic cohort. These differences are summarized in Table 1.

Genus	Psoriatic cohort	Healthy cohort	P-value	FDR
Blautia	0.131	0.025	0	0.00002
Faecalibacterium	0.069	0.033	0.006	0.028

(continued)

Continued

Genus	Psoriatic cohort	Healthy cohort	P-value	FDR
Ruminococcus	0.057	0.016	0.001	0.005
Prevotella	0.055	0.37	0.0003	0.003
Coprococcus	0.039	0.01	0.0002	0.002
Bifidobacterium	0.035	0.01	0.0003	0.003
Dorea	0.02	0.003	0	0.00001
Lachnospira	0.007	0.015	0.009	0.04
Collinsella	0.004	0.0007	0.006	0.03
Sutterella	0.001	0.005	0.00001	0.0003
Actinomyces	0.0002	0.00006	0.0006	0.004
Christensenella	0.0001	0.00001	0.012	0.05

[Table 1: Taxonomic differences between the healthy cohort and psoriatic patients at the genus level].

Conclusion: The data demonstrate a unique fecal microbial and metabolic signatures for psoriatic patients. These may directly impact regulation of the immune responses and influence the pathogenesis of psoriasis.

Introduction: Dysbiosis of intestinal microbiota is promoting the development of colorectal cancer (CRC). We confirmed the intestinal microbiota composition from fecal sample of Korean CRC patients. Metagenomic analysis was performed and we isolated single microbes through culture-based method.

Aims and Methods: CRC fecal samples were collected from 12 individuals. Metagenome Sequencing was based on the 16S rRNA gene amplicon on the Illumina MiSeq platform. The bacteria strains were subcultivated on the agar plate medium in aerobic and anaerobic and further identified by using the 16s rRNA gene sequencing.

Results: Bacteria diversity by metagenome analysis was decreased in CRC group compared to control group. In CRC group, relative abundance of Firmicutes and Bacteroidetes were increased while the prevalence of Proteobacteria was decreased. The difference of microbial composition between control and CRC group was found at the genus level. Bacteroides, Parabacteroides of Bacteroidetes have increased and Acinetobacter, Pseudomonas of Proteobacteria have significantly decreased in CRC compared to control group. Using culture method, we isolated diverse bacteria of species level including 5 strains of Bacteroides; *B. ovatus, B. uniformis, B. salyersiae, B. vulgatus and B. xylanisolvens* and 2 strains of Fusobacterium; *F. gonidiaformans* and *F. necrophorum* from CRC patients.

Conclusion: Metagenome analysis showed the genus Bacteroides, Parabacteroides of the phylum Bacteroidetes has increased and the genus Acinetobacter, Pseudomonas of Proteobacteria decreased in CRC group compared to control group. In addition to, we have isolated various strains associated with CRC by culture-based method.

Introduction: Diet and lifestyle characteristics were previously shown to be associated with colorectal neoplasia, mainly in the distal colon and less at the proximal colon. However, these associations need further confirmation and elaboration and were not tested with a global lifestyle score.

Aims and Methods: We aimed to explore the association between nutritional and lifestyle components, and a global lifestyle score, with the presence and laterality of colorectal polyps. We conducted a case-control study among patients undergoing colonoscopies during 2010–2015 at our department. Cases were defined by detection of an adenomatous or serrated polyps. Polyp location was defined as proximal (cecum to splenic flexure), or distal (descending to anus). Controls were defined as those without past/current colonic polyps. Data collection included: anthropometrics, medical history and dietary intake evaluated by a structured questionnaire. We adopted a lifestyle score composed of four healthy lifestyle factors from the strategic goals of the American Heart Association: refraining from current/past smoking, absence of obesity, regular performance of physical activity, and a healthy diet (adherence to ≥5 of 11 dietary recommendations).

Results: A total of 328 cases of adenomas (proximal n = 164 and distal n = 164), and 376 controls were included in the study. The proportion of participants adhering to an unfavorable lifestyle pattern (≤2 lifestyle factors) was lower among controls relative to cases of colorectal adenomas (28.3% vs. 44.2% $p < 0.001$). This difference was detected both in cases with proximal adenoma (39.6%, $p = 0.009$ compared with controls) and distal adenomas (48.8%, $p < 0.001$ compared with controls). Similar results were obtained for all polyps types (adenomas and serrated polyps).

In multivariate analysis, each addition of one of the four healthy lifestyle factors was negatively associated with colorectal adenomas (OR = 0.76, 95% CI 0.65–0.90). Associations were significant for both distal and proximal adenomas (OR = 0.78, 0.63–0.96 and OR = 0.73, 0.60–0.90, respectively). Refraining from smoking and maintaining a healthy diet were the factors most strongly associated with lower odds of colorectal adenomas (OR = 0.69, 0.50–0.97 and OR = 0.63, 0.45–0.89, respectively), after adjustment for age, gender, low socio-economic status, use of aspirin, NSAIDs, statin and antidiabetic medication, daily caloric intake, colonoscopy indication and for one another. These associations were significant for both distal adenomas (OR = 0.63, 0.42–0.95 and OR = 0.63, 0.42–0.96, respectively) and proximal adenomas (OR = 0.70, 0.46–1.65 and OR = 0.59, 0.38–0.90, respectively). The number of healthy lifestyle factors was negatively associated with odds of colorectal adenoma, both distal and proximal (Table 1). Also in these analyses similar results were obtained for all polyps types, and for serrated polyps compared with controls.

Conclusion: Adherence to a healthy lifestyle is inversely associated with both distal and proximal colorectal adenomas. The protective association seems to start from adherence for a minimum of 2 healthy lifestyle characteristics. An independent protective association was detected between refraining from smoking and maintaining a healthy diet.

Number of healthy lifestyle factors	All adenomas (n = 403)	Cases of proximal adenomas (n = 198)	Cases of distal adenomas (n = 205)
0–1	Reference	Reference	Reference
2	0.51 (0.34–0.76)	0.62 (0.38–1.01)	0.41 (0.25–0.66)
3–4	0.50 (0.32–0.77)	0.55 (0.32–0.96)	0.43 (0.25–0.73)

[Adjusted association between the number of healthy lifestyle factors and colorectal adenomas.]

Introduction: Many countries or regions have implemented colorectal cancer (CRC) screening by faecal occult blood testing (FOBT), in particular by means of faecal immunochemical testing (FIT). (1) FOBT as screening method is also recommended by the European guidelines.(2) The effectiveness of population-based screening programmes is not only driven by the sensitivity of the screening method, but also depends on the availability of resources, healthcare infrastructure and population preferences in each country. Population preferences will especially be reflected in participation rate.

Aims and Methods: This study compared design and performance of four faecal immunochemical testing (FIT)-based screening programmes for colorectal cancer (CRC) in Flanders (Belgium), France, Basque country (Spain) and the Netherlands with the aim of future optimization of the different programmes. Background information and data on main performance indicators were collected and compared for the four screening programmes.

Results: Invitation approach differed most strikingly between the four programmes: In France only an invitation letter is send by mail, while the sample kit needs to be collected at general practitioner (GP). In the other programmes, an invitation letter including the sample kit is send by mail. In addition, Basque country and the Netherlands also send a pre-invitation letter prior to the invitation. Interestingly, participation rates vary substantially with method of invitation with the highest participation rates in the Netherlands (73.0%) and Basque country (72.4%), followed by Flanders (54.5%) and France (33.5%). FIT positivity rate ranged from 4.6–6.6% in the programmes. Basque country (91.5%) and France (88.9%) had the highest participation rate with colonoscopy following a positive FIT test.

Conclusion: Large differences in screening participation were observed between programs in line with invitation method used. This finding suggests that changes to the design of the programme, such as a pre-invitation latter and including the sample kit with the invitation, might increase participation. The high participation to colonoscopy in Basque country and France might indicate that in programmes with active involvement of GPs individuals are more likely to undergo a colonoscopy.

	France	Flanders	Netherlands	Basque country
Year	2015–2016	2016	2016	2016
Age (year)	50–74	56–74	55–75	50–69
Participation rate FIT	28.6%	54.5%	73.0%	72.4%
Cut-off level (Hb/g feces)	30 µg	15 µg	47 µg	20 µg
Positivity rate	4.6%	6.6%	5.5%	5.2%
Participation rate colonoscopy	88.9%	85.8%	82.8%	91.5%
Detection rate Advanced neoplasia	1.3%	1.1%	2.3%	1.9%
Diagnostic yield program Advanced neoplasia	0.5%	0.5%	1.6%	1.4%

[Table 1: Performance indicators for France, Flanders, the Netherlands and Basque country]

Introduction: Colorectal cancer (CRC) is a leading cause of cancer mortality in the Veneto Region (North-east Italy). Population screening of adults between 50 and 74 for CRC was begun in 2002, and it became standard practice in all 21 local health units (LHU) of the region in 2008.
This study was carried out to evaluate the impact on surgery rates of CRC screening programs.

Aims and Methods: This is a retrospective cohort study carried out from a population-based archives represented by hospital discharge records (HDR) that includes all hospitalizations with up to six diagnoses recorded according to the ICD9-CM.
All discharges from 1 January 2000 to 31 December 2017 of Veneto population in screening age with principal diagnosis of CRC treated with surgery were included in the study
The number of patients studied by screening rose approximately of 20% reaching 1,597,826 for the last year (2017) and Veneto region can be subdivided into 3 areas stratifying by screening programs introduction period: A – early (2002–2004), B – intermediate (2005–2007), and C – late (2008) areas.
The Standardized Hospitalization Ratio (SHR) per five-year age group (ref. pop. Veneto 2009) was calculated and espressed per 100,000 population.

Results: During the study period, 29,704 surgical procedures for colorectal cancer were performed (colon 63%, rectum 36%, secondary malignant neoplasm 1%) with a SHR of 116.1, higher in males (OR: 1.65; 95% CI: 1.61–1.72; $p < 0.05$).
An analysis of the annual SHR distribution uncovered two distinct phases: during the first phase there was a rising tendency that reached a maximum value in 2007 (143.1; $\chi 2$ trend: 43.731; $p < 0.001$) and during the second there was a falling tendency that reached its minimum value in 2017 (85.3; $\chi 2$ trend: 438.784; $p < 0.001$), with a total reduction of 29.7%.
The cancer stratification by site shows that the rate of surgical procedures of the proximal colon during the last year was the same as the 2000 value (33.2), instead there was a significant decrease (−41.8%; $\chi 2$ trend: 531.356; $p < 0.001$) in the rate of procedures on the distal colon and rectum which fell from 86.5 to 50.3.
The stratification for screening programs intrductions shows how the peak of surgical procedures was reached about in three years from the introduction and then started to drop.

Conclusion: Study findings confirmed that CRC screening was effective in reducing the number of oncological surgical oncology procedures particularly with regard to the distal colon and rectum.
Data analysis showed that in Veneto Region the screening seemed to accelerate reaching the peak rate in surgical procedures that took place in 2007 and then started to fall off.

Introduction: Screening for colorectal cancer (CRC) with the fecal immunochemical test (FIT) has suboptimal sensitivity for detecting advanced neoplasia (cancer and advanced adenomas). To increase the sensitivity and yield of a FIT-based screening program, FIT could be combined with other risk factors for advanced neoplasia, such as family history of CRC. We evaluated the incremental yield of adding questionnaire on family history of CRC and Lynch syndrome associated tumors to a FIT-based screening program.

Aims and Methods: In this prospective population-based CRC screening trial, we randomly selected 6,000 screening-naive men and women in North-Holland, aged 59 to 75 years. All of them received an invitation to complete a FIT (FOB-Gold) and a validated, online family history questionnaire. Participants with a positive FIT (cut-off value 275ng/ml) and/or a positive family history, confirmed after genetic counseling, were referred for colonoscopy. The yield of detecting advanced neoplasia in the FIT-only strategy was compared to the combined strategy.

Results: Of the 5,979 invitees, 1,952 (33%) participants completed FIT only, 2,379 (40%) completed both FIT and the family history questionnaire and 95 (2%) completed only the family history questionnaire. Of the 125 participants eligible for referral to a clinical geneticist based on their questionnaire responses, only 50 (40%) underwent genetic counseling; 46 (37%) declined referral and 29 (23%) had previously received genetic counseling or colonoscopy surveillance. After genetic counseling, fourteen additional colonoscopies were performed in individuals with a FIT negative result, with no additional advanced neoplasia detected. The positive predictive value for advanced neoplasia of the combined strategy was 54% (95% CI: 47–61%) compared to 58% (95% CI: 51–65%) using the FIT only strategy (p-value = 0.43).

Conclusion: In this study in the Dutch FIT-based screening program we observed no added value of using a validated, online family history questionnaire in detecting advanced neoplasia. However, patients at increased risk of developing CRC, who should undergo colonoscopy screening instead of participating in the CRC screening program, were identified.

Introduction: The Serrated Polyposis Syndrome (SPS) is defined by the World Health Organisation (WHO) revised clinical criteria and is characterised by the presence of multiple Sessile Serrated Lesions (SSLs) within the colon. It confers an increased risk of colorectal malignancy. The exact prevalence of the condition is unknown and is there is significant geographic variability. There is a lack of data on the epidemiology of the SPS in an Australian setting.

Aims and Methods: To evaluate the epidemiology of the SPS in an Australian setting. All patients undergoing colonoscopy at an Australian regional gastroenterology practice between January 2015 and March 2018 were screened for this study. Patients found to have the SPS, as defined by the WHO revised criteria, were included. Polyp histology was independently reviewed by a histopathologist to confirm the diagnosis. Clinical records of patients were reviewed to extract demographic and clinical data.

Results: In the study period, 3725 separate patients underwent colonoscopy and the SPS was identified in 110 of these (2.95%). This group was predominately female (68/110; 62%) and had an average age of 66.3 years (SD = 13.1; range 24–88 years). Baseline characteristics for this group are presented in table 1. The majority of patients (107/110, 97%) were diagnosed with the SPS based on WHO criterion two (five or more polyps proximal to the splenic flexure with at least two greater than 10mm). 3 (3%) patients had a 1st degree relative with SPS and at least one SSL. The median number of SSLs detected during colonoscopy was 8

(range: 5–30) and then mean size of the largest SSL was 18mm (SD = 5.4mm). Dysplasia was detected within a serrated polyp in 30% of patients. In the majority of patients other polyp types were also detected during colonoscopy (83%) with conventional tubular adenomas (33%) and hyperplastic polyps (7%) being the most common (42% had multiple other polyp types).

Characteristic	N = 110
Gender	Female (62%)
Mean age	66.3 years (range 24–88 years)
Smoking history	Current smokers – 5% Former smokers – 16%
Diabetes	9%
Alcohol (≥2SD/day)	20%
Family history of bowel cancer	1st degree relative – 32% 2nd degree relative – 15%
FOBT positive	15%

[Table 1- Baseline characteristics for SPS patients]

Conclusion: The SPS is more common that previously recognised, being detected in 2.95% of Australian patients undergoing colonoscopy in a regional centre. This data set confirms a slight female predominance to the condition. Patients with the SPS are also at increased risk of conventional adenomas.

Introduction: Appendiceal mucinous tumors (AMTs) are reported to be rare, therefore their tumorigenesis and progression pattern are still unclear. AMTs are classified histologically into low-grade mucinous appendiceal neoplasms (LAMNs) or mucinous adenocarcinomas (MACs). These tumors have been considered to be genetically distinct tumors: MACs harbor frequently *TP53* but not *GNAS* mutations, while LAMNs contain frequent *GNAS* but not *TP53* mutations. However, a recent report demonstrated a possibility that LANM could show progression into MAC, because MAC contained a focal area of LAMN component within tumor and could have sometimes the same genetic mutations such as *KRAS* and *GNAS* reported to be frequently occur in LAMNs.

Aims and Methods: The aims of this study are to evaluate the tumorigenesis and the progression mechanism of the AMTs and to deeply examine the clinicopathological and the molecular characteristics of AMTs. We examined 44 cases of AMTs (LAMN: 33, MAC: 11) surgically resected at the Juntendo University Hospital, Tokyo, JAPAN and its affiliated hospital (Shizuoka hospital, Nerima hospital, Urayasu hospital, and Tokyo Koto geriatric medical center) between 2001 to 2018. Among 11 MACs, 7 cases accompanied with LAMNs within the same tumors. DNA was extracted from formalin-fixed paraffin-embedded (FFPE) samples. We performed NGS for 17 cases (LAMN: 11, MAC: 6) using Ion PGM[™] system and cancer hot spot panel v2 targeting 50 genes, 2,790 sites (Thermofisher Scientific). We also performed *KRAS, GNAS* and*TP53* mutation analysis by the Sanger method for the specimens for the remaining cases. Furthermore, mutations of *RNF43*, which was not listed on the hot spot panel and had been shown to be frequently mutated in mucinous tumors of other organs, were examined for all cases.

Results: The mean age of patients with MAC is 64.2 years (from 43 to 81 years) and LAMNs is 58.2 years (from 36 to 81 years). Both MACs and LAMNs occurred preferentially in female patients. Eight out of 33 patients with LAMNs had pseudomyxoma peritonei at operation, and 4 out of them experienced disease relapse. In contrast, 3 out of 11 patients with MAC had pseudomyxoma peritonei at operation, and 3 patients with MAC experienced relapse, whereas 2 of them did not have pseudomyxoma peritonei at operation. NGS revealed the *KRAS* and *GNAS* as the most frequently mutated genes in AMTs. By combination with Sanger sequencing data, both LAMNs and MACs showed almost the same mutation rate for the oncogenic driver, including *KRAS* (54.5%, 18/33 vs 54.5%, 6/11), *GNAS* (21.2%, 7/33 vs 36.4%, 4/11), *RNF43* (33.3%, 11/33 vs 36.4%, 4/11). In addition, six LAMNs (18.2%) and three MACs (27.3%) had both mutations in *KRAS* and *GNAS*. *TP53* mutations were frequently occurred in MAC (36.4%; 4/11) than LAMN (6%; 2/33), being this difference statistically significant. Notably, LAMN component within MAC showed more complicated mutation patterns than pure LAMN by NGS. Furthermore, both components in MAC with LAMN shared common alterations, however, it also seemed that each component obtained their own additional genetic alterations after development of MAC, respectively.

Conclusion: Pure LAMNs had simple mutation patterns compared to LAMN components within MAC.

The shared mutation profiles between both components within MAC with LAMN support the hypothesis that LAMNs at least in part progress into MACs. In addition, relapse in MAC was not associated with the presence of pseudomyxoma peritonei at operation.

Introduction: Colorectal cancer (CRC) tumors are highly colonized by *Escherichia coli*. Interestingly these *E. coli* frequently possess the *pks* genomic island (*E. coli pks*) responsible for the synthesis of a not yet purified genotoxic compound named colibactin. Colibactin-producing *E. coli* increase the number of tumors and promote invasive carcinoma in CRC mouse models. It has been shown that *pks E. coli*-infected cells secrete growth factors responsible for proliferation of uninfected cells. Epithelial to mesenchymal transition (EMT), as first described in embryonic development, results in the transition of epithelial (E) cells to cells with a mesenchymal (M) phenotype. EMT plays important roles in cancer progression from primary tumor growth, invasion, dissemination and metastasis as well as in resistance to therapy.

Aims and Methods: We investigated whether *pks E. coli*-infected cells induce, through their secretions, EMT in uninfected cancer cells. Human intestinal epithelial cells HT29 were infected using a *pks E. coli* strain isolated from a human CCR biopsy or its isogenic mutant unable to produce colibactin (Δ*pks E. coli*). 5-days post-infection, conditioned media (CM) were collected and used to stimulate uninfected cells. EMT markers were analyzed by Western blot and qRT-PCR. Cell motility was assessed by scratch tests and drug sensitivity assays were performed *in vitro* and in a xenograft mouse model.

Results: We found that CM derived from *pks E. coli*-infected cells induced EMT in recipient uninfected cells. This was characterized by an increase of Zeb1 and Snail transcription factors involved in EMT, an increase of the mesenchymal marker vimentin and a decrease of the epithelial marker E-cadherin. Furthermore, wound healing was greater in cells receiving CM derived from *pks E. coli*-infected cells. Importantly, EMT led to an increase of resistance of chemotherapeutic drugs 5-fluorouracil and irinotecan. Finally, when cells treated with CM derived from *pks E. coli*-infected cells were engrafted to *nude* mice, they exhibited a higher resistance to irinotecan compare to cells treated with CM derived from Δ*pks E. coli*-infected cells.

Conclusion: Our work demonstrates that colibactin-producing *E. coli* might increase the severity of CCR by inducing EMT which leads to chemotherapeutic drug resistance.

[2]*Sheba Medical Center Dept. of Gastroenterology, tel Hasomer, Israel*

Contact E-Mail Address: dr.dancarter@gmail.com

Introduction: Fecal incontinence (FI) and chronic constipation (CC) are not only physically and psychologically disabling symptoms, but also a significant social and public health problem. The pathophysiological basis of combined constipation and fecal incontinence in active women is not fully understood.

Aims and Methods: The aim of the study was to compare clinical, manometric and pelvic floor anatomical pathologies between chronically constipated women with or without fecal incontinence.

In a cross-sectional study, we compared clinical information, anal manometric results and pelvic anatomical pathology as assessed by dynamic pelvic ultrasound in a group of 62 constipated women with FI to that of 207 women with CC without FI

Results: The CC group was older (55 vs 50 years, p = 0.07). The number of vaginal and instrumental assisted deliveries was similar in both groups (2.8 vs. 2.3, p = 0.3; 2.15 vs 1.8, p = 0.3, respectively). The number of pelvic surgeries was similar in both groups. Anal resting and squeeze pressures were significantly lower in the FI group (48 vs. 64, p = 0.001; 97 vs 141, p = 0.03, respectively). Rectal hypersensitivity was more common in the FI group (OR = 1.59, p = 0.05), and dyssynergic defecation was more common in the CC group (0R = 1.8,

p = 0.04); however, the rates of other pelvic floor anatomical pathologies were similar in both groups.
Conclusion: Specific clinical and physiologic parameters define women with coexisting FI and CC.

Introduction: Recent studies have shown that colorectal serrated lesions, including sessile serrated adenomas (SSAs) and traditional serrated adenomas (TSAs), are precursors of colorectal cancers. However, these molecular mechanisms of carcinogenesis are still not well characterized.
Aims and Methods: To clarify the molecular and clinicopathological characteristics of serrated lesions, we assessed mutations and DNA methylation of cancer-associated genes in these lesions. Seventy-eight patients with colorectal serrated lesions were endoscopically diagnosed and treated in Nagoya City University Hospital, Fukui Prefectural Hospital, and Komatsu Municipal Hospital. Hematoxicilin and eosin-stained slides were examined to confirm the diagnosis by a pathologist who was blinded to the clinical and molecular information. The lesions included TSAs (n = 36), SSAs (n = 18), microvesicular hyperplastic polyps (MVHPs, n = 22), and serrated lesions (MVHP or TSA) with adenoma (n = 2). After extracting DNA from formarin-fixed, paraffin-embedded (FFPE) sections, we performed target exon sequence analyses of 39 genes including frequently mutated genes in colorectal cancers and/or serrated lesions, as well as genes known to be associated with WNT signaling pathway. We also assessed the methylation status of a number of tumor-associated genes including *SFRP1, SFRP2, IGFBP7, SOX5*, *MLH1,* and *SMOC1*, as well as marker genes of CpG island methylator phenotype (CIMP) (*MINT1, MINT2, MINT12, MINT31*, and *CDKN2A*) using bisulfite pyrosequencing. A cutoff value of 15% was used to define genes as methylation-positive. Tumors were defined as CIMP-positive when methylation was detected in three or more out of five methylation markers.
Results: *BRAF* mutations were observed in 64% of TSAs and 78% of SSAs, while *KRAS* mutations were observed in 31% of TSAs and 6% of SSAs, respectively. Mutations in WNT pathway-associated genes including *APC*, *CTNNB1*, *FBXW7*, and *RNF43* were significantly higher in TSAs than SSAs (58% and 28%, respectively, p = 0.046). Additionally, prevalence of CIMP-positive lesions in TSAs and SSAs was not significantly different (44% and 42%, respectively). Notably, frequency of methylation-positive cases of *SMOC1* was significantly higher in TSAs than in SSAs (53% and 0%, respectively, $p < 0.01$).
Conclusion: Significance of gene mutations in WNT signaling pathway components was emphasized in carcinogenesis of colorectal serrated lesions, especially in TSAs. It was confirmed that epigenetic silencing of *SMOC1* was significantly associated with development of TSAs, as a previous report indicated.

Introduction: Surveillance of colonic polyps is based on their size, number and pathological features. The role of their genetic profile to predict advanced metachronous lesions (AML) remains poorly investigated.
Aims and Methods: The aim is to study the relation between genetic profile of adenomatous and serrated polyps regarding as risk of AMLs as time to develop them along the surveillance. 308 patients with colonic polyps were consecutively enrolled between 2007 and 2009, and followed until 2014, for this retrospective cohort study. They were divided according to the presence of adenomatous (249 patients) or serrated polyps (59 patients) in the first colonoscopy. 995 polyps were analyzed for somatic mutations on BRAF and KRAS genes using allelic discrimination by real-time PCR and direct DNA sequenciation, respectively. High level of methylation on CpG islands (CIMP-H) was also tested using MS-MLPA. AML was defined by a size higher than 9mm, high-grade dysplasia or villous component for adenomas and size higher than 9mm with any grade of dysplasia or proximal location for serrated lesions. Risk of AML for genetic markers was studied using Chi-square test and logistic regression for univariate and multivariate analysis, respectively. Log-rank test for univariate and Cox-regression model for multivariate analysis were also performed. Logistic and Cox regressions were adjusted by sex, age, previous colorectal cancer, smoking and features of AML in first colonoscopy. P value of 0.05 was considered significant.
Results: Patients were followed up for a median of 36 months (range 5–75). Those ones with adenomatous polyps in the first colonoscopy presented mutations on BRAF and KRAS in 8% and 24% of cases, respectively. 17% contained polyps with CIMP-H pattern. Concerning patients with serrated polyps, mutations on BRAF and KRAS were found in 47% and 36% of cases, respectively, besides 20% of patients with CIMP-H polyps. Only the presence of BRAF-mutations differed between both groups (8% in patients with adenomatous polyps vs 47% in those with serrated polyps; $p < 0.001$). Regarding patients with adenomatous polyps, a higher risk of AML was seen examining KRAS (48% KRAS-mutated vs 29% non-mutated; p = 0.02) in the univariate analysis, with similar results regarding CIMP-H (55% CIMP-H vs 30% non-CIMP; p = 0.008). No association was found with BRAF-mutated ones. Logistic regression showed as KRAS (OR 5.2, 95% CI 1.4–19.8; p = 0.015) as CIMP-H (OR 11.6, 95% CI 2.3–58.4; p = 0.003) as genetic markers of risk for AML. There were found shorter intervals to develop AML in patients with CIMP-H polyps (median of 33 vs 45 months in CIMP-H vs non-CIMP; p = 0.005) in univariate analysis, and also in multivariate (HR 7.9, 95% CI 3.1–20.0; $p < 0.001$). No differences concerning BRAF and KRAS status were seen. Concerning patients with serrated polyps, they showed higher risk of AML (67% CIMP-H vs 22% non-CIMP; p = 0.01) and shorter intervals to develop them (median of 33 vs 51 months in CIMP-H vs non-CIMP; p = 0.045) related to CIMP-H pattern in univariate analysis, but not in the multivariate. No significant results were obtained examining BRAF and KRAS genes.
Conclusion: Presence of CIMP-H and mutations on KRAS in adenomatous polyps associates higher risk of subsequent AML, but only CIMP-H correlates with shorter intervals to their development. In serrated polyps, CIMP-H shows results only in univariate analysis. Genetic profile of polyps emerges as useful tool for colonoscopy surveillance.

Introduction: Inflammation could contribute to carcinogenesis through the activation of immune cells, the release of pro-inflammatory cytokines and the sustained stimulus for epithelial cells to proliferate. In this context, extracellular matrix proteins play a role by modulating cellular adhesion and migration, tumor angiogenesis, and growth factor activation. EMILIN2 is an extracellular matrix molecule playing multifaceted functions in the tumor microenvironment, overall functioning as a tumor suppressive molecule[1,2,3]. Interestingly, EMILIN2 expression is down-modulated by methylation in a number of tumors including colorectal cancer (CRC)[4].
Aims and Methods: Given EMILIN2 function as negative regulator of the Wnt axis[5], a crucial pathway in colon carcinogenesis, we took advantage of the EMILIN2 null mouse model (*Emilin2*$^{-/-}$) to assess its role in the development of CRC. Mice were treated with AOM/DSS to induce CRC. DSS was administered to induce acute inflammation and colitis. Colitis progression and tumor development were assessed by colonoscopy. Histopathological and IHC analyses were performed on colon samples at 1 week for acute inflammation, 12 weeks for colitis and 25 weeks for CRC. Wnt pathway activity was assessed by WB and qPCR. Cytokine analyses were performed through Luminex Screening and qPCR. The inflammatory infiltrate was analysed by flow cytometry and IHC.
Results: Upon AOM/DSS treatment, *Emilin2*$^{-/-}$ mice developed a significantly higher number of tumors compared to control mice. Moreover, tumors from

Emilin2$^{-/-}$ mice were more undifferentiated and at an advanced stage. Contrary to our expectations, the increased number of lesions was not associated with a misregulation of the Wnt signaling pathway. Interestingly, *Emilin2*$^{-/-}$ mice displayed an altered tumor associated inflammatory microenvironment characterized by an higher number of macrophages and granulocytes and an altered expression of many important molecules as IL-10 and Ccl5. Notably, the immune checkpoint proteins PD-1 and PD-L1 were increased in *Emilin2*$^{-/-}$ mice. Moreover, *Emilin2*$^{-/-}$ tumors were characterized by an increased percentage of M2 polarized macrophages displaying low MHCII. *In vitro* analysis confirmed that macrophages isolated from *Emilin2*$^{-/-}$ mice were more prone to acquire an M2 phenotype. Similar alterations in the *Emilin2*$^{-/-}$ model were found during the acute fase of inflammation: mice subjected to DSS treatment alone developed a more severe colitis than *wild type* mice. Interestingly, *Emilin2*$^{-/-}$ mice were characterized by an impaired expression of inflammatory cytokines such as IL-1beta, INF-gamma, TNF-α and IL-10, which was associated with an increased number of myeloid-derived suppressor cells (MDSC) in the colonic mucosa. Consistently, computational analyses of CRC patients datasets highlighted a correlation between EMILIN2 expression levels and the immune landscape characterizing the tumors[6].

Conclusion: The absence of EMILIN2 in the murine model led to the formation of a higher number of colorectal tumors associated with enhanced pro-tumorigenic inflammation. In particular, we found increased expression of the immune checkpoints proteins PD-1 and PD-L1 and a higher percentage of MHCII low macrophages. Moreover, in the very early steps of tumorigenesis, the lack of EMILIN2 expression promoted MDSC recruitment, which could account for the higher tumor number observed in *Emilin2*$^{-/-}$ mice. Preliminary observation highlighted a correlation between EMILIN2 and the traits of the immune microenvironment also in samples from CRC patients, suggesting that EMILIN2 could represent a prognostic marker.

Introduction: The adenoma-carcinoma sequence is generally recognized as a main route of colorectal cancers (CRC). We proposed the presence of depressed and flat colorectal lesions at early phase, and some of these lesions are regarded as "*de novo*" cancers. Depressed cancers have an inclination to invade massively nevertheless the small tumor size, and indicated the severe malignant potentials to metastasize.

Aims and Methods: The aim of this study is to clarify the molecular characteristics of depressed CRC with integrated genomic analysis using next-generation sequencer. We extracted DNA and RNA from 8 submucosal-invasive depressed CRC and 8 submucosal-invasive protruded CRC, and conducted whole exome sequence (WES) and RNA sequence (RNA-seq). We compared the mutation and copy number profile, and expression of RNA using Gene Set Enrichment Analysis (GSEA), which enable to analysis the comprehensive gene expression in multiple molecular pathways, between depressed CRC and protruded CRC.

Results: The results of WES showed that the rates of APC and TP53 mutations were higher in depressed CRC (100%, 75%, respectively) than in protruded CRC (62.5%, 62.5%, respectively). While, the rate of KRAS mutations was lower in depressed CRC (12.5%) than protruded CRC (62.5%) remarkably. The copy number analysis showed that the arm level amplification in 20q, 7p, 7q, and 8q were observed in both cases, however the amplification in 20p, 13p, and 13q arms were observed specifically in depressed CRC (87.5%, 37.5%, and 37.5%, respectively). GSEA clarified that the Epithelial-Mesenchymal Transition (EMT) related genes and angiogenesis pathway related genes were expressed overwhelmingly in depressed CRC than protruded CRC.

Conclusion: According to the genomic analysis, we validated the presence of the depressed early CRC, and unveiled the difference with protruded CRC. In comparison to the protruded CRC, the depressed CRC showed the APC and TP53 mutations and high copy number amplifications, which might activate EMT and angiogenesis-related genes and exacerbate the clinical outcome of cases with depressed CRC.

Introduction: Serrated polyposis syndrome (SPS) is characterized by the development of multiple serrated polyps throughout the colorectum and an increased CRC risk. Etiology of this disease remains largely unknown, with scarce evidence of familial aggregation. Aberrant promoter hypermethylation is associated with the serrated pathway of carcinogenesis, and the existence of a methylation field effect in the normal mucosa of SPS patients has been suggested. However, comprehensive analysis of methylation in this setting is lacking.

Aims and Methods: We aimed at investigating the methylation profile of normal colorectal mucosa of patients with SPS and healthy subjects to better understand the etiology of this disease. We analyzed the methylation status of the normal colonic mucosa in two segments of the colon (proximal and distal to splenic flexure) using Illumina Infinium 850k array in 30 cases with SPS (14 with CRC and 16 without CRC) and 10 healthy individuals (normal colonoscopy). We calculated differentially methylated CpGs (DMCs; Δ20%) for the comparison of normal mucosa from SPS vs. healthy individuals (FDR $<$ 0.05) using ChAMP software, adjusting for age, sex, location and tobacco use. Differential methylation within mucosa from patients with SPS was analyzed controlling for potential confounders (age; sex; CRC).

Results: Overall, we found that patients with SPS display a differential and heterogeneous methylation profile in their normal mucosa compared to healthy individuals, who showed an homogeneous methylation profile. When comparing SPS with and without CRC, we did not observe differences in their methylation profiles (n.s. FDR for Δ20% DMCs), and thus we analyzed them together for further analysis. In SPS patients we found that mucosas from the proximal colon display more DMC and more hypomethylation than distal mucosas (proximal colon: 3,017 DMC, 954 hypermethylated and 2,063 hypomethylated; distal mucosa: 149 DMC, 116 hypermethylated and 33 hypomethylated). Up to 18% of the DMC were located in promoter regions (15% of the hypomethylated DMCs; 18% of the hypermethylated), and a great proportion of the remaining DMC allocate at intronic and intergenic regions (77% of the hypomethylated DMC and 73% of the hypermethylated DMC).

Interestingly, when we studied the cellular pathways involving the nearest genes to DMCs we found a significant enrichment in cancer-related pathways and MAP-kinases pathways, including *PRDM8*, *PRDM6*, *MAD1L1* and *DIP2C*.

Conclusion: Patients with SPS display a methylation field defect in their normal mucosa, especially in the proximal colon and mainly based on hypomethylation. Methylation profiles do not differ in patients with and without CRC. Aberrant methylation occurs in genes involved in CRC-related pathways suggesting a role in the carcinogenesis. Analyses for validation, including methylation and expression experiments in an independent cohort of patients, are ongoing.

Introduction: Immunoprofiling is useful for predicting prognosis and provides a target for immunotherapy in various malignancies. The immune system of colitis-associated cancer (CAC) can be different from that of sporadic colorectal cancer (CRC) because chronic inflammation contributes to the pathogenesis of CAC. A quantitative multispectral imaging system, which allows simultaneous detection

of several immune markers, is a novel method to comprehensively examine the tumor immune environment.
Aims and Methods: The aim of our study is to compare the expression of immune cells in CAC and in sporadic CRC by using this method and to assess the clinical implications of immunoprofiling in CAC. The tumor specimens from 24 CAC patients (8 Crohn's disease and 16 ulcerative colitis) and 48 sporadic colorectal cancer patients, matched by age, sex, and tumor location to CAC, were included in the analysis. The expressions of $CD3^+$, $CD8^+$, $Foxp3^+$ or programmed death-ligand 1 $(PD\text{-}L1)^+$ cells at the invasive margin of tumor tissue were evaluated by quantitative multispectral imaging, and the mean counts per mm^2 of immune cells between CAC and sporadic CRC were compared.
Results: CAC showed more advanced stage (stage IV, 33.3% *vs.* 8.4%; $p = 0.015$) and higher disease-related deaths (41.7% *vs.* 14.6%; $p = 0.018$) compared to sporadic CRC. The $CD3^+$, $CD8^+$, $Foxp3^+$, and $PD\text{-}L1^+$ cells of the CAC group were significantly less dense than those of the sporadic CRC group as measured by both the phenotyping method and the co-expression method. The co-expression densities of $CD3^+Foxp3^+$ and $CD8^+Foxp3^+$ cells were significantly lower in CAC than in sporadic CRC (all, $p < 0.001$). In the CAC group, the expressions of $CD3^+$, $CD8^+$, and $Foxp3^+$ cells were significantly lower in patients with stage IV than in those at stages I-III. In addition, the patients with high expression of $CD3^+$ and $CD8^+$ had better overall survival than the patients with low expression of those cells.
Conclusion: The immune profiling pattern of CAC is different from that of sporadic CRC, indicating distinct disease phenotypes. Immunoprofiling can be helpful for the evaluation of clinical prognosis in CAC and sporadic CRC.

P1036 CLINICOPATHOLOGIC FEATURES, MICROSATELLITE INSTABILITY STATUS AND CHARACTERISTIC MOLECULAR ALTERATIONS OF COLORECTAL SIGNET RING CELL CARCINOMAS

S.M. Lee[1], R. Broaddus[2], H. Chen[2]
[1]*Jeju National University, School of Medicine, Department of Pathology, Jeju-si, Korea (Republic of)*
[2]*The University of Texas MD Anderson Cancer Center, Molecular Diagnostic Laboratories, Department of Pathology, Houston, United States*

Contact E-Mail Address: drsunmi@yahoo.com
Introduction: Signet ring cell carcinoma (SRCC) is an uncommon subtype of colorectal carcinoma (CRC), accounting for only 0.1–2.4% of all CRCs. By definition of World Health Organization classification, SRCC consists of more than 50% of tumor cells with signet ring cell morphology. Colorectal SRCCs are often diagnosed at an advanced stage and in young aged patients showing a poor prognosis with reported 5-year overall survival rate of 40%. Although clinicopathologic features of colorectal SRCCs are relatively well known, molecular alterations and microsatellite instability (MSI) status of this variant has not well elucidated. We investigate further clinicopathologic findings, MSI status and overall somatic mutations of SRCCs revealed by next-generation sequencing (NGS).
Aims and Methods: We retrospectively reviewed cases of CRCs with signet ring cell component and selected 203 cases of SRCC for review and 80 SRCCs subject to molecular profiling using NGS on the Ion Torrent PGM and Iron Proton (Thermo Fisher Scientific). We examined substitutions and small indels in 50 cancer-related genes using Ion ampliseq Cancer Hotspot and Iron ampliSeq Comprehensive Cancer panels. Sequence alignment and analysis were performed using Torrent Suite software (Thermo Fisher Scientific) and lab-developmented software (OncoSeek). MSI analysis was performed by immunohistochemistry followed by multiplex polymerase chain reaction (PCR) with seven quasi-monomorphic mononucleotide repeat markers.
Results: Study patients comprised of 128 (63%) males and 75(37%) females aged 52.4yr. Twenty-two (11%) patients have a history of inflammatory bowel disease (7%) or Lynch's syndrome (4%). Histologically, colorectal SRCCs occurred frequently in ulcerated mass (88%) and consists of two subtypes; mucin-rich and mucin-depleted tumors (48% and 52%). Lymphovascular invasion (91%), extramural venous invasion (80%), tumor deposits (44%), positive margin status (14%), lymph node metastasis (88%) and distant metastasis (40%) at the time of diagnosis were more frequently identified in 203 colorectal SRCCs (all, $p < 0.05$) compared to those of the 200 conventional CRCs. Twenty-four (12%) SRCCs revealed high level of microsatellite instability by mismatched repair proteins subsequently confirmed by MSI PCR. Molecular alterations revealed by next-generation sequencing demonstrated low frequencies of common oncogenic driver mutations including *KRAS* ($p < 0.001$), *APC* ($p < 0.001$), *TP53* ($p = 0.0018$) and *PIK3CA* ($p < 0.001$) compared to those of 200 conventional CRCs.
Conclusion: In our study, patients with colorectal SRCCs have shown to be significantly related with underlying inflammatory bowel disease or Lynch's syndrome, a male predominance, young age onset, predisposition to ulcerated mass and consist of mucin-rich or depleted tumors. Colorectal SRCCs revealed worse histologic factors related with a poor prognosis such as high frequencies of lymphovascular invasion, extramural venous invasion, presence of tumor deposits, positive resection margin and lymph node and distant metastasis compared to those of conventional CRCs. Overall, colorectal SRCC has shown 12% of MSI-high tumors and low frequencies of main oncogenic mutations; *KRAS*, *APC*, *TP53* and *PIK3CA*. This distinct activating or inactivating mutations of these genes suggest different therapeutic approaches and promising consideration of targeted therapy by inhibiting related pathways in patients with advanced colorectal SRCC.

P1037 CLINICOPATHOLOGICAL DIFFERENCES BETWEEN RIGHT AND LEFT-SIDED T1 COLORECTAL CANCER: A SINGLE CENTER RETROSPECTIVE STUDY

K. Mochizuki, S. Kudo, K. Ichimasa, Y. Kouyama, T. Sakurai, S. Matsudaira, Y. Yagawa, H. Nakamura, K. Takeda, T. Ishigaki, N. Toyoshima, Y. Mori, M. Misawa, N. Ogata, T. Kudo, T. Hisayuki, T. Hayashi, K. Wakamura, T. Baba, E. Hidaka, H. Miyachi, F. Ishida
Showa University Northern Yokohama Hospital, Digestive Disease Center, Yokohama, Japan

Contact E-Mail Address: snatch.mdk1@gmail.com
Introduction: It has been reported that the clinicopathological features and prognosis of right- and left-sided advanced colorectal cancers (CRCs) are different. However, there are few reports on these differences in T1 CRCs. In this study, we aimed to compare the clinicopathological features of right- and left-sided T1 CRCs.
Aims and Methods: Subjects were 738 cases with T1 CRCs undergoing surgical resection with lymph node dissection between April 2001 and April 2017 at Showa University Northern Yokohama Hospital. Of these, 214 cases were right-sided (cecum to transverse colon), and 524 cases were left-sided (descending colon to rectum). Analyzed clinicopathological features included patient age, sex, initial treatment, tumor size, morphology, invasion depth, histological grade, lymphatic invasion, vascular invasion, tumor budding, and lymph node metastasis.
Results: Right-sided T1 CRCs showed significantly lower rates of lymph node metastasis (right-sided 4.7% vs. left-sided 11.5%, $p < 0.05$) and were accompanied by lower rates of lymphatic invasion (right-sided 34.1% vs. left-sided 41.4%, $p < 0.05$) and initial surgical cases (right-sided 36.4% vs. left-sided 50.2%, $p < 0.05$). In contrast, right-sided T1 CRCs showed significantly higher rate of depressed-type morphology (right-sided 35.0% vs. left-sided 27.7%, $p < 0.05$) and poorly differentiated carcinomas/mucinous carcinomas (right-sided 10.7% vs. left-sided 3.4%, $p < 0.05$). Patients with right-sided T1 CRCs were older (right-sided 67.0 ± 11.7 years vs. left-sided 64.6 years ± 11.0 years, $p < 0.05$). No significant difference was found between the other factors.
Conclusion: Right-sided T1 CRCs exhibited significantly lower rates of lymph node metastasis than left-sided T1 CRCs, followed by lower rate of lymphatic invasion. This may influence the prognosis or management of these lesions.

Introduction: Based on current histologic risk stratification, most T1 colorectal carcinomas (CRC) are classified as high-risk T1 CRCs. However, the majority of these patients are not found to have lymph node metastasis (LNM) when referred for surgery, and could – in hindsight – also have been treated with endoscopic resection. In advanced CRC, the mesenchymal consensus molecular subtype (CMS-4) and a low Immunoscore have been associated with poor prognosis.[1,2] In this study, we aimed to evaluate whether molecular- and immune-based tumor

subtypes could be of value for risk stratification in patients with non-pedunculated T1 CRC.

Aims and Methods: A multicenter case-cohort study was performed. Data from 653 patients with non-pedunculated T1 CRC (median follow-up time: 46 months; IQR 19–76) treated with surgery, diagnosed from January 2000 through December 2014, were collected from 13 Dutch hospitals. Primary endpoint was adverse outcome, defined as LNM or recurrent cancer. The case-cohort included a random sample of 50% of the cohort and all patients with the outcome outside the random sample. H&E stained slides were reviewed by a blinded expert pathologist on conventional histological risk factors (i.e. poor differentiation, deep submucosal invasion, (lympho-) vascular invasion, and tumor budding). Tissue microarray samples were immunostained to determine the Immunoscore (I-low or I-high) and the CMS (CMS-1, CMS-2-3 or CMS-4). Uni- and multivariable Cox proportional hazard models for case-cohort data were performed to evaluate the association between the CMS-classification and Immunoscore and adverse outcome.

Results: The distribution of the CMS-classification was: CMS-1: 7%, CMS-2-3: 91%, and CMS-4: 2%. I-low was observed in 36% of patients. Although no significant association was observed between the CMS-classification and the Immunoscore ($p = 0.40$), a trend was observed towards higher Immunoscores for CMS-1 vs the other molecular subtypes (p-trend = 0.07). The case-cohort included 60 patients with an adverse outcome (46 patients with LNM and 22 with recurrence among which 5 patients with both LNM and recurrence). Risk for an adverse outcome was 6%, 14% and 33% for CMS-1, CMS-2-3 and CMS-4, respectively, and 11% and 18% for I-high and I-low, respectively. CMS-4 was associated with an increased risk for adverse outcomes (HR 3.9, 95% CI 1.1–13.7, $p = 0.04$; reference CMS-2-3), which remained after adjusting for conventional risk factors (adjusted HR 4.6; 95% CI 1.3–16.4, $p = 0.02$; reference CMS-2-3). In univariable analysis, I-low showed a trend towards increased risk for adverse outcomes (HR 1.6, 95% CI 1.0–2.8, $p = 0.08$). However, no significant association was observed for I-low when adjusting for conventional risk factors (adjusted HR 1.3; 95% CI 0.7–2.3, $p = 0.44$).

Conclusion: Non-pedunculated T1 CRCs with CMS-4 have an increased risk for LNM and recurrent cancer, in line with the poor prognosis of this subtype in advanced CRC. In contrast to advanced CRC, the aggressive mesenchymal subtype (CMS-4) has a very low prevalence in early CRCs which might limit its use for risk stratification in these patients. Our results suggest limited additional value of the Immunoscore for risk stratification in T1 CRC.

Introduction: Colorectal cancer (CRC) diagnosis at early stages associates with good prognosis and reduced mortality rates, while detection and removal of premalignant advanced adenomas (AA) result in the reduction of CRC incidence [1]. Invasive approaches for CRC screening, such as colonoscopy, have low participation rates and high cost. On the other hand, non-invasive procedures like faecal immunological test have the advantage of increased acceptance, though sensitivity for proximal colorectal tumours and AA is moderate to low [2]. Thus, there is a clear demand for novel non-invasive tests for the early detection of CRC and AA, to be used in population-wide screening programs.

DNA methylation detected in liquid biopsies, such as serum circulating cell-free DNA (cfDNA), is a promising source of non-invasive biomarkers, because it has been demonstrated that cfDNA reflects the aberrant methylation events occurring in neoplastic and tumour cells [3].

Aims and Methods: In a previous work we reported that, when using cfDNA, a sample pooling strategy offers a new affordable approach for methylation biomarker discovery [4]. In this study, applying the sample pooling strategy, we aim to identify novel non-invasive methylation biomarkers for the early detection and screening of colorectal advanced neoplasia (AN: CRC or AA).

We extracted cfDNA from serum samples from 130 individuals with no colorectal neoplasia (including individuals with no colorectal findings, benign pathologies and non-advanced adenomas) and from 150 advanced neoplasia cases (comprising patients with proximal AA, distal AA, and CRC stage I-IV). Pooled samples were prepared for each pathological group using equal amounts of cfDNA from 10 individuals, sex-, age- and recruitment hospital-matched. DNA methylation levels of 866,836 CpG positions across the genome were measured with the MethylationEPIC array. Bioinformatics preprocessing and statistical analyses were conducted with methylation specific R/Bioconductor packages.

Results: The epigenome-wide analysis of serum cfDNA revealed 376 differentially methylated positions (DMPs) at 10% false discovery rate, between no neoplasia and advanced neoplasia cases, mostly of which (86.7%) were hypermethylated in AN. Some of the differentially methylated CpG sites were found within 49 differentially methylated regions. Unsupervised clustering analyses showed that differential methylation patterns could distinguish advance neoplasia samples from no neoplasia controls.

We applied the Statistically Equivalent Signature algorithm [5] for feature selection and we identified 3,256 combinations of 118 DMPs with statistically equivalent predictive value for "no neoplasia vs advanced neoplasia" classification. We used cross-validation to select a subset of 30 CpG sites as the most robust and predictive candidate set for biomarker validation.

Conclusion: We found a differentially methylated signature between no neoplasia and advanced neoplasia groups using pooled serum cfDNA, obtaining promising biomarker candidates for colorectal cancer screening. The diagnostic performance of our novel non-invasive methylation candidates should be further evaluated in an independent cohort.

P1040 COLORECTAL CANCER AND EXPERIENCE IN TESTING FOR LYNCH SYNDROME IN A WEST LONDON HOSPITAL

A. Cavazza[1], C. Radia[2], C. Harlow[2], K.J. Monahan[2]

[1]*West Middlesex University Hospital, Chelsea & Westminster Hospital NHS Trust, Family History of Bowel Cancer Clinic, Department of Gastroenterology, London, United Kingdom*

Contact E-Mail Address: a.cavazza1@gmail.com

Introduction: Colorectal cancer (CRC) causes over 16000 deaths every year and it is the second most common cause of cancer death. NICE guideline DG27 recommends universal testing for Lynch Syndrome (LS) at diagnosis of colorectal cancer, by testing the CRC for mismatch repair (MMR) status, a hallmark of the disease.

Aims and Methods: We collected data prospectively from Nov 2016 to December 2017 of consecutive newly diagnosed CRC patients at West Middlesex University Hospital (WMUH) in London. CRCs were universally screened for tumour features suggestive of LS (Defective MMR, or dMMR) with immunohistochemistry. We also collected clinicopathological data including age at diagnosis, stage, tumour site, histological findings and MMR tumour-status. Statistical analysis was performed using chi-square test and 2 tailed T test for binary and continuous variables respectively.

Results: A cohort of 123 consecutive CRC patients were universally tested for dMMR. Twelve patients (9.8%) were MMR-deficient of which only 6 (50%) were predicated by the Bethesda Criteria. 11/12 dMMR CRCs were early stage tumours (Dukes' A or B, $p = 0.002$), and in 20 Dukes' B CRCs in patient under 70 years of age, the result was directly relevant to personalised treatment with 5-FU based chemotherapy. The median age in patients with normal or abnormal MMR IHC was 64.6 years and 68.3 years respectively (p 0.41). With regard to histological features: mucinous tumours were more frequently manifested dMMR (p 0.0052), with the presence of this, signet ring cells or a lymphocytic response predictive of dMMR CRC (p 0.023). In all 12 patients with dMMR the cancer was located in the right colon (p 0.00001). MMR germline mutations were

found in a total of 4 patients of which 2 (50%) had mutation of *MLH1*, in 1 case (25%) of *MSH2* and in 1 case (25%) of *MSH6*.
Conclusion: Our results demonstrate that universal testing is feasible and effective in the UK. There were significant differences with regard to dMMR CRC site, stage and histological features compared to proficient MMR CRCs. Our data also indicates the importance of genetic testing and personalised oncological care as we were able to identify patients that may have not be selected for MMR testing by the Bethesda criteria.

Introduction: Early detection of colorectal cancer (CRC) has considerable value in treatment and prognosis. The aim of this study was evaluating predictive value of methylation SOX21 gene's promoter testing for diagnosis of CRC.
Aims and Methods: This cross-sectional study was done on 64 eligible patients with colorectal cancer (case group) and 64 healthy volunteers. Then 5cc of blood sample was taken and DNA was extracted. DNA was extracted using GeNet Bio DNA extraction kit. The quality and quantity of extracted DNA assessed by spectrophotometry method in 260 and 280 nm wavelength and electrophoresis in agarose gel %1After primer designation methylation-quantification was assessed using Real-time PCR, and expressed in two groups. The Chi-square test performed on both groups using SPSS V.20 software.
Results: There were 32 (50%) and 28 males (43.8%) in case and control group respectively (p-value = 0.62). The mean age of case and control group were 55.9 ± 16.6 and 56.7 ± 10.7 years respectively (p-value = 0.8). The value of methylation of SOX21 gene's promoter in case and control group were 71.6% ± 20.1% and 31.9% ± 11.3% respectively ($p < 0.001$) with sensitivity and specificity of %81.3 and %71.9 respectively. Positive predictive value and negative predictive value were %74.3 and %79.3 respectively.
Conclusion: The quantity of SOX21 gene promoter methylation in the genomic DNA of peripheral blood samples can be used as a good screening test for early diagnosis of CRC.

Contact E-Mail Address: doenja.lambregts@gmail.com
Introduction: Patients who are managed non-operatively with a 'wait-and-see' policy after chemoradiotherapy are typically monitored using a combination of imaging (MRI) and endoscopy. On MRI, morphologic patterns indicating a complete response can vary from a completely normalised rectal wall to various degrees of fibrotic scar tissue.
Aims and Methods: Aim of this study was to study whether morphologic imaging patterns of response are related to long-term functional outcome, assessed in terms of the Vaizey-score, a 0–24 point score on bowel function/faecal incontinence.
N = 68 patients were retrospectively analysed. All patients were included in a wait-and-see programme and had a sustained clinical complete response (median FU 34 months; range 16–62). Patients underwent follow up with MRI 3–6 monthly as part of the wait-and-see programme. Morphology of the rectal wall was assessed by two radiologists in consensus on the various MRIs and classified according to 4 patterns: [1] no fibrosis (= normalised rectal wall), [2] minimal fibrosis, [3] thick but regular fibrosis or [4] irregular/spiculated fibrosis. Long-term functional outcome was assessed using the Vaizey-score, which was acquired using questionnaires after 1–2 years of FU. Mean Vaizey-scores were compared between the 4 morphological patterns.
Results: 5 patients showed no fibrosis, 45 minimal, 15 thick and 3 irregular/spiculated fibrosis. Mean Vaizey-score was 1.6 for the patients with no fibrosis versus 4.5/3.9/4.0 for the patients with minimal/thick/irregular fibrosis, respectively (p = 0.56 when comparing the 4 individual patterns; p = 0.24 when comparing the 3 patterns with fibrosis combined to the no fibrosis group). No significant differences in Vaizey scores were observed amongst the different fibrosis patterns, although there was a slight trend towards lower scores for patients with only minimal fibrosis, particularly in patients who originally presented with distal rectal tumours (≤3 cm from the anorectal junction) where the mean Vaizey-score was 4.7 for the minimal fibrosis patients versus 6.5 for the other fibrosis patterns (p = 0.198).
Conclusion: Rectal cancer patients with a clinical complete response after CRT who show a normalised rectal wall without any signs of fibrosis on MRI appear to have a more favourable functional outcome in terms of incontinence and bowel function compared to patients with visible fibrosis, although results did not reach statistical significance in this small patient cohort.

P1043 THE VALIDITY OF ENDOSCOPIC SUBMUCOSAL DISSECTION WITH SMALL-CALIBER ENDOSCOPE FOR THE LESIONS SPREADING TO APPENDIX ORIFICE

J. Tachikawa[1], H. Chiba[1], J. Arimoto[1], K. Ashikari[1], H. Kuwabara[1], M. Nakaoka[1], T. Goto[1], K. Ohata[2]
[1]*Omori Red Cross Hospital Dept. of Gastroenterology, Dept. of Gastroenterology, Tokyo, Japan*
[2]*NTT Medical Center Gastroenterology, Gastroenterology, Shinagawa-ku, Japan*

Contact E-Mail Address: tachijun1989@gmail.com
Introduction: The difficulty of colorectal endoscopic submucosal dissection (ESD) sometimes depends on the location. The lesion spreading to the appendix orifice is one of the most difficult location, because the working space during ESD is very narrow and it is hard to confirm a distal border of the lesion invading the vermiform appendix. From the view point of the tip diameter size, we consider small-caliber endoscopes (GIF-Q260J, tip diameter 9.9mm or PCF-PQ260L, tip diameter 9.2mm), which can go into the vermiform appendix easier, are more efficient than conventional therapeutic colonoscopy (PCF-Q260JI, tip diameter 10.5mm). In this study, we evaluated the efficacy and the safety of small-caliber endoscope for ESD of lesions spreading to appendix orifice.
Aims and Methods: We retrospectively reviewed 341 lesions in cecum performed ESD at Omori Red Cross Hospital and NTT Medical Center Tokyo from May 2011 to December 2017. Among them, 36 lesions were spreading to appendix orifice. We classified according to the scope and compared the treatment outcomes.
Results: 17 cases treated by conventional scope (PCF-Q260JI) (C group), and 19 cases treated by small-caliber scope (GIF-Q260J or PCF-PQ260L) (S group) were enrolled. There was no significant differences between C group and S group in morphological type (Is/ IIa/ LST-G/ LST-NG = 1/8/8/0 vs. 0/13/5/1), histology of tumor (adenoma/ cancer/ SSA/p = 5/4/8 vs. 9/4/6), fibrosis (8 vs. 7), tumor diameter (29.6 ± 12.5mm vs. 29.4 ± 12.3mm), en bloc resection rate (100% vs. 100%), and resection rate of the margin negative (88.2% vs. 100%). With respect to complications, there were 2 cases of perforation in C group (0 case in S group). Mean procedure time was significantly shorter in S group (66.5 ± 42.8min vs. 46.1 ± 18.3, $p < 0.05$). There was 1 case that we ceased ESD for the flat elevated lesion spreading to appendix orifice because the border of lesion could not be confirmed with PCF-Q260JI and succeeded the procedure with PCF-PQ260L later. There was no recurrence and delayed appendicitis in mean follow-up period 26.3 months.
Conclusion: ESD with small-caliber endoscope for the lesions spreading to appendix orifice, especially for the lesions of that we could not confirm the border, can be effective and safe.
Disclosure: Nothing to disclose

P1044 THE PREDICTORS OF SEVERE SUBMUCOSAL FIBROSIS IN PATIENTS UNDERGOING COLORECTAL ENDOSCOPIC SUBMUCOSAL DISSECTION

K. Ashikari[1], H. Chiba[2], J. Tachikawa[2], J. Arimoto[2], H. Kuwabara[2], M. Nakaoka[2], A. Nakajima[1]

Contact E-Mail Address: kei1.ashikari@gmail.com
Introduction: Although colorectal endoscopic submucosal dissection (CESD) has been spread as an effective therapy for epithelial neoplasms, its application to lesions with severe fibrosis is difficult because of technical difficulties and risks of complications.
Aims and Methods: This study aimed to investigate the predictors of severe submucosal fibrosis in CESD. From April 2012 to February 2018, consecutive 457 lesions were performed CESD at Omori Red Cross Hospital. Submucosal tumors and non-neoplastic tumors were excluded and 399 lesions were evaluated retrospectively. The degree of submucosal fibrosis was determined during ESD procedures and classified as F0 (no fibrosis), F1 (mild fibrosis), or F2 (severe fibrosis) and we divided the lesions into two groups, group F (F2) and group N (F0/1). We investigated the clinical backgrounds, features of tumors, and

preoperative procedures (biopsy, local injection, tattooing), and analyzed the predictors of severe submucosal fibrosis. We also evaluated the safety of performing CESD to lesions with severe fibrosis by reviewing the postoperative courses and outcomes of the patients. We defined that lesions step over folds were called ''over the fold lesions'' and Ip or Isp lesions exceeding 30mm were called ''large protruded lesion''. In addition, recently we proposed Double Tunnel Method (DTM) which could resect lesions with severe fibrosis or with muscle retracting sign (Chiba H et al. *Endoscopy*, 2018 in press) and we evaluate the feasibility of the new method.
Results: 19 lesions (4.8%) were assigned to group F (66.9 ± 12.1 years old), and 380 lesions (95.2%) were assigned to group N (69.5 ± 11.2 years old). Characteristics of the patients (age, sex, BMI and comorbidities) were similar. With respect to the features of the lesions, over the fold lesions were 12 (63.2%) in group F and 107 (28.2%) in group N ($p = 0.003$). Lesions with tattooing before ESD were 3 (15.8%) / 2 (0.5%), large protruded lesions were 7 (36.8%) / 7 (1.8%), lesions over 50mm in size were 5 (26.3%) / 22 (5.8%), and cancers with submucosal invasion were 9 (47.4%) / 30 (7.9%) in group F and N respectively ($p < 0.01$). On the other hand, the rate of lesions performed biopsy or local injection, and local recurrence were similar. The lesion size was 36.2 ± 15.9 mm in group F, and 28.2 ± 14.0 mm in group N. Multivariate analysis (Variables were included in the multivariate model if the p value was < 0.10 on univariate analysis) showed the predictors were lesions over the fold, lesions with preoperative tattooing, and large protruded lesions. Postoperative courses were similar between two groups. ESD procedure time was 134.2 ± 69.0 min in group F, and 42.1 ± 32.1 min in group N ($p < 0.01$). En bloc resection rate and curative resection rate (%) were 94.7 / 57.9 in group F, and 100 / 96.6 in group N ($p < 0.05$), but there were no differences in complication rate between two groups. DTM was done for two cases safely.
Conclusion: Lesions over the fold, lesions with preoperative tattooing, and large protruded lesions might be the predictors of severe submucosal fibrosis. DTM could be an effective treatment for them.

P1045 USEFULNESS OF HYBRID ENDOSCOPIC SUBMUCOSAL DISSECTION USING MULTIFUNCTIONAL NEW DEVICE

J. Tachikawa[1], H. Chiba[1], J. Arimoto[1], K. Ashikari[1], H. Kuwabara[1], M. Nakaoka[1], T. Goto[1], K. Ohata[2]
[1]*Omori Red Cross Hospital Dept. of Gastroenterology, Dept. of Gastroenterology, Tokyo, Japan*
[2]*NTT Medical Center Gastroenterology, Gastroenterology, Shinagawa-ku, Japan*

Contact E-Mail Address: tachijun1989@gmail.com
Introduction: Hybrid endoscopic submucosal dissection (ESD) was developed as relatively easier procedure compare of colorectal ESD that still remains technically difficult. Hybrid ESD has advantage both ESD and EMR because the snaring is performed after mucosal incision and submucosal dissection. However, cost is one of the problem since it needs ESD device and snare. In this study, we evaluated the efficacy of hybrid ESD using the new device, SOUTEN, that has 1.5mm needle-knife at the top of loop.
Aims and Methods: We retrospectively reviewed lesions treated at Omori Red Cross Hospital and NTT Medical Center Tokyo from April 2012 to February 2017. We compared 33 lesions performed hybrid ESD (Hybrid group) and 33 lesions performed ESD (ESD group), those were matched by location, tumor diameter, and macroscopic type. Indication of hybrid ESD is mucosal tumor 20–30mm diameter that could be snared en bloc. We excluded obvious submucosal invasive cancer, recurrent tumor, and lesion with severe scar.
Results: The tumor locations were as follows: 7 were in cecum, 11 were in ascending colon, 6 were in transverse colon, 3 were in descending colon, 2 were in sigmoid colon, 4 were in rectum. Morphological type was that LST-G-H was 2, LST-G-M was 2, LST-NG-FE was 26, and LST-NG-PD was 3 in each group. The mean diameter of Hybrid group and ESD group was 22.8 ± 4.4mm and 23.0 ± 7.2mm, respectively. Mean procedure time was significantly shorter in Hybrid group (13.2 ± 6.6min vs. 34.4 ± 21.8min, $p < 0.01$). There was no significant difference in fibrosis (3 vs. 4) and pathological diagnosis (adenoma/ mucosal cancer = 10/23 vs. 11/22). En bloc resection was 100% in both groups. The mean hospitalization was significantly shorter in Hybrid group (4.9 ± 1.7 days vs. 6.5 ± 1.1 days, $p = 0.020$). The complications were not significantly different between the two groups: 1 vs. 0 episodes of bleeding, and there was no perforation.
Conclusion: It was considered that hybrid ESD using the new device, SOUTEN, has efficacy for reducing the procedure time and hospitalization.

Introduction: After curative resection of colorectal cancer (CRC), postoperative surveillance is aimed at reducing disease specific morbidity and mortality by early detection of recurrent or second primary cancers. Even though endoscopic surveillance has become a routine part of clinical practice, controversy exists on the timing of the first postoperative colonoscopy. Several studies have reported the highest incidence of CRC within two to three years after surgery, reason why most guidelines now recommend a one year surveillance interval after resection.
Aims and Methods: To assess the yield of CRC at the one year surveillance colonoscopy after CRC resection.
Retrospectively, files of patients having undergone a curative surgical resection of a first CRC between June 2013 and April 2016 were checked for eligibility in four hospitals. Patients were included in the database when a complete clearing colonoscopy was performed prior to surgery and when the interval between the pre- and postoperative colonoscopy was 6–20 months. Patients with hereditary CRC or inflammatory bowel disease were excluded. Data were collected on patient demographics, quality of colonoscopy, baseline CRC characteristics, and adenomas and serrated polyps detected during the preoperative colonoscopy and one year surveillance colonoscopy. A sample size of 571 individuals was needed to assess whether the CRC yield exceeded the 0.5% yield of CRC of primary colonoscopy screening. A multivariable logistic regression was performed to identify risk-factors associated with finding advanced neoplasia (*i.e.* CRC, advanced adenomas or advanced serrated lesions) at follow-up.
Results: Five-hundred seventy-two patients (54.9% male, mean age 66.2 (±9.9) years) met the inclusion criteria and were enrolled in the study. After a mean surveillance interval of 13.7 (±2.8) months, 10/572 (1.7%, 95% CI: 0.7–2.8%) were diagnosed with CRC. Of these, five were second primary cancers and five were recurrences at the anastomosis. The second primary CRCs encompassed mostly T3 and T4 tumours (4/5; 80%), of which two qualified for palliative treatment only. In two of these five patients a polyp had been resected at the preoperative colonoscopy in the same segment as the second primary cancer (*i.e.* 25mm tubulovillous adenoma with low-grade dysplasia (clear resection margin) and 8 mm hyperplastic polyp). Of the recurrent CRCs, 4/5 (80%) were either T3 or T4, and one of these qualified for palliative treatment only. Resection margins of the baseline CRC were clear in all five patients with recurrent CRC. In 11.4% (95% CI: 8.9–13.8%) of all patients included in the study advanced neoplasia was detected at the one-year surveillance colonoscopy. Synchronous baseline advanced neoplasia was a risk-factor for finding advanced neoplasia at follow-up.
Conclusion: The yield of CRC at the one year surveillance colonoscopy after CRC resection was 1.7% (95% CI: 0.7–2.8%). This concerned recurrences as well as second primary tumours, which were often of advanced stage. The high yield justifies the increased colonoscopy demand of one-year surveillance interval.

P1047 ENDOSCOPIC RESECTION OF T1 COLORECTAL CANCER – INFLUENCE OF THE RISK FACTORS ON DECISION-MAKING AND PROGNOSIS

F. Taveira[1], M. Areia[1], L. Elvas[1], S. Alves[1], D. Brito[1], S. Saraiva[1], A.T. Cadime[1]
[1]*Portuguese Oncology Institute of Coimbra, Gastroenterology, Coimbra, Portugal*

Contact E-Mail Address: fctav@hotmail.com
Introduction: Colon lesions diagnosed as T1 colorectal cancer (CRC) might be treated only with an endoscopic approach. Additional surgery or surveillance depends on the presence of high-risk factors for lymph node metastasis (LNM). The follow-up strategy for these patients remains controversial.
Aims and Methods: We intend to know the influence of histopathological risk factors on therapeutic offering and the overall prognosis of patients with resected T1 CRC at our unit.
Prospective cohort study of T1 CRC lesions endoscopically removed between January/2013 and January/2018 and in follow-up at our unit. ''High-risk lesion'' if at least 1 of the criteria: histological high grade, lymphovascular invasion,

budding, Kikuchi-sm2/3 or Haggitt-4, deep submucosal invasion > 1000μm, distance to margin < 1mm.
Results: Resected 92 lesions in 92 patients (67% male, age 65 ± 10.5 years). Mostly pedunculated (65.2%), mean size 19 ± 1 mm; Left colon in 89%, particularly in sigmoid colon (n = 53); Histological high grade – 11%; lymphovascular invasion – 16%; Haggitt-4 in 4 lesions; Kikuchi-sm2/3 in 15 lesions; Median distance to margin – 1.5 mm.
Median follow-up time of 36 months. 56.5% (n = 52) categorized as ''High-risk lesion'', with 30 patients undergoing surgery and 22 surveillance due to patient choice or relevant comorbidities. In the patients intervened surgically residual tumor in 13% (n = 4). Disease progression confirmed in 6 cases (6.5%), all ''High-risk lesion'' (11.5% vs. 0%; p = 0.03); From those, 4 had surgery and 2 were on endoscopic surveillance (13% vs. 9%; p = 0.08). Two deaths reported, 1 ''high-risk'' and 1 ''low-risk'' patient (2% vs. 2.4%; p = 1). On multivariable analysis lymphovascular invasion presented as the only statistically significant criteria for disease progression (OR 6.2, IC 95% 1.1–34.2).
Conclusion: Endoscopic resection appears to be effective on treating low-risk lesions and we confirm the risk of disease progression on high-risk lesions. In our sample, lymphovascular invasion has a major influence in the prognosis. More studies are needed to optimize decision-making and follow-up strategy to offer based on patients risk profile.

Introduction: Symptomatic left-sided malignant colonic obstruction is a medical and surgical emergency and it is present in about 10% of the patients[1]. This condition requires an emergency intervention, which has been classically emergency surgery (ES), wich still represents a high morbidity (30–60%) and mortality (10–30%) compared with elective surgery (mortality rate less than 5%)[2].
The aim of stenting bridge to surgery (SBTS) is to restore intestinal transit and transform emergency surgery into elective surgery. Since the first report of this technique, it has been the subject of many reviews which highlight its efficacy, particulary in reducing ostomy rates[3].
Aims and Methods: The aim of our study is to determine wether the SBTS strategy confers clinically relevant short-term advantages in terms of stoma rate, short-term morbidity and short-term mortality over ES in the treatment of symptomatic left-sided malignant colonic obstruction.
We retrospectively selected patients with clinically and radiologically left-sided malignant colonic obstruction between January 2006 to May 2012 in two Specialty Hospitals of Spain. Exclusion criteria were age under 18, tumour located in right or transverse colon, or in medium/inferior rectum; metastasic disease (stage IV of the American Journal Committee on Cancer (AJCC)) and perforation at the moment of the diagnosis.
Firstly, we analyzed demographic data, perioperative data, short-term mortality and global mortality rates between both hospitals, achieving an homogeneous sample for the analysis without statistical differences.
Results: After applying exclusion criteria, there were 137 patients suitable for the study, 71 in the SBTS group and 66 in the ES group. There was no difference between groups in sex, ASA score or tumor location.
We found a significant higher anastomosis rate (p < 0.005) in the SBTS group (83.1%) compared to the ES group (45.5%). In addition, stoma rate including temporary ostomies was lower in the SBTS group (16.9% vs. 54.5%)(p < 0.005).
There was not any difference between both groups regarding the median time from admission to the emergency procedure, 1(0–26) days in the SBTS and 0(0–24) in the ES group (p = 0.310).
There were 11 perforations after stenting that required surgery.
There was a trend to lower rate of postoperative complications in the SBTS group (11 vs 19, p = 0.060) without differences in the type of complication. We observed a higher number of reinterventions in the ES group (p = 0.018).
Median time from stent insertion to programmed surgery was 13 days (1–184).

	SBTS (n = 71)	ES(n = 66)	p
Age	69(61;77)	73.5(62.5;81)	0.077
Primary anastomosis	59(83.1)	30(45.5)	<0.005
Stoma at discharge	12(16.9)	36(54.5)	<0.005
Postoperative complications	11(15.5)	19(28.8)	0.060
Reintervention rate	2(2.8)	9(13.8)	0.018
In-hospital 30-days mortality	5(7.0)	5(7.6)	0.905
Global mortality rate	29(40.8)	37(56.1)	0.075

[Results of the analysis between groups. Values are presented as median (p25-p75) or n (%)]
Conclusion: Our study shows statistically significant better results for SBTS compared to ES in terms of ostomy rate, primary anastomosis rate and reintervention rate, and a trend towards fewer postoperative complications. We did not find differences in terms of short and long-term mortality.

Introduction: Self-expanding metal stents (SEMS) as bridge to surgery (BTS) are an alternative to emergent surgery (ES) in acute malignant colonic obstruction (AMCO). However, there are controversies regarding their use due to the association between adverse events (AEs), oncological outcomes and impact on survival.
Aims and Methods: The aim of this study was to compare the efficacy, morbidity, short and long-term oncological outcomes between SEMS and ES in the management of AMCO.
Single-center retrospective study that evaluated patients who underwent SEMS placement or ES due to left-sided AMCO between January 2010 and December 2017. Clinical success was defined as resolution of occlusive symptoms after SEMS placement or ES, without need for further intervention or surgical reintervention. Morbidity was defined as the occurrence of any AE directly or indirectly related to SEMS placement and/or ES. Surgery AEs were classified according to the Clavien-Dindo classification.
Results: A total of 94 patients were included; 48 were submitted SEMS placement and 46 underwent ES. The median age was 69 years (IQR 58–80) and 53% were male. The majority (58%) of the tumors were located in the sigmoid colon. Tumor stage was significantly higher in the SEMS as BTS group compared with ES (stage III/IV: 71% vs. 37%, p = 0.002), with no differences regarding age (p = 0.175), gender (p = 0.839), ECOG status (p = 0.113), ASA-score (p = 0.708), tumor location (p = 0.326) and tumor size (p = 0.556). Overall clinical success was 87%, with no significant differences in the two groups (88% SEMS vs. 87% CE, p = 0.937). In the SEMS group, all patients underwent surgery after a median of 10 days (7–17). The rate of immediate AEs was 6%, with no difference between the two groups (6% SEMS vs. 7% ES, p = 0.957). The overall morbidity was 25% in the SEMS group (13% post-procedure stent-related AEs and 15% surgery-related AEs) and 41% in the ES group; however, no statistically significance was found (p = 0.125). SEMS placement was also associated with a lower rate of surgery-related AEs (15% vs. 41%, p = 0.005); no differences were observed regarding surgery-related AEs Clavien-Dindo classification (III-V: 43% SEMS vs. 41% ES, p = 0.838). In the ES group 41% underwent stoma reversal with anastomosis construction, with a rate of surgical AEs of 23% (Clavien-Dindo III-V: 33%). The permanent stoma rate was significantly lower in SEMS group (17% vs. 43%, p = 0.006). There were no differences between SEMS and ES regarding recurrence-free survival (median: 52 months vs. 69 months, p = 0.119) and overall survival (median: 37 months vs. 55 months, p = 0.654). Overall morbidity (BTS and ES) was associated with a lower survival (median: 25 months vs. 74 months; p = 0.008) – SEMS group: 5 months vs. 52 months, p = 0.039; ES group: 28 months vs. 74 months, p = 0.05. In the multivariate analysis, only SEMS-related AEs were independently associated with survival estimate (HR 4.3, 95% CI 1.1–16.5; p = 0.037).
Conclusion: SEMS placement as BTS when compared to ES is associated with a lower rate of surgical AEs and definitive stoma rate, with no significant differences in oncological outcomes and long-term survival. However, the occurrence of SEMS-related AEs has a significant impact on survival. These results highlight the need for reference centers with enough expertise in order to achieve a high technical success with low SEMS-related AEs, maximizing the potential benefits of this approach.

P1050 APOPTOSIS INDUCTION IN COLON CANCER CELL BY NEWLY DEVELOPED ENDOSCOPIC IRREVERSIBLE ELECTROPORATION ABLATION DEVICE

Y.-T. Jeen, S. Jang, J.H. Kim, S.H. Kim, J. Han Jo, S.J. Choi, J.M. Lee, S.H. Kim, J.M. Lee, H.-S. Choi, E.-S. Kim, B. Keum, H. Lee, H.J. Chun, C.D. Kim
Korea University College of Medicine, Department of Internal Medicine, Seoul, Korea (Republic of)

Contact E-Mail Address: ytjeen@korea.ac.kr
Introduction: Irreversible electroporation (IRE) effectively removes unwanted cells without thermal damage of surroundings. We used multiphoton microscopy (MPM) to evaluate IRE ablation response to cancer cell. By using MP (multiphoton) probes, we focused on two vital intracellular organelles, nucleus and mitochondria, and could get real-time image of IRE-induced apoptosis.
Aims and Methods: Colon cancer cell lines (normal & neoplasm tissues) obtained from 10 patients were stained with MP probes, ABI-Nu for nucleus and PMT for mitochondria respectively. To observe IRE response using MPM, we first compared the states of colon cancer cell lines before and after the IRE with electrical pulses administered in a Harvard apparatus. Then, compared those of normal colon and colon cancer tissue in the same manner. 3-D images, co-labelled with ABI-Nu and PMT were reconstructed. To assess apoptosis, colon cancer cells were stained with the fluorescent dye Annexin V or propidium iodide (PI). To determine whether IRE induces apoptosis, membrane blebbing was examined after applying.
Results: MPM images of cancer cells stained with MP probes revealed that ABI-Nu stained quicker after IRE ablation. Nuclear staining was present earlier and more prominent after IRE application. IRE had a relatively stronger effect on cancer. We obtained MPM images of each tissue slice, including 4 images for every 150 section at a depth of 90–150 μm along the z-direction. Staining was positive for Annexin V and PI, providing the evidence of apoptosis. Blebs, which are distinctive of apoptosis were developed after IRE in the colon cancer cell.
Conclusion: Using MPM, we observed that nuclear staining due to increased cell membrane permeability and bleb was formed after electric pulse exposure. Those real time images may help us to understand the process of IRE more. MPM can replace other apoptosis assessment methods, including Annexin V-FITC and PI staining by providing in vivo images.

P1051 EFFECT OF ORAL ANTICOAGULANTS AND NSAIDS ON THE ACCURACY OF FECAL IMMUNOCHEMICAL TESTS (FIT) WITHIN A COLORECTAL CANCER SCREENING PROGRAMME – A SYSTEMATIC REVIEW AND META-ANALYSIS -

S.A.V Nieuwenburg[1], F.E.R. Vuik[1], M.J.H.A. Kruip[2], M.C.W. Spaander[1], E.J. Kuipers[1]
[1]*Erasmus MC University Medical Center, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands*
[2]*Erasmus MC University Medical center, Department of Hematology, Rotterdam, Netherlands*

Contact E-Mail Address: s.nieuwenburg@erasmusmc.nl
Introduction: Most colorectal cancer (CRC) screening programmes globally are now based on fecal immunochemical testing (FIT). The positive predictive value for advanced neoplasia (PPV_{AN}) of FIT has been reported to range between 35 and 55%. The PPV_{AN} is known to depend on gender, FIT cut-off, and screening round. A significant proportion of subjects in the screening age range use oral anticoagulants (OACs) or non-steroidal anti-inflammatory drugs (NSAIDs). These may in theory increase the tendency of neoplastic lesions to bleed, and thus increase PPV_{AN}. In contrast, these drugs could increase the tendency of non-neoplastic lesions to bleed too, and cause a decrease in PPV_{AN}. Previous studies into the effect of OAC and NSAID use on FIT performance were inconclusive. Screening guidelines thus lack recommendations on FIT screening in NSAID / OAC users. The aim of this meta-analysis was to study the effect of OAC and NSAID use on FIT performance.
Aims and Methods: A systematic search was conducted until June 2017 to retrieve studies from Pubmed, Embase, Medline, Web of science, Cochrane central and Google Scholar. Studies were included when reporting on FIT results in users versus non-users of OAC and/or NSAID in average risk FIT-based CRC screening populations. Primary outcome was PPV_{AN} of FIT in relation to NSAID / OAC use. Values were obtained by conducting analysis for pooled OAC use and also separately for NSAIDs (including aspirin) by random-effect forest plots.
Results: Our literature search identified 2022 records, of which 8 studies were included in total. Four studies provided data on OAC use and six studies on NSAID use. A total of 3563 FIT positive screening participants were included for OAC analysis and a total of 2901 for NSAID analysis. Pooled PPV_{AN} of FIT in OAC users vs. non-users was 37.6% (95% CI 33.9–41.4) vs. 40.3% (95% CI 38.5–42.1) ($p = 0.75$). Pooled PPV_{AN} in NSAID users vs. non-users was 38.2% (95% CI 33.8–42.9) vs. 39.4% (95% CI 37.5–41.3) ($p = 0.59$). Subgroup analysis of one included study showed that the detection rate of advanced neoplasia significantly decreased with long-term aspirin use (>5 years) compared to short-term use (<5 years); 38.5% vs. 61.2%, respectively ($p = 0.03$).
Conclusion: Accuracy of FIT is not affected by OAC and NSAID use at time of sampling. Based on the current literature, withdrawal of OACs or NSAIDs before FIT screening is not recommended. Future studies should focus on duration of use and drug specifics in association with accuracy of FIT to conduct specific guideline recommendations.

P1052 COMPARISON OF INCIDENCE AND SURVIVAL OUTCOMES IN MUCINOUS AND SIGNET-RING CELL COLORECTAL CANCERS WITH CLASSICAL ADENOCARCINOMA: A SEER ANALYSIS

T. Mehmood[1]
[1]*Northwest General Hospital and Research Centre, Radiation Oncology, Peshawar, Pakistan*

Contact E-Mail Address: drtahirmehmood@msn.com
Introduction: Besides classical adenocarcinoma (AC), mucinous adenocarcinoma (MAC) and signet-ring cell carcinoma (SRCC) are less frequent subtypes of colorectal cancer, and their recent epidemiologic data are lacking. The current study was designed to explore the evolving epidemiology and prognosis of patients with colorectal MAC and SRCC, compared with AC.
Aims and Methods: The Surveillance, Epidemiology and End Results (SEER) registry database was adopted for patients with pathologically confirmed colorectal neoplasms as their first malignancy. Incidence and survival trends were estimated by age and histologic subtype. 5-year cancer specific survival (CSS) were evaluated for entire cohort, and compared in subgroups by age, grade and stage. Multivariate analysis of CSS was conducted for entire cohort.
Results: MAC incidence (per 100,000) declined slightly from 6.1 in 1975 to 5.6 in 2001, and fell to 2.5 in 2012 with an APC of −7.8% (95% CI = −8.8%–6.8%, $p < 0.001$), then reached a plateau. SRCC incidence gradually climbed from 0.1 in 1975 to 0.6 in 1999 with an APC of 8.3% (95% CI = 7.2%–9.4%, $p < 0.001$) and went down to 0.4 in 2014 with an APC of −3.0% (95% CI = −5.0%–1.0%, $p < 0.001$). Among patients younger than age 50 years, MAC incidence decreased at an APC of −2.6% (95% CI: −3.6%–1.6%, $p < 0.001$), and SRCC remained stable, whereas AC incidence increased greatly at an APC of 1.9% (95% CI: 1.6%–2.2%, $p < 0.001$). Survival of both MAC and AC increased over time, while the survival of SRCC fluctuated without evident improvement. The 5-year CSS of SRCC was 31.3%, significantly lower than AC (66.6%) and MAC (60.4%). For AC and MAC Survival rate of patients aged below 50 years was superior to those aged 50 years or over through time, while in SRCC, after follow-up of approximately 20 months, the survival rate of younger patients dropped and became lower than older patients. Histologic subtype was an independent factor for CSS of CRC.
Conclusion: The incidence and survival of colorectal MAC and SRCC differs from traditional AC. Despite the low incidence of SRCC, the survival is significantly worse than AC and MAC, especially for patients aged younger than 50 years. Further studies of the etiologies and treatment for rare subtypes of CRC are needed.

P1053 A SEER ANALYSIS OF INCREASING DISPARITIES IN AGE-RELATED CAUSE SPECIFIC SURVIVAL (CSS) AMONG PATIENTS WITH COLORECTAL CANCER

T. Mehmood[1]
[1]*Northwest General Hospital and Research Centre, Radiation Oncology, Peshawar, Pakistan*

Contact E-Mail Address: drtahirmehmood@msn.com

Introduction: Survival for patients with colorectal cancer (CRC) has improved over the past decades. However, it is unclear whether older patients have benefited to the same extent as younger patients.

Aims and Methods: The Surveillance, Epidemiology, and End Results (SEER) 9 registries database was queried for patients diagnosed with colorectal cancer from 1975 to 2009. Patients were categorized by age as being ≤54, 55–64, 65–74, 75–84, and ≥85 years. We presented yearly data for survival with overlying loess smoothing lines across all age groups. Another cohort was created using the SEER 18 registries database for patients diagnosed with CRC from 1973 to 2014. Survival analyses for the periods of 1973–1979, 1980–1989, 1990–1999, and 2000–2012 were conducted. Yearly data for surgery-performed rate and stage proportion were performed with overlying loess smoothing lines across all age groups.

Results: In the analysis of the SEER 9 registries database, 5-year CSS of patients aged ≤54, 55–64 and 65–74 years showed robust increase since 1975; however, survival of patients aged 75–84 years remained low despite modest improvement, and patients aged 85 or older even showed no survival gains since 1990. Same trend exists after stratifying the disease as localized, regional and distant. In the analysis of the SEER 18 registries database, there has been a steady increase in the survival of patients aged ≤54, 55–64, 65–74 and 75–84 years as time period advanced; however, of CRC patients aged 85 years and older, the survival curves of period 1990–1999 and 2000–2012 couldn't be distinguished from each other and presented with a negligibly small gap from the survival curve of 1980–1989.

Conclusion: The strong interaction between age and year of diagnosis implies that older patients have benefited less over time than younger patients, especially for patients aged ≥85 years. Further studies are needed to determine the cause for these trends and identify potential strategies.

Introduction: There has been studies about the relationship between increased body mass index (BMI), and risk of colorectal neoplasia. Visceral obesity may affect outcome of colorectal neoplasia.

Aims and Methods: This study aimed to investigate the associations between visceral fat and oncologic outcomes in stage III colorectal cancer (CRC). 472 patients were identified with stage III CRC (2007.01.01–2009.12.31). BMI, subcutaneous fat and visceral fat were measured volumetrically via CT scan for each patient at three levels, lumber spine 3 to 4 (L3-4), 4 to 5 and lumbar spine 5 to sacrum. Adjusting age, sex, medication and underlying condition, the effect of visceral fat volume on mortality and recurrence were evaluated using Cox proportional hazard regression.

Results: Total 111 deaths and 114 cases of recurrence were noted and among recurrent cases, 25 cases were peritoneal seeding recurrence. Higher visceral fat volume was not associated with overall survival or progression-free survival. However, higher visceral fat to total fat volume ratio (HR 1.069, 95% CI 1.01–1.131, $p = 0.02$) and higher visceral fat to subcutaneous fat volume ratio (HR 1.024, 95% CI 1.003–1.045, $p = 0.023$) were both related to higher risk of peritoneal seeding recurrence. Moreover, among each level, higher visceral to total adipose tissue ratio of L3-4 showed higher risk of peritoneal seeding recurrence (HR 4.969, 95% CI 1.303–18.949, $p = 0.019$). In the additional survival analysis, patients with BMI under 18.5 were associated with higher risk of cancer-specific mortality (HR 3.236, 95% CI 0.122–0.855, $p = 0.024$).

Conclusion: Visceral obesity is closely related with increased risk of peritoneal seeding recurrence in patients with stage III colorectal cancer. Furthermore, underweighted patients are associated with higher risk of cancer-specific mortality.

Introduction: Guidelines consider both endoscopic and surgical removal as first-line treatment options, but the optimal therapeutic approach to malignant colorectal polyps is still debatable.

Aims and Methods: The aim of this single center retrospective observational study was to assess medium-term outcomes of endoscopic removal of early malignant colorectal polyps at the University of Szeged between 2012 and 2016, and to compare them with that of surgical resection. For endoscopic removal (group I), inclusion criteria consisted of histopathological diagnosis of pT1 adenocarcinoma after endoscopically completed (based on the endoscopist's opinion) polyp removal without additional surgery. For surgical removal (group II), inclusion criteria included surgical resection of pT1 adenocarcinoma with superficial submucosal invasion with or without previous endoscopic removal attempt. Recurrence (primary outcome; including local recurrence and distant metastases) was compared between the two groups. Secondary outcome was nodal involvement in those underwent surgical resection (with vs. without prior endoscopic polypectomy). Mean follow-up was 24 ± 2 months [7–67 months], follow-up endoscopy was available in 69% of the cases.

Results: Complete endoscopic removal was achieved in 69 patients (en bloc resection was carried out in 76%), of which 15 underwent additional surgical resection, and follow-up was chosen in the other 54 patients. Primary surgical resection was performed in 31 cases; thus, surgery was performed in a total of 46 cases. Mean patient age was 68.1 ± 1 years, 43% were female, and median polyp size was 20 mm (range: 6–80 mm). There was no difference between the rate of flat/sessile polyps in the groups (35% for endoscopic and 50% for surgical removal, $p = 0.139$), while pedunculated polyps were predominantly removed endoscopically (52% vs. 24%, $p = 0.004$). Endoscopically removed lesions located mainly in the left colon (54%), followed by the rectum (39%), and the right colon (7%), while surgically resected lesions tended to be in the rectum (48%), followed by the left (28%) and the right colon (24%). No difference was found between patient and lesion characteristics of those underwent surgery with and without previous endoscopic removal.

Recurrence rate was 1.9% for group I, and 4.3% for group II, $p = 0.485$. All recurrences were distant metastases, no local recurrence was observed in either group during the follow-up period. In case of pedunculated lesions, recurrence was only observed after endoscopic removal (3.6%), and for flat/sessile lesions, only after surgical removal (8.7%). Lymph node involvement was detected in a total of 11% of all surgically resected specimens. All lymph node positive cases ($N = 5$) were primarily operated without previous endoscopic removal attempt.

Conclusion: No significant difference was found between recurrence rate of malignant colorectal polyps removed endoscopically and surgically. Previous endoscopic removal does not increase the risk of lymph node involvement in case of surgical removal of malignant polyps. Thus, endoscopic polypectomy can be recommended in case complete removal is expected to be achieved, with additional surgery if necessary.

Introduction: Patients with locally advanced rectal cancer (LARC) are treated with neoadjuvant chemoradiotherapy (nCRT) followed by surgery. To date, there is a growing interest in the non-operative 'watchful waiting' management of patients with a clinically complete response to nCRT, as this is associated with good survival rates and reduced long-term morbidity. However, current restaging techniques are suboptimal to identify patients that might benefit from watchful waiting. Therefore, we investigated if quantitative molecular fluorescence endoscopy (Q-MFE) can improve clinical response assessment after nCRT in LARC patients.

Aims and Methods: We evaluated Q-MFE with 4.5mg of the near-infrared (NIR) fluorescent tracer bevacizumab-800CW targeting vascular endothelial growth factor A in 30 patients with LARC. Q-MFE procedures were scheduled at two different time points during neoadjuvant treatment: 1) at baseline, prior to the start of nCRT; 2) following completion of nCRT. At both time points, fluorescence was visualized using a NIR molecular fluorescence endoscopy platform. Additionally, fluorescence signals were quantified *in vivo* and *ex vivo* using multi-diameter single fiber reflectance and single fiber fluorescence (MDFSR/SFF) spectroscopy. Results were correlated with current clinical standards:

radiological restaging, white-light endoscopy and the pathological outcome of the surgical specimen.
Results: Firstly, Q-MFE procedures performed at baseline showed clear fluorescence in tumor tissue ($Q\mu^{f}_{a,x} = 3.7510^{-4}$) compared to normal rectal tissue ($Q\mu^{f}_{a,x} = 1.2010^{-4}$). Higher fluorescence signals were seen in tumor tissue of good responding patients compared to patients with an intermediate and poor response to nCRT ($4.6210^{-4} \pm 0.2910^{-4}$, $3.7410^{-4} \pm 0.4410^{-4}$ and $2.4810^{-4} \pm 0.5610^{-4}$ respectively). Secondly, Q-MFE procedures performed after nCRT showed significantly higher fluorescence in tumor tissue compared to normal rectal tissue and fibrosis, with an area under the curve of 0.925. Q-MFE results showed a promising correlation to pathological staging of the surgical specimen with for Q-MFE and white-light endoscopy respectively a positive predictive value after nCRT of 92% vs. 90% and negative predictive value of 100% vs. 20%. Overall, Q-MFE correctly changed restaging diagnosis in 4 (16%) of the LARC patients.
Conclusion: VEGFA-targeted Q-MFE showed to be a promising new tool for individualized treatment of LARC patients by prediction of tumor response to nCRT already at baseline and recognizing a clinical complete response after nCRT. These results might lead to a paradigm shift in the management of patients with locally advanced rectal cancer.

Contact E-Mail Address: l.carot.lc@gmail.com
Introduction: The implementation of CRC screening program has conditioned assistance and economic burden to our Health care System. The findings on baseline colonoscopy has generated the need for other subsequent colonoscopies, which cannot be considered following up. The incidence and the presence of prior factors associated with additional explorations are unknown. Moreover, the accumulation of consecutive rounds may have modified the indication of them.
Aims and Methods: We assess the incidence; analysis the modification of the additional colonoscopies and identify factors associated with a population CCR screening program in three consecutive rounds.
Data were collected from all colonoscopies included first (1R), second (2R) and three (3R) round screening program for colorectal cancer of Barcelona, Spain. Definition- *additional colonoscopy*: colonoscopy performed before one year from baseline colonoscopy and not indicated for follow-up once the resection of all basal polyps has been assured.
Results: We review 3981 colonoscopies in three consecutive rounds. A total of 330 colonoscopies (8.6%) had to repeat en a second time. The number of additional colonoscopies has decreased in the consecutive rounds; 133 (13.0%), 62 (5.1%) and 80 (6.0%) in 1R, 2R and 3R, respectively ($p < 0.001$).
The main indications for repeat colonoscopy were different depends of the round: control of complete resection of a polyp mostly by fragmented resections (58% in 1R, 8.1% in 2R and 10% in 3R), additional polypectomy (13% in 1R, 11.3% in 2R, 1.2% in 3R) and poor preparation (16.3% in 1R, 62.2% in 2R, and 80% in 3R). The values associated with the additional colonoscopy were: the participation in 1R (OR 2.34; IC 95%: 1.78–3.07), male but only in the 1R (OR 1.49; *IC 95%: 1.08–2.06*), the presence of high risk adenomas (OR 5.15; *IC 95%: 3.48–7.62*) and the fecal hemoglobin concentration assessed by immunochemical test (OR 1,4; *IC 95%: 1.46–1.80*). The previous factors to baseline colonoscopy independently associated with the need to repeat the test were the participation in 1R (OR 2.48; *IC 95%: 1.97–3.12*) and fecal hemoglobin concentration (OR 1,38*; IC 95%: 1,10–1,74*).
Conclusion: The need to repeat colonoscopies determines an additional burden on CRC screening program. Additionally, having a positive immunochemical test is a cause the repetition and therefore the message of adequate intestinal preparation must be reinforced, especially as it participates in consecutive rounds.

Introduction: Most T1 colorectal cancers (CRCs) undergo surgical colectomy in accordance with established clinical guidelines despite the low incidence (approximately 10%) of lymph node metastasis (LNM). Decisions concerning additional surgery after endoscopic resection of T1 CRC are difficult because preoperative prediction of LNM is problematic. In this study, we investigated whether artificial intelligence (AI) can predict LNM presence of T1 CRCs, thus optimizing the treatment strategy for additional surgery of these lesions.
Aims and Methods: A total of 700 consecutive patients with T1 CRCs that were surgically resected in 2001–2016 were retrospectively analyzed. We divided patients into two groups according to date: data from 590 patients were used for machine learning for the AI model, and the remaining 110 patients were included for model validation. The AI model analyzed 45 clinicopathological factors (patient age, sex, tumor size, location, lymphatic invasion, depth of invasion, blood test result and so on) and then predicted positivity or negativity for LNM based on support vector machine which is a representative machine learning method. Operative specimens were used as the gold standard for the presence of LNM. The AI model was validated by calculating the sensitivity, specificity, and accuracy for predicting LNM, and comparing these data with those of the American, European, and Japanese guidelines.(1–5)
Results: Sensitivity was 100% (95% CI, 59%-100%) in all models. Specificity and accuracy of the AI model, American, European and Japanese guidelines were 66% (56%-75%) vs. 44% (34%-54%) vs. 0% (0%-5%) vs. 0% (0%-5%), and 69% (60%-78%) vs. 49% (39%-59%) vs. 9% (4%-16%) vs. 9% (4%-16%), respectively. The rate of unnecessary surgeries of the AI model was calculated as 31% in comparison with American 51% ($P < 0.01$), European 91% ($P < 0.01$), and Japanese 91% ($P < 0.01$).
Conclusion: Compared with the current guidelines, AI significantly reduced unnecessary additional surgery after endoscopic resection of T1 CRC without missing LNM positivity. AI will help in making decisions as to whether additional surgery is indicated after endoscopic resection of T1 CRCs.

P1059 LOCAL INJECTION OF A WATER JET AND MAGNIFIED ENDOSCOPIC OBSERVATION USING SPECIAL LIGHT ARE USEFUL FOR PREVENTING RESIDUAL LESIONS IN COLD POLYPECTOMY

M. Yasuda[1], Y. Naito[2]

Introduction: Cold polypectomy, which does not require an electric current, is of 2 types: cold snare polypectomy (CSP) and cold forceps polypectomy (CFP). Compared to hot polypectomy, which uses an electric current, cold polypectomy has advantages such as easier preparation and procedures, less muscle layer damage, and lower risk of postoperative hemorrhage. Therefore, both cold techniques have been widely accepted for excising small polyps of the large intestine. However, in contrast to hot polypectomy, which can be performed with a clear field of vision, with cold polypectomy, it is difficult to judge whether polyps have been completely removed. Thus, there is a possibility that residual lesions remain. Therefore, we examined whether the local injection of a water jet and magnified endoscopic observation using a special light are useful for preventing residual lesions.
Aims and Methods: We conducted a prospective study, from October 2016 to April 2017 at our hospital, of 200 consecutive patients who underwent cold polypectomy for endoscopic excision of large intestinal polyps. Patients were randomly assigned to either Group A (100 patients) in whom local injection of a water jet after excision and magnified endoscopic observation using special light were performed or Group B (100 patients) in whom those procedures after excision were not performed. We excluded all patients diagnosed with cancer via magnifying endoscopy with narrow-band imaging (M-NBI) or with blue laser imaging (M-BLI). The size, shape, and degree of dysplasia of lesions and the rate of complete resection were histopathologically investigated in both groups. In Group A, additional excision was performed instantly if residual lesions were observed. For local injection of the water jet, we used the Olympus Flushing Pump (Olympus, Ltd., Japan) as a water supply machine, and an endoscope (Olympus, Ltd., Japan or Fujifilm Ltd., Japan) that was used with the machine.
Results: There were no differences in lesion size, shape, or degree of dysplasia between both groups. The rate of complete resection was 96% in Group A and 84% in Group B, showing that Group A had a significantly higher rate.
Discussion: In Group A, the margin of the resection surface was observed with local injection of the water jet after polyp excision. By using a combination of image-enhanced endoscopy and magnified endoscopic observation (M-NBI or

M-BLI), we could observe the presence or absence of residual lesions instantly without a pathological diagnosis.
This allowed us to resect the residual part of polyp as required. Therefore, our ability to completely resect the lesion improved.
Conclusion: To prevent residual lesions in cold polypectomy, local injection of a water jet and magnified endoscopic observation using a special light are useful. This should therefore be performed as a routine procedure.

Introduction: Irritable bowel syndrome (IBS) is common and is characterised by recurrent abdominal pain, which is a major contributor to healthcare seeking. The neurobiological basis of this pain is incompletely understood. Conditioned pain modulation (CPM), a way the brain controls the afferent barrage by descending pathways, has been implicated in the pathophysiology of IBS, although to date only in studies with relatively small sample sizes. We aimed to clarify this relationship by undertaking a systemic review and meta-analysis.
Aims and Methods: A systematic review off MEDLINE and Web of Science databases were searched (up to April 2017). Studies examining CPM in adults with IBS and healthy subjects were included. Data were pooled for meta-analysis to calculate the odds ratio of abnormal CPM in IBS, with 95% confidence intervals (CI).
Results: The search strategy identified 645 studies, of which 24 were relevant and 12 met the inclusion criteria. CPM was reduced in IBS patients versus healthy subjects, odds ratio 4.84 (95% CI 2.19–10.71, $p < 0.0001$). There was significant heterogeneity in effect sizes (Q-test $\chi^2 = 52$, $p < 0.001$, $I^2 = 78.8\%$) in the absence of publication bias. Numerically, the Rome III criteria was associated with more deficient CPM than Rome II odds ratio 5.65 (95% CI 1.87–17.04) vs 3.44 (95% CI 1.76–6.70), respectively.
Conclusion: CPM is significantly reduced in patients with IBS when compared to healthy subjects. These data provide evidence that abnormal descending pathways are an important pathophysiological facet in IBS, which could represent a novel investigation target to allow personalization of neuromodulatory therapy.

Introduction: Functional gastrointestinal disorders (FGID) are characterized by a broad range of gastrointestinal (GI) and extra-GI symptoms, and an absence of recognizable disease. Mechanisms underlying these phenotypes are unclear, but may be linked to host or microbiome metabolism.
Aims and Methods: We investigated underlying mechanisms by studying associations between gas production and symptom genesis during fructose and lactose breath tests in 2042 successive patients with FGID. Breath hydrogen and methane gas concentrations and evoked GI and extra-GI symptoms were assessed for 5 hours following sugar ingestion. Symptom and gas time profiles were compared, Treelet Transforms were used to derive data-driven symptom clusters, and the symptom severities of the clusters were analyzed for their association with breath gas characteristics.
Results: The time profiles of eleven symptoms, as well as of hydrogen and methane gas concentrations, showed significant changes over time following fructose and lactose ingestion ($p < 0.0001$). Treelet Transform analysis identified two distinct sugar-evoked GI and CNS symptom clusters. The intensities of the GI and CNS symptom clusters were closely correlated following both fructose and lactose (all $p < 0.0001$). The GI symptoms were significantly associated with the production of hydrogen and methane gases (all $p < 0.0001$), while this was not the case for the CNS symptoms.
Conclusion: Clearly defined clusters of GI and CNS symptoms were evoked by fructose and lactose ingestion in patients with FGID. The GI and CNS cluster time profiles correlated significantly, but only the GI symptoms were related to breath gas concentrations. This implies distinct underlying mechanisms likely relating to microbiome metabolism, such as mechanical and chemical sensitization.

Introduction: The complex pathophysiology of Irritable Bowel Syndrome (IBS) is based on incompletely understood disturbances in the microbiota-gut-brain interaction. Faecal microbiota profiles have been associated with IBS and severity of symptoms in IBS patients. However, while the composition of the intestinal microbiota may be altered, the available data on the metabolic activity in the intestinal lumen of IBS patients, which is modulated by diet, microbiota composition and microbial activity, use of medication and host metabolism, is limited.
Aims and Methods: The aims of the present study were to identify profiles of faecal metabolites associated to IBS, IBS subtypes and gastrointestinal (GI) symptom severity in IBS.
In a cross-sectional analysis we included 163 extensively phenotyped and clinically diagnosed IBS patients (all according to ROME III criteria) and 121 age and gender matched healthy controls (HC); a subset of the Maastricht IBS cohort. All subjects completed questionnaires on demographics, use of medication, GI symptom severity, anxiety and depression, quality of life, and dietary intake. Faecal water was extracted from stool samples and faecal metabolites were measured using proton nuclear magnetic resonance (^{1}H NMR) spectroscopy.
Outliers from the data were excluded based on auto-scaled Principal Component Analysis and the 95% CI of Hotelling's T^2 statistic. The remaining samples were modelled using Monte Carlo Cross-Validated Partial Least Squares Discriminant Analysis (MCCV-PLS-DA) with 250 iterations of the MC in which 1/5th of the data was left out completely to be used for validation. The left-out samples were predicted using the parameters from the training set. Variable importance was assessed using bootstrap resampling to estimate the variance of the regression coefficients used to calculate a t-score and *p*-value for each variable. The p-values were corrected for multiple testing using the false discovery rate (q-value).
Results: A total of 146 IBS patients and 121 HC were included in the data analysis. Most outliers contained high amounts of polyethyleneglycol, which was used as laxative by the patients. All 250 models consistent of two components with a goodness of fit (R^2_Y) of 0.58 across the MCCV. The goodness of prediction (Q^2_Y) was 0.22. The distributions of predicted IBS and HC samples show some overlap, but a Wilcoxon rank sum test indicates they are significantly different at $p = 2.18 \times 10^{-18}$. After multiple testing correction and pairwise comparisons, there were no differences witnessed in predicted values of the IBS subtypes compared to each other. Branched-chain amino acids (Leu, Val, Ile) and aromatic amino acids (Tyr, Phe) were found in higher concentrations in faecal water of IBS patients compared to HC, as were glucose, formate and (tentatively) orotate. Other unidentified spectroscopic signatures are yet to be identified; these include resonances from sugar-like compounds found higher in HC. No differences were observed for fatty acids butyrate and propionate, nor for acetate, lactate, succinate and glutamate.
Conclusion: Spectroscopic profiling of faecal water shows differences between IBS patients and HC in terms of the metabolic profile, indicating altered intraluminal gut metabolic activity in IBS.
Perspective: Additional analyses will be performed to study differences between IBS subtypes, the relation between GI symptoms and metabolic profiles, and the correlation between faecal microbiota compositions and faecal water metabolites. This method has the potential to identify biological pathways related to IBS phenotype and its pathophysiology.

Introduction: Protease-activated receptor-2 (PAR-2), a G-protein-coupled receptor of mast-cell tryptase and trypsin, is highly expressed in the intestine. Role of PAR-2 in the pathogenesis of abdominal pain in irritable bowel syndrome (IBS) is not well defined.
Aims and Methods: We aimed to investigate the role of PAR-2-mediated visceral hypersensitivity by using a post-infectious IBS (PI-IBS) mouse model. *T. spiralis*

infected PI-IBS mouse model was used. Fecal serine protease activity and intestinal mast cells were evaluated. PI-IBS mice received intraperitoneally PAR-2 antagonist (FSLLRY-NH2) or normal saline, and control mice received intracolonically PAR-2 agonist (SLIGRL-NH2) or normal saline. Intestinal permeability was assessed by urine lactulose/mannitol ratio, and colonic expressions of PAR-2 and tight junction (TJ) proteins were examined by Western blot. Intestinal immune profile was assessed by measuring Th (T helper) 1/Th2 cytokine expression. Visceral sensitivity was evaluated by abdominal withdrawal reflex (AWR) in response to colorectal distension (CRD).
Results: Mice infected with *T. spiralis* developed visceral hypersensitivity after 8 weeks. PI-IBS mice had higher AWR scores for all levels of distention (20, 40, 60, and 80 mmHg) and lower pain and volume thresholds compared to the control mice (all $P < 0.05$). Colonic PAR-2 expression (19.54 ± 6.4 vs. 0.23 ± 0.1, $P = 0.03$) as well as fecal serine protease activity (127.2 ± 39.1 U/mg vs. 25.6 ± 15.8 U/mg, $P = 0.02$) and intestinal mast cell counts (19.1 ± 2.7 vs. 2.8 ± 0.7, $P < 0.001$) were elevated in PI-IBS compared to the control mice. Decreased colonic TJ proteins (occludin: 0.45 ± 0.16 vs. 4.89 ± 2.26, $P = 0.009$; ZO-1: 0.48 ± 0.23 vs. 1.94 ± 1.06, $P = 0.015$) expression, increased lactulose/mannitol ratio (0.35 ± 0.04 vs. 0.15 ± 0.03, $P = 0.001$), and elevated colonic Th1/Th2 cytokine ratio (3.5 ± 0.4 vs. 1.4 ± 0.1, $P = 0.001$) were observed in PI-IBS compared to the control mice. Administration of PAR-2 agonist in control mice demonstrated similar changes observed in PI-IBS mice, while PAR-2 antagonist normalized intestinal hyper-permeability (0.15 ± 0.02 vs. 0.35 ± 0.04, $P = 0.001$), led a trend towards decreased Th1/Th2 ratio (2.4 ± 0.3 vs. 3.5 ± 0.4, $P = 0.07$) and reduced visceral hypersensitivity (decreased AWR scores and higher pain and volume thresholds) in PI-IBS mice.
Conclusion: PAR-2 activation induces intestinal hyper-permeability leading to immune activation and visceral hypersensitivity in PI-IBS mouse model. PAR-2 plays an important role in the pathogenesis of PI-IBS.

Introduction: Chronic relapsing and remitting pain is a central feature of common gastrointestinal disorders including both functional (e.g. irritable bowel disorder) and organic (e.g. Crohn's disease) disorders. The role of aetiology in chronic pain is not well understood. One approach to classifying chronic pain disorders is to consider whether the condition has an identifiable pathophysiology or not. Hence the use of the terms organic and functional conditions, respectively. In addition, the contemporary treatment of chronic pain has highlighted the importance of psychological therapies, such as Cognitive Behavioural Therapy (CBT). Recent work by the eCentreClinic has developed transdiagnostic CBT models for chronic pain which should make organic versus functional aetiology irrelevant.
Aims and Methods: The aim of the present study is to determine whether pain-related treatment outcomes are moderated (altered) by a functional or organic pain aetiology, among individuals undergoing CBT for chronic pain. The possibility of transdiagnostic, aetiology-independent therapy opens the potential for efficacious and cost-effective pain relief for patients.
The present study is a secondary analysis of data collected from an internet-delivered pain management program, known as The Pain Course. Participants pain aetiology was identified as functional or organic, via interview and self-reported data provided. A formal test of moderation was undertaken via analysis of covariance in which all dependent variables (pain disability, pain intensity, pain self-efficacy, pain acceptance, fear avoidance, depression and anxiety). The interaction between treatment group (active CBT or Control) and pain condition classification (organic or functional), were used as the independent variables.
Results: N = 471 participants engaged in a 5 week trail of CBT for chronic pain. Between group differences of both the active CBT and waitlist control, for functional or organic status, age, gender, mean pain duration and average number of painful sites were non-significant. All dependent variables were not moderated by a functional or organic status (pain disability: $F(1, 417) = 0.012$, $p = 0.91$, pain intensity: $F(1, 417) = 3.68$, $p = 0.06$, pain self-efficacy: $F(1, 417) = 0.10$, $p = 0.75$, pain acceptance: $F(1, 417) = 3.14$, $p = 0.08$, fear avoidance: $F(1, 416) = 0.02$, $p = .89$, depression: $F(1,417) = 3.14$, $p = 0.08$ and anxiety: $F(1, 417) = 1.75$, $p = 0.19$).
Conclusion: The present study identifies that the therapeutic change experienced by participants undergoing CBT for chronic pain is not altered by the presenting aetiology being organically driven. This reinforces a biopsychosocial formulation of those experiencing persistent pain, independent of the driving stimuli. Future research should identify further predictors of treatment responses which optimize outcomes and reduce the overall financial costs associated with chronic pain.

P1065 HOW THE PLACEBO EFFECT PLATEAUS: PREDICTORS OF THE SHAPE OF PLACEBO RESPONSE IN IBS-C

A.P. Beath[1], S. Ballou[2], A.J. Lembo[2], M.P. Jones[1]

Introduction: Placebo effects are common in clinical trials. In IBS specifically, approximately 40% of patients experience a placebo effect. While previous research has demonstrated some predictors of placebo response, limited research to date has investigated how placebo effects change over time, and what factors predict this changing pattern of response.
Aims and Methods: This study aimed to establish (1) the specific shape of the time course of the placebo effect over a 12-week clinical trial, and (2) the predictors of this time course.
Data were obtained from 599 women enrolled in the placebo arm of a phase-III clinical randomized control trial. Daily measures of abdominal pain (rated on a 1–10 scale) and number of complete spontaneous bowel motions (CSBMs) were used as outcomes throughout the 12-week period. Latent growth curve models were fitted to identify the specific shape of the time course of the placebo effect.
Results: A quadratic curve was the best fit for placebo trends in both pain and CSBM; that is, across the 12-week period, there was, on average, an initial decrease in symptoms, which on average plateaued around week 5. For that reason, the model chosen required two components: one which captured the initial improvement in symptoms at week 1 of the trial (the linear term), and the other which measured the extent to which the improvement plateaus over time (the quadratic term). Models showed significant between-individual variability in both the linear and quadratic terms for both outcomes, which indicates that there is individual variability in the rapidity of the initial improvement, and also when the improvement begins to plateau.
For the pain outcome, predictors of greater initial decrease in pain (the linear term), but subsequent plateau of pain relief (quadratic term), included higher average baseline pain, abnormal baseline stool form, no history of migraine or drug hypersensitivity, a history of asthma, and experiencing early adequate pain relief.
For the CSBM outcome, predictors of greater initial increase in CSBMs (linear term), but subsequent plateau of CSBM increase (quadratic term), were a history of asthma and experiencing early adequate pain relief. (See Table 1.)
Conclusion: The quadratic shape of the placebo response demonstrated that, over 12 weeks, many individuals experience an early peak, which subsequently plateaus. These results show that abdominal pain at baseline, medical history and stool form influence the extent and shape of the placebo response. The placebo response for pain appears to be more dependent upon symptom severity, whereas the placebo response for CSBMs seems more independent of patient factors. Understanding which individuals experience a less stable placebo response, and which symptom outcomes are more affected by patient factors, can potentially help both researchers and clinicians in comparing active therapy effects with placebo effects, as well as better understand mechanisms underlying the placebo effect.

Pain Outcome

Introduction: Although previous studies show conflicting results, colonic mast cell (MC) accumulation and increased proportions of MC in close proximity to intestinal nerves have been proposed to be associated with more severe Irritable Bowel Syndrome (IBS) symptoms, altered intestinal barrier properties and visceral hypersensitivity.

Aims and Methods: This study aimed to determine if IBS patients displayed an altered MC profile compared with healthy subjects and if MC profiles correlated with IBS symptoms, barrier integrity or visceral sensitivity.

Biopsies from the sigmoid colon (25–35 cm from the anus) were collected from a Swedish cohort of IBS patients meeting the ROME III criteria and from healthy subjects. Mucosal MC profile was determined using anti-tryptase antibody, immunofluorescence and blinded quantification with a computer-assisted analysis system. The IBS Severity Scoring System (IBS-SSS), Gastrointestinal Symptom Rating Scale-IBS (GSRS-IBS), Visceral Sensitivity Index (VSI) and Hospital Anxiety and Depression Scale (HADS) questionnaires were used to evaluate the symptom profile. Expression of mucosal barrier proteins CLD-1, MUC, TJP1 and OCLN was measured with Real-time quantitative PCR and normalised to housekeeping genes 18S, POLR2YA and RPLPO. Fecal serine protease activity was detected using azocasein or tryptase substrate protease assays and AEBSF inhibitor. Visceral sensitivity was determined with a rectal barostat test. Univariate analyses, hierarchical cluster analysis (HCA) and multivariate orthogonal partial least squares-discriminant analysis (OPLS-DA) were performed. Data are presented as median (25th-75th percentiles).

Results: This study included 43 IBS patients (30 females; 32 (25–44) years) of subtypes IBS-C (n = 9), IBS-D (n = 18), IBS-nonCnonD (n = 16), and with IBS-SSS total score of 269 (196–365), and 20 healthy subjects (14 females; 27 (24–38) years). Total HAD scores were 13 (9–19) in IBS patients and 7 (3–13) in healthy subjects ($p = 0.0002$). MC frequencies were 2 (0–6) cells in IBS patients and 3.5 (1.1–9.1) cells in healthy subjects ($p = 0.26$, univariate analysis). MC in close proximity to nerve fibres were 0 (0–20) % in IBS patients and 3.1 (0–17.6) % in healthy subjects ($p = 0.76$). There were no differences between the different IBS subtypes concerning MC numbers and location. HCA identified two distinct groups among IBS patients, based on MC numbers and location. These groups were characterized by higher MC numbers and proportions of MC in close proximity to nerves (MC high), or by lower MC numbers and proportions of MC in close proximity to nerves (MC low). Univariate analysis showed no differences in total IBS-SSS, VSI and HAD scores between MC high and MC low IBS patient groups. OPLS-DA showed that MC high and MC low groups could not be discriminated with regards to IBS symptoms (GSRS, IBS-SSS, HAD and VSI) or barrier properties (mucosal expression of CLD-1, MUC, TJP1 and OCLN, and activity of fecal serine proteases). Finally, parameters of visceral sensitivity were equivalent in MC high and MC low groups when investigated by OPLS-DA.

Conclusion: This study was not able to identify any differences in mast cell frequencies, or proportions of mast cells in close proximity to nerves, between IBS patients and healthy subjects. Furthermore, there were no links between mast cell profile to individual or global IBS symptoms, expression levels of barrier proteins or degree of visceral sensitivity in IBS patients. These findings indicate that quantity and location of mucosal mast cells are factors not involved in the pathophysiology of IBS.

Introduction: Although not a life-threatening disease, irritable bowel syndrome (IBS), associating abdominal pain with transit disorders, can alterate the quality of life (QoL) in all its domains. Studies in the USA have shown that the disease can alter sexuality in two-thirds of patients and sometimes have repercussions on the partner.

Aims and Methods: Our goal was to determine in a French cohort of patients the prevalence of possible sexual dysfunction and its links with IBS characteristics, as well as the partner burden. This online study was conducted among members of the French Association of Patients Suffering from IBS (APSSII). For IBS members, demographic data and IBS characteristics were noted: disease duration, transit subtype, severity (IBS-SSS), QoL, and state of depression and anxiety (HAD score). Study of sexual dysfunction was performed using the Female Sexual Function Index score (FSFI) in women (19 questions, 6 domains, abnormal if <26.55, score 2- 36) and the International Index of Erectile Function (IIEF) in men (15 questions, 5 domains, abnormal if <26). The partner burden was evaluated among partners of IBS members participating in the study: age, sex, burden assessment questionnaire (ZBI, Zarit et al.[1]) includes 22 items (score 0–88; severe if >60; i.e. studies have shown an average score of 32.9 for dementia and 18.5 for terminal cancer stage) and a validated 7-questions Relationship Scale were completed.

Results: (mean ± SD) 257 patients (73.2% F), mean age 46.3 ± 16.15 years, with a disease duration of 7.5 ± 9.8 years were included. Transit subtypes were: IBS-D 33.7%; IBS-C 21.4% and IBS-M 42.9%. A colonoscopy was performed in 85.7% of participants and 66.9% had an employment at the time of the survey. Among IBS participants, 33.5% of women were menopausal; 5.8% of men had prostate surgery; 62.6% had at least minimal physical activity, 2% had diabetes, 11.4% had hypertension, 6.6% took beta blockers, and 30% antidepressants and/or anxiolytics. According to HAD score 61% of IBS participants had anxiety and 24.7% depression. The IBS-SSS score was 301 ± 94 (minimal in 10%, moderate in 38%, severe IBS in 51%); the fatigue score was 46.68 ± 13.03. The IBS-QoL score was 60.9 ± 17.8 with sexual sub-score of 48.31 ± 33.5. Sexual dysfunction was present in 67.5% of women and 53.3% of men with erectile dysfunction that was moderately severe in 38.3% and severe in 20%. In women, sexual dysfunction was related neither with IBS-SSS nor with HAD score, but only with IBS-QoL sexuality subscore, bloating (IBS-SSS), employment, physical activity, spousal status. In men, no relationship was found with sexual dysfunction and other characteristics.

Forty-seven partners of IBS participants, mean age 44.65 ± 14.38 years (Men 63.8%) had also responded to the survey. The average Zarit's burden score was 23.6 ± 16.68 (The burden was absent in 50%, mild in 36.8%, moderate in 10.5% and severe in 2.6%), and relationship scale was 3.2 ± 0.6. There was no correlation between ZBI and IBS-SSS but a negative correlation between ZBI and relationship scale ($r = -0.337$; $p = 0.039$).

Conclusion: In this survey of IBS participants, with 50% of severe IBS, a sexual dysfunction was present in 2/3 of women and a moderately severe to severe sexual and erectile dysfunction in more than one in two men. This study also confirms a partner burden in half of them that was not correlated with disease severity may be because of the strength of the relationship.

P1068 ADHERENCE WITH LOW FODMAPS DIET IN IRRITABLE BOWEL SYNDROME: ARE EATING DISORDERS THE MISSING LINK?

A. Mari[1], D. Hosadurg[1], L. Martin[2], **V. Passanati**[1], N. Zarate Lopez[1], A. Emmanuel[1]

[2]*University College Hospital London, Nutrition, London, United Kingdom*

Contact E-Mail Address: valentina.passanati@uclh.nhs.uk

Introduction: The low FODMAP diet has emerged as an option for the treatment of irritable bowel syndrome (IBS). One major challenge of this dietary treatment is the need to restrict a range of foods and high levels of adherence are required for effective outcomes. Preliminary findings suggest an association between eating disorder (ED) and the risk of developing IBS. We hypothesised that high adherence to this diet is associated with an increased risk of eating disorder behaviour.

Aims and Methods: We report a single-centre study in the IBS patient population at University College London Hospital (UCLH). 233 consecutive patients (186 female) who commenced a low FODMAP group programme for IBS (Rome III or IV). Self-reported diet adherence at the end of the 6-week programme was measured. At baseline, participants completed the SCOFF questionnaire (a validated 5-item screening tool for EDs) and the IBS-symptom severity score (IBS-SSS).

Results: The SCOFF questionnaire identified 54 (23%) patients at an increased risk of ED behaviour. Overall, 95 (41%) participants were diet-adherent at 6 weeks (defined as adhering to low FODMAP foods for $>75\%$ of intake), with significantly greater adherence in identified ED individuals (57%). The highest adherence rate was in the IBS-D subtype (51%) and the lowest rate in IBS-C(10%). There was no significant relationship between IBS symptom severity and either adherence or ED severity

Conclusion: In our IBS patient cohort greater adherence to a low FODMAPs diet is associated with greater risk of eating disorder behaviour. The implications of our study are for clinicians to be aware of the risks associated with following a restrictive diet in the context of the prevalence of EDs in IBS patients. It is

important low FODMAP dietary advice to the general IBS population includes an explanation of the psychological risks of following restricted diets.

[2]*University of Bergen, Department of Global Public Health and Primary Care, Bergen, Norway*

Contact E-Mail Address: awensaas@online.no
Introduction: Irritable bowel syndrome (IBS) is a common condition with a pooled global prevalence of 11%. The prevalence varies depending on the year and geographic location of the study, method for data-collection and the criteria used (1). In 2016 the new Rome IV criteria for the diagnosis of IBS were announced (2). No studies on the prevalence of IBS based on the Rome IV criteria have been published, but it has been reported that Rome IV criteria will identify a smaller patient population with more severe IBS compared to the previous Rome III criteria (3).
Several studies have shown an overlap of IBS with other syndromes and symptoms, such as chronic fatigue, fibromyalgia, and widespread pain (4). Mostly, these studies are small, with patients in secondary or tertiary care.
Aims and Methods: The aims of this study were to estimate the prevalence of IBS according to Rome IV criteria in a primary care population, and to establish the association with chronic widespread pain and fatigue.
During the sixth year of their studies, all medical students at the University of Bergen have a four-week placement in general practice. Each student was asked to distribute a one-page questionnaire to 20 consecutive patients aged 18 and above who visited the practice. The data collection for this study took place in the fall of 2017 and winter of 2018.
The main outcome was IBS based on questions composed to fit Rome IV criteria. Secondary outcomes were the symptoms 'chronic fatigue' based on the two questions from Chalder's Fatigue Questionnaire that corresponded best with chronic fatigue in the control group of a previous study (4), and 'pain'-based on questions about back pain and muscular pain. Explanatory variables were age, sex, education and country of birth.
Results: The response rate was 83% (1926/2307). The mean age was 49.7 years, 63.1% of the respondents were female, and 9.3% were born outside Norway.
The overall prevalence of IBS was 5.9% (107/1817), 7.4% among women and 3.3% among men (relative risk (RR) 2.3, 95% confidence interval (CI) 1.4–3.6). Patients with IBS were younger than those without IBS (41.9 vs. 49.5 years, $p < 0.001$). IBS status was not associated with level of education or country of birth.
The prevalence of chronic fatigue was 23.7% (421/1777) and of pain 20.0% (355/1775). IBS was associated with both these outcomes. Among patients with IBS 51.9% also reported chronic fatigue (RR 2.44, 95% CI 1.98–2.99) and 41.9% reported chronic pain (RR 2.40, 95% CI 1.87–3.08).
Conclusion: The prevalence of IBS in Norwegian primary care was 5.9%. IBS was associated with younger age and being female, and a high proportion of patients with IBS also reported chronic fatigue or pain.
Disclosure: Nothing to disclose

Introduction: Irritable Bowel Syndrome (IBS) is a highly prevalent functional disorder that carries a substantial socioeconomic burden due to increased healthcare utilization and productivity losses. Actual data on this topic for the Dutch situation is lacking.
Aims and Methods: This study aimed 1) to determine the socioeconomic cost of IBS and 2) to identify sociodemographic and clinical characteristics associated with direct and indirect costs in a Dutch IBS population.
Baseline data from patients enrolled in the PERSUADE trial (peppermint oil versus placebo) was used. IBS patients (ROME IV), aged between 18 and 75 years old, were included via primary and secondary/tertiary care recruitment or self-referral and completed questionnaires regarding demographics and life style, symptom severity, Quality of Life, and anxiety and depression. Direct and indirect health related costs were measured using the iMTA/Trimbos Medical Cost Questionnaire (MCQ, recall period 3 months) and Productivity Cost Questionnaire (PCQ, recall period 4 weeks) respectively. Costs were calculated by multiplying resource use by the cost price per resource unit, adopting reference prices derived from the Dutch guidelines for cost calculations in health care. The friction cost method was applied for the determination of long term absenteeism costs. Data regarding short-term absenteeism was extrapolated to estimate costs for a 3-month period.
Results: 111 patients (86% female, mean age 33 years old; Sd 13) were included in the current analysis. Data was highly skewed. Table 1 shows the total direct and indirect costs.

Category	Total direct and indirect costs, sum in € (%); mean (Sd)
N = 111	
Absenteeism	45.619 (39.8); 205 (1.150)
Mental health care	13.622 (11.9);123 (329)
Outpatient consultation	11.439 (10); 122 (329)
Physiotherapy	8.775 (7.7); 79 (142)
Diagnostics or treatment without hospitalization	7.931 (6.9); 36 (268)
Impaired unpaid work	5.291 (4.6); 48 (135)
General Practice	5.270 (4.6); 48 (58)
Hospitalization	3.416 (3.0); 31 (249)
Medication	3.345 (2.9); 30 (45)
Other costs	9.794 (8.6); 12 (77)
Total	114.513 (100); 1031 (2022)

N.B.: other costs comprise of i.e. costs for ER (emergency room) and ambulance, dietary advice, domestic help, etc.
[Total direct and indirect health related costs.]
Mean total direct costs for a period of 3 months were +/− €573, Sd €999 (median €285; IQR €74–689). Visits to mental health care providers and outpatient visits (to a physician other than psychiatrist) contributed most to these direct costs (22% and 18% respectively), followed by physiotherapist consultations (14%). Depression symptom scores were positively associated with direct costs (B €108, $P < 0.00$; CI 51–165). Mean total indirect costs for 3 months were +/− €459, Sd €1608, but were caused entirely by a subgroup of 31 patients. In this subgroup (87% female, mean age 34 years old; Sd 11), mean indirect costs were €1642, Sd €2735 (median €729; IQR €286–1924). Indirect costs were primarily related to absenteeism.
Conclusion: Both direct and indirect costs lead to a substantial socioeconomic burden in a Dutch IBS population. Mental health care and absenteeism appear to be important driving factors of costs in these patients.
Disclosure: The PERSUADE trial is funded in part by WillPharma.

P1071 STRONG EVIDENCE SOMATISATION MEASURES BASED ON SYMPTOM CHECKLISTS ARE MORE REFLECTIVE OF PSYCHOLOGICAL RATHER THAN PHYSICAL HEALTH: IMPORTANT CONSEQUENCES FOR GASTROENTEROLOGY RESEARCH AND PRACTICE

M. Jones[1], D. Loxton[2], M. Harris[2], A. Beath[3], N.J. Talley[4], N. Koloski[2], A. Ejova[5]

Introduction: Functional gastrointestinal disorders (FGIDs) have been strongly associated with psychological disorders, including somatisation (1). Somatisation in gastrointestinal (GI) research is typically defined as a physical expression of psychological distress and a number of scales are commonly used to measure it, including somatic symptom checklists (SSCLs) (2) and measures centred around psychological distress [e.g. DSM]. Some of these have been criticised as not truly measuring somatisation as they can be confounded with actual organic co-morbidities, especially in the absence of clinical examination or structured interview (3). Consequently neither researchers nor clinicians can be certain whether they reflect psychological distress or somatic illness burden.
Aims and Methods: We aimed to determine whether somatisation as measured through an SSCL was primarily driven by measures of psychological state or measures of physical health in a large, longitudinal study of women's health.

Two waves (3 and 4) of data collected from the cohort born 1973–1978 of the Australian Longitudinal Study of Women's Health (n = 4368) (4) were analysed to determine whether somatisation as measured in one wave was better predicted by psychological traits or physical health and lifestyle three years earlier. The same analysis was repeated cross sectionally to determine whether the SSCL was more influenced by concurrent psychological state or physical health. To reduce optimism bias in model development predictors were chosen based on Bayesian Information Criterion (BIC) rather than conventional tests.

Results: As shown in the table below, almost the same number of psychological and physical health measures were found to be longitudinal predictors of SSCL. However the psychological predictors accounted for approximately twice as much of the variance in SSCL as did physical health predictors. Cross-sectionally, a much larger list of concurrent physical health predictors were identified (Table) and slightly fewer psychological predictors were involved. However the variance in SSCL explained by concurrent psychological predictors was again approximately twice the variance explained by physical health and lifestyle predictors.

Conclusion: Despite being a list of potential health complaints, the SSCL utilised in this large, population-representative longitudinal study of women appears to be more a reflection of psychological distress than physical health.

Introduction: The symptom-based diagnostic criteria for IBS have recently been revised in the Rome IV consensus. In a tertiary care cohort, compared to Rome III, Rome IV identifies a subgroup with more severe symptoms, co-morbidity and quality of life impact (Vork 2018). On the other hand, with rising public awareness of IBS, self-diagnosis and self-management are likely to increase as well. The prevalence and impact of Rome IV-based IBS versus self-diagnosed IBS was compared in the general population.

Aims and Methods: An internet panel filled out an online survey on bowel symptoms and their impact. Questions addressed demographics, IBS symptoms based on Rome IV criteria, their frequency, and their impact on healthcare utilization and daily activities.

Results: A representative internet panel of 1,012 subjects, which reflected the Belgian population in terms of educational level, professional activity, and regional distribution, completed the online survey. Rome IV IBS criteria were fulfilled by 5.5% of the Belgian population who were younger and more likely to be female (7% of women vs. 3.9% of men, 42.4 ± 1.9 vs. 45.4 ± 0.5 years, $p \leq 0.05$). Thirty-seven percent had consulted a physician for IBS symptoms (27% primary care, 15% a specialist) over the last year, with an average of 41 ± 2.2 doctor visits per patient; colonoscopy was performed in 12% and radiological examination in 15%. Rome IV IBS subjects reported as a consequence of their symptoms bothersome fatigue (88%), irritability (85%), insomnia (65%), anxiety (69%), loss of appetite (69%), depressive mood (54%), shame (58%), staying home from social activities (54%), anger (54%) and interference with ability to work (27%). Sixty-one percent of these subjects were employed, and 7% reported absence from work due to IBS symptoms, leading to 14 days of absence from work due to bowel symptoms over the last year.

Based on a brief description of the condition, 17.6% of the population self-identified as suffering from IBS ($p < 0.001$ compared to Rome IV), and these were more likely to be female, but without significant age difference (28.2% of women vs. 14.9% of men, $p = 0.0003$, 45.7 ± 0.9 vs. 45.1 ± 0.5 years, NS). Concordance with the Rome IV criteria was only 17%. Thirty-two percent had consulted a physician over the last year (27% primary care, 13% a specialist; NS compared to Rome IV); colonoscopy was performed in 11% and radiological examination in 14% (NS compared to Rome IV). Subjects self-reporting with IBS attributed to these symptoms a major impact on daily life through associated fatigue (83%), irritability (83%), insomnia (65%), anxiety (59%), loss of appetite (61%), depressive mood (54%), shame (49%), staying home from social activities (50%), anger (40%) and interference with ability to work (24%). Sixty-seven percent of these subjects were employed and 19% reported absence from work due to bowel symptoms, generating a total of 134 days over the last year.

Conclusion: In the general population, the prevalence of self-reported "IBS" is three-fold higher than the prevalence of IBS according to Rome IV criteria and the concordance is very low. In the general population, compared to those fulfilling Rome IV criteria, self-reported IBS is associated with similar or higher impact on healthcare utilization, quality of life, and ability to work.

P1074 DOES BLINDING AFFECT THE OUTCOME OF FRUCTOSE BREATH TESTING IN PATIENTS WITH FUNCTIONAL GASTROINTESTINAL DISORDERS?

Introduction: The fructose breath test is widely used for the investigation of fructose intolerance and malabsorption as contributing factors to symptoms of functional gastrointestinal disorders (FGID). Additionally, it is useful in predicting responders to a dietary reduction of fermentable sugars (low FODMAP diet)(1). Patients with FGID are, however, well known to have high placebo response susceptibility. As the breath test is normally applied in open fashion, it is unknown what the contribution of knowledge of the substrate is to the test outcome.

Aims and Methods: The aim of this single-centre, placebo-controlled prospective trial was to compare the outcome of breath tests when fructose is given in open versus blinded fashion in successive patients with FGID. Identical breath tests were performed in randomized sequence at least one week apart with either a) water (neutral placebo), b) artificial sweetener (Assugrin®: cyclamate/saccharine, sweet placebo), c) fructose given double-blind or d) fructose given open. Breath samples were collected in 30 male and female patients with FGID (defined by Rome III criteria, mean age 29 ± 9 years) for measurement of hydrogen and methane concentrations, and GI symptom intensities (abdominal bloating, flatulence, fullness, nausea, diarrhoea, abdominal cramps or pain, borborygmi, and gastroesophageal reflux) were each scored on a 3-point Likert scale for 5 hours after substrate ingestion. Patients were not selected based on symptom or gas responses. The areas-under-the-curve (AUC) of the individual and aggregate GI symptom scores and of the breath hydrogen and methane concentrations were compared between substrate arms.

Abstract No: P1074
Table: Baseline-corrected means and standard deviations are shown.

	water	fructose open	fructose blind	artificial sweetener	p-value across all arms (Dunn's test, Bonferroni corrected)
AUC GI aggregate symptom score	1.42 ± 5.17	6.47 ± 9.04	4.37 ± 8.27	1.81 ± 3.98	0.01
AUC hydrogen concentration	−8.92 ± 18.94	23.39 ± 50.16	20.44 ± 53.09	−6.05 ± 26.12	0.002
AUC methane concentration	−1.16 ± 4.54	8.83 ± 21.74	5.32 ± 13.10	0.08 ± 9.22	0.02

Results: There were no significant differences between the open fructose and blinded fructose arms in the AUCs of any of the individual or aggregate GI symptom scores (see Table). However, the AUCs of the aggregate GI symptom scores were greater following open fructose than water ($p = 0.003$). There were no significant differences in the AUCs of either hydrogen or methane concentrations between open and blinded fructose breath tests, but hydrogen gas concentration AUCs were greater following open and blinded fructose than after water and artificial sweetener (all $p < 0.05$). A similar trend towards higher methane breath gas concentrations following open and blinded fructose than after water and artificial sweetener was seen. Blinding was maintained very effectively, as only 5 of 120 (4%) treatment substrates were attributed correctly by the patients.
[Baseline-corrected means and standard deviations are shown.]
Conclusion: The absence of significant differences in symptom scores and gas concentrations between breath tests with fructose given open or blinded clearly indicates that clinical breath testing can be performed in open fashion in patients with FGID. The comparisons of GI symptoms and breath gas concentrations between the neutral and sweet placebos and the fructose arms are marked by wide variability due to the inclusion of patients across the entire spectrum of responses, i.e. with and without fructose intolerance or malabsorption.
Disclosure: Sponsored by Forschungsstftung Hirslanden, Zurich, Switzerland.

P1075 BLOATING IN A LARGE OUTPATIENT POPULATION: DISCHARGE OR INVESTIGATE?

C. Zammit[1], P. Ellul[2], M. Vassallo[3]
[1]*Mater Dei Hospital, Department of Medicine, Msida, Malta*
[2]*Mater Dei Hospital, Mater Dei Hospital, Msida, Malta*
[3]*Mater Dei Hospital, Department of Medicine, La Valletta, Malta*

Contact E-Mail Address: catriona.zammit@gmail.com
Introduction: Bloating is a common presenting complaint and affects approximately up to 20% of the population, though objective abdominal distension only occurs in half of the cases. It can have a significant impact on the patient's everyday activities. Its severity may vary from transient without the need for treatment, to severe and debilitating symptoms that cause multiple outpatient clinic visits or even to the emergency department. However, its evaluation and management may be difficult, thus necessitating multiple medical appointments and investigations.
Aims and Methods: The aims of this study were to determine the prevalence of this symptom among patients presenting to a gastroenterology out-patient clinic and the pathologies that were diagnosed in this group of patients. This was a retrospective analysis of patients presenting to a single consultant gastroenterology secondary care out-patients clinic (2013–2015) where one of the symptoms was bloating. The clinical case notes and investigations (blood tests, faecal calprotectin, radiology and endoscopic procedures) were reviewed.
Results: From an overall cohort of 840 patients, 256 patients with bloating (73.4% females) were identified. The mean patient age was 42.4 (SD +/− 14.1) years. The mean time of follow up for these patients was 47.5 months (range: 20.5–71.3).
Other symptoms were: abdominal pain (73.8%), dyspepsia (32%), nausea (14.8%), vomiting (4.7%), bleeding pr (7%), change in bowel habit to diarrhoea (29.7%), change in bowel habit to constipation (17.6%) and weight loss (9%),
In 9.4% of patients the following pathologies were diagnosed: coeliac disease ($n = 6$), small bowel intussusception ($n = 1$); renal cell carcinoma ($n = 2$); endometrial carcinoma ($n = 1$); hypothyroidism ($n = 2$); ulcerative colitis ($n = 5$); small bowel Crohn's disease ($n = 3$); microscopic colitis ($n = 2$); unclassified inflammatory bowel disease ($n = 2$). All malignancies occurred in patients above the age of 50 years.
Conclusion: This data demonstrates that bloating contributes to a significant patient load in an out-patient setting as 30.5% of patients had this symptom. Routine blood investigations, a faecal calprotectin and abdominal ultrasonography are initial baseline investigations that should be considered in all such patients as approximately 10% of these patients had significant pathologies diagnosed.

Introduction: *Aloe barbadensis* Mill. has been suggested to reduce symptoms in patients with irritable bowel syndrome (IBS).
Aims and Methods: We aimed to determine the effects of a commercially available *Aloe barbadensis* Mill. (Aloe) extract AVH200®, on symptoms and fecal microbiota in patients with IBS, in a randomized, double-blind, placebo-controlled study. After a 2 week screening period, 173 patients with IBS according to the ROME III criteria, were randomized to active treatment ($n = 91$) (250 mg aloe extract, 60 mg ascorbic acid and inulin) or placebo ($n = 82$) (60 mg ascorbic acid and inulin), for 4 weeks. Patients completed IBS Symptom Severity Scoring (IBS-SSS) questionnaires on a weekly basis. Response was defined as a reduction of IBS-SSS ≥ 50, compared with baseline. Faecal samples were collected before and after the intervention from 52 patients and microbiota composition was evaluated by GA-map™ Dysbiosis Test of 54 DNA probes targeting ≥ 300 bacteria which were analyzed with Orthogonal Projections to Latent Structures Discriminatory Analysis (OPLS-DA) implementing a VIP cut-off of 0.7. Statistical analysis were carried out using non-parametric tests.
Results: In total, 160 IBS patients completed the study. The overall severity of IBS symptoms was reduced in patients receiving active treatment ($n = 84$; 242 (199–291) vs. 218 (138–281), $P < 0.001$) and placebo ($n = 76$; 236 (171–289) vs. 197 (126–258), $P < 0.001$) comparing baseline vs. end of intervention, without difference between the groups ($P = 0.61$). However, a reduction in overall symptom severity was recorded in diarrhea predominant patients (IBS-D) receiving active treatment ($n = 21$; 273 (196–330) vs. 226 (101–308), $P = 0.003$) but not placebo ($n = 22$; 229 (138–259) vs. 196 (118–238), $P = 0.07$), without difference between the groups ($P = 0.21$). Further, pain severity, pain frequency, bloating and daily life were similarly reduced in both groups (data not shown). However, bowel habit was improved by active treatment (70 (52–88) vs. 60 (41–81), $P = 0.001$), but not placebo (70 (46–85) vs. 66(46–80), $P = 0.17$), although without difference between the two groups ($P = 0.43$). The frequency of responders did not differ between active treatment ($n = 27$, 32%) and placebo ($n = 31$, 41%) ($P = 0.26$).
In the active treatment group, faecal microbiota profiles differed between responders ($n = 10$) and non-responders ($n = 14$) both before ($R2 = 0.96$, $Q2 = 0.55$) and after intervention ($R2 = 0.94$, $Q2 = 0.73$). The abundance of *Akkermansia muciniphila* was higher in responders than non-responders before (65.5 (35.8–187.3) vs. 3.5 (1–44), $P = 0.03$) but not after the intervention (54 (14.5–226.8) vs. 23 (1–106.78), $P = 0.32$). In the placebo group, the fecal microbiota profiles of responders ($n = 12$) and non-responders ($n = 16$) did not differ before or after the intervention.
Conclusion: Aloe extract and placebo were similarly effective in reducing overall symptoms of IBS patients, but a tendency towards better effect of aloe extract were seen in IBS-D patients. Further, faecal microbiota profiles may help predict IBS patients' responsiveness to aloe extract.

Introduction: Irritable bowel syndrome with diarrhea (IBS-D) is a functional gastrointestinal disorder with limited treatment options. We evaluated the efficacy and safety of eluxadoline, an FDA-approved mixed μ-opioid receptor (OR) and κ-OR agonist and δ-OR antagonist compared to placebo in IBS-D patients

who reported inadequate symptom control with prior use of loperamide, an over-the-counter μ-OR agonist.
Aims and Methods: Adults with IBS-D (Rome III criteria) who reported inadequate symptom control subsequent to loperamide use within the preceding 12 months were randomized 1:1 to placebo or eluxadoline 100 mg twice daily taken with food for 12 weeks. Patients recorded daily IBS-D symptoms, including worst abdominal pain (WAP) on a 0 to 10-point scale and stool consistency (evaluated by Bristol Stool Score [BSS]). The primary efficacy endpoint was the proportion of composite responders, defined as patients who met daily composite response criteria (WAP improvement by ≥40% **AND** BSS score <5 or absence of bowel movement accompanied by ≥40% WAP improvement compared to baseline) for at least 50% of treatment days, and had ≥60 days of diary entries over the 12-week treatment period
Results: 346 patients were enrolled. The majority (70%) were female, and mean age was 44 years. A significantly greater proportion of patients receiving eluxadoline achieved the primary composite responder endpoint compared to placebo (22.7% [39/172] vs. 10.3% [18/174]; p = 0.0022). Additionally, a higher proportion of patients achieved the secondary endpoints of improvements in stool consistency (27.9% [48/172] vs. 16.7% [29/174]; p = 0.0119) and WAP (43.6% [75/172] vs. 31.0% [54/174]; p = 0.0174) with eluxadoline than placebo, respectively. Throughout the 12-week study, a greater proportion of eluxadoline patients met the monthly composite responder endpoint compared with placebo (Weeks 1–4: 14.0% vs. 6.9%, p = 0.0330; Weeks 5–8: 26.7% vs. 14.9%, p = 0.0063; Weeks 9–12: 30.8% vs. 16.7%, p = 0.0018). A comparable number of patients reported treatment-emergent adverse events (TEAEs) with eluxadoline (124 events; 37.4% [64/171]) and placebo (112 events, 35.3% [61/173]). More patients discontinued treatment due to TEAEs with eluxadoline compared with placebo (10 vs. 3). No treatment-related serious AE was reported.
Conclusion: Eluxadoline appears safe, effective, and well tolerated for treating IBS-D symptoms in patients who report inadequate symptom control with prior loperamide use.

[3]*Hospital "Universitario Infanta Elena, Psychiatry, Valdemoro (Madrid), Spain*

Contact E-Mail Address: marta_tejedor@hotmail.com
Introduction: Functional gastrointestinal disorders (FGIDs) are prevalent and resource consuming. Biopsychosocial interventions have proven useful for symptom control. Shared medical appointments have been successfully used in other diseases to reduce waiting times, limit costs and increase patient satisfaction, but their use in FGIDs is still limited. No specific multidisciplinary programmes have been developed for FGIDs.
Aims and Methods: A multidisciplinary (Gastroenterology, Dietetics, Psychiatry) approach was used in a group of patients diagnosed with FGIDs attending shared medical appointments. Efficacy of a series of non-pharmacological interventions (dietary modifications, psychoeducation, stress and anxiety control) over a 4-month period was assessed on several health indicators (presence and intensity of gastrointestinal (GI) and psychological symptoms, drug use) and a dietary journal. (Table 1: time course of the intervention).
Results: 25 patients have been included so far. 80% were women. Mean age was 46.2 years (range 29–68). Initial diagnoses were, as per the ROME IV criteria (1, 2): 36% irritable bowel syndrome, 12% functional diarrhoea, 32% functional abdominal distension, and 88% dyspepsia. 96% of patients attended at least one formative session. The severity of the GI symptoms (3) improved from a baseline score of 324.8 ± 16.7 points (severe) to 104 ± 28.4 (mild) (p < 0.00005). Adherence to low fodmap diet was good (7.3 ± 1.4 vs 1.4 ± 1.1 servings of high fodmap foods per day, p = 0.025). A trend towards a reduction in waist circumference (97.4 ± 8.9 vs 92.8 ± 8.3 cm, p = 0.076) in the absence of significant changes in body mass index suggests an improvement in abdominal bloating. The number of drug groups used during the 6 months prior to the intervention was 2.7 ± 0.4, and it was reduced to 0 ± 0 (p = 0.0037). Baseline anxiety and depression scores (4) were within the pathological and borderline range respectively and did not improve significantly after the intervention (11.4 ± 0.8 vs 10.2 ± 2.3 points for anxiety; 7.2 ± 1.1 vs 6.6 ± 2.8 for depression).
Conclusion: A multidisciplinary shared medical appointment approach to implement non-pharmacological measures in the treatment of FGIDs is useful to alleviate GI symptoms in these patients. A stronger psychological intervention might be needed for adequate control of anxiety. A dietary reintroduction phase is currently being implemented to tailor the individual needs and prevent nutritional deficits. A 6 and 12-month post intervention assessment will be needed to see whether improvement persists.

Introduction: Numerous studies have shown that hypnotherapy (HT) improves the symptoms of irritable bowel syndrome (IBS) using clinical outcome measures. In light of the increasing interest in capturing the patient's perception of their illness and treatment, it was felt it would be helpful to record how patients perceive the hypnotherapeutic process, on which there is currently little information.
Aims and Methods: In addition to measuring symptom change, we have recently started to record the patient's perception of hypnotherapy for their IBS, including their expectations, and now report the results for the first 50 patients.
50 consecutive IBS patients (38 females and 12 males, age range 18–76) attending for hypnotherapy were asked to complete questionnaires recording their IBS symptom severity (IBS SSS), quality of life, non-colonic symptoms, anxiety and depression before and after treatment. In addition, they completed questionnaires detailing their perception of HT, other people's perception of HT and their expectations about the efficacy of HT. Their perceptions about the hypnotherapeutic process were assessed quantitatively and also qualitatively using patient descriptions. Furthermore, the analysis compared the characteristics of responders and non-responders.
Results: 39 out of 50 patients (78%, P < 0.001) responded to treatment (50 point or more reduction in IBS SSS), which is exactly consistent with our previously published data. Pain scores, non-colonic symptoms, quality of life, anxiety and depression also significantly improved after HT (all P < 0.001). When asked how patients felt before treatment, 52% of responses portrayed hypnotherapy negatively compared to 3% after treatment. The relatives and doctors of patients were generally supportive of HT although one cognitive behavioral therapist advised against it. In responders, 19 patients (48.7%) expected hypnotherapy to be effective prior to starting it, whereas in non-responders, 7 (64%) expected treatment to be successful. Interestingly, 9 of 11 non-responders (82%) considered treatment worthwhile despite no significant effect on their symptoms. This may be because 46 patients (92% of all patients) had found HT helped them with other issues, such as dealing with stressful situations or poor sleep.
Conclusion: Although initially being perceived negatively, hypnotherapy significantly improved symptoms and resulted in other benefits not related to the gastrointestinal system. Interestingly, those with greater expectation about treatment did not seem to do quite so well, suggesting that high expectations are not necessary for a good outcome.

Introduction: The pathogenesis of IBS is multifactorial and not completely understood. Epidemiological observations have demonstrated the development of IBS symptoms following disruption of the individual 'normal' microbiota and multiple studies have described differences between the microbiome in IBS patients and healthy cohorts. While probiotic therapy for IBS is the subject of intense investigation, its mechanisms of action are not clear.

Aims and Methods: We aimed to evaluate the impact of a multispecies probiotic on the enteric microbiota composition in women with diarrhea-predominant irritable bowel syndrome (IBS-D) and to determine whether these effects are associated with changes in IBS symptoms or inflammatory markers.

In this double blind, placebo-controlled study, Rome III IBS-D women completed a two-week run-in period. Eligible women were then assigned at random to a probiotic capsule (BIO- 25) or an indistinguishable placebo, twice daily for 8 weeks. IBS symptoms and stool consistency were rated daily by visual analogue scales and the Bristol stool scale. High-sensitive C-reactive protein was tested at baseline and 4 and 8 weeks. Fecal calprotectin and microbial composition (diversity and taxa) were tested at baseline and 8 weeks. Microbial sequencing of the 16S rRNA was performed using the pyrosequencing platform. Data was analyzed to compare patients who responded to treatment and those who did not using QIIME and Linear discriminate analysis with effect size estimation (LEfSe).

Results: One-hundred and seventy-two IBS-D patients were recruited, and 107 eligible patients were allocated to the intervention (n = 54) or placebo (n = 53) group. Compared to placebo, BIO-25 did not result in significant fecal microbial alterations, except for higher *Lactobacillus* levels in the BIO-25 group (P = 0.002). Among patients receiving BIO-25, the prevalence of specific microbial groups at baseline was predictive of the response to probiotic therapy: higher proportions of *Bilophila* at baseline were associated (P = 0.003) with symptomatic relief (clinical response) and higher proportions of *Hemophilus* (P = 0.01), *Enterobacter* (P = 0.05), *Slackia* (P = 0.03), *Faecalibacterium* (P = 0.03) *and Odoribacter* (P = 0.05) were associated with a decrease in CRP/calprotectin levels (inflammatory response) compared to the non-responders (Table 1).

Parameter	Genus	Non-responders	Responders	P-value
Bristol stool scale		n = 39	n = 11	
	Bilophilia	0.0006	0.0022	0.02
Abdominal pain reduction		n = 30	n = 21	
	Bilophilia	0.0014	0.0025	0.03
hs-CRP		n = 32	n = 15	
	Haemophilus	0.0013	0.0027	0.01
	Enterobacter	0.0006	0.0026	0.05
	Slackia	0.0006	0.0016	0.03
Fecal calprotectin		n = 25	n = 15	
	Faecalibacterium	0.076	0.088	0.03
	Odoribacter	0.0018	0.0027	0.05
	Ruminococcus	0.132	0.111	0.01
	Lactococcus	0.0014	0.0002	0.02

[Table 1 – Proportions of fecal bacterial genera associated with IBS response to the probiotic Bio-25].

Conclusion: This study provides insights into potential microbial composition tools for the identification of female IBS-D patients who may respond to probiotic therapy. Additional studies should be performed with other probiotic agents to replicate these findings.

Introduction: Structured patient group education (IBS School), has previously been evaluated and found efficacious for symptom improvement in patients with irritable bowel syndrome (IBS) (Ringstrom et al 2012). In this randomized controlled study we compared the effects with a similar education provided via the internet. We hypothesized that patient education provided via the internet would give effects comparable to patient education in a group format.

Aims and Methods: The study population consists of IBS patients >18 years, referred to our unit to participate in the IBS School. Patients were included in blocks of 20 and were then randomized 1:1 to IBS School in group-format or via Internet. A total number of 120 patients were included in the study (57 in the group condition and 63 in the internet condition). The IBS school in group-format consisted of three, two-hour sessions held once per week with eight to ten patients in each group. A nurse and a dietician lead the sessions. At the first session, general information was provided about IBS, symptoms, pathophysiology and treatment options. At the second session, food-related issues were discussed and at the third session the effects of other life style factors like stress, physical activity and relaxation were discussed. The participants in the Internet group received texts in a stepwise fashion over the three weeks, with the same information that were covered in the group condition. The patients were also able to communicate reflections and questions concerning the written information with the nurse and the dietician via e-mail. They were also encouraged to attend a closed online forum where they had the opportunity to discuss and reflect over information material from the last week with other patients. GI symptom severity (IBS-SSS and GSRS-IBS), GI-specific anxiety (VSI), self-rated disease knowledge (VAS 0–100 score), anxiety and depression (HADS) were assessed with validated questionnaires at baseline and 6 months after the intervention.

Results: For the primary endpoint, the IBS-SSS, 90 patients (75%) had provided follow-up data. Taken together, both groups showed significant improvement of GI symptoms, measured with the IBS-SSS ($p < .001$) and GSRS-IBS ($p < .001$), respectively, but there were no differences between the groups (p = . 30 and p = .73, respectively). Both groups showed improvement in GI-specific anxiety ($p < .001$), self-rated disease knowledge ($p < .001$), and anxiety (p = .005). There were no differences between the groups in any of these outcomes (p = .31, p = .87, and p = .46, respectively). There was no overall improvement in symptoms of depression (p = .54) and no differences between the groups (p = .93). See Table 1 for means and standard deviations for the two groups at the assessment points.

Conclusion: This study demonstrates that patient education for patients with IBS can both be delivered in traditional group format and over the internet with significant improvements in GI symptom severity, GI-specific anxiety, general anxiety, and self-rated disease knowledge and with comparable effects between the two education formats.

	Baseline		6- months follow-up	
Outcome	Group	Internet	Group	Internet
IBS-SSS	297.5 (103.4)	288.9 (77.3)	243.3 (102.2)	246.1(101,1)
GSRS-IBS	51.3 (14.3)	50.4 (10.3)	45.1(14.5)	43.5 (13.5)
VSI	40.3 (20.0)	39.2 (18.8)	34.2 (20.8)	30.8 (18.5)
Knowledge (VAS 0–100)	48.3 (21.8)	40.9 (22.6)	71.5 (17.2)	66.0 (19.0)
HADS (Depression)	8.2 (4.3)	7.6 (4.4)	7.4 (4.9)	6.2 (4.2)
HADS (Anxiety)	5.3 (3.9)	5.0 (4.2)	4.9 (3.5)	4.9 (3.7)

P1082 USE OF COMPLEMENTARY AND ALTERNATIVE MEDICINE BY PATIENTS WITH ROMA IV CRITERIA FOR IRRITABLE BOWEL SYNDROME: A SINGLE-CENTER ITALIAN SURVEY

T. Larussa, M. Rossi, E. Suraci, R. Marasco, M. Imeneo, F. Luzza
Department of Health Sciences – Magna Graecia University of Catanzaro, Catanzaro, Italy

Contact E-Mail Address: tiziana.larussa@gmail.com

Introduction: Complementary and alternative medicine (CAM) is an emerging option for irritable bowel syndrome (IBS), whose features have been recently revised by the Rome IV criteria.

Aims and Methods: The study was conducted to evaluate the impact of CAM in IBS patients as assessed by the Rome IV criteria. Consecutive patients referring for IBS were re-evaluated according to the Rome IV criteria. Demographic features and characteristics potentially associated with the use of CAM were collected. A validated, self-administered, survey questionnaire dealing with CAM and patients' level of knowledge, motivation, perception, and information seeking-behavior toward the use of CAM was analyzed. Multivariate logistic regression analysis was performed in order to identify predictors of CAM use among participants.

Results: Among 156 patients claiming IBS, 137 (88%) met the Rome IV criteria and 62 of them (45%) were CAM users. Biologically based therapy was the most chosen CAM (78%). Mind-body interventions and homeopathy account for the 11% and 5% of preferences, respectively, while none had ever used energy therapies. Significant risk factors (adjusted odd ratio, 95% confidence interval) for the use of CAM were female gender (7.22, 2.31–22.51), higher BMI (1.16, 1.02–1.33), not having children (0.25, 0.07–0.95), and a good knowledge of CAM (4.46, 1.73–11.45). Only 19% of patients used CAM due to medical advice, while 34% of them indicating media, such as television and newspapers, as a source, and 24% citing the internet. Over half (51%) thought it was a ''more natural'' approach, 25% were motivated because of the lack of therapeutic options offered by traditional medicine, while 24% expressed apprehension towards adverse drug reactions. Even though a minority of patients (16%) had full satisfaction from CAM, 81% of users would repeat the CAM experience for their IBS symptoms.

Conclusion: In a native local resident setting of IBS patients from southern Italy, the Rome IV criteria confirmed their specificity in diagnosing IBS, compared to the Rome III criteria. The widespread use of CAM in IBS, the patients' belief in its safety, and their vocation to re-use it, suggest that knowledge of health-care providers and patient education should be improved.

P1083 THE MEANING OF BILE ACIDS AND VIOLATIONS OF MICROBIAL METABOLISM IN THE COLON IN THE PATHOGENIC MECHANISM OF DIARRHEA IN PATIENTS THAT SUSTAINED CHOLECYSTECTOMY OR RESECTION OF THE SMALL INTESTINE

S. Silvestrova, L. Indeykina, T. Kuzmina, E. Sabelnikova, A. Parfenov
Moscow Clinical Research Center n.a. A.S. Loginov, Moscow, Russian Federation

Contact E-Mail Address: syusilvestrova@yandex.ru

Introduction: Cholecystectomy and resection of the small intestine result in increased risk of bile acid diarrhea development due to a large amount of bile acids (BA) entering the colon. Long-term presence of BA in the colon may result in violation of microbiota composition and inflammation of its mucous membrane.

Aims and Methods: The aim of this work is to evaluate the influence of BA on colon microbiocenosis in patients with chronic diarrhea that had cholecystectomy or and resection of the small intestine.

18 patients with chronic diarrhea were studied that had cholecystectomy (group 1), as well as 20 patients with post-resection short small intestine syndrome (group 2). Daily BA excretion was determined in the feces of all patients with the help of spectrophotometric enzymatic analysis. Metabolic activity of colon microflora was evaluated according to the content of short-chain fatty acids (SCFA) – acetic, propionic, butyric (Bu), valeric, caproic acids and their isoforms in coprofiltrates. SCFA were identified by gas-liquid chromatography.

Results: In group 1 patients, average daily BA content in feces amounted to 564.5+ 116.3 mg/day, in group 2 patients – 1,674.8+440.1 mg/day, $p < 0.012$. In both groups, daily BA excretion with feces considerably exceeded the norm (50–200 mg/ day), $p < 0.001$. The data obtained confirmed the leading role of BA in diarrhea development in these patients. Metabolomic study of the large bowel microbiocenosis showed pronounced reduction in metabolic activity of colon microflora in the examined patients. Average values of total SCFA concentration (TSCFA) made up 4.11 + 1.81 mg/g vs norm 10.6 + 0.23 mg/g, $p < 0.005$. In this case, the value of TSCFA in the 1st group was somewhat higher – 4.79 + 0.63 mg/g than in the 2nd group – 3.61 + 0.27 mg/g (NS). The analysis showed true correlation level between the TSCFA and daily BA excretion: $r = -0.42$, $p = 0.05$. Special attention is drawn by reduced concentration of butyrate (Bu conc.) and its share (%Bu) in the total concentration of metabolites. It reached 1% with the norm of 16% in 61% of the studied patients. It is butyrate that shows high correlation with BA concentration: Bu conc. – BA conc. $r = -0.49$, $p = 0.03$; %Bu – BA conc. $r = -0.52$. $p = 0.02$.

Conclusion: The reason for diarrhea development in patients that had cholecystectomy or resection of the small intestine is high BA concentration in the colon. Besides, BA considerably suppress bacterial metabolism in the colon. Butyrate-producing bacteria suffer the most. As butyrate is an energy substrate for colonocytes, disease chronization may entail progressing dystrophy of colon mucosal epithelium.

P1084 PSYCHOLOGICAL MORBIDITY AND IMPACT ON THE QUALITY OF LIFE OF BENIGN ANORECTAL DISORDERS

R. Morais, R. Coelho, A.L. Santos, P. Costa-Moreira, G. Macedo
Serviço de Gastrenterologia, Centro Hospitalar São João, Porto, Portugal

Contact E-Mail Address: ruimorais20@gmail.com

Introduction: Benign anorectal disorders (BADs) are very common, with associated symptoms that may have a significant impact on the quality of life.

Aims and Methods: The aim of the study was to evaluate the prevalence of anxiety/depression symptoms and quality of life (QOL) in patients with BADs. Single-center prospective study that included consecutive patients with BADs evaluated at the Coloproctology outpatient clinic and a group of healthy volunteers (blood donors). Psychological morbidity was assessed using the Hospital Anxiety and Depression Scale (HADS) questionnaire, including anxiety (HADS-A) and depression (HADS-D) subscales. A HADS score greater than 8 was considered abnormal. The QOL was evaluated using the *Short Form (36) Health Survey* (SF36), summarized in a physical (PCS) and mental (MCS) component score (with lower scores representing a lower QOL).

Results: Fifty-one participants (31 patients and 20 healthy volunteers) were included, 59% women, with a median age of 52 years (IQR 38–62). There were no differences between the two groups regarding gender ($p = 0.250$) but the control group was younger (median 45 vs. 59 years, $p = 0.002$) and had a higher education (high school 55% vs. 26%, $p = 0.044$). The main BADs were hemorrhoids (32%), pruritus ani (29%) and anal fissure (19%). More than one BAD was present in 23% of patients. Compared with controls, patients with BADs had higher mean scores of HADS-A (10 ± 4 vs. 4 ± 3, $p < 0.001$) and HADS-D (7 ± 4 vs. 2 ± 3, $p < 0.001$). In the BADs group the proportion of patients with abnormal scores of HADS-A (77% vs. 10%, $p < 0.001$) and HADS-D (47% vs. 10%, $p = 0.012$) was significantly greater than in controls. Mean scores of PCS (46 ± 10 vs. 54 ± 5, $p < 0.001$) and MCS (31 ± 22 vs. 48 ± 17, $p = 0.004$) were lower in the BADs group. In the subanalysis of the BADs group the presence of pruritus ani was significantly associated with a higher HADS-A score (13 ± 5 vs. 9 ± 4; $p = 0.013$) and lower MCS (16 ± 20 vs. 35 ± 20; $p = 0.031$). The presence of more than one BAD showed a tendency for a lower PCS (39 ± 7 vs. 48 ± 10; $p = 0.057$) and MCS (16 ± 15 vs. 34 ± 22; $p = 0.06$) but it did not reach statistical significance.

Conclusion: Bening anorectal disorders are associated with a considerable prevalence of anxiety/depression symptoms and a negative impact on quality of life. A high degree of suspicion of an undiagnosed BADs-associated psychological disorder may be important, in order to allow for a timely and adequate therapeutic approach.

P1085 ANATOMICAL AND FUNCTIONAL FEATURES OF THE INTERNAL RECTAL PROLAPSE DETERMINED WITH 3D ENDORECTAL ULTRASONOGRAPHY AND HIGH-RESOLUTION ANORECTAL MANOMETRY. AN OBSERVATIONAL CASE-CONTROL STUDY

S. Tolone, L. Brusciano, G. del Genio, P. Limongelli, M. Lanza Volpe, G. Terracciano, G. Gualtieri, S. Parisi, L. Docimo
University of Campania, Surgery, Naples, Italy

Contact E-Mail Address: salvatore.tolone@unina2.it

Introduction: Approximately half of constipated patients suffer from obstructed defecation. Obstructed defecation syndrome (ODS) is the inability to empty the rectum satisfactorily during defecation and is well defined in the Rome IV. Internal Rectal Prolapse (IRP), a full-thickness intussusception of the rectum, often associated with rectocele, plays an important role in the pathophysiology of ODS. Furthermore, there are scarce data on rectal anatomical evaluation and its relationship with a possible impairment of rectal function.

Aims and Methods: The aim was to investigate whether any correlation between rectal wall thickness (RWT) and rectal pressure (RP), determined by means of 3D endorectal ultrasound (EUS) and high-resolution anorectal manometry (HRAM), can offer new insights in the pathophysiology of patients with ODS caused by IRP.

Patients with ODS caused by IRP were selected. Healthy volunteers (HVs) served as controls and to define normal data. Standardized clinical questionnaire were administered. Subjects underwent 3D EUS to measure RWT and HRAM to measure pushing endorectal pressure (PEP), and recto-anal gradient. Total rectal wall volume (TRWV) was calculated; 3 TRWV grades were defined according to HVs percentile. Relationships between clinical score, HRAM features and TRWV were investigated.

Results: We enrolled 35 ODS patients and 25 HVs. HVs showed 68.45 cm3 median TRWV value, mean PEP was 51.2+-6.4 mmHg, mean recto-anal gradient was 20.1+-5.8 mmHg. Patients showed a marked decrease in TRWV (median 57.32 cm3, $p < 0.001$ vs HVs). Three patients had normal TRWV, 22 had mild pathological TRWV ($p < 0.001$), and 10 had severe pathological TRWV ($p < 0.001$), Table 1. Patients had a significantly decrease in mean PEP and recto-anal gradient (35.0+-3.90 mmHg, $p < 0.001$ and 10.2+-0.8 mmHg, $p < 0.001$). Eight patients had normal PEP, 22 had slightly hypotonic PEP ($p < 0.05$) and 5 had markedly hypotonic PEP ($p < 0.001$). A linear correlation was found between patients with a markedly reduced TRWV and those with a markedly hypotonic PEP (r 0.8).

Conclusion: This study suggested that patients with ODS can have a reduced muscular function of the rectal wall, leading to a decreased pushing ability during defecation. HRAM and 3D endoanal ultrasound should be performed in the ODS assessment, in the effort to better understand anatomic-functional profile and employ the best patient-tailored approach.

	Healthy Volunteers N. 25 mean ± SD (IQR)	Patients N 35 mean ± SD (IQR)	P Value

Contact E-Mail Address: cambombo@hotmail.com
Introduction: Faecal incontinence is a complaint that some type 2 diabetic patients frequently refer[1,2]. The factors involved with are not well known.
Aims and Methods: The aim of this study was to compare the frequency of faecal incontinence between type 2 diabetic patients and non diabetic healthy individuals and to analyse some factors involved in this perturbation in diabetics.
A questioner of Gastrointestinal Symptoms Rating Scale was performed to 140 type 2 diabetics and 132 non diabetic healthy individuals, matched by age and gender.
Results: The frequency of faecal incontinence in diabetics vs. non-diabetics was 14.3% vs. 3.1%, $p<0.01$. According to the severity, the frequency of faecal incontinence between diabetics vs. non diabetics was the follow: minor symptoms, 3.6% vs. 2.3%; moderate symptoms, 7.9% vs. 0.8%; severe symptoms, 2.1% vs. 0.0%; very severe symptoms, 0.7% vs. 0.0%, $p=0.03$.
When analysing the frequency of faecal incontinence in diabetics according to the disease duration, ≤10 years vs. >10 years the results was 9.5% vs. 24%, $p<0.01$. The symptoms severity was also significantly higher in diabetics with more than 10 years of disease, $p=0.01$. In diabetic patients, age, gender and glycaemia control did not influence the frequency and severity of faecal incontinence.
Conclusion: 1- Faecal Incontinence is more frequent and more severe in type 2 diabetics than non diabetic healthy individuals. 2- Diabetes duration influences the frequency and the severity of faecal incontinence. 3- Age, gender and glycaemia control did not influence the frequency and the severity of faecal incontinence in diabetic patients.

Introduction: Patients with pelvic floor dysfunctions may benefit of biofeedback therapy (BFT), before considering surgical treatment for coexisting anomalies. The efficacy of BFT has been reported to be an effective treatment of fecal incontinence (FI) and dyssynergic defecation (DD).
Aims and Methods: To evaluate the effect of BFT in patients with pelvic floor dysfunctions. The population referred to the outpatient Unit of Gastroenterology of two Italian Hospitals, in Rome and Milan, included 125 patients (M 16%, F 84%), mean age 64 ± 17 s.d. (range 16–95 year) with DD (74.4%) and FI (25.6%). All patients received behavioural treatments such as anal sphincter exercises/pelvic floor muscle training with 8 sessions of BFT, in a 3-month period. Clinical presentation (history, symptom profile and severity) and anorectal physiological evaluation (digital examination, manometry, rectal sensory testing, balloon expulsion test) were performed before and after BFT. Improvement of resting/squeezing pressure and reduction in laxatives therapy were considered as clinical improvement of FI and DD, respectively.
Results: In the FI group (F 94%), 44% of patients reported a complete resolution of symptoms, 53% had a considerable improvement, 3% no effect. Resting pressure increased from 42 ± 28 s.d. mmHg to 53 ± 17 s.d. mmHg after BFT, squeezing pressure from 96 ± 28 mmHg to 117 ± 24 mmHg; the rectal volume for first sensation from 37 ± 12ml to 34 ± 11ml.
In the DD group (F 81%), 41% of patients reported a complete resolution of symptoms, 52% considerable improvement, 7% had no effect. Resting pressure and rectal volume for first sensation were normal at baseline (73 ± 21 mmHg and 41 ± 30 ml, respectively). Before BFT, 46% of patients had no complete relaxation straining, 68% had a failure of balloon expulsion test (EBT). After BFT, 69% of patients had a complete relaxation during straining and 84% were able to expel the balloon.
Conclusion: BFT is considered an effective treatment for DD and FI and is widely used. Our data confirm the ability of BFT to improve manometric parameters and clinical symptoms of pelvic floor dysfunctions.

Contact E-Mail Address: silvia.speroni@studenti.unipr.it
Introduction: Autoimmune gastritis (AG) is a chronic disease in which anti-parietal cell antibodies cause an inflammatory damage to the gastric mucosa, leading to parietal cell atrophy, reduction of the acid secretion and consequently, hypergastrinemia. Although it is generally associated with few symptoms or none at all, it represents a precancerous condition that warrants an appropriate follow-up due to the increased risk of developing gastric adenocarcinoma and neuroendocrine neoplasms.
Aims and Methods: The aim of the study was to evaluate the prevalence of the following autoimmune diseases in the general population: Hashimoto's thyroiditis (HT), celiac disease (CD), rheumatoid arthritis (RA), psoriatic arthritis (PA), Sjögren's syndrome (SS) and vitiligo (VI), and to assess cases of patients with multiple autoimmune diseases.
The secondary aim was to investigate in these patients the prevalence of chronic atrophic AG through a non-invasive method, and to evaluate its usefulness for the diagnosis of AG in patients affected primarily by a different autoimmune disease. The study was performed at a tertiary regional hospital and patients affected by the mentioned autoimmune conditions were enrolled through the specific diagnosis code, according with Italian Health System rules, obtaining a population sample of 5291 patients (4299 F, mean age 51.9 ± 17.6); 609 of them (532 F, mean age 52.4 ± 14.3) underwent a non-invasive evaluation of gastric functionality through the serum dosage of pepsinogen I (PGI) and gastrin-17 (G-17) (Biohit Oyj, Finland). Accordingly to literature, patients were considered affected by gastric atrophy when PGI < 30 μg/l and G-17 > 7 pmol/l.
Results: The overall prevalence of the six studied autoimmune diseases in the population sample was 2.84% (1.85% for HT, 0.30% for CD, 0.40% for RA, 0.26% for PA and 0.06% for SS); the prevalence of VI wasn't assessable for incomplete data. Among the 609 patients evaluated in the study, 22 were affected by more than one autoimmune disease: 7 HT+CD (5 F, mean age 41.1 ± 8.3), 4 HT+VI (3 F, mean age 49.3 ± 21.7), 4 HT+PA (4 F, mean age 59.1 ± 11.9), 3 HT+RA (3 F mean age 62.8 ± 7.7), 1 HT+SS (1 F, 44.4 y.o.), 1 RA+PA (0 F, 75.2 y.o.), 1 RA+SS (1 F, 42.4 y.o.) and 1 HT+CD+SS (1 F, 43.1 y.o.).

Gastric atrophy was found in 97 patients (15.9%); only patients affected by CD didńt show cases of atrophy, neither as a single disease, neither in association.
Conclusion: Atrophic gastritis is more frequently found in patients with autoimmune diseases compared to the general population. The serological evaluation of PGI and G-17 can be a useful non-invasive method for the assessment of the presence of chronic atrophic AG in asymptomatic patients affected by autoimmune diseases.

Introduction: Autoimmune gastritis (AG) is a chronic disease that affects the corpus-fundus of the stomach, and is characterized by the development of two types of auto-antibodies: anti-parietal cells antibodies (APCA) and anti-intrinsic factor antibodies (AIFA). The hypergastrinemia that ensues as a consequence of gastric cell destruction and hypochlorhidia increase the risk of adenocarcinoma and neuroendocrine tumors; an early diagnosis and an appropriate follow-up are therefore warranted. AG is usually diagnosed using a combination of APCA positivity and histological criteria. However, the latter is an invasive and costly method, and lacks an evaluation of gastric function.
Aims and Methods: The aim of this study was to assess the usefulness of two serological gastric function markers, pepsinogen I (PGI) and gastrin-17 (G-17), in association with APCA determination, in the evaluation of AG.
A cohort of patients with autoimmune diseases who, as part of our tertiary hospital protocol, underwent routine upper endoscopy with histological evaluation (two antral, one angularis, and two corpus biopsies) for the exclusion of autoimmune gastritis, were considered for this study. All patients were also evaluated from a functional standpoint, with the non-invasive determination of serum pepsinogen I (PGI) and gastrin-17 (G-17). Cut-off values of PGI < 30 µg/l and G-17 > 7 pmol/l were considered diagnostic for atrophic gastritis of the stomach body and fundus. APCA dosage was also performed in all patients, and a title of $> 1/80$ was considered positive.
Results: A total of 237 patients (F = 205, mean age = 54.6 ± 14.8 years) were included in the study. Stomach body atrophy was histologically determined in 97 patients (AG group). PGI and G-17 were significantly reduced in patients with body mucosal atrophy (PGI mean value 16.63 ± 15.38; G-17 mean value 88.66 ± 99.78), with respect to patients without this histological feature (non-AG group) $p < 0.0001$. APCA were more frequently found in the AG group (87/97, 89.69%) than in the non-AG group (78/140, 55.71%) ($p < 0.0001$).
Conclusion: The positivity of APCA in patients with autoimmune diseases is considerable even in the absence of histological and functional features of AG. On the other hand, histological damage well correlates with impaired gastric function. Thus, a gastric function evaluation including determination of PGI and G-17 could be a useful and cost-effective method for early stomach body atrophy, especially in asymptomatic patients without indication for performing upper endoscopy. Finally, an evaluation of the isolate presence of APCA is inadequate and should be integrated with gastric functional markers (PG I and G-17) that adequately reflect both disease presence and severity.

Introduction: It is known that increased intraepithelial lymphocyte (IEL) infiltration of gastric mucosa may be associated with active coeliac disease and *Helicobacter pylori* (HP)-induced gastritis. However, there are no data regarding lymphocytic infiltration of the gastric corpus in patients suffering from autoimmune atrophic gastritis (AAG), an organ-specific disease where T-lymphocytes have a major pathogenic role.
Aims and Methods: We aimed at assessing the number of CD3 and CD8-positive IELs infiltrating the gastric corpus mucosa of patients affected by AAG, in comparison to healthy controls (HC). Patients with HP-induced gastritis and untreated coeliac disease (UCD) were studied as positive controls. We evaluated sections from paraffin-embedded biopsies of gastric corpus of 8 patients with severe AAG (mean age 54 ± 12 years, F:M ratio 2:1), 9 HC (mean age 52 ± 14 years, F:M ratio 1.5:1), 8 patients with HP-induced gastritis (mean age 42 ± 7 years, F:M ratio 1:1) and 6 patients with CD at diagnosis (mean age 32 ± 16 years, F:M ratio 1:1). CD3- and CD8-positivive IELs were evaluated through immunoperoxidase staining, counted *per* 100 epithelial cells. IELs count was divided in superficial (glands apex) and deep (glands crypt).
Results: In the gastric corpus of AAG patients, both deep CD3-positive IELs (mean 12.8 ± 3.5) and deep CD8-positive IELs (mean 13.7 ± 3.9) were significantly ($p < 0.01$) higher in comparison to those of HC (mean 4.9 ± 1.2 and 5.5 ± 2.5, respectively), those of HP-induced gastritis (mean 4.1 ± 2.1 and 3.1 ± 0.8, respectively), and those of UCD (6.8 ± 3.6 and 4.7 ± 1.4, respectively). Regarding superficial IELs count, no statistical differences were seen among the four groups for both CD3- and CD8-positive cells (complete data shown in Figure). None of the patients fulfilled the criteria of lymphocytic gastritis (i.e., IELs > 25/100 cells).
Conclusion: We here described an increased deep IEL infiltration of the stomach corpus of AAG patients as compared to both negative and positive controls. This feature should raise the suspicion of AAG even in the absence of anti-parietal cell antibodies and may be ascribed as a peculiar feature of this condition. Further data are needed in order to confirm this hypothesis.

Introduction: Peptic ulcer is one of the most common gastrointestinal diseases. Excessive ethanol ingestion results in gastritis characterized by mucosal edema, subepithelial hemorrhages, cellular exfoliation, and inflammatory cell infiltration. Caffeic acid is a natural phenolic compound found in many plants and present in diets as part of fruits, vegetables, tea and wine. It has been reported to have broad spectrum of bioactive activities including antidiabetic, antihypertensive, antioxidant, immunomodulatory, anti-inflammatory and neuroprotective properties.
Aims and Methods: Aim of the study is to investigate the anti-ulcerative effects of caffeic acid on ethanol induced ulcer model and to determine the pathways that are involved in action mechanism of caffeic acid. Following a 18-h starvation period, ulcer was induced in Sprague-Dawley rats (250–300g) by intragastric administration of absolute ethanol while control group received saline. 60 minutes before ulcer induction, rats were treated with either 1 ml 10% tween-80 as vehicle or caffeic-acid (100, 250 or 500 mg/kg dissolved in 1ml vehicle, per oral). 250 mg/kg of caffeic acid was found to be most efficient dose. To elucidate the roles of nitric oxide (NO) and cholinergic pathway, 10 mg/kg L-NAME or 1 mg/kg atropine was administered 30 minutes before 250 mg/kg of caffeic acid treatment to ulcer induced rats. All rats were decapitated 60 minutes after ulcer induction and stomach samples were scored macroscopically, and analyzed for myeloperoxidase activity (MPO; index of tissue neutrophil infiltration), malondialdehyde (MDA; an end product of lipid peroxidation) and glutathione (GSH; a key antioxidant) levels. Student's t-test was used for statistical analyses. Values of $p < 0.05$ was regarded as significant.
Results: Ethanol administration resulted in an increase in macroscopic damage scores ($p < 0.001$) and only 250 mg/kg caffeic acid treatment reduced macroscopic damage score significantly ($p < 0.05$). In addition, increased gastric MDA levels ($p < 0.001$) and MPO ($p < 0.01$) activity with concomitant decrease in GSH levels were measured with the ulcer induction. Treatment with 250 mg/kg caffeic acid decreased MDA levels ($p < 0.05$). Both 250 mg/kg and 500 mg/kg caffeic acid treatment decreased MPO activity ($p < 0.05$) while gastric GSH was replenished ($p < 0.05$ and $p < 0.01$, respectively). Administration of atropine before 250 mg/kg caffeic acid elevated the reduced MDA levels ($P < 0.05$). Furthermore, increased GSH levels by caffeic acid decreased by L-NAME administration ($P < 0.05$).
Conclusion: Results showed that caffeic acid ameliorates the ethanol-induced gastric mucosal damage by preventing neutrophil infiltration, tissue damage derived from lipid peroxidation and endogenous anti-oxidant GSH depletion. Moreover, caffeic acid may display these effects via NO and/or cholinergic pathway. Future studies are needed to investigate the mechanism of anti-ulcerative effects of caffeic acid as a therapeutic agent.

P1094 GASTRIC MICROBIOTA ALTERATION FOLLOWING ERADICATION OF *H. PYLORI*

Y. Nadatani[1], T. Watanabe[1], K. Otani[1], S. Hosomi[1], Y. Nagami[1], F. Tanaka[1], N. Kamata[1], K. Taira[1], H. Yamagami[1], T. Tanigawa[1], Y. Fujiwara[1]
[1]*Osaka City University Graduate School of Medicine, Department of Gastroenterology, Osaka, Japan*

Contact E-Mail Address: dada@med.osaka-cu.ac.jp
Introduction: The human gastric microbiota studies are mainly focused on *H. pylori* (HP) infection, and few studies focused on bacteria other than HP. Moreover, the results of these studies are controversial. Bik et al. reported that

the human gastric flora was not affected by HP infection. On the other hand, Maldonado-Conteras et al. reported that HP infection increased the rate of Proteobacteria in the human stomach, and decreased the rate of Firmicutes.
Aims and Methods: The aim of this study is to clarify the composition of the gastric bacterial flora using the next generation sequencer and the changes in gastric microbiota composition before or after HP eradication.
Between December 2012 and July 2016, 24 patients who underwent upper gastrointestinal endoscopy before and after HP eradication were enrolled. Stomach body and antrum biopsy specimens were collected using upper gastrointestinal endoscopy. Bacterial DNA was extracted and purified from the collected samples by the complex enzyme method. After PCR amplification of the 16S rRNA gene V1-2 region of the extracted DNA, barcode sequencing was carried out using Miseq (Illumina) which is a high-speed sequencer. The stomach bacterial flora was clarified through the informational analysis of the obtained sequence data by using Operational Taxonomic Unit (OTU) analysis.
Results: Twelve pairs of samples obtained from the antrum before and after *HP* eradication and seventeen pairs of the stomach body samples were PCR amplifiable and analysis was performed thereafter. There were many kinds of bacterial species other than HP in the gastric environment. In antrum, average OTU is 120.9 and 118.3 before and after eradication, respectively. In gastric body, average OTU is 90.9 and 123.8 before and after eradication, respectively. HP eradication was associated with a significant increase of α-diversity in gastric body microbiome in Shannon's diversity and there was no significant difference in α-diversity of antrum microbiome between before and after eradication. Principal coordinates analysis (PcoA) of weighted and unweighted Unifrac distances of both gastric body and antrum microbiome were significantly different between before and after HP eradication based on Permutational Multivariate Analysis of Variance. While HP is the most dominant species before HP eradication in both gastric body (64%) and antrum (24%), *Streptococcus mitis,* which is the second dominant bacteria before HP eradication, became the most dominant bacteria species after eradication. The population of many bacteria species were increased and the population of some bacteria species were decreased after HP eradication compared to before the eradication.
Conclusion: There were a lot of bacterial species in the gastric environment. HP eradication changes the gastric microbiota dramatically.

Introduction: Although the high-throughput sequencing technique is useful for evaluating gastric microbiome, it is relatively expensive and requires gastric mucosal samples (or juice). Therefore, we aimed to develop a predictive model for gastric microbiome using serologic testing.
Aims and Methods: This study was designed to further analyze the Hanyang University Gastric Microbiome Cohort, which was originally established to investigate gastric microbial distribution according to the intragastric environment. We obtained the relative abundance of nitrosating/nitrate-reducing bacteria or type IV secretion system (T4SS) protein gene-contributing bacteria, IgG anti-*Helicobacter pylori* (HP) antibody, and pepsinogen (PG) levels.
Results: We included 57 and 26 participants without and with HP infection, respectively. The relative abundance of nitrosating/nitrate-reducing bacteria was 4.9% and 3.6% in the HP(-) and HP(+) groups, respectively. The relative abundance of T4SS protein gene-contributing bacteria was 20.5% and 6.5% in the HP(-) and HP(+) groups, respectively. The relative abundance of both nitrosating/nitrate-reducing bacteria and T4SS protein gene-contributing bacteria increased exponentially as PG levels decreased. In the multivariable analysis, advanced age (only for nitrosating/nitrate-reducing bacteria), a negative IgG anti-HP antibody result, low PG I and II levels, and high Charlson comorbidity index were associated with a high relative abundance of nitrosating/nitrate-reducing bacteria and T4SS protein gene-contributing bacteria. Adjusted coefficient of determination (R^2) was 53.7% and 70.0% in the model for nitrosating/nitrate-reducing bacteria and T4SS protein gene-contributing bacteria, respectively.
Conclusion: Negative results of IgG anti-HP antibody and low PG levels were associated with a high abundance of nitrosating/nitrate-reducing bacteria and T4SS protein gene-contributing bacteria.
Disclosure: This work was supported by the research fund of Hanyang University (HY-2017).

P1096 CHARACTERIZATION OF MUCOSAL AND FLUID MICROBIOME ACROSS STAGES OF GASTRIC CARCINOGENESIS

Introduction: Recently a complex microbiota has been uncovered within the stomach and the mucosal microbiota dysbiosis is associated with gastric cancer (GC). However, the alterations of mucosal microbiota among stages of GC are inconsistent in different studies. It is also not uncertain the role of fluid bacteria in this process and its difference with mucosal microbiota.
Aims and Methods: The aim of this study was to perform a comparative analysis of the microbiome in both luminal and mucosal niches along the histological stages of gastric tumorigenesis. We performed 16S rRNA gene sequencing of gastric mucosal samples from 179 patients including 61 superficial gastritis (SG), 54 intestinal metaplasia (IM) and 64 GC, as well as gastric fluid samples from 96 patients of the same cohort including 42 SG, 26 IM and 28 GC, to determine their alterations across stages of GC.
Results: The composition of gastric mucosal microbiome was different from fluid with lower bacterial diversity. *Helicobacter pylori* (*H. pylori*) which were observed to dominate the mucosal community strikingly influenced the overall microbial structure in the stomach that correlated with its abundance. Microbial dysbiosis was shown in mucosa rather than fluid during the progression of GC. Three enterotypes were identified in gastric mucosa with compositional and functional differences and the changes along disease stages varied between enterotypes. The specific taxa consistently altered in IM and GC were identified in each enterotype and their effect for discriminating GC from SG was validated.
Conclusion: The detailed analysis of the whole gastric microbiome along carcinogenesis demonstrated for the first time that the dysbiosis of mucosal instead of luminal bacteria was associated with GC. The characteristic profiles of gastric mucosal enterotypes in GC development suggest that the potential necessity of enterotype classification before evaluating the correlation between gastric microbiota and GC.

P1097 COMPREHENSIVE ANALYSIS OF HISTOLOGICAL MICRORNAS OF PANCREATIC CANCER COLLECTED BY EUS-FNA

K. Kato[1], H. Kamada[1], K. Kobayashi[1], T. Masaki[1]
[1]*Kagawa University, Kagawa, Japan*

Contact E-Mail Address: kato-k@med.kagawa-u.ac.jp
Introduction: The microRNA is a small RNA molecule whose full length is 18–25 bases, whose biological roles are to regulate its expression by binding to and disrupting target messenger RNA in cells. Recently, it has been reported that these miRNA are involved in metastasis and expression of various cancers. The aim of this study was to comprehensively analyze the extracted miRNA of cancer tissue obtained by EUS-FNA, which was performed for the definite diagnosis of pancreatic cancer, and to identify miRNA targets related to prediction of metastasis, grade, and prognostic factors.
Aims and Methods: The subjects were 51 patients (21 men and 30 women) with invasive ductal adenocarcinoma diagnosed histologically by EUS-FNA (written informed consent was obtained with approval from the hospital ethics committee). The observation period was from April 2013 to February 2018. MiRNAs extracted from tissues collected by EUS-FNA performed for definitive diagnostic purposes was comprehensively analyzed using a microarray tip equipped with 2555 molecules. MiRNAs comparisons were made using the following three areas of clinical features, clinical stage, sites of recurrences and metastases, and prognoses. The miRNAs of candidates for defining clinical pathology was identified using statistical methods such as cluster analysis.
Results: 1. We identified miRNAs (oncogenic miRNA) with increased expression and miRNAs (tumor suppressor genotype miRNAs) with decreased expression in the Stage IV group with distant metastases compared with the Stage I-III groups. 2. There were the increase and decrease of the genes which seemed to correlate in miRNAs and recurrence position of the postoperative recurrence patients. 3. Median survival in cumulative survival rates (Kaplan-Meir Methods) was calculated, and microRNA with significant differences were identified by comparing survival greater than or less than the median survival time between the groups.
Conclusion: In this study, we identified a miRNAs that may define the clinical features of invasive ductal carcinoma of the pancreas by comprehensively analyzing the miRNAs obtained by EUS-FNA. Functional analysis of these miRNAs was used to evaluate their potential as biomarkers for early detection of pancreatic cancer, progression of metastasis, evaluation of therapeutic effects, and prediction of prognosis.

P1098 ALTERATIONS IN GUT MICROBIOTA COMPOSITION DURING AGING

W. Xu[1,2], **L. Chen**[1,2], L. Wang[1,2], S. Chen[1,2]
[1]*Run Run Shaw Hospital, Zhejiang University School of Medicine, Hangzhou, China*
[2]*Institute of Gastroenterology, Zhejiang University, Hangzhou, China*

Contact E-Mail Address: clyemma@163.com
Introduction: The gut microbiota have been considered to play an important role in health. Meanwhile aging is a degenerative process that accompanied by a number of diseases and poor health, such as atherosclerosis, dementia, or

cancer. Several researchers have reported that gut microbiota were closely related with aging in recent years. However, the distinct species of age-related changes in microbiota composition remains unexplored.
Aims and Methods: The present study was conducted to deepen our knowledge on the relationship between the composition of the gut microbiota and host's age. 116 healthy adults were enrolled for this study in Hangzhou. The 116 healthy adults were divided into 3 groups: young group (n = 36, 20–34 years, 27.89 ± 3.37), middle-aged group (n = 53, 35–55 years, 45.58 ± 5.70) and elderly group (n = 27, ≥56 years, 63.00 ± 5.52). Feces were collected and stored at -80°C, total bacterial DNA was extracted from all samples. The fecal microbiota of the 116 samples was characterized by Illumina sequencing of the V3-V4 region of the bacterial 16S rRNA gene.
Results: No significant difference was observed among the three groups with regard to baseline characteristics. Among the detected gut microbes, the chao index was decreased in middle-aged and elderly groups compared with young group, which represents the community richness. The Shannon index was also decreased with aging, which shows the community diversity. Moreover, the genera *Prevotella*, *Paraprevotella*, *Veillonella* and *Klebsiella* were enriched with aging. The genera above were mostly the source of common infection. However, the genera *Phascolarctobacterium*, *Faecalibacterium*, *Bifidobacterium*, *Streptococcus*, *Dorea* and *Bilophila* were negatively correlated with age, some of which were well known as beneficial to the gut health. Meanwhile, the presence of *Faecalibacterium prausnitzii*, *Dorea formicigenerans* and *Bifidobacterium longum* were negatively correlated with age, which has a significant difference. The three specific species above were known to have anti-inflammatory or protective properties in gastrointestinal tract.
Conclusion: These results suggested the evolving microbial-host associations and relations across the lifespan of a human being. Furthermore, we proved that the microbiota aimed at improving healthy outcomes were decreased with aging. On the other hand, the opportunistic bacteriums were elevated with aging.

Species	Young group (%)	Middle-aged group (%)	Elderly group (%)	P value

Introduction: Several risk assessment scores have been developed to predict mortality, need for hospital intervention, rebleeding for patients with acute upper gastrointestinal bleeding. The Rockall score has been widely used and it has been suggested that the PNED score and AIMS65 are superior to it. The Glasgow Blatchford (GB) score seems useful in identifying very low risk patients not needing of endoscopic treatment but is often considered for predicting death.
Aims and Methods: To compare the four risk assessment scores to predict mortality and rebleeding in acute upper gastrointestinal bleeding. Clinical, biochemical, endoscopic and treatment delivered data on patients consecutively hospitalized for AUGIB were collected from January 1st 2014 to December 31st 2015. Haemorrhage-related death was defined as any event occurring within 30 days for patients with non-variceal bleeding and 42 days for those with variceal bleeding. Rebleeding was endoscopy proved and defined as new episode of hematemesis after index endoscopy, melena or hematochezia after normalization of the color of feces, tachycardia (> 110 m/min) or hypotension (PA <90 mmHg) in absence of any plausible cause, hemoglobin (HB) fall >2gr/dl following two stable HB scores, HB fall >3gr/dl in 24 hours associated with melena or hematochezia. Comorbidity and its clinical seriousness was evaluated by ASA scores.
Results: A total of 3324 patients were included; males were 67.8% and their mean age was 68.1 ± 15.7. The source of bleeding was non-variceal in 2,764 (83.1%) and variceal in 560. Comorbidities were present in 79.8% of the patients; at admission, mean Hb value was 9.2 ± 2.6; 7.6% had hemodynamic instability, 59.3% of the patients received al least one transfusion (Nr.1972) Overall mortality (variceal and non-variceal) was 223 patients (6.7%.) and overall rebleeding was 6.2%. PNED score showed the best area under the receiver operating characteristic curve (AUCROC) 0.80 [cl.95% 0.77–0.84] for predicting death compared with the Rockall score 0.68 [c.l.95% 0.64–0.72], GB score 0.69 [c.l.95% 0.65–0.73] and AIMS65 score 0.61 [c.l.95% 0.57–0.65] all P < 0.001 see figure. The PNED score (AUCROC: 0.79 [c.l.95% 0.77–0.82]) showed the best performance also for the prediction of rebleeding (chi2 = 44.53 p < 0.000) (Rockall score 0.68 [c.l.95% 0.64–0.72]; GB 0.69 [c.l.95% 0.65–0.73]; AIMS65 0.61 [c.l.95% 0.57–0.65]).
Conclusion: The PNED score is accurate and superior to other scores for the prediction of death and rebleeding.

Introduction: We conducted a network meta-analysis to compare efficacy and safety of interventions for primary prophylaxis of esophageal variceal bleeding
Aims and Methods: We searched Medline, Embase, Cochrane Library and grey literature sources through October 2017. We included randomised controlled trials (RCTs) that compared non-selected betablockers (NSBB) (propranolol, nadolol), carvedilol, isosorbide-5-mononitrate (ISMN), endoscopic variceal ligation (EVL), either alone or combined, to each other for the prevention of first variceal bleeding. Efficacy outcomes were incidence of variceal and upper gastrointestinal bleeding, incidence of bleeding related and all-cause mortality. Safety outcomes included incidence of any adverse event (AE) and discontinuation rate due to AE. We combined direct and indirect evidence through multivariate random-effects network meta-analyses and relative ranking of treatments was assessed using surface under the cumulative ranking (SUCRA) probabilities. We also estimated Predictive intervals (PrI), which indicate the interval within which the relative effect of a future study is expected to be, in order to facilitate interpretation of the results in the light of the magnitude of heterogeneity. We assessed quality of evidence using GRADE criteria.
Results: We included 36 RCTs (3859 patients). Low quality of evidence suggested that EVL (OR 0.55; 95% *CI* 0.39–0.78, SUCRA: 69%) and carvedilol (OR 0.48; 95% CI 0.26–0.87, SUCRA: 80.1%) reduced significantly the risk of first variceal bleeding compared to NSBBs (SUCRA: 23.8%). However, the advantage was not retained when predictive intervals were included in analysis. Combined therapy of EVL and NSBBs (SUCRA: 76.8%) did not demonstrate significant improvements in rates of variceal bleeding compared to monotherapy with EVL (OR 0.87, 95%CI 0.37–2.06), carvedilol (OR 1.00, 95%CI 0.37–2.75) or NSBBs (OR 0.48, 95%CI 0.21–1.13). ISMN was inferior compared to other interventions in incidence of variceal bleeding. EVL (OR 0.70, 95%CI 0.50–0.97) was superior to NSBBs in terms of upper gastrointestinal bleeding but predictive intervals were wide, extending to both sides of "no effect" line. Compared to each other none of the interventions either alone or in combination showed superiority in terms of bleeding related mortality and all-cause mortality (low and very low quality of evidence). Incidence of any adverse events did not differ among interventions (low quality of evidence). Combination therapy of NSBBs and ISMN showed higher rates of discontinuation due to AE compared to most interventions.
Conclusion: EVL, NSBBs, carvedilol and combination of EVL plus NSBBs are equally effective in primary prophylaxis of upper gastrointestinal bleeding in patient with esophageal varices. Any differences among interventions were imprecise with low confidence in our estimates. Combination of NSBBs and ISMN had also beneficial effect but there are safety concerns.

P1102 EFFECT OF GASTROPROTECTIVE AGENTS ON PREVENTING UPPER GASTROINTESTINAL BLEEDING IN PATIENTS RECEIVING DIRECT ORAL ANTICOAGULANTS: A RETROSPECTIVE MULTICENTER STUDY

H. Lim[1]
[1]*University of Hallym College of Medicine, Hallym University Sacred Heart Hospital, Dept. of Internal Medicine, Anyang, Korea (Republic of)*

Contact E-Mail Address: lh10004ok@hanmail.net
Introduction: Direct oral anticoagulants (DOACs) are effective in the prevention and treatment of thromboembolism; however, they are associated with upper gastrointestinal bleeding (UGIB). In this study, we evaluated the efficacy of gastroprotective agents (GPAs) in reducing the risk of UGIB in patients receiving DOACs.
Aims and Methods: We retrospectively reviewed the medical records of 2076 patients who received DOACs for the prevention or treatment of thromboembolic events between January 2008 and July 2016. A cumulative incidence analysis using the Kaplan-Meier method was performed to determine the rate of UGIB and its association with GPAs administration.
Results: Of the 2076 patients, 360 received GPAs. Over the follow-up period (1160 person-years), 1 patient in the GPA group (0.7 per 100 person-years) and 29 patients in the non-GPA group (2.8 per 100 person-years) developed UGIB ($P = 0.189$). In the multivariate analysis, UGIB was associated with older age (hazard ratio [HR], 1.041; $P = 0.048$), a history of peptic ulcer or UGIB (HR, 5.931; $P < 0.001$), and concomitant use of antiplatelet agents (HR, 3.121; $P = 0.014$). GPAs administration did not reduce the risk of UGIB (HR, 0.200; $P = 0.116$). However, based on the subgroup analysis of 225 patients with concomitant use of antiplatelet agents or a history of peptic ulcer or UGIB, the GPA group (0 per 100 person-years) showed reduced incidence of UGIB compared with the non-GPA group (11.3 per 100 person-years) ($P = 0.065$).
Conclusion: Routine use of GPAs for UGIB is not mandatory in patients receiving DOACs. However, GPAs could reduce the risk of UGIB in patients receiving DOACs, who are at a high risk.

P1103 DEVELOPMENT OF A NEW SCORE TO PREDICT MORTALITY AND INTERVENTION IN UPPER GASTROINTESTINAL BLEEDING. THE HA(MA)SH SCORE

E. Redondo-Cerezo, R. Jiménez-Rosales, F. Vadillo-Calles, E.J. Ortega-Suazo, F. Valverde López, J. Martínez-Cara
Virgen de Las Nieves University Hospital, Gastroenterology and Hepatology Unit, Granada, Spain

Contact E-Mail Address: eredondoc@gmail.com
Introduction: There has been a special interest in the development of scores to establish patients' risk of death and need for intervention in an early phase after upper gastrointestinal bleeding (UGIB). However, some of them such as Glasgow-Blatchford score (GBS), are troublesome to calculate, whereas others such as Rockall score need an endoscopy to be completed. Recently, AIMS65 changed the paradigm, shifting to a simple type of score, easy to use and applicable.
For these reasons, provided that the most important decision to make in the ER is whether an immediate intervention is needed, we decided to develop a score centered in this outcome, as well as in mortality.
Aims and Methods: The database was built with information of consecutive UGIB patients admitted to the "Virgen de las Nieves" University Hospital emergency room over 48 months from January 2013 to January 2017. All patients received upper endoscopy, and information regarding patients' demographic data, comorbidities, current medications, clinical presentations, hemodynamics, laboratory test results on admission, and endoscopic findings were collected. An univariate and multivariate analysis were performed, looking for individual odds ratio for every risk factor. After this analysis, we built a score weighting the relative risk of every factor, and giving to values above or below the cutoff point 1 or 2 points depending on their individual odds ratio. The score was tested both for mortality and for two composite endpoints, considering interventions (Endoscopic intervention, surgery or 30 days mortality) or any given intervention (the before mentioned plus transfusions). Comparison between curves were performed by means of the Hanley and McNeill Method.
Results: The score was validated in our database of 547 patients (367 males; aged 64.14 ± 16.4). Factors included in the multivariate analysis after achieving significance in the univariate analysis for any intervention or death were: Impaired mental status, Albumin < 2.5 g/dL, Systolic blood pressure < 90 mmHg, Hematemesis, Hemoglobin < 10 g/dl; and ASA score > 2.
Our score, denominated HAH(MA)S (Hematemesis, ASA score > 2, Hemoglobin < 10, Altered mental status, albumin < 2.5 and systolic blood pressure < 90) gives two points to the variables inside the brackets and one to the rest, performed for death prediction better than AIMS65 (AUC 0.776 vs 0.751; $p < 0.05$), Glasgow-Blatchford score (GBS) (0.736; $p < 0.05$) and postendoscopic Rockal score (0.754; p = n.s.) in our series (Figure 1). Regarding intervention, it was slightly better than AIMS65 (AUC 0.654 vs. 0.627; p = n.s.) and GBS (AUC 0.623; p = ns). When considering every intervention (adding red cells transfusions) there were no differences between the HA(MA)SH and GBS scores, but there were between both ones and AIMS65 ($p < 0.005$) (AUC: HA(MA)SH 0.792; GBS 0.811; AIMS65 0.706). With a HAH(MA)S = 0 no patient died and only 3% required intervention.
Conclusion: The HA(MA)SH score can be an option for risk assessment in the Emergency Room. Although still far from perfect, it points towards simpler and more clinically based scores, provided that the Glasgow-Blatchford score is somehow troublesome to calculate and the AIMS65 is not optimal predicting interventions. Previous to its external validation, de HA(MA)SH score seems a very promising option.

P1104 THE STATISTICAL COMPARISON OF ENDOSCOPIC PROCEDURE AND TRANSARTERIAL EMBOLIZATION FOR HEMORRHAGE CAUSED BY DUODENAL ULCER

Y. Yonemoto, Y. Fukami, H. Hara, T. Mochida, T. Machida, Y. Sugiyama, A. Watanabe, M. Kaneshiro, H. Ikemiyagi, K. Yoshino, S. Sakita
Yokohama City Minato Red Cross Hosipital, Yokohama, Japan

Contact E-Mail Address: km.p81md@gmail.com
Introduction: Endoscopic procedure is performed for active duodenal ulcer hemorrhage. But if endoscopic hemostasis fails, transarterial embolization (TAE) or operation are additionally selected. We made statistical analysis for the feature between the group which only endoscopic procedure are performed (endoscopy group) for duodenal ulcer and the group which interventional radiology is additionally performed (TAE group).
Aims and Methods: From April 2005 to December 2017, 141 patients with hemorrhage of benign duodenal ulcer are admitted in our hospital. The patients were divided into two group retrospectively, endoscopy group and TAE group. We made statistical analysis for laboratory data (Alb, Hb, Plt, PT—INR) at initial diagnosis, number of endoscopic treatment, the amount of blood transfusion, comorbid disease, and 30-day mortality.
Results: Of 141 patients, 129 patients (91.5%) were success in only endoscopic procedure. 11 patients (7.8%) were underwent TAE additionally, 2 patients (1.4%) were underwent operation. 109 patients (77.3%) were male, the mean age was 62.8 year-old, range 21 to 97 years.
Based on the results of t-test for laboratory data at initial diagnosis, Alb and Hb in TAE group was statistically lower than in endoscopic group ($P < 0.05$). In addition, the number of endoscopic examination was larger ($P < 0.05$). In terms of comorbid disease, hemodialysis was risk factor in TAE group. Then we performed logistic regression analysis to identify cut-off value for Alb, Hb and times of endoscopic exam. The cut-off value were Alb = 2.3, Hb = 8.3, times of

endoscopy was twice. Sensitivity was 84.5%, 48.8%, 94.6% respectively, and specificity was 54.5%, 81.8%, 63.6% respectively.
Conclusion: This study may show the opportunity to select TAE for patients who were difficult to control duodenal ulcer hemorrhage with endoscopic procedure. Alb, Hb at initial diagnosis, number of endoscopic exam after the admission, and comorbid disease of hemodialysis might be predictable value for TAE treatment for duodenal hemorrhage.
Disclosure: Nothing to disclose

P1105 A RETROSPECTIVE SINGLE-CENTRE REVIEW OF HEMOSPRAY® IN GI BLEEDING

E. Prentice[1], J. Masegosa Ataz[2], M. Barron[2], J. Todd[2], C. Mowat[2], M. Groome[2]
[1]*University of Dundee, Dundee, United Kingdom*
[2]*NHS Tayside, Gastroenterology, Dundee, United Kingdom*

Contact E-Mail Address: e.v.prentice@dundee.ac.uk
Introduction: Upper GI bleeding can have a poor outcome in the absence of haemostasis. Hemospray is an inorganic powder that creates an adhesive barrier over the bleeding site and has been used as an adjunct to conventional endotherapy in high-risk non-variceal, and more recently variceal bleeds.
Aims and Methods: We wished to review Hemospray ® use in NHS Tayside and assess clinical outcome. From the endoscopy database we identified Hemospray ® use between January 2014 and October 2017. We recorded demographics, indication, co-morbidities, Blatchford score, endoscopic findings and therapy, haemostasis and 30-day mortality.
Results: We identified 49 applications in 46 patients (M22:F24, mean age 68.4 years, range 30–91). Indications were primary acute GI bleeding (87.8%) and bleeding post endoscopic procedure [12.2%]. 11 patients had liver disease and 6 malignancy (2 pancreatic, 2 oesophageal, 1 hepatoma, 1 haematological).
The mean Blatchford score was 10.96 (range 2–19) and was >6 in 86.3%.
In 100% of cases immediate haemostasis was achieved.
Overall 30 day mortality was 10.9% (5/46 patients) only 1 death was directly related to GI bleeding (oesophageal stent erosion into a sub-mucosal vessel).
Overall 30 day haemostasis in those surviving was 79.6%.
Hemospray ® Application by site is shown below (Table 1).
In 12 cases, at the discretion of the endoscopist, Hemospray ® was used as monotherapy; these applications and the associated 30-day haemostasis is also displayed in the table.
In the three cases of oesophageal varices this was used as a salvage measure in the setting of massive haematemsis. In one case the patient was palliated and re-bled at day 6 but died beyond 30 days. In the other two cases Hemospray ® provided a bridge to either TIPSS or endoscopy with banding 24 hours later – neither patient re-bled.
In 2 duodenal cases the patients were electively sent for interventional radiology despite immediate haemostasis.
30 day haemostasis in the monotherapy group was 91.7%.
Conclusion: We have shown our centres experience with Hemospray ®. It provides effective immediate haemostasis from a range of causes of GI bleeding when used either in combination or as monotherapy. We have also had success when used in massive variceal haemorrhage as a bridge to other adjunct therapy such as interventional radiology. Longer term haemostasis has been shown to be better than in similar cohorts.
Disclosure: Nothing to disclose

P1106 IS TOPICAL TRANEXAMIC ACID EFFECTIVE IN UPPER GI BLEEDING?

M. Khodadoostan[1], A. Shahbazi[1], A. Shavakhi[2], A. Shavakhi[3]

Introduction: Non-variceal upper gastrointestinal bleeding (NVUGIB) is the most common emergency that gastroenterologists encounter. The aim of this study is evaluating effect of topical Tranexamic Acid via endoscopic procedure for control of NVUGIB.
Aims and Methods: In this study, 100 eligible patients with NVUGIB enrolled and divided to two equal groups: In control group the ulcer underwent epinephrine injection plus Argon Plasma Coagulation as the standard treatment. In second group, topical Tranexamic Acid solution spraying was added to standard treatment (intervention group). Estimated blood loss volume, blood transfusion volume, hemoglobin, blood pressure, heart rate, need to second endoscopy, mortality rate, need to surgery, hospitalization duration was evaluated in both groups and the differences expressed statistically.
Results: The mean average ages of intervention and control groups were 62.8 ± 19.6 and 63.1 ± 17.8 yrs. respectively. Demographic features were not different between two groups. Estimated blood loss, need to transfusion, hospitalization duration and re-bleeding were significantly lower in intervention group (p -value <0.05). Eight patients (16%) in the intervention group and 17 (34%) in control group had re-bleeding and underwent re-endoscopy ($p = 0.038$). Mortality rate, need for surgery and drug effectiveness regarding the ulcer location (duodenum or stomach) had no statistically significant differences in two groups (P-value >0.05).
Conclusion: Topical tranexamic Acid is a useful additive treatment to control NVUGIB and prevent re-bleeding. Therefore it can be used in addition to the standard treatment.
Disclosure: Nothing to disclose

P1107 CLINICAL COURSE AFTER HEMORRHAGE IN PATIENTS TAKING DOAC AND SIGNIFICANCE OF GASTROINTESTINAL BLEEDING

D. Yanagisawa, K. Abe, S. Osumi, H. Yamato, K. Maruyama, N. Nakamura, A. Miki, T. Okamura, H. Aoyagi, A. Isono, S. Kodashima, T. Yamamoto
Teikyo University Hospital, Tokyo, Japan

Introduction: Several direct oral anticoagulants (DOAC) have been developed to prevent cardiogenic thrombosis in patients with non-valvular atrial fibrillation. The major adverse effect of DOACs is hemorrhage, and the gastrointestinal tract is one of common sites of involvement. However, clinical course after gastrointestinal bleeding (GIB) during DOAC therapy have not been fully elucidated. This retrospective cohort study was conducted to investigate the course after hemorrhagic events during DOAC therapy. The significance of GIB was also evaluated.
Aims and Methods: First, all 662 patients prescribed dabigatran, rivaroxaban, apixaban, or edoxaban between April 2011 and November 2015 were listed. Their medical charts were reviewed to examine whether any hemorrhagic events developed from the day of initial prescription until the end of August 2017. Regarding 126 patients with hemorrhage, the cause of bleeding was identified to clarify the clinical significance of GIB. Additionally, the course after bleeding was investigated until the end of March 2018, if available. Finally, after excluding 30 patients with insufficient description or lack of data, 96 patients were selected as subjects.
Results: Of hemorrhagic events occurred during DOAC therapy, GIB was identified in 38 patients (2.8%/year), majority of which were clinically relevant GIB (Bleeding Academic Research Consotium type 2 or above). Regarding 96 patients with follow-up data, observational period was 157 patients-year. Of these, 11 minor bleeding occurred (7%/year) including 2 GIB, 1 anorectal bleeding and 1 small intestinal bleeding, and no serious bleeding was seen. On the other hand, 2 major thrombotic events developed during observation (1.3%/year); 1 cerebral infarction and 1 acute arterial occlusion. Both patients developed GIB initially and had stopped taking anticoagulants after bleeding because of the fear for re-bleeding.

Abstract No: P1105
Table 1

	Oesophageal (Variceal)	Oesophageal (Non Variceal)	Gastric (Variceal)	Gastric (Non Variceal)	Duodenal	Colonic
Total Applications of Hemospray	6	16	4	7	14	2
Immediate Haemostasis	100% (6)	100% (16)	100% (4)	100% (7)	100% (14)	100% (2)
30 Day Haemostasis	83.3% (5)	75% (12)	50% (2)	100% (7)	85.7% (12)	100% (2)
Applications where Hemospray was used as Monotherapy	3/6 (50%)	6/16 (37.5%)	0/4 (0%)	1/7 (14.3%)	2/14 (14.3%)	0/2 (0%)
Monotherapy 30 Day Haemostasis	2/3 (66%)	6/6 (100%)	–	1/1 (100%)	2/2 (100%)	–

Conclusion: GIB is common and serious adverse event during DOAC therapy. However, once GIB occurred, it seemed important for clinicians to continue anticoagulant therapy.

Introduction: The principal goal of band ligation is to strangulate and finaly obliterate the perforating veins connecting varices to extraesophageal collaterals. But the patients still face the risk of rebleeding after endoscopic treatment. We hope to find a more effective way in preventing early rebleeding.
Aims and Methods: We aimed to evaluate the effect of EEVD (Endoscopic Exploratory Varices Devascularization) for acute esophageal variceal bleeding in patients with cirrhosis.
In the retrospective study, we compared endoscopic exploratory varices devascularization and endoscopic band ligation in 75 patients with cirrhosis (Child-Pugh score range from 7–12 points) and esophageal variceal bleeding. 46 patients underwent EEVD, and 29 did band ligation. We compared the mean time to recurrence between EEVD group and band ligation group. And the presence of the varices measured by Computed tomographic angiography (CTA) at different time points and under different conditions (before performent of EEVD; at least 24 hours after performent of EEVD into hemodynamically stable patients; 2 weeks after performent of EEVD).
Results: The number of esophageal varices in 46 patients were significantly more before performent of EEVD than at least after 24 hours. The results at least 24 hours later and after 2 weeks were similar, no newly gastroesophageal varices were observed. The number of gastric varices appears to decrease after EEVD. Mean bleeding recurrence time after EEVD was significantly longer (7.63 ± 3.63 months) than band ligation (5.60 ± 2.39 months, $P < 0.05$).
Conclusion: 1. The results show the effectiveness of varices occlusion by EEVD for gastric varices and the esophageal varices originated from them.
2. EEVD may delayed the occurrence of variceal rebleeding by thrombosis of the potential varices, compared to band ligation.

Introduction: Hereditary hemorrhagic telangiectasia (HHT) is a genetic disease that leads to vascular malformations in multiple organs. Approximately 25% of the HHT patients have symptoms of gastrointestinal (GI) bleeding with iron deficiency anaemia as a consequence. Endoscopic argon plasma coagulation is the first-line therapy, but often not a long-term solution due to recurrent bleeding and the impossibility to treat all GI lesions. Therefore, current treatment focuses on managing anaemia with blood transfusions, which is associated with multiple hospital visits, admissions, and a significant burden for the patients and healthcare.
Aims and Methods: The aim of this study is to investigate the efficacy and safety of octreotide as a treatment for severe gastrointestinal bleeding in patients with HHT. We initiated an open-label, phase II, prospective, non-randomized, multicenter clinical trial. Patients with HHT and transfusion dependency (≥2 units blood and/or intravenous iron in the 6 months prior to inclusion) and prior attempt for endoscopic treatment were included between December 2016 and September 2017. Octreotide LAR 20 mg monthly was administered for 6 months. The primary outcome was response to treatment, defined as complete responder (no need for blood, iron and APC during the study period), partial responder (decrease in need for blood or iron) or non-responder (no decrease in need for blood and iron). Follow-up was until one month after the end of treatment.
Results: Nine patients, with a mean age of 56.9 years (SD 7.5) and of which 5 were men, were enrolled. Eight patients (89%) were partial responder with a reduction in iron and/or blood transfusions. None of the patients were complete responder and one patient was a non-responder (11%). The overall mean difference in units of blood transfusions decreased with 6 units, from 21 (SD 32.6) in the six months prior to study inclusion to 15 (SD 28.5) during the treatment period. Intravenous iron decreased with 1.1 from 6 units (SD 7.3) at baseline to 4.9 units (SD 8.5) during the treatment period. Due to the small sample size and wide variation, both treatment effects were not statistically significant (i.e. blood transfusion $p = 0.33$, intravenous iron $p = 0.35$). As secondary outcome the epistaxis severity score decreased not statistical significant from baseline 4.7 to 3.8 ($p = 0.19$). One patient stopped octreotide treatment after three months due to complaints of dizziness. Other side-effects were graded as non-serious, grade I adverse events: abdominal discomfort for less than two days after injection ($n = 4$), light colored stool ($n = 1$). Eight of the nine patients chose to continue octreotide therapy after the end of study, because they experienced improvement of quality of life.
Conclusion: Octreotide is safe and seems to be effective in reducing the number of iron and blood transfusions in HHT patients with gastrointestinal bleeding. Further research in a larger number of patients in a well-controlled study is needed to investigate if there is a clinical relevant effect of octreotide.

Introduction: Small bowel angiodysplasias (SBAs) account for 50% of cases of obscure gastrointestinal bleeding and due to delays in diagnosis and ineffective treatments are associated with high levels of morbidity and mortality. The development of effective treatments for SBA is impeded by a limited knowledge of the pathophysiology, and the lack of any specific therapeutic targets. We have previously presented our work outlining abnormalities in the Angiopoietin pathway (Angiopoietin 1 and 2) in both tissue and serum of patients with SBA compared to controls, however as angiogenesis is controlled by the interaction between a multitude of pro and anti-angiogenic factors this is likely to only be the tip of the iceberg in identifying a future therapeutic target for SBA.
Aims and Methods: Serum samples were collected from patients with a definite diagnosis of SBA by capsule endoscopy and from controls with no history of overt gastrointestinal bleeding who had undergone panendoscopy and capsule endoscopy to outrule bleeding, and were not anaemic. Using a commercially available human angiogenesis antibody array profiler kit (R&D systems) the relative levels of 55 angiogenesis related proteins was measured using near infrared fluorescence detection. Based on the detection of possibly significant factors identified by this putative assessment, quantitative assessments of three factors – Endostatin, TIMP1 (metallopeptidase inhibitor-1) and Platelet derived growth factor (PDGF) AA were measured using commercially available ELISA antibody array kits (R&D systems) in a larger group of patients and controls. Samples were measured in duplicate and the median relative level and mean level of each factor was then compared between SBA patients and controls using a Mann Whitney U test, with a p value of < 0.05 considered to be statistically significant.
Results: An initial assessment using the 55 antibody array assay was performed in 13 samples (7 SBA patients and 6 controls). Significantly lower levels of 4 factors were found in patients with SBA vs controls including: Angiopoietin-1 ($p < 0.004$), Platelet derived growth factor (PDGF) AA ($p < 0.009$), Endostatin ($p < 0.03$) and TIMP1 (metallopeptidase inhibitor-1) ($p < 0.04$). Quantitative ELISA assessments of serum levels of PDGF-AA, Endostatin and TIMP1 in 20 SBA patients and 20 controls were then performed. As outlined in the table, SBA patients had significantly lower levels of TIMP1 ($p < 0.003$) and higher levels of Endostatin ($p < 0.004$) than controls (Table 1 shows the mean level of each factor). No differences were detected in levels of PDGF-AA.

	Endostatin ng/ml	TIMP1 ng/ml	PDGF-AA pg/ml
SBA n = 20	579.63 (208.92–909.39)	425.10 (134.34–616.30)	31170.91 (410.19–66117.12)
Controls n = 20	357.21 (123.26–554.25)	566.75 (374.20–808.92)	41323.51 (2586.39–70024.52)
p value	0.0035	0.0028	0.1247

[Table showing mean values of each factor for SBA patients and controls]
Conclusion: This assessment has revealed two previously unidentified factors possibly associated with SBA formation, which will be useful in directing further cellular based work to elucidate the pathophysiology of SBA. Endostatin and TIMP1 are both angiogenesis inhibitors. Elevated serum levels of Endostatin have been associated with a number of vascular malignancies and hypoxia driven conditions such as chronic kidney disease and peripheral vascular disease which are also associated with SBA. TIMP1 is a regulatory protein inhibiting metalloproteinases with an important role in extracellular matrix composition and healing. The identification of both Endostatin and TIMP1 as potential

drivers of SBA warrants further investigation and may yield exciting advances in the diagnosis and treatment of SBA.

Introduction: Esophageal achalasia is a rare chronic progressive disease characterized by incomplete lower esophageal sphincter (LES) relaxation. The disease occurs due to Auerbach plexus degeneration. Viruses and autoimmune disorders have been suggested as the cause of the disease; however, the exact cause remains unknown. Micro RNA (miRNA) is a single-stranded RNA that controls gene expression and plays a crucial role in many biological phenomena. In 2016, per-oral endoscopic myotomy (POEM) for esophageal achalasia was developed and became covered by health insurance. To identify the cause of achalasia, we conducted biopsies sampling from the circular muscle layer of LES during POEM and undertook a comprehensive analysis of miRNA expression patterns.
Aims and Methods: We conducted biopsies sampling from the LES of esophageal achalasia cases during POEM. As controls, we conducted biopsies sampling from the LES of operative cases in which the esophagogastric junction was excised and had no abnormal esophagus motility. Following RNA extraction, a microarray analysis was conducted (Agilent Technology). We quantified miRNA thought to have fluctuation over 2-fold based on the microarray with SYBR Green real time PCR using Exiqoṅs locked nucleic acid (LNA) primers (11 achalasia cases, 6 controls). We investigated correlations with diverse clinical factors.
Results: The expression of human herpes virus 1 (HSV-1) derived hsv1-miR-H1-3p ($p<0.05$) and hsv1-miR-H18 ($p<0.05$) was significantly prominent in achalasia patients. No clear relationships were observed with expansion type, expantion level, or disease duration. Furthermore, esophageal mucosal biopsy did not reveal the HSV-1 derived miRNA in either achalasia or control groups.
Conclusion: Considering miRNA genes constitute a latency associated transcript (LAT) and influence herpes virus pathogenicity, enhanced expression of miRNA derived from neurotropic HSV-1 in the achalasia LES implies a causal relationship.

Introduction: Chinese medicine Jianpiliqi formula has shown strong therapeutic effects in the treatment of functional dyspepsia (FD). However, little is known about the underlying molecular basis. Recent reports have demonstrated that impaired duodenal mucosal integrity and low-grade inflammation contribute to the pathogeneses of FD.
Aims and Methods: FD was induced by stimulating rats via tail clamping that simulates pathological change of FD as determined by visceral sensitivity and gastric compliance. FD rats were randomly divided into two groups, which received saline or the Jianpiliqi formula in the drinking water for 7 days.
Results: We found that Jianpiliqi formula restored duodenal epithelial integrity and suppressed low-grade inflammation. Ussing chamber analysis showed an increase in transepithelial electric resistance in Jianpiliqi-treated FD rats as compared to the control FD rats. Western blotting further showed that the expression of tight junction proteins occludin and claudin-1 were increased by Jianpiliqi formula. Moreover, Jianpiliqi formula ameliorated the production of tumor necrosis factor alpha (TNF-α) and interferon gamma (INF-γ) in duodenal mucosa as determined by ELISA. Mast cells acts as a key effector in stress-induced mucosal injury and inflammation. We observed that the number of mast cells was significantly increased in FD rats compared to the healthy rats as indicated by immunofluorescence staining. Importantly, treatment by Jianpiliqi formula significantly negated the increase in mast cell number in duodenum of FD rats. A concurrent decrease was also found in the mRNA expression of tryptase and PAR-2 that activate proinflammatory pathways leading to low-grade inflammation and high permeability.
Conclusion: The therapeutic effect of Jianpiliqi formula on FD is at least partially through the improvement of duodenal mucosal integrity and the attenuation of low-grade inflammation in the duodenum by suppressing the mast cell-mediated tryptase-PAR-2 signaling pathway. Our findings highlight the molecular basis of Jianpiliqi formula-based treatment of FD in human patients.

Introduction: Some studies support that there is a significant overlap between the different functional disorders of the digestive tract.
Aims and Methods: The aim of this study was to compare oesophageal motor characteristics between type 2 diabetics with and without constipation.
Oesophageal manometry was performed in 16 diabetic individuals with complaints of constipation and 20 without constipation. Glycaemic control was similar. Waves were evaluated in the 3 thirds of the oesophagus (P1 = upper, P2 = middle, and P3 = distal). Results are in mean ± standard error.
Results: In constipated vs. non-constipated diabetics, wave distribution was as follows: peristaltic waves, $85.54 \pm 3.85\%$ vs. $91.45 \pm 2.32\%$, $p = 0.16$; simultaneous waves, $3.50 \pm \%1.19\%$ vs. $0.93 \pm 0.28\%$, $p = 0.015$. The percent of no transmitted waves and of retrograde waves between groups were similar. Wave amplitude did not reveal significant differences between groups. Wave duration (sec.) in constipated vs. non-constipated was as follow: P1-P2, 4.76 ± 0.67 vs. 4.15 ± 0.53, $p < 0.47$; P2-P3, 7.24 ± 0.93 vs. 4.90 ± 0.47, $p < 0.017$ and P1-P3, 6.71 ± 1.20 vs. 3.37 ± 0.42 $p = 0.013$. Velocity duration (cm/s) registered in constipated vs. non-constipated was: P1-P2, 2.93 ± 0.64 vs. 4.03 ± 0.58, $p < 0.21$; P2-P3, 3.42 ± 0.67 vs. 5.07 ± 0.51, $p < 0.05$ and P1-P3, 2.69 ± 0.58 vs. 4.27 ± 0.37, $p < 0.01$.
Conclusion: (1) Simultaneous oesophageal waves were significantly more frequent in constipated diabetics. (2) Wave duration was significantly higher within the middle and distal oesophagus of constipated diabetics. (3) Wave velocity was significantly higher within the middle esophagus of non-constipated individuals. (4) Constipated individuals have some differences in esophageal motility when compared with non-constipated individuals.

Introduction: Gastric electrical stimulation (GES), which has been reported to have therapeutic potentials for gastroparesis. However, effective application methods of GES on stomach is not defined. The interstitial cells of Cajal (ICC) are recognized as mediators of neuromuscular transmission in the gastrointestinal tract and as pacemakers involved in the modulation of gastrointestinal motility. We aimed to investigate the efficacy of GES according to distribution of ICC in various gastric lesions of porcine models.
Aims and Methods: The study was performed in healthy fasted weaner pigs surgically implanted with gastric serosal electrodes and endoscopically applied electrodes. The experiment consisted of a 10-minute baseline, a 10-minute GES, and a 10-minute recovery. Acquisition of gastric electrical signals was performed before, during, and after electrical stimulation. A multi-channel recorder (Acknowledge 4.4, MP150; Biopac Systems, Santa Barbara, CA) was used to record gastric myoelectrical activity throughout the study. Immunohistochemical labelling of interstitial cells of Cajal was performed using an anti-Kit antibody.
Results: The number of c-kit (+) cells appeared to be 12.13 ± 6.02 in the fundus, 18.93 ± 11.93 in the body, and 23.04 ± 6.86 in the antrum when observed at high-power magnification. Electrogastrogram recordings demonstrated that elevated frequency amplitude ratio with increased density of c-kit (+) cells during gastric electrical stimulation.
Conclusion: Intensity and distribution of interstitial Cells of cajal in gastrointestinal tract might affect gastric slow wave patterns during electrical stimulation.
Disclosure: Nothing to disclose

P1115 HOW CAN WE MEASURE ACID SECRETION IN THE SINGLE PATIENT? A VALIDATED NON-INVASIVE SURROGATE TEST COMPARED WITH MAXIMAL ACID OUTPUT IN 600 PEOPLE

Introduction: Direct measurement of gastric acid production is out of order in clinical practice but many GI symptoms are claimed to be related with acid disorders andempirically cured. Hypochlorhydria is associated with precancerous conditions such as chronic atrophic gastritis (CAG). Acid measurement with non-invasive methods (pepsinogens) is supported by international guidelines. Their correlation with the gold standard invasive method (aspiration test) is unknown.

Aims and Methods: This study aimed to assess the efficacy of Pepsinogen I (PGI) and Gastrin 17 (G17) both in hyposecretory and hypersecretory status, as well as in heathy patients, in comparison with the gold standard. Serum PGI and G17 were measured in 600 pts (M/F = 426/176, mean age 44.2 years) with upper GI symptoms, undergoing EGD. Basal acid output, B.A.O. (n.v. 1–5 mEq/h), and maximal acid output, M.A.O. (n.v. 5–25 mEq/h), have been determined through a nasogastric tube respectively in basal condition and after pentagastrin stimulation (i.m. 6 mcrg/kg). All measurements were made off-therapy.

Results: The correlation between M.A.O. and PGI was statistically significant ($R = 0.876$, $p < 0.0001$), as well as the correlation B.A.O.-PGI ($R = 0.0567$, $p < 0.01$). The relationship between M.A.O. and G17 was inverse ($R = -0.579$ $p < 0.001$). In 344 patients (M/F = 284/60) affected by duodenal ulcer, with M.A.O. >25 mEq/h, the correlation between M.A.O. and PGI was high ($R = 0.646$, $p < 0.0001$) as well as the comparison PGI-BAO ($R = 0.234$, $p < 0.0001$) and G17-MAO ($R = -0.247$, $p < 0.0001$). In 64 pts (M/F = 30/34) affected by CAG with M.A.O. <5 mEq/h, the correlation M.A.O.-PGI was statistically significant ($R = 0.357$, $p < 0.004$).

The PGI-B.A.O. relationship showed $R = 0.234$, ($p < 0.115$) and G17-M.A.O. inverse $R = -0.309$ ($p < 0.013$). In 192 control pts (M/F = 112/80) with negative EGD and M.A.O.> 5 mEq/h and <25 mEq/h, the correlation between M.A.O. and PGI was confirmed ($R = 0.617$, $p < 0.0001$) as well as the comparison PGI-B.A.O. ($R = 0.212$, $p < 0.0004$) and G17-M.A.O. ($R = -0.454$, $p < 0.0001$).

Conclusion: PGI and G17 have been separately reported as significantly related to M.A.O. and B.A.O. in different clinical conditions. The correlation coefficient between serum markers and invasive test varied depending on the diagnosis, but it was always statistically significant. The simple value of PGI resulted able to identify the presence of a normal acid secretion. In gastric cancer screening and clinical practice measuring both serum PGI and G17 levels provides a non-invasive method to identify hypoclorhydria.

Introduction: Dumping syndrome (DS) is a common complication of gastric/esophageal surgery including under-diagnosed/-treated early and late symptoms. Clinical recommendations for its diagnosis and management are lacking.

Aims and Methods: Thus, we initiated a Delphi consensus process with international multidisciplinary experts to generate such recommendations.

We defined the scope, proposed statements, and searched electronic databases by a systematic literature surveyavailable on a online access point. A Delphi consensus process (80% agreement threshold) byGRADE (Grading of Recommendations Assessment, Development and Evaluation) was used to categorize the quality of evidence and strength of recommendations.

Results: Consensus (>80% agreement) was reached for 52 of 62 statements. The panel agreed on a simple definition of DS, recognizing its impact on quality of life.

There was agreement on the pathophysiological relevance of rapid passage of nutrients to the small bowel, but not on decreased gastric volume capacity in generating DS.

Symptom recognition is crucial in DS diagnosis but the usefulness of questionnaires like Sigstad's questionnaire for diagnosis and assessement of therapeutic response is not established. Arts' questionnaire can discriminate early from late DS symptoms. The modified oral glucose tolerance test is considered useful for DS diagnosis while gastric emptying tests are not for diagnosis confirmation (low sensitivity and specificity).

Dietary intervention is the agreed first step in DS treatment, while lying down after meals and dietary supplements increasing foods viscosity were not agreed upon.

Pharmacological treatment was agreed for the management of DS not responding to diet. Acarbose is effective for late DS symptoms only. Somatostatin analogues are the preferred treatment for patients with well established DS non-responding to diet and/or acarbose. Short-acting formulations are more effective than long-acting ones for symptom-control although repeated injections limit their long-term use.

In refractory DS treatment, continous enteral feeding via jejunostomy can be a valid alternative and gastric tube enteral feeding can be useful for DS after Nissen fundoplication only.

Surgical reintervention should be considered in DS non-responding to dietary and/or pharmacological interventions (best results achieved with gastric bypass reversal and gastric pouch restriction). No agreement was reached on the efficacy of partial pancreatectomy for management of refractory hypoglycemia.

Conclusion: This multidisciplinary international consensus process generated key clinical recommendations for definition, diagnosis and treatment of DS in clinical practice.

Introduction: The Plummer Vincent syndrome (PVS) or Kelly Paterson is a rare entity defined by the association of higher dysphagia, iron deficiency anemia and a fibrous ring of the cervical esophagus. Although correction of sideropenia may improve these symptoms, endoscopic dilatation of the oesophageal diaphragm is often necessary. The main objective of our work is to analyze the results of endoscopic treatment and then to study the epidemiological, clinical and endoscopic characteristics of PVS

Aims and Methods: We included in this study study of 77 cases of PVS collected in our unit between September 2005 and April 2018. All patients underwent martial treatment and endoscopic dilation of the esophageal ring with Gillard Savary Bougies or hydrostatic balloon under or without scopy. Other session (s) of dilatation was performed in case of recurrence of dysphagia and/or oesophageal stenosis under sedation with propofol.

Results: 11,373 upper gastrointestinal endoscopies were performed, including 184 in the context of PVS, over a period of 13 years (1,6%)

A total of 77 patients with PVS were included, including 66 women (85.7%) and 11 men (14.3%). The average age was 39 (range: 16–78 years). All patients presented dysphagia and anemic syndrome. The anemia found in all patients was iron deficient, the mean hemoglobin level was 9.5 g/dl and ferritinemia 10 µg/l. High gastrointestinal endoscopy was performed in all patients; 74 cases (96%) had a single ring while 3 patients had 2 rings (3.9%). Only one patient (1.3%) had 3. All our patients underwent endoscopic dilation with an average of 1.5 dilations with Savary Gillard's bougies in 70 cases (91%) and balloons of dilation in 4 cases (5.2%). No cases of perforation were noted after dilatation. The clinical, biological and endoscopic evolution was favorable; no case of malignant degeneration was noted with a mean follow-up of 31.5 months.

Conclusion: Management of PVS is based on endoscopic dilatation and martial supplementation. Our experience confirms that endoscopic dilation is effective, well tolerated and safe.

Regular endoscopic monitoring is required despite endoscopic dilatation because the PVS is a premalignant condition

Disclosure: Nothing to disclose

P1118 ENDOSCOPIC TREATMENT OF LARGE GASTRIC PHYTOBEZOARS WITH A SIMPLE HANDMADE BEZOARATOME

Introduction: Big phytobezoars can not be effectively fragmented by using conventional endoscopic equipments such as basket and snare.

Aims and Methods: We aimed to present the efficacy of a special designed handmade bezoarotome in fragmenting big bezoars. The study was conducted on patients who underwent endoscopic treatment of big gastric phytobezoars at ourcenter within the last 3 years by using a handmade bezoarotome. The handmade bezoarotome was designed by using the sheath and handle of a mechanica llithotriptor used for fragmentation of common bile duct stones during endoscopic retrograde cholangiography and a guidewire. A large snare was created by inserting a folded guidewire through the sheathand it was inserted through the working channel of a gastroscope in order to capture phytobezoars. Later on the snare was squeezed by using the handle and the phytobezoars were fragmented into small pieces as much as possible by repeated procedures. Patients were adviced to drink cola or pineapple juice after the procedure. The endoscopic sessions were repeated every 3 days if necessary.

Results: The study group included 37 patients (16 female, mean age: 57.6 (33–81)). Predisposing factors were type II diabetes mellitus in 13 patients and subtotal gastrectomy in 5 patient. Epigastric pain was the most common symptom (73%). The mean size of the maximum diameter of the bezoars were 81mm (60–100). Seven patients had more than one bezoar. Bezoars were effectively fragmented in all of the patients with relief of symptoms and no side effects, other than one (2.7%) who developed intestinal obstruction following treatment and required surgery. The mean number of thesessions were 1.53(1–3) and the mean total endoscopy procedure time was 14.24+6.12 minutes.

Conclusion: Handmade bezoarotome is a simple and feasible equipment which can be effectively used in the treatment of big gastric phytobezoars.

Introduction: Interaction between stimuli at different segments of the intestine is critical to maintain gut homeostasis. In patients with functional gut disorders, overlap between symptoms referred to different segments of the intestinal tract is common, but the underlying mechanisms are not completely understood.

Aims and Methods: We aimed to determine the effect of increased volume of colonic contents on gastric motor responses and satiety in patients with constipation predominant irritable bowel syndrome (IBS-C) and concomitant dyspeptic symptoms.

In ten healthy subjects (4 women and 6 men, age range 20–36 years) and 11 patients with IBS-C and concomitant dyspeptic symptoms (10 female and 1 male; age range 33- 67 years), gastric motor responses and satiety were studied in 2 different days: 1) during colonic gas filling with a non-absorbable gas mixture infused at 24 ml/min for 40 min (Total 960 ml), and 2) during sham infusion of gas into the colon for 40 min. During colonic gas filling, gastric tone was continuously recorded using an electronic barostat, and abdominal perception was registered from 0–6 using a graded questionnaire at 10-min intervals. At the end of colonic filling a satiety test was performed each study day by ingestion of Nutridrink 100 ml/min up to maximal tolerance.

Results: In healthy subjects, colonic gas infusion was associated to a progressive increment in gastric tone (gastric tone increment 65 ± 32 ml greater than during sham infusion; $p < 0.05$), but induced no increment in perception of abdominal symptoms (mean score 1.4 ± 0.4; NS vs score 1.7 ± 0.3 during sham infusion). By contrast, in patients with IBS-C colonic gas infusion was not associated to gastric contraction (gastric tone increment -15 ± 21 ml greater than during sham infusion; $p < 0.05$ vs healthy controls), but induced significant perception of abdominal symptoms (mean score 2.6 ± 0.1; $p < 0.05$ vs health during gas infusion), an effect that was not observed during sham infusion (1.7 ± 0.3; $p < 0.05$ vs real gas infusion; NS vs healthy controls). The nutridrink test revealed a minor decrease in the maximal volume tolerated after colonic gas infusion in healthy subjects (860 ± 94 ml; NS vs 940 ± 70 ml after sham infusion), whereas in IBS-C patients the maximal volume ingested was significantly smaller when the colon was filled with gas (491 ± 58 ml; $p < 0.05$ vs health), but remained similar to healthy controls after sham gas infusion (791 ± 87 ml; $p < 0.05$ vs gas infusion, NS vs sham infusion in health).

Conclusion: In patients with IBS-C and concomitant dyspeptic symptoms, increments in the volume of the colonic contents produce abdominal symptoms that are associated to early satiety and a reduction in the tolerance to ingestion of nutrients. These effects suggest that dietary and pharmacological advice to treat IBS-C, should consider avoidance of substances that increase the volume of colonic contents, especially in those patients with concomitant dyspeptic symptoms.

P1120 EVALUATION OF THE EFFECT OF ITRACONAZOLE, A POTENT CYP3A4 INHIBITOR, ON THE PHARMACOKINETICS OF A SINGLE ORAL DOSE OF TAK-906, A PERIPHERALLY-SELECTIVE D_2/D_3 DOPAMINE RECEPTOR ANTAGONIST

C. Chen[1], W. Zhang[1], M. Bari[2], M. Baratta[1], M. Rosario[1]

Introduction: Gastroparesis is characterized by delayed gastric emptying in the absence of mechanical obstruction. There is an unmet need for novel treatment options for gastroparesis owing to the safety concerns of existing therapies. For example, domperidone, a peripherally-selective dopamine D_2/D_3 receptor antagonist, is approved in some countries for short-term antiemetic and prokinetic therapy. However, the US FDA has not approved domperidone because of the risk of QT interval prolongation leading to torsade de pointes. The prolongation is amplified by inhibition of an enzyme in its primary metabolic pathway, CYP3A4.[1] This phase 1 study evaluated the pharmacokinetics (PK) and safety of TAK-906, a novel peripherally-selective D_2/D_3 dopamine receptor antagonist, in the presence and absence of a potent CYP3A4 inhibitor, itraconazole.

Aims and Methods: This was a phase 1, single-sequence, open-label, two-period crossover trial in healthy volunteers (NCT03161405). On day 1, period 1 (3 days), eligible individuals received a single oral dose of TAK-906 25 mg. During period 2 (6 days), individuals received itraconazole 200 mg once daily on days 1–5; they also received a single oral dose of TAK-906 25 mg 1 hour after the itraconazole dose on day 4. There was a minimum washout period of 4 days between the TAK-906 dose on day 1 of period 1, and the beginning of period 2. Blood samples were collected at protocol-specified times following TAK-906 dosing during both periods to assess PK. The following safety assessments were performed throughout the study: AE and vital signs monitoring, physical examinations and triplicate ECG measurements. The QT effects (placebo-corrected, change-from-baseline QTcF [ΔΔQTcF]) of TAK-906 at the geometric mean peak exposure (C_{max}) in the presence and absence of itraconazole were predicted using a linear mixed-effects model. The primary objective was to evaluate the effect of itraconazole on the PK of TAK-906. The secondary objective was to assess the safety and tolerability of TAK-906 in the presence and absence of itraconazole.

Results: A total of 12 men with a median age of 33.0 years were included in the study. Compared with administration of TAK-906 alone, co-administration of TAK-906 with itraconazole increased total systemic exposure to TAK-906 (area under the concentration-time curve from zero to infinity [$AUC_{0-\infty}$]) by 1.28-fold (90% CI: 1.10, 1.49) and C_{max} by 1.98-fold (90% CI: 1.64, 2.39; Table 1). ΔΔQTcF of TAK-906 alone (C_{max}: 9.53 ng/mL) and TAK-906 with itraconazole (18.0 ng/mL) were estimated to be 1.31 milliseconds (90% CI: -0.39, 3.01) and 1.54 milliseconds (90% CI: -0.15, 3.24), respectively. There were no AEs in period 1, and two mild AEs in period 2 considered unrelated to TAK-906 (swelling of the face prior to TAK-906 dosing and constipation after dosing). During the study, there were no deaths, and no AEs led to treatment discontinuation. No clinically significant abnormalities were observed in vital signs, ECGs (including QT interval), physical examinations, haematology and chemistry parameters or urinalysis.

Conclusion: Compared with TAK-906 alone, co-administration of itraconazole with TAK-906 increased the C_{max} of TAK-906 by 1.98-fold and $AUC_{0-\infty}$ by 1.28-fold, indicating that TAK-906 is not a sensitive CYP3A4 substrate. The cardiovascular safety concerns associated with domperidone are unlikely to be elicited by TAK-906 under similar conditions.

Analyte	PK parameter	Geometric mean ratio[a]	90% CI of geometric mean ratio[a]
TAK-906	$AUC_{0-\infty}$ (h*ng/mL)	1.28	1.10, 1.49
	C_{max} (ng/mL)	1.98	1.64, 2.39

[a]Ratio = test:reference (test, geometric mean of TAK-906 25 mg with itraconazole 200 mg; reference, geometric mean of TAK-906 25 mg alone). $AUC_{0-\infty}$, area under the concentration-time *curve* from time zero to infinity; C_{max}, geometric mean peak exposure; PK, pharmacokinetic.

[T1: Summary of the PK parameters of TAK-906 after administration of a single oral dose of TAK-906 25 mg in the presence and absence of itraconazole]

Introduction: Upper esophageal sphincter (UES) abnormality has been associated with achalasia and shown to be predictive of inferior response to treatment in these patients. UES function following pneumatic dilatation (PD) of the lower esophageal sphincter (LES) for achalasia has not been accessed. This study's objective is to investigate change in UES function following PD of LES for achalasia.
Aims and Methods: A Retrospective analysis of high resolution manometry (HRM) data regarding LES and UES function, before and after PD for achalasia. Continuous variables are presented as median (interquartile range-IQR).
Results: From June 2011 until December 2017, 116 patients underwent PD for achalasia, preceded by HRM in our center. Thirty-three of them had a HRM performed before and after the procedure. Median age of patients was 66.2 (IQR 18) years, 55% men. 76% had type 2 achalasia. Median LES integrated relaxation pressures (IRP) before and after PD were 21.9 mmHg (IQR 16.2) and 10.7 mmHg (IQR 10.7) respectively ($P < 0.001$). Similar UES mean-basal pressure and relaxation duration were observed at baseline compared to post-PD, 53.0 mmHg (IQR 47.8) vs. 49.0 mmHg (IQR 53.5) and 808 msec (IQR 386) vs. 746 msec (472) respectively ($P > 0.5$). Nevertheless, median UES IRP decreased by more than 65%, 3.8 mmHg (IQR 5.1) vs. 1.3 mmHg (IQR 5.0), ($P = 0.013$).
Conclusion: PD for achalasia was associated with a significant decrease in lower and upper esophageal sphincter IRPs. The pathophysiologic mechanism behind UES IRP decrease and its significance in the setting of PD of LES is unclear and mandates further investigation.

Introduction: POEM is an established, safe and successful treatment of esophageal motor disorders. Although the procedural aspects seem validated, the pre-procedural evaluation, the indications, and the follow-up remain heterogeneous. Considering the growing place of POEM, it appears necessary to build European Clinical Practice Guidelines. As first step, our objective was to assess the clinical practice in various European expert centers.
Aims and Methods: French and European centers performing POEM routinely were identified, and were proposed to complete (one/center) an online survey about their current practice in the management of achalasia, divided in 4 parts: 1/ Pre-procedure evaluation; 2/ Indications; 3/ Detailed procedural technique; 4/ Follow-up (including post-operative treatment, clinical and paraclinical tests).
Results: Twenty-one centers responded, 13 from France, 8 from Spain, Switzerland, England, Italy and Belgium. There is a mean of 1.5 operator/center [1–3], mostly gastroenterologists (86%), performing a mean of 28 POEM/year [8–70]. Fellows are trained in 43% of them and the estimated learning curve was 11 +/− 7 cases. The pre-operative clinical assessment includes Eckardt score in 100% of the cases and BMI in 62%. The paraclinical assessment includes an EGD in all the cases as well as a high resolution manometry (HRM). POEM is indicated in first intention in 100% of centers for Chicago type III achalasia, 81% for type I, and 76% for type II. POEM is also indicated as first treatment in 95% of centers after failure of Heller, 81% if high Eckardt score and young men, and 67% in patients >80 years-old. In case of previous dilation, 45% of centers indicate POEM after one session of any diameter. The two main contra-indications are paraneoplastic achalasia (71%) and systemic diseases (52%). Regarding pre-operative care, patients have liquid diet in 67% of centers, 1.8 days before the POEM [1–5] and are fasting 12 hours before. Aspirin is stopped in 29% of centers (100% of AVK and antiplatelets).
The patients are always hospitalized in conventional unit. Procedures are always performed with general anesthesia and intubation, in supine position in 90% of centers. Patients are curarized in 62% and receive antibiotic prophylaxis in 86%. A regular endoscope is used in 90% of the cases, always with CO2. The most used knife is the Triangle (Olympus, Japan) for tunneling (n = 9/21) and the myotomy (n = 12/21). The operators use one device in 62% of centers and CoaGrasper in 76%. In achalasia, the tunnel is posterior (86%) with a mean tunnel length of 13.6cm [10–17]. The myotomy is anterograde in 81% of centers, only on the circular fibers in 86%, with mean length of 10cm [6–15]. The mean number of clips is 5.3 [4–7], equally distributed in terms of size. The mean procedure time is 55 min [25–100].
Post-operatively, patients resume liquid diet from POD 1 in 81% of the cases, normal diet from POD 4 in 71% of the cases. 43% of the centers discharge patients at POD 1, but the mean hospital stay after POEM is 2.2 days [1–5]. Patients have oral PPI in 100% of centers, resume antiplatelets after 3 days and anti-coagulants after 6 days. The median of reevaluation is 3 months, including Eckardt score (100%) and BMI (76%). A HRM is routinely performed in 52% of the centers. Patients are followed annually in most of the cases (71%).
Conclusion: Despite its growing place in the treatment of esophageal motor disorders, the policy of management differs in few points among European expert centers. A Delphi method could be used to propose European Clinical Practice Guidelines for POEM practice.

Introduction: Peroral endoscopic myotomy (POEM) is an excellent endoscopic treatment for achalasia (AC). Short-term studies are ample but long-term studies are few. This study aimed to evaluate the long-term efficacy of peroral endoscopic myotomy for patients with achalasia.
Aims and Methods: A total of 115 patients (median age 45 years; interquartile range 34–57) with AC who underwent POEM at the First Affiliated Hospital of ZheJiang Chinese Medical University with a median follow-up of 36 months were enrolled in this study. Eckardt score and the lower esophageal sphincter pressure changes were analyzed, and gastroesophageal reflux was observed.
Results: During the final follow-up, the median Eckardt score reduced from 7.5 ± 1.9 preoperatively to 2.2 ± 1.3 ($P < 0.001$). Treatment success after 12, 24, 36, and 48 months was observed in 90.4% [confidence interval (CI) 85.7–95.0], 89.3% (CI 84.5–94.0), 87.7% (CI 82.3–93.1), and 80.8% (CI 72.7–88.9) of patients, respectively. A total of 16 (13.9%) failures occurred. Four patients were nonresponders (failure within 3 months), nine were early recurrence (between 3 months and 3 years), and three were late recurrence (after 3 years). Further, 21 (23.1%) patients had symptoms of reflux during the 2-year follow-up. Only one patient with new-onset reflux symptoms was added during the subsequent 2-year follow-up. Moreover, 71 (61.7%) patients underwent gastroscopy after POEM, and 13 (18.3%) patients were diagnosed with reflux esophagitis.
Conclusion: POEM is safe and effective for treating AC and has a better long-term effect.
Disclosure: Nothing to disclose

Introduction: The spectrum of esophageal body hypomotility on high resolution manometry (HRM) includes fragmented, weak and failed sequences, the latter two are considered ineffective. The Chicago Classification (CC) 3.0 criteria for diagnosis of fragmented peristalsis and ineffective esophageal motility (IEM) are based on consensus 50% thresholds of fragmented and ineffective sequences respectively. Objective proportions and type of hypomotile sequences predicting abnormal esophageal reflux burden are incompletely understood.

Aims and Methods: Our aim was to evaluate thresholds of fragmented, weak and failed esophageal sequences on HRM that predict abnormal acid exposure time (AET) and mean nocturnal baseline impedance (MNBI) on ambulatory pH-impedance monitoring performed off acid suppressive therapy. Clinical data, HRM and ambulatory pH-impedance studies performed on patients with persisting reflux symptoms were reviewed from six centers (5 in Europe and 1 in US) for this preliminary report. Incomplete studies, achalasia, esophageal outflow obstruction and prior foregut surgery were exclusions. HRM studies were analyzed according to CC 3.0, using distal contractile integral (DCI) to designate fragmented (DCI > 450 mmHg.cm.s with breaks > 5 cm on 20 mmHg isobaric contour), weak (DCI 100–450 mmHg.cm.s) and failed (DCI < 100 mmHg.cm.s) sequences. Total AET > 6% and MNBI < 2292 ohms defined abnormal reflux metrics on pH-impedance testing. Odds ratios (ORs) with 95% confidence intervals (CI) were calculated to determine likelihood of abnormal reflux metrics with varying proportions of fragmented, weak and failed sequences, using normal HRM studies (10 intact sequences with DCI > 450 mmHg.cm.s) for comparison.

Results: Of 351 patients (52.1 ± 0.8 yr, 67%F), 61.5% presented with typical symptoms. AET > 6% was found in 103 (29.3%), and MNBI < 2292 ohms in 217 patients (61.8%). Compared to normal HRM, ≥50% fragmented peristalsis had OR 3.6 (CI 1.3–9.8, p = 0.01) in predicting abnormal AET, and OR 3.7 (CI 1.2–11.8, p = 0.03) in predicting abnormal MNBI. Both AET and MNBI were significantly abnormal with > 70% fragmented sequences compared to ≤80% (AET 8.8 ± 1.5% vs 4.5 ± 0.6%, MNBI 1225 ± 193 vs 2232 ± 87 ohms, p < 0.05 for each). IEM as currently defined by CC 3.0 also predicted abnormal AET (OR 2.4, CI 1.3–4.4, p = 0.009), and abnormal MNBI (OR 2.3, CI 1.3–4.2, p = 0.006). When weak and failed sequences within IEM were separately analyzed, ≥50% weak sequences did not predict abnormal AET (OR 1.9, CI 0.8–4.2, p = 0.14) but predicted abnormal MNBI (OR 3.8, CI 1.6–9.1, p = 0.002); > 70% weak sequences resulted in numerically higher AET (5.0 ± 1.1% vs. 4.5 ± 0.5%, p = ns) and lower MNBI (1811 ± 372 vs. 2123 ± 86 ohms, p = ns). The role of contraction reserve in modifying esophageal reflux burden could not be evaluated because of insufficient numbers with MRS data. ≥50% failed sequences uniformly predicted abnormal AET (p ≤ 0.009), but MNBI was consistently low with failed sequences (1815 ± 151 ohms) and not discriminative (p≥0.2).

Conclusion: Long breaks in esophageal peristaltic integrity seen with fragmented and failed sequences are more relevant to abnormal esophageal acid burden than weak sequences, but all hypomotility processes can contribute to low MNBI. Fragmented sequences can be graded into mild (≤70%) and severe based on abnormal reflux metrics. Failed sequences consistently predict abnormal reflux metrics, in contrast to weak sequences. Our findings suggest that further review of the CC 3.0 diagnostic criteria for IEM and fragmented peristalsis is warranted in the context of reflux disease.

Introduction: Combined multichannel intraluminal impedance and high-resolution manometry improves detection of clinically relevant esophagogastric junction outflow obstruction.

Aims and Methods: A total 169 patients diagnosed as having EGJOO between June 2011 and February 2018 were analyzed. All the patients received a combined MII and high resolution manometry (CMII-HRM, Sandhill system). MII was reported as having abnormal liquid bolus transit (LBT) if < 80% of swallows had complete bolus transit. EGJOO was defined as a median integrated relaxation pressure of > 20 mmHg and when the criteria for achalasia were not met. Patients who progress to achalasia, show significant passage disturbance, or require pneumatic dilatation were defined as having a clinically relevant EGJOO.

Results: Among the patients with EGJOO ($n = 169$), the clinically relevant group ($n = 10$) had higher incidence rates of dysphagia (100% vs 25.2%, $p < 0.001$), compartmentalized pressurization (CP; 90.0% vs 22.0%, $p < 0.001$), and abnormal LBT (100% vs 66.7%, $p = 0.032$) than the non-relevant group ($n = 159$). The combination of dysphagia, CP, and abnormal LBT showed the best predictive power for clinically relevant EGJOO (sensitivity 90%, specificity 92.5%, positive predictive value 42.9%, negative predictive value 99.3%, positive likelihood ratio 11.9, and negative likelihood ratio 0.1). When CMII-HRM was used, an additional 8.3% of clinically relevant EGJOO cases were identified as compared with HRM alone.

Conclusion: Clinically relevant EGJOO can be predicted using CMII-HRM and clinical factors.

Introduction: Per-Oral Endoscopic Myotomy (POEM) is nowadays a widely accepted treatment method for esophageal achalasia, not only because of its attractiveness but also favorable mid-term efficacy and safety profile, although long-term outcomes are still yet to be proved. Furthermore, serious concerns regarding post-POEM reflux are more than legitimate.

Aims and Methods: The aim of our prospective single-center case series was to assess the long-term clinical outcomes of POEM in terms of efficacy, durability and complications. A total of 266 POEM procedures were performed in 254 consecutive patients with confirmed achalasia referred to our tertiary center from 12/2012 to 4/2018. Follow-up visits at 3, 12, 24, 36 and 48 months were completed in 217, 164, 115, 66 and 44 patients. All patients underwent upper GI endoscopy, high-resolution manometry (HRM) and 24-hour pH-monitoring at 3 months after POEM; endoscopy was then repeated between 24–36 months. The main outcomes were treatment success defined as Eckardt score < 3, recurrence rate, adverse events and post-POEM reflux.

Results: At 3, 12, 24, 36 and 48 months, treatment success was achieved in 97.7% (CI 96–98), 96.0% (95–97), 91.0% (89–93), 85.5% (82–89) and 81.6% (77–87) of patients. A total of 19 patients experienced treatment failure (n = 5) or recurrence (n = 14). The recurrences occurred most often in patients with type I achalasia (8 out of 43, 18.6%). At 3 months, reflux esophagitis was endoscopically confirmed in 86/214 patients (40.1%; 9 patients had LA C/D esophagitis) and abnormal acid exposure was found on pH-metry studies was detected in 74/192 patients (38.5%). At 24–36 months, endoscopy was performed on 71 patients and reflux esophagitis was present in 21 (29.6%) of them. The proton pump inhibitors were administered on average to 37% of patients at the follow-up visits. So far there have not been any complications detected with regard to the post-POEM reflux such as Barrett's esophagus or stenosis. The procedure-related complications were as follows: decompression of capnoperitoneum (145/254, 57.1%), subcutaneous emphysema (90/254, 35.4%), and in less than 5% of patients periprocedural bleeding, mucosal injury or postprocedural fever were each observed. Unfortunately, we experienced one fatal complication during POEM which was due to sudden cardiac death in a patient with silent pulmonary hypertension. Two cases of prolonged hospitalization were caused by fluidothorax/pneumofluidothorax.

Conclusion: POEM successfully amended the spectrum of effective treatment modalities for achalasia with sustained treatment success of 91% at 2 years, which slightly decreases over time to 81.6% at 4 years after the procedure. The rate of post-POEM reflux is detected in as high as 40% of patients. Despite POEM being considered a safe method overall, severe complications may still occur.

Introduction: Supragastric belching (SGB) is a behavioral disorder where air is ingested in to the esophagus and immediately expelled. It can appear as excessive belching and it may reduce quality of life but might not be related to anxiety or depression.

Aims and Methods: The aim of this study was to evaluate the efficacy of behavioral therapy in reducing belching, improving quality of life, and relieving depression and anxiety in a six-month follow-up compared to standardized doctors information. Patients (n = 20, age 26–79, 16 female) with SGB diagnosed in

esophageal 24-hour impedance monitoring were randomized to receive either 5 sessions of behavioral therapy performed by a speech therapist or only standardized doctor's information about the mechanisms of supragastric belching. The frequency and intensity of gastric belching and quality of life (QOL) were evaluated by a visual analog scale (0–10) at onset and after 6 months follow-up. RAND-36 and 15D questionnaires were used to evaluate QOL and BAI and BDI for anxiety and depression. After the initial 6 months follow-up also the controls had the possibility of behavioral therapy with additional evaluation after 6 months.
Results: The frequency and intensity of belching were significantly reduced in the therapy group ($n = 7$, $P = 0.042$, $P = 0.027$) but not in the controls ($n = 6$) at 6 months follow-up. Anxiety and depression were relieved but not significantly. QOL did not change. In all patients after therapy ($n = 10$, including 3 patients from control group) both the frequency ($P = 0.005$) and intensity ($P = 0.005$) of belching were significantly reduced. The study was interrupted by 2 patients and 5 patients are coming to follow-up.
Conclusion: Behavioral therapy seems to be effective in reducing belching in patients with SGB and to be superior to standardized doctor's information.
Disclosure: Nothing to disclose

P1128 AGE AND MALE GENDER ARE ASSOCIATED WITH A DECLINE IN FUNCTIONAL GASTROINTESTINAL SYMPTOMS: 10-YEAR FOLLOW-UP OF THE KALIXANDA STUDY

Introduction: Functional dyspepsia (FD) and irritable bowel syndrome (IBS) are prevalent conditions in the population. The overall prevalence in the population is stable but presentation of symptoms may fluctuate over time. Overlap of FD/IBS symptoms is common and higher than expected by change. Known factors influencing symptom fluctuation include anxiety at baseline, however to date, age and gender have not been evaluated.
Aims and Methods: Our aim was to explore the role of age and gender in symptom stability in a prospective population based follow-up study. Study participants ($n = 3000$) were randomly selected from the national Swedish population register and surveyed in 1998 by a validated abdominal symptom questionnaire (ASQ). 1000 individuals randomly selected completed an oesophagogastroduodenoscopy in 1999–2001. All eligible from those ($n = 887$) were invited to a follow-up in 2010 with the ASQ. Data were analyzed by testing difference of mean age of subjects with FD and IBS versus controls at baseline and at follow-up with the T test.
Results: In total 703 out of 887 subjects (79.3%) completed the questionnaires. FD was reported by 110 subjects at baseline and by 92 at follow-up. FD without overlap with IBS was reported by 56 subjects at baseline and by 34 subjects at follow-up. IBS was reported by 200 subjects at baseline and by 185 subjects at follow-up (Table). IBS without overlap with FD was reported by 144 subjects at baseline and by 127 subjects at follow-up. The mean age of those with FD was not lower than that of controls at baseline (52.2 vs 53.2 years, $p = 0.45$) but at follow-up it was (60.0 vs 63.7 years, $p = 0.009$). The mean age of those with FD at follow-up was significantly lower in male (57.0 vs 63.7 years, $p = 0.004$) but not in female (61.5 vs 63.7 years, $p = 0.19$). However, in FD cases without overlap with IBS there was no significant difference in mean age at follow-up (62.6 vs 63.7 years, $p = 0.62$). The mean age of those with IBS was not lower than that of controls at baseline (51.8 vs 53.5 years, $p = 0.11$) but at follow-up it was (60.1 vs 64.3 years, $p < 0.001$). In IBS the mean age was significantly lower both in male (57.5 vs 64.3 years, $p < 0.001$) and in female (61.4 vs 64.3 years, $p = 0.020$) at follow-up. In cases with IBS without overlap with FD there was a significant difference in mean age both at baseline (51.1 vs 53.5 years, $p = 0.04$) and at follow-up (60.8 vs 64.3 years, $p = 0.004$). There was no significant difference in mean age at follow-up in female (62.0 vs 64.3 years, $p = 0.11$) but in male there was (58.6 vs 64.3 years, $p = 0.003$).
Conclusion: The mean age of those with FD or IBS was statistically significantly lower at follow-up but not at baseline, except in IBS without FD at baseline, showing that functional GI symptoms decline with age which is associated with male gender.
Disclosure: Nothing to disclose

P1129 DIFFERENT DYSREGULATION OF SYMPATHETIC AND PARASYMPATHETIC AUTONOMIC RESPONSE TO STRESS IN PATIENTS WITH FUNCTIONAL DYSPEPSIA

Introduction: Functional dyspepsia (FD) is a common functional gastrointestinal disorder (FGID). The pathophysiological mechanisms of FGID are complex. Accumulating evidence indicates that autonomic dysregulation contributes to FGID. The symptoms of FGID are often triggered by stress, however, the mechanisms of autonomic dysregulation in FGID, especially in response to stress are incompletely understood.
Aims and Methods: The aim of this study was to assess potential changes of vagal and sympathetic regulation in patients suffering from FD in response to distinct types of stressors (active mental stress vs. passive physical stress). Studied population included 10 patients diagnosed with FD and 11 age- and sex-matched healthy controls. All patients were diagnosed according to ROME IV criteria for functional gastrointestinal disorders. Blood pressure (BP) and heart rate were continuously recorded using Finometer MIDI (FMS, Netherlands) at rest and during two distinct stressors – mental arithmetic test and cold pressor test (cooling of forearm in 1–3°C water bath for 5 min). Evaluated parameters: 1) baroreflex sensitivity (BRS, calculated from spontaneous heart rate variability and BP variability) reflecting vagally-mediated heart rate regulation in response to changes of BP, 2) spectral power in low-frequency band of systolic BP variability (LF-SBP) reflecting sympathetic alpha-adrenergic stimulation of vascular smooth muscles, 3) systolic and diastolic BP, and 4) mean heart rate.
Results: BRS (reflecting vagal function) in patients with FD was substantially (by 50%) reduced compared to controls at rest and in response to both mental arithmetic test and to cold pressor test ($p < 0.01$ for all comparisons). In contrast, LF-SBP (reflecting sympathetic function) was normal at baseline, but significantly increased in FD compared to controls during both mental arithmetic test and cold pressor test ($p < 0.05$, $p < 0.01$, respectively). No differences were found in systolic and diastolic BP and heart rate.
Conclusion: Our data show impaired dynamic sympatho-vagal balance in patients with functional dyspepsia at rest and in response to different types of stressors. The vagal function is reduced at baseline and not influenced by stress, while the sympathetic response is exaggerated by stress. These findings support the hypothesis of altered autonomic regulation during stress as a potential mechanism worsening the symptoms of FD. We suggest that comprehensive evaluation of stress response using noninvasive analysis of distinct autonomic effectors could help to better understand the role of autonomic dysregulation in functional gastrointestinal disorders.

P1130 MAST CELL ACTIVATION SYNDROME (MCAS) IN PATIENTS WITH RAPID ONSET OF FOOD INDUCED SYMPTOMS OF DYSPEPSIA, IBS, DIARRHOEA, NAUSEA OR VOMITING REACTS FAVOURABLY ON HISTAMINE 1 OR 2 BLOCKERS OR CROMOGLYCATE. AN OBSERVATIONAL STUDY

Introduction: Many patients with functional dyspepsia or IBS indicate that their symptoms are being provoked by specific food or food components. This may be due to the mast cell activation syndrome. MCAS of the digestive tract is characterized by 2 major criteria: 1. Multifocal or disseminated infiltrates in mucosal biopsies of >20 CD 117 stained mast cells (MC) per high power field (hpf 400x). 2. Presence of symptoms attributable to pathologically increased MC activity. An additional minor criterion is symptomatic response to inhibitors of MC activation or mediator production. The awareness of MCAS is limited. This milder form of MC hyperreactivity must be distinguished from the more severe and systemic mast cell activation *disease* (MCAD) or mastocytosis where often skin and bone marrow are infiltrated with abundant MC. In regular HE stained slides MC are overlooked. Special staining with CD 117 displays the cells in characteristic brown color followed by cell count per hpf. We investigated the efficacy of histamine receptor antagonists and MC stabilizers in patients with distinct food induced MCAS.

Aims and Methods: Fifty-two patients (45 female, age 41.3 ± 23.3 yrs) with one or more rapid onset (<60 min), food induced symptoms of diarrhea (n = 23), functional dyspepsia (n = 15), IBS (n = 14), nausea (n = 12), abdominal pain (n = 11), bloating (n = 6), vomiting (n = 5) and cyclic vomiting syndrome (n = 3) were included. Biopsies of duodenum (n = 47) and colon or ileum (n = 6) showed an increase of CD 117 stained MC (30,0 ± 13.1) per hpf. Many patients had long standing and persistent complaints with an average of 10.5 ± 18.4 yrs. Therapy was initiated for four weeks, first with H1 receptor antagonist and MC stabilizer ketotifen 1–4 mg bid or fexofenadine 120–180 mg bid and subsequently H2 receptor antagonist ranitidine 150 mg bid or cromoglycate nalcrom 100 or 200 mg qid.

Results: Medication was tried and changed until the desired clinical response was achieved with one of the drugs. Ultimately 12 patients responded to ketotifen, 15 to fexofenadine, 2 to ranitidine and 14 to nalcrom. The therapeutic efficacy varied from excellent (no to minimal residual symptoms) in 17 (33%), substantial improvement in 15 (29%), modest amelioration in 10 (19%) or no effect in 10 (19%). Three patients used a combination of 2 or 3 drugs.

Conclusion: This observational study shows that when rapid onset, food induced symptoms are present and an increased number of MC (>20 per hpf) is found in mucosal biopsies trial and error treatment of MCAS with H1 or H2 receptor blockers or cromoglycate may substantially improve or remedy often longstanding and frequently debilitating symptoms of the GI tract.

P1131 OBSERVATIONAL STUDY OF FD/IBS OVERLAP SYNDROME CHARACTERISTICS AND EFFICACY OF TREATMENT

S. Vyalov[1]
[1]*Peoples Friendship University of Russia, Gastroenterology, Moscow, Russian Federation*

Contact E-Mail Address: svialov@mail.ru

Introduction: Gastrointestinal (GI) symptoms profile and prevalence or associated factors for the overlap between functional dyspepsia (FD) and irritable bowel syndrome (IBS) group still remain unclear.

Aims and Methods: The aim of study was evaluation of the clinical and demographic features of FD, IBS, and FD-IBS overlap and efficacy of STW 5 as a standard treatment.

In this observational comparative study a total of 1006 patients (254 in the control group, 226 in the FD, 261 in the IBS, and 265 patients in the overlap group, who met the criteria for both FD and IBS) were included. Diagnostics were based on the Rome IV criteria for functional GI disorders. A total of 752 patients from all groups were treated with 3 × 20 drops/day of STW 5. At 4 and 8 week of treatment the symptom assessment was made. The main outcome criterion was the change in a validated Gastrointestinal Symptom Score (GIS) and Visual Analogue Scale (VAS).

Results: Patients with FD-IBS overlap had more severe symptoms (bloating, nausea, vomiting, hard or lumpy stools, defecation straining, and a feeling of incomplete bowel movement) and higher depression scores compared with non-overlap patients. The factors and symptoms, most frequently associated with overlap syndrome in comparison to FD or IBS groups are summarized.

Unmarried status, nausea, bloating, and a feeling of incomplete emptying were more frequent factors in FD-IBS overlap group vs IBS group. In contrast, young age, depression, bloating, and postprandial distress syndrome were positively associated with FD-IBS overlap group vs FD group.

Postprandial fullness (38.4%), belching (28.5%), and regurgitation (27.1%) were the three most prevalent upper GI symptoms in IBS. Functional dyspepsia (47.5%), belching disorders (34.5%), and functional heartburn (27.2%) were the three most frequent upper FGID in FD patients. During STW 5 treatment GIS and VAS showed significant improvement from 8.6 to 3.7 points. In all groups the tolerability of the STW 5 was good with no adverse events.

Conclusion: Bloating was a more frequent symptom for FD-IBS overlap. Patients with postprandial distress syndrome more frequently had concomitant IBS. Mixed IBS is a more frequent factor for FD-IBS overlap. This study confirmed the efficacy of STW 5 in FD, IBS and FD-IBS patients during 8-weeks treatment period. The combination of extracts with specific gastrointestinal mode of action appears to be advantageous for a heterogeneous condition such as functional dyspepsia, irritable bowel syndrome and overlap syndrome.

Introduction: Suicide ideation, one symptom of depression, was associated with irritable bowel syndrome (IBS), but not with other functional gastrointestinal disorders (FGIDs).

Aims and Methods: The aim of the present study is to search if suicide ideation is associated with FGIDs.

1469 FGIDs patients (71% females) were included in this observational study. They fill the Rome III questionnaire, Beck depression inventory, and state and trait anxiety questionnaires. Data were analyzed using ANOVA with Bonferroni correction and logistic regression analysis.

Results: Suicidal ideation was reported by a minority of patients (15 %), with low intensity (''I have thoughts of killing myself, but I would not carry them out'') in 190 patients (13%), Moderate intensity (''I would like to kill myself'') in 11 patients (1%) and High intensity (''I would kill myself if I had the chance'') in 22 patients (1%) (Table 1).

It was not associated with significant difference of sex ratio (P = 0.520) (Table 2), of age (P = 0.225) or of BMI (P = 0.300).

The presence of suicidal ideation is associated with increase of the three psychological scales: depression (P < 0.001; OR = 1.086; 95%CI = [1.063–1.110]), state anxiety (P = 0.006; OR = 1.025; 95%CI = [1.007–1.043]) and trait anxiety (P = 0.021; OR = 1.030; 95%CI = [1.005–1.057]).

In addition, patients with suicidal ideation report a higher frequency of two IBS subtypes: IBS-Diarrhea (P = 0.016; OR = 1.754; 95%CI = [1.109–2.774]) and Mixed-IBS (P = 0.008; OR = 2.104; 95%CI = [1.210–3.660]).

Conclusion: This study shows a specific association between suicide ideation and some IBS subtypes, and not with other FGIDs.

Introduction: Functional dyspepsia (FD) is one of the most common chronic gastrointestinal disorders with undefined mechanisms. The phenomenon that FD patients cluster in families supported the crucial role of genetic factors in the pathogenesis of FD. Several epidemiological studies have been performed to explore the associations between gene polymorphisms and FD susceptibility and gave inconsistent results.

Aims and Methods: We performed a meta-analysis of all available data to systematically clarify the associations between gene polymorphisms and FD risk. We conducted a systematic computerized literature search from PubMed, EMBASE, the Cochrane Library prior to April 2018 using the following keywords: ''functional dyspepsia'' or ''dyspepsia'', and ''polymorphism'', ''mutation'', or ''variant''. Inclusion criteria were as follows: (1) case-control studies or cohort studies evaluating the relationship between any gene polymorphism and FD; (2) sufficient data on genotypic frequencies between all participants for estimating an odds ratio (OR) with a 95% confidence interval (CI); and (3) studies with related clinical characteristics limited to those using human subjects and containing demographic information of subjects. Two investigators extracted available data independently to make sure accuracy. ORs with 95% CI were calculated to assess the intensity of the association of related gene polymorphism and FD. *P* value <0.05 was defined as statistical significance.

Results: Thirty case-control studies were included in present systematic review. Of all, 14 studies referred to *GNB3* 825C>T with a total of 1492 cases and 3206 controls, 5 studies referred to *SCL6A4* 5HTTLPR with a total of 428 cases and 1433 controls, 3 studies referred to *CCK-1R* 779T>C with a total of 397 cases and 558 controls were further included into meta-analysis. Four different genetic models (allelic, dominant, recessive, and homozygote) were applied. *GNB3*

polymorphism was associated with increasing risk of FD based on recessive (TT vs CC+CT, OR = 1.20, 95% CI 1.01–1.43, $P = 0.04$) and homozygote (TT vs. CC, OR = 1.26, 95% CI 1.02–1.55, $P = 0.03$) models. Furthermore, subgroup analysis identified TT and T-allele (TT+CT) genotypes both were associated with increased susceptibility to epigastric pain syndrome (EPS) compared with the CC and C-allele genotype. No association was observed in any of four allelic genetic model of *SCL6A4* with FD susceptibility. However, L-allele (LL+SL) genotype of *SCL6A4* was found to be significantly associated with an increased risk of EPS (OR = 1.33, 95% CI 1.04–1.70, $P = 0.03$) and postprandial distress syndrome (PDS; OR = 1.25, 95% CI 1.03–1.52, $P = 0.04$) compared to SS genotype respectively. Finally, recessive model (CC vs. TT+CT, OR = 0.44, 95% CI 0.26–0.73, $P = 0.002$) and homozygote model (CC vs. TT, OR = 0.43, 95% CI 0.25–0.74, $P = 0.002$) demonstrated CC genotype of *CCK-1R* is associated with decreasing risk of FD.

Conclusion: The available evidence of our meta-analysis has shown that there are associations between *GNB3*, *SCL6A4*, and *CCK-1R* polymorphisms and FD susceptibility.

Introduction: Altered gut-brain axis signalling may play an important pathophysiological role in functional gastrointestinal disorders (FGID). We aimed to investigate relations between psychological factors (anxiety, depression and neuroticism) and dyspeptic symptoms and gastric dysmotility in a cohort of patients with irritable bowel syndrome (IBS; n = 85), functional dyspepsia (FD; n = 94), or a combination (IBS/FD; n = 65).

Aims and Methods: Patients were recruited consecutively and examined with ultrasound of the proximal and distal stomach after drinking 500 mL low caloric meat soup (Toro klar kjøttsuppe, Bergen, Norway), and scored their dyspeptic symptoms on a visual analogue scale (0–100 mm) before and after the meal. Psychological symptoms were assessed by HADS (anxiety and depression; n = 46), VSI (gastrointestinal specific anxiety, n = 58), and EPQ-N (neuroticism; n = 203). Correlations were calculated by linear regression, and differences between means were evaluated by Student's t-test.

Results: Mean neuroticism scores for patients with FD and IBS were 3.4 and 3.7, respectively ($p > 0.05$). When analysing all patients with FD and/or IBS (n = 248), we found only a weak correlation between diameter of the fundus 10 minutes after soup intake and neuroticism score by linear regression ($r = -0.156$, $p = 0.047$). There were no other significant correlations between EPQ-N and ultrasonographic measurements of the stomach. We found weak correlations between the following dyspeptic symptoms in a fasting state and EPQ-N: epigastric pain ($r = 0.159$, $p = 0.024$), bloating ($r = 0.215$, $p = 0.002$), and upper abdominal discomfort ($r = 0.171$, $p = 0.015$), but not to postprandial symptoms. Gastrointestinal specific anxiety (VSI) had weak, positive correlations to epigastric pain ($r = 0.308$, $p = 0.008$), bloating ($r = 0.255$, $p = 0.030$) and upper abdominal discomfort ($r = 0.239$, $p = 0.044$) in fasting state. We found no correlations between VSI and postprandial symptoms or ultrasonographic measurements of the stomach.

We found a significant correlation between HAD-D and fasting nausea in FD patients ($r = 0.544$, $p = 0.004$, n = 25). In patients with IBS, we found a correlation between change in nausea after the meal and HAD-D ($r = 0.562$, $p = 0.045$, n = 12). HAD-A was not correlated with any dyspeptic symptoms.

Conclusion: Neuroticism scores in patients with FD and IBS were lower than expected, and EPQ-N-scores were not strongly correlated to gastric dysmotility or upper GI symptoms. VSI had weak correlations to fasting upper GI symptoms, but not postprandial symptoms. The strongest correlations were between HAD-D and nausea scores, suggesting a link between depression and nausea.

Introduction: Itopride is a prokinetic with dopamine D_2-antagonistic and cholinesterase inhibitor properties, evaluated for the treatment of functional dyspepsia. The effects of itopride on the perception of gastric distention and postprandial fundus relaxation, two major pathophysiological mechanisms in functional dyspepsia besides delayed gastric emptying, are unknown.

Aims and Methods: The aim of this study was to evaluate the impact of itopride on the sensitivity to gastric distention and on meal-induced gastric accommodation in healthy volunteers and compare to D_2-antagonist domperidone. Fifteen healthy volunteers (6 male, mean age 28.3 ± 5.8) were studied on four separate occasions, after pre-treatment for two days t.i.d. with placebo (P), itopride 50mg (I50), itopride 100mg (I100) or domperidone 10mg (D10) in a placebo-controlled, double-blind cross-over design. A gastric barostat study was performed to assess gastric compliance, sensitivity to distention and accommodation. Symptoms were evaluated by visual analogue scales (VAS). Results are given as mean ± SEM and compared by Student's t-test and ANOVA.

Results: D10, I50 or I100 did not influence pre- and postprandial gastric compliance and sensitivity to gastric distension compared to placebo before and after meal. Consequently, the pressures needed to induce first perception or discomfort and corresponding intra-balloon volumes did not differ significantly between placebo and drugs. No significant differences in accommodation were observed after I100 (preprandial 261 ± 32 ml, postprandial 429 ± 28 ml, accommodation 167 ± 32 ml) compared to placebo. Preprandial intragastric volumes were similar with D10, I50 or P (respectively 244 ± 21, 225 ± 23, and 261 ± 36 ml, NS). However, postprandial gastric volumes after I50 and D10 were significantly lower compared to placebo (respectively 303 ± 34 and 334 ± 37 vs. 448 ± 50 ml, both $p < 0.05$) and gastric accommodation was significantly reduced after D10 (90 ± 26 ml) and I50 (78 ± 25 ml) compared to placebo (186 ± 37 ml, both $p < 0.01$). VAS scores during balloon distentions and before and after meal ingestion did not differ between placebo and any of the treatment arms.

Conclusion: In healthy subjects, itopride and domperidone do not alter gastric compliance or sensitivity to distension. Itopride 50 mg and Domperidone 10 mg t.i.d. decrease gastric accommodation to a meal. No consistent effect on distention-induced symptoms was observed.

P1136 NOT ONLY DUODENAL BUT ALSO JEJUNAL MUCOSAL INTEGRITY ARE IMPAIRED IN PATIENTS WITH FUNCTIONAL DYSPEPSIA. A STUDY USING SMALL BOWEL HRM/IMPEDANCE

K. Nakagawa, E. Yazaki, Q. Aziz, D. Sifrim
Centre for Neuroscience and Trauma Blizard Institute at The Barts & The London School of Medicine & Dentistry, Queen Mary University of London, London, United Kingdom

Contact E-Mail Address: k.nakagawa@qmul.ac.uk

Introduction: Impaired duodenal mucosal integrity has been reported as a pathophysiological mechanism in functional dyspepsia (FD). Little is known about jejunal mucosal integrity in FD. Low baseline impedance (BI) is used as a surrogate marker of impaired esophageal mucosal integrity. We have recently reported that measurement of BI in the duodenum and proximal jejunum is best immediately after the passage of Phase III of the MMC.

Aims and Methods: The aim of this study was to assess duodeno-jejunal mucosal integrity (BI) in patients with FD compared to healthy controls (HC). Fifteen HC (7 females; mean age 36.7 ± 11.5 y) and 9 patients (9 females; mean age 35.4 ± 8.4 y) with FD (Rome IV criteria; 7 postprandial distress syndrome (PDS), 2 PDS + IBS-C) underwent ambulatory duodeno-jejunal HRM/impedance (HRM/Z). The ambulatory HRM/Z system (MMS, Netherlands) included a catheter (UniSensor, Switzerland) with 20 pressure sensors (2 cm apart) and 9 impedance channels. HRM data was analysed to identify MMC phase IIIs (pIIIs). BI in the duodenum (D1, D2, D3, D4) and the proximal jejunum (J1) were determined by measuring impedance immediately after the passage of nocturnal MMC pIIIs (when intestinal fluids are minimal).

Results: A total of 84 nocturnal MMC pIIIs were identified, (72 in healthy subjects, 25 in patients with FD). The BI (mean ± SD) in the D1 was 242.4 ± 44.7Ω in HC and 167.9 ± 49.8 Ω in FD ($p = 0.028$), in D2: 248.5 ± 35.1 Ω and 176.9 ± 28.6 Ω ($p < 0.001$), in D3: 281.3(±37.2) and 206.5 ± 52.7 Ω ($p < 0.001$), in D4: 349.3 ± 44.3 and 255.7 ± 49.5 Ω ($p < 0.001$), and in J1: 383.9 ± 35.6 and 277.4 ± 41.0 Ω ($p < 0.001$), respectively.

Conclusion: This study has confirmed that duodenal mucosal integrity is impaired in patients with FD. Furthermore, we have shown, for the first time using prolonged impedance recordings and BI, a significantly lowered BI in the proximal jejunum in patients with FD. Whether this is a finding exclusively related to FD or it is related to concomitant intestinal functional disorders (IBS) is a matter of current investigation.

increased rapidly. However, figures vary widely and updated population-based data for Europe are scarce.

Aims and Methods: To estimate the incidence and prevalence of EoE in both children and adult patients in a central region of Spain and analyzed the changes along the 2006–2017 period. Reference population and annual variations data for the catchment area (Hospital General de Tomelloso & Hospital Virgen de Altagracia) were obtained from the National Institute for Statistics. Data of all patients diagnosed with EoE (evidence-based diagnosis criteria 2017) and living in these areas in the study period were prospectively collected. Socio-demographic variables, symptoms, endoscopic findings, personal and familial atopic background and season of diagnosis were registered. Incidence, prevalence, diagnosis delay and length of symptoms before a first consultation were determined.

Results: Between January 2006 and December 2017, 117 patients were diagnosed to EoE overall in the area (reference population of 103,636.89 inhabitants in 2017), including 98 adults & 19 children. Mean age was 29.8 years (SD 10.4, rank 5–82) and 87.2% were male. Half of patients were aged between 20 and 40. In adult population, the overall prevalence of EoE was 111.94 per 100,000 inhabitants in 2017 (being 199.7 per 100,000 in males and 25.2 per 100,000 in females). In children, an overall prevalence of 111.9 per 100,000 inhabitants was found (being 172 and 48.4 cases per 100,000 for boys and girls, respectively). The average annual incidence rate was 10 new cases per 100,000 inhabitants, in both adults and children (Table 1). No seasonal variations in the diagnosis was found (45.3% during pollen season *vs* 54.7% in no pollen season; $p = 0.191$). A median of 6.2 months from first consultation to final diagnosis was found, with no differences between children and adults ($p = 0.185$). In contrast, duration of symptoms from onset to first consultation was significantly longer in adults than in children (4 *vs* 37.2 months; $p = 0.002$). The increase in the number of new diagnoses of EoE exceeded that of the number of upper endoscopies in the same period.

Conclusion: Incidence and prevalence of EoE continue to increase, with this research providing the highest figures reported to date, and approach to those described for Crohn's disease. The growth of the epidemiology of EoE exceeds the increase in the number of endoscopies in the same study period.

Introduction: The incidence of Eosinophilic Esophagitis (EoE) has increased in recent years. Currently, esophageal biopsies are recommended in all patients with symptoms of esophageal dysfunction.

Aims and Methods: The aims of this study were to evaluate this strategy and determine the incidence and characteristics of EoE in an adult population with dysphagia. We conducted a prospective observational study of ≥18-year-old consecutive patients referred for esophagogastroduodenoscopy (EGD) due to dysphagia, between January 2016 and December 2017. Two biopsies were performed on the proximal, middle and distal thirds of the esophagus. Patients with another etiology for dysphagia on EGD were excluded. Patients with EoE (≥1 biopsy with ≥15 eosinophils/hpf) started a proton pump inhibitor (PPI) and repeated endoscopy after 8 weeks of therapy. The accuracy of the *UNC Clinical Predictor*[1] in EoE prediction was evaluated.

Results: 113 patients were included, 54.9% ($n = 62$) female, mean age = 52.4 ± 17.5 years. The incidence of EoE was 15.9% ($n = 18$). Patients diagnosed with EoE presented lower age, longer duration of dysphagia, less heartburn, more frequent history of food impaction and atopy (asthma, rhinitis, conjunctivitis and/or food allergy), higher blood concentrations of eosinophils and IgE, more rings and furrows in EGD and more presence of microabscesses, spongiosis and papillary elongation in histology ($p < 0.05$). The area under the ROC curve of the *UNC Clinical Predictor* for EoE prediction was 0.98 (95%CI 0.96–1.00; $p < 0.001$). Considering EoE patients, 55.6% ($n = 10$) presented histological response (<15 eosinophils/hpf in all biopsies) to PPI therapy. No different characteristics were found between patients with and without response to PPI.

Conclusion: The incidence of EoE in adults with dysphagia was 15.9%, a proportion in accordance with recent literature and that demonstrates the importance of esophageal biopsies in this group of patients. Demographic, clinical, endoscopic and histological characteristics were associated with EoE diagnosis but did not predict response to PPI.

Introduction: HEROES was a 16-week double-blind, placebo-controlled phase 2 multicenter trial that evaluated the efficacy and safety of RPC4046 in adults with active eosinophilic esophagitis (EoE). Fibrostenosis of the esophagus is a known complication of EoE and may be mediated in part by epithelial-mesenchymal transition (EMT). We sought to determine whether treatment with RPC4046 modulates EMT.

Aims and Methods: Esophageal biopsy sections were taken at baseline and week 16 from 69 of the 99 patients randomly assigned to weekly subcutaneous (SC) RPC4046 360 mg ($n = 26$), 180 mg ($n = 19$), or placebo ($n = 24$). Slides were stained by duplex immunofluorescence for e-cadherin and vimentin (Cell Signaling Technologies), counterstained nuclei with DAPI, and scanned at 20x on a Vectra® (PerkinElmer) multispectral digital microscopy system. Using inForm® software, a machine learning algorithm mapped the epithelial compartment in each slide. Nuclear, cytoplasmic, and membrane areas of each epithelial cell were defined and fluorescence intensity of each marker on a per-cell basis was recorded. For this EMT substudy, the primary endpoint was change from baseline in percentage of vimentin-positive epithelial cells and secondary endpoints were change in total e-cadherin expression per cell and change in vimentin:e-cadherin ratio per cell.

Results: The change from baseline in mean percentage of vimentin-positive cells was -4.24%, -2.75%, and -0.94% in the RPC4046 360 mg, 180 mg, and placebo groups, respectively ($p < 0.05$ for 360 mg vs. placebo). The change in mean e-cadherin expression per cell was 101.6, 102.4, and 18.3 in the 360 mg, 180 mg, and placebo groups ($p < 0.05$ for each active dose group vs. placebo). The change in vimentin:e-cadherin ratio was significantly different from zero in both dose groups (360 mg, -0.30; 180 mg, -0.18; $p < 0.05$ for each active dose group vs. zero). Similar effects for all markers were observed in each esophageal sampled region (proximal, mid, distal).

Conclusion: RPC4046 treatment for 16 weeks significantly improved EMT markers in esophageal tissue in patients with active EoE. A greater effect generally was observed with 360 mg than with 180 mg. These results, together with the overall clinical data presented separately, support the hypothesis that prevention of IL-13 binding to receptor subtypes IL-13Rα1 and IL-13Rα2 favorably impacts inflammatory and remodeling pathways and may reduce development of esophageal fibrostenotic complications that occur in EoE. Larger studies with longer term treatment are required to determine the impact of these results on the course of EoE.

Introduction: Eosinophilic esophagitis (EoE) is a chronic, immune-mediated disease characterized by symptoms related to esophageal dysfunction and eosinophil-predominant inflammation. There is some overlap between EoE and GERD, with similar esophageal motility abnormalities [1], particularly in those EoE patients responsive to proton pump inhibitor (PPI) therapy [2]. Normal esophageal acid exposure time (EAET) has been found in two thirds of 51 EoE cases at pH-only monitoring, and EAET was not a predictor of clinical and histological response to PPI [3]. However, the limits of pH-only monitoring have long been recognized. A comprehensive reflux assessment, based on impedance-pH monitoring and including analysis of post-reflux swallow-induced peristaltic wave (PSPW) index and of mean nocturnal baseline impedance (MNBI), improves our ability to diagnose GERD [5,6] and to predict PPI response [7], and could contribute to clarify the pathogenesis of EoE.
Aims and Methods: We investigated 52 (43 males, mean age 43 years) consecutive incident EoE cases (≥15 eosinophils/HPF in esophageal biopsies) with impedance-pH monitoring, always preceded by high resolution/conventional esophageal manometry. Impedance-pH parameters were compared with those found in 52 (41 males, mean age 39 years) healthy controls (HCs) and 52 (31 males, mean age 45 years) patients with hypersensitive esophagus (HE), the latter group defined by normal endoscopy, normal EAET and positive heartburn-reflux association. Results were examined by analysis of variance and chi-square test with Bonferroni correction, significance set at $P < .05$.
Results: All EoE patients complained of dysphagia, and 24 (46%) reported heartburn. Main impedance-pH parameters are shown in the Table. EAET was comparable among the three groups. On the other hand, the number of total refluxes was significantly higher in EoE and HE than in HCs. PSPW index and MNBI were significantly different among the three groups of subjects, and were significantly lower in EoE than in HE and in both groups of patients than in HCs.
Conclusion: Reflux parameters in EoE and HE are quite similar and significantly different from those found in HCs, suggesting that reflux could play a role in the pathogenesis of EoE. Low values of PSPW index reflect a primary defect of esophageal chemical clearance determining mucosal damage, as shown by low MNBI values, in turn favoring penetration of food antigens and their contact with immune cells; in genetically susceptible individuals this event could be followed by interleukin 5,4 and 13 secretion with subsequent eosinophils recruitment and development of EoE.

Impedance-pH variables	HCs (n = 52)	EoE (n = 52)	HE (n = 52)
EAET (%), mean (SD)	1.0 (1.0)	1.8 (1.9)	1.8 (1.3)
P > .05 for all pairwise comparisons			
Total Refluxes (n), mean (SD)	23 (12)	38 (24)	44 (22)
P < .05 for HC vs. EoE and HE			
Acid Refluxes (n), mean (SD)	16 (11)	30 (21)	30 (18)
P < .05 for HC vs. EoE and HE			
Weakly Acidic Refluxes (n), mean (SD)	6 (6)	8 (9)	14 (13)
P < .05 for HC and EoE vs. HE			
PSPW index (%), mean (SD)	75 (16)	28 (16)	42 (17)
P < .05 for all pairwise comparisons			
MNBI (Ohms), mean (SD)	3045 (843)	937 (552)	2251 (1080)
P < .05 for all pairwise comparisons

Introduction: Eosinophilic esophagitis (EoE) is an increasingly recognized immun-mediated disease and a common cause for dysphagia and bolus obstruction. The aim of our survey was to evaluate the therapeutic management of EoE among adult gastroenterologists in Germany.
Aims and Methods: Between 11/2017 und 2/2018 a web-based questionnaire was sent to 1393 gastroenterologists (1126 in private practice (bng) and 267 hospital-based (ALGK)), containing a total of 22 questions to general, diagnostic and therapeutic aspects of EoE. Data capture and evaluation was performed using SurveyMonkey.
Results: The responder rate was 28% (bng) and 36% (ALGK). The majority of responder treat and monitor EoE patients by themselves (85%/59%).
In newly diagnosed EoE patients, the initial treatment was mainly either PPI (37%/39%) or topical steroids (34%/40%). Only few initiated elimination diet (4%/6%) or combination therapy (25%/15%). PPI-regimens were diverse: once daily for 4 weeks (20%17%) or 8 weeks (31%/24%), twice daily for 4 weeks (29%/45%) or 8 weeks (20%/25%). Budesonid was the preferred steroide (63%/68%), either nebulized (45%/41%) or as liquid suspension (40%/46%). The most frequently used elimination diet (ED) was 6-Food-ED (54%/46%), followed by allergy test-based ED (17%/15%), 2-Food-ED (14%/23%) or 4-Food-ED (11%/15%). Treatment response was usually monitored (mainly endoscopy-based) after 12 weeks (42%/35%) or 8 weeks (23%/43%). The devices used for endoscopic dilatation (hospital-based) were mainly bougies (61%) followed by ballons (39%). Based on their experience, most responders estimated that 25–50% of patients (47%/49%) or >50% of patients (23%/24%) need long-term treatment of EoE.
Conclusion: The results suggest a significant heterogeneity in the therapeutic management of EoE among gastroenterologists in Germany, both in private practice and in hospitals. This underlines the need of national guidance and for more educational activities.

Introduction: Eosinophilic Oesophagitis (EO) is a chronic inflammatory condition characterised by eosinophilia of the oesophagus. It can progress to a fibrostenotic disorder, with dysphagia and strictures. EO commonly presents with chronic, intermittent solid food dysphagia. The hallmark of the condition is the presence of >15 eosinophils/high powered field on histology[1].
Treatment includes dietary modification, pharmacological therapy and endoscopic dilatation. We aim to describe the demographics of our DGH patient population and their response to therapy.

Aims and Methods: We retrospectively analysed patient data collected from 2009 -2016 from a single district general hospital in Bury St Edmunds in the UK. All patients presenting with dysphagia with >15 eosinophils/high powered field on histology from random oesophageal biopsies were included.
Results: 86 patients were identified with EO. 52 were male. Average age was 52.1 years.
Response to therapy: 57 of the 86 patients identified attended gastroenterology clinic as follow-up for commencement of treatment.
43% were commenced on an 8 week course of PPI as first-line therapy. 80% of these had symptom resolution following PPI course completion.
35% were offered a 3 month trial of swallowed Fluticasone inhaler, as first-line therapy. 75% had symptom resolution following completion.
10% had symptom control with dietary changes. Additionally, 1 patient required oesophageal dilatation for a stricture which was maintained at 1 year review.
12% of patients had persistent symptoms despite trail of medical therapy.
Follow-up endoscopy findings 10 of the identified 86 patients had repeat OGD between 2009–2016. 5 were performed as follow-up following medical therapy and 5 were performed for alternate reasons listed in table 1.

Reason for OGD	Histological resolution	Dysphagia improved	Time between OGD	Therapy (s)
Follow-up	Yes	Yes	12 weeks	Swallowed fluticasone spray
Follow-up	Yes	Yes	16 weeks	PPI
Follow-up	Yes	Yes	8 weeks	PPI
Follow-up	Yes	Yes	12 weeks	PPI
Follow-up	Yes	No	12 weeks	PPI
Abdo pain	Yes	Yes	3 years	Swallowed fluticasone spray
Abdo pain	Yes	No	5 years	PPI
Dysphagia	No	No	2 years	PPI, Oral steroids
Reflux	Yes	Yes	6 months	PPI
Repeat food bolus	No	No	6 years	Unknown

[Repeat OGD Findings]
In the follow-group, there was 100% histological resolution of eosinophilia, with 80% improvement in symptoms in.those treated with a PPI.
Conclusion: EO is an increasingly recognised condition. European guidelines have recently been published though standadised treatment is yet to be defined[2]. Our data shows PPIs and topical corticosteroids are the most effective therapies, in keeping with known findings. PPIs were the most popular treatment choice.
It is recommended that efficacy of treatment be evaluated by repeat endoscopy. In a DGH, with increasing service pressures this may be challenging. Our asymptomatic patients who had repeat OGDs had histological resolution. One solution, therefore, may be to limit repeat OGDs to those with ongoing symptoms to observe for ongoing present of oesophageal eosinophilia.
In patients not achieving symptom resolution or histologic remission with monotherapy, a trial of combination therapy was shown to be effective and we recommend this should be attempted. Our experience is that combination of PPI and swallowed corticosteroid inhaler therapy was most effective.
Future directions would be evaluation of long-term follow-up of our patients as often they were discharged to GP so long-term resolution of symptoms is unknown.

Introduction: Eosinophilic esophagitis (EoE) is a chronic, allergen-driven, immune-mediated disease that is increasingly recognized as a leading cause of dysphagia and foregut symptoms in children and adults. The diagnosis of EoE requires an invasive endoscopic evaluation with esophageal biopsies showing at least 15 eos/hpf in at least one hpf. Moreover, since symptoms are not predictive of therapeutic medical response, current guidelines recommend to repeat the upper endoscopy in order to confirm histological disease remission after any kind of treatment (i.e. steroids, diet). Thus, a non-invasive tool to support the need of performing an upper endoscopy in patients with symptoms suggestive of EoE and to monitor EoE after therapeutic interventions and during time is desirable. Calprotectin is a granulocyte cytosolic protein that is considered to be a promising marker of subclinical inflammation. High faecal calprotectin (FC) concentrations have been found in several intestinal diseases, but no data are currently available on patients with EoE.
Aims and Methods: The aim of this prospective pilot study was to evaluate FC levels in incident cases of EoE and to correlate them with clinical score, endoscopy and histological characteristics. Consecutive patients with symptoms suggestive of EoE underwent upper endoscopy to assess the presence of at least 15 eos/hpf on oesophageal biopsies at mid/proximal esophagus and, then, were treated with twice-daily PPI for at least 8 weeks and/or topical steroids. Clinical assessment was carried out in all patients. Endoscopic, according to Endoscopic Reference Score (EREFS), and histologic features were blindly reviewed for each patient. Patients with upper gastro-intestinal symptoms, without evidence of esophageal eosinophilic infiltration, investigated during the same period of time, were used as controls. FC levels were determined by ELISA at the time of index endoscopy (i.e. in presence of active disease).
Results: Seventy patients [58M/12F; mean age 37] reporting dysphagia (94%), bolus impaction (65%) and chest pain (28%) were diagnosed with PPI-REE (n = 32) or EoE (n = 38) and were prospectively recruited. Moreover, a group of 70 [56M/10F; mean age 41] subjects, sex and age matched, were also enrolled. FC levels in incident cases of active PPI-REE/EoE were not significantly different from those in controls (mean 48 ± SD 34 μg/g vs 42 ± 39 μg/g; p = ns). Furthermore, among PPI-REE/EoE, FC concentrations were not significantly different in relation to the level of clinical score, endoscopic severity or histological evaluation (p = ns, p = ns and p = ns, respectively).
Conclusion: This study shows that FC levels in incident cases of PPI-REE/EoE patients do not differ significantly from those in controls. Our data suggest that FC is not a useful tool for the diagnosis and management of patients with eosinophilic esophagitis.

P1144 DO WE HAVE TO EXCLUDE EPIGASTRIC SYMPTOMS TO DIAGNOSE GERD?

M. Zhang, N. Tan, M. Chen, Y. Xiao
The First Affiliated Hospital of Sun Yat-Sen University, Department of Gastroenterology and Hepatology, Guangzhou, China

Contact E-Mail Address: zhangmny@mail2.sysu.edu.cn

Introduction: Gastroesophageal reflux disease (GERD) could be diagnosed by the typical heartburn symptom. GERDQ is a symptom-based tool for GERD diagnosis, and the epigastric symptoms are excluded to rule out functional dyspepsia. However, it is reported that the rate of pathologic esophageal acid reflux (PEAR) of heartburn patients is quite low in China.
Aims and Methods: The aim of the current study is to assess the epigastric symptoms for GERD diagnosis. Consecutive outpatients aged 18–65 years presented with substernal symptoms including heartburn, regurgitation, dysphagia, substernal pain and epigastric symptoms including epigastric pain, epigastric burning, early satiety and postprandial fullness were enrolled. Patients who had esophageal or gastric surgery, peptic ulcers, upper GI cancer were excluded. All patients underwent upper endoscopy, high-resolution manometry and 24-hour esophageal pH monitoring. Patients with esophagitis would be given esomeprazole 20mg bid for 8 weeks and those who with normal findings for 4 weeks. PEAR was defined as the percentage total time for which a pH value <4 was >4.2% in the distal esophagus. The symptom scores were measured by the frequency score multiplied by the severity scores of the predominant symptom before and at the end of the treatment, and the PPI test was defined as positive if the overall scores of the predominant symptom decreased by >50 % compared with those of the baseline.
Results: A total of 334 patients were included, with predominant symptoms of heartburn (N = 80), regurgitation (N = 66), substernal pain (N = 60), dysphagia (N = 11), epigastric pain (N = 33), epigastric burning (N = 25), early satiety (N = 1) and postprandial fullness (N = 58). Overall, 23.95% of patients (N = 80) had PEAR, with 26.73% (N = 58) in those with predominant substernal symptoms and 18.8% (N = 22) in those with epigastric symptoms. The rates of PEAR were 6%, 28% and 22.41% in patients with epigastric pain, epigastric burning and postprandial fullness, respectively. And the rate of PEAR in patients with epigastric burning (28%, 7/25) is almost the same as those with heartburn (28.75%, 23/80). Moreover, a total of 155 patients (50.82%) had positive PPI test, including 56.34% (N = 111) of those with substernal symptoms and 40.74% (N = 44) of those with epigastric symptoms, of whom the rates were 44.8%, 54.2% and 33.3% in patients with epigastric pain, epigastric burning and postprandial fullness, respectively. There was no significant difference in the positive rate of PPI test between patients with epigastric burning and those with heartburn (54.2% vs 56.2%, p > 0.05). Endoscopy indicated that 65 patients (19.46%) had esophagitis including 20.74% (N = 45) of those with substernal symptoms and 17.1% (N = 20) with epigastric symptoms. If we combined 24h esophageal pH monitoring, PPI test and upper endoscopy, a total of 167 patients (50%) were diagnosed with GERD, 70% of whom (N = 117) had predominant substernal

symptoms and 30% (N = 50) had epigastric symptoms. Among them, 26% of patients presented with heartburn, 23% with regurgitation, 4% with dysphagia, 17% with substernal pain, 8% with epigastric pain, 9% with epigastric burning, 13% with postprandial fullness.
Conclusion: Approximately one-third of GERD patients complain of predominant epigastric symptoms. Excluding epigastric symptoms during symptom-based evaluation of GERD in primary care may miss and delay the diagnosis of real GERD. It is suggested that epigastric symptoms should not be neglected for GERD diagnosis.

Introduction: Esophageal manometry is the gold standard for lower esophageal sphincter (LES) localization and for accurate positioning of catheter based pH and multichannel intraluminal impedance pH monitoring (MII-pH). pH variation step-up method is not as accurate as esophageal manometry for LES localization, and needs patients to be OFF therapy. Gastric impedance has very low values compared to esophageal impedance and is not influenced by acid suppression.
Aims and Methods: Our aim was to evaluate feasibility of impedance variation with the step-up method for LES localization. 75 patients (31 male, mean age 48 years, range 38–57) who underwent 24-hr MII-pH monitoring were prospectively enrolled. A catheter with six impedance channel and 1 pH channel was used. Patients with known Barrett's oesophagus were excluded. High-resolution manometry (HRM) was performed before MII-pH monitoring in order to locate the upper and lower border of the LES and to evaluate esophagogastric junction (EGJ) type. A second operator, blinded to HRM finding, performed the MII-pH study: the catheter was introduced into the stomach (presence of stable impedance values <500 ohm in the second distal impedance channel located at the level of the pH sensor) and withdrawn gradually (1 cm every 15 seconds; each cm was marked with the "symptom" button) until a sharp impedance rise was seen (increase of $>50\%$ with respect to gastric baseline); in 62 patients step-up was repeated twice. Abnormal pH-MII study was defined as acid exposure time (AET) $>5\%$ and/or positive SI/SAP. A third operator blinded to both HRM and impedance results, reviewed the step-up impedance of all patients. Bland-Altman analysis with Lin concordance and correlation coefficient were used to compare MII-pH and HRM. Subgroups analysis were performed for the following parameters: ON and OFF PPI test and presence and absence of EGJ type ≥ 2. Interobserver agreement and concordance between the two step up impedance performances were evaluated using Spearman rho correlation coefficient.
Results: Descriptive data are shown in table 1. 12/75 patients were on PPI. Median impedance rising point was on average 0.8 cm caudal (95% limits of agreement, LOA: -2.6 cm to 4.2 cm) to manometric upper border of LES and 1.8 cm cranial (95% LOA: -5.1 cm to 1.5 cm) to manometric lower border of LES (Lin concordance correlation coefficients 0.81 and 0.72 respectively). Agreement between the two step-up impedance performances was excellent (mean 44.9 and 45 cm, rho 0.97). Interobserver agreement was excellent (mean 44.9 and 44.8 cm, rho 0.94). Impedance variation performances were similar between patients OFF and ON PPI and between presence/absence of EGJ type ≥ 2.
Conclusion: In this ongoing study we observed a good correlation between impedance rise and manometric localization of the upper border of the LES. ON-PPI examination and presence of EGJ type ≥ 2 do not alter performance reliability. Intra and interobserver agreement were excellent. Impedance variation with the step-up method is a promising method for LES identification and an alternative to HRM, where it is not available, also for patients ON-PPI.

Introduction: Patients with ENT symptoms are often poor responders to PPIs and present upper endoscopy and 24h mutichannel intraluminal impedance-pH (MII-pH) within the normal range. It has been shown that mean nocturnal baseline impedance (MNBI) and post-reflux swallow-induced peristaltic wave (PSPW) indexes increase the diagnostic yield of MII-pH monitoring in GERD patients. These new variables have been assessed primarily in patients with typical GERD symptoms and few data on patients with ENT symptoms are available. Moreover, their relationship with PPI response has not been fully elucidated in these patients.
Aims and Methods: To explore whether MNBI and PSPW improve the diagnostic yield of impedance pH monitoring in GERD patients with ENT symptoms and their relationship with PPI response in these patients.
Of consecutive GERD patients presenting with ENT symptoms, 121 with absence of hiatal hernia and/or erosive esophagitis at upper endoscopy, performed within 3 months before the study, underwent MII-pH after a 3-weeks wash out from PPIs. The response to previous PPI treatment was evaluated and considered as non-satisfactory if symptom improvement was $<50\%$ on a visual analogue scale. MNBI at 3cm above the lower esophageal sphincter, PSPW, symptom association probability (SAP) and acid exposure time (AET) were calculated according to standardized criteria and considered for the data analysis.
Results: Among all 121 patients, 63 were responders and 58 non-responders to PPIs. The mean reflux number was similar between responders and non-responders. 39/63 (62%) responder and 24/58 (41%) non-responder patients presented positive AET and/or SAP ($p < 0.05$). A positive PSPW and/or MNBI was observed in 41 responders (65%) and 27 non-responders (47%) ($p < 0.05$). 13/24 responder patients with both negative AET and SAP presented a positive PSPW and/or MNBI. 8/34 non-responder patients with both negative AET and SAP (functional heartburn patients), presented a positive PSPW and/or MNBI. Patients with positive AET and/or SAP and patients with positive PSPW and/or MNBI presented a higher probability of PPI response. Results are summarized in Table 1.
Conclusion: The present data show that MNBI and PSPW are promising variables in patients with ENT symptoms, since increase the diagnostic yield of MII-pH. The presence of pathologic MNBI and/or PSPW is able to discriminate ENT patients with a satisfactory response to PPIs.

	Responders (N. 63)	Non responders (N. 58)	Relative Risk for PPI response (95% confidence interval)
Mean reflux number (mean ± 95% confidence interval)	46 ± 29	49 ± 37	
AET+	13 (%)	10 (%)	0.8 (0.5–1.2), p:ns
SAP+	16 (%)	8 (%)	0.6 (0.4–1.0), p:ns

Introduction: It has been shown that mean nocturnal baseline impedance (MNBI) increases the diagnostic yield of 24h mutichannel intraluminal impedance-pH (MII-pH) monitoring in patients with GERD. The MNBI is directly correlated with mucosal esophageal integrity and intra-luminal clearance. However, the relationship between of esophageal motility and MNBI value needs to be fully elucidated.
Aims and Methods: To explore the relationship between peristaltic vigor and MNBI in GERD patients.
Consecutive GERD patients, with recurrent typical and absence of hiatal hernia and/or erosive esophagitis at upper endoscopy underwent high resolution manometry (HRM) followed by 24h MII-pH. 87 patients with proven GERD (positive AET and/or SAP) were finally enrolled. HRM was performed with patients in a

Abstract No: P1147

	Pts with at least 1/10 peristaltic break (N: 28)	Pts without peristaltic breaks (N: 47)	Pts with at least 1/10 weak contraction (N: 30)	Pts without weak contractions (N: 45)	Pts with at least 1/10 failed contraction (N: 17)	Pts without failed contractions (N: 58)
MNBI 3cm	1478 ± 283Ω	1885 ± 651Ω	1169 ± 412Ω*	2250 ± 783Ω	1142 ± 323Ω**	1828 ± 642Ω
MNBI 19cm	1887 ± 722Ω	2210 ± 887Ω	1709 ± 595Ω	2310 ± 914Ω	2070 ± 493Ω	2090 ± 882Ω

*p < 0.01 vs Pts without weak contraction **p < 0.01 vs Pts without failed contraction.

semi-recumbent position, using a catheter incorporating 24 solid state pressure sensors. 10 saline (5 ml) swallows at 30-sec intervals were analyzed in each patient. Distal contractile integral (DCI) was calculated for each swallow. Each contraction was defined as failed (DCI < 100 mmHg*s*cm) or weak (DCI > 100 mmHg*s*cm and < 450 mmHg*s*cm). Presence of large (> 5cm) breaks of esophageal peristalsis was assessed. MNBI was calculated at 3cm and 19cm above the lower esophageal sphincter according to standardized criteria. Data are shown as mean ± confidence interval.

Results: Overall mean DCI value was 1426 ± 623 mmHg*s*cm. MNBI at 3cm and 19cm values were 1693 ± 575Ω and 2006 ± 893Ω. A positive linear correlation was found between individual mean DCI and MNBI 3cm values (R: 0.8). There was no linear correlation between mean DCI and MNBI at 19cm (R: 0.4). There was no difference between MNBI at 3cm and 19cm in patients with and without presence of at least 1/10 large peristaltic break. Patients with at least 1/10 weak or failed contraction presented significant lower MNBI values at 3cm compared to patients without presence of weak or failed contraction. MNBI at 19cm did not differ in these two groups of patients. Results are in Table 1.

Conclusion: MNBI at distal esophagus is directly correlated with DCI values in GERD patients. Presence of large breaks does not affect the MNBI value. Presence of weak or failed contraction is associated to lower MNBI values at distal esophagus. These results confirm the potential role of esophageal peristaltic dysfunction on epithelial integrity. Larger studies are needed.

Introduction: Obesity is a global epidemic and consequently bariatric surgery is increasingly performed. Since there are numerous surgical techniques, the effects of these on the esophageal function are still poorly understood. Furthermore, some bariatric techniques proved to be very effective as antireflux procedures, such as Roux-en-y gastric bypass (RYGB), whereas "de novo" gastroesophageal reflux disease (GERD) and dysmotilities were reported after some bariatric procedures, such as Sleeve Gastrectomy (SG).

Aims and Methods: We aimed at assessing the effect of the most commonly performed bariatric techniques on esophagogastric junction (EGJ) function, esophageal peristalsis and reflux exposure using high-resolution manometry (HRM) and impedance-pH monitoring (MII-pH).

All obese (body mass index, BMI, > 35) patients underwent symptomatic questionnaires (GerdQ), endoscopy, HRM and MII-pH before and one year after surgery. We enrolled only obese without dysmotility or any evidence of GERD, in order to verify the real incidence of de novo GERD. Esophageal motor function and EGJ were classified according to Chicago Classification V. 3.0. EGJ contractile integral (EGJ-CI) was also calculated. Intragastric pressure (IGP) and gastroesophageal pressure gradient (GEPG) were assessed. Total acid exposure time (AET %), total number of refluxes and symptom association probability (SAP) were assessed. A group of healthy-volunteers (HVs) served as control.

Results: One hundred and twelve obese subjects (39 ± 12 years-old, mean weight 135 (97–202) Kg, mean BMI 42 (37–69) Kg/m^2 and 15 HVs (normal weight) were studied. Thirteen underwent endoscopic balloon placement (EBP), 12 gastric banding (GB), 26 sleeve gastrectomy (SG), 18 roux-en-y gastric bypass (RYGB), 15 mini gastric bypass (MGB), 16 biliointestinal bypass (BIBP), and 12 biliopancreatic diversion (BPD). All patients showed a significant decrease of weight and BMI one year after surgery. IGP and GEPG significantly decreased after RYGP, BPD and BPBP, whereas they significantly increased after GB and SG. EGJ morphology changed only after GB, with 6 patients showing Type III morphology. EGJ-CI, IRP and DCI increased significantly ($p < 0.001$) only after GB. Hypercontractile and premature contractions waves were present in 40% of patients after GB, whereas ineffective motility (36%) waves were present after SG. "De Novo" GERD symptoms were observed in 1 SG and 2 GB. Postoperative greater AET ($p < 0.05$) and increased total number of reflux ($p < 0.001$) were present after GB and SG. RYGB and MGB showed a significant decrease in AET ($p < 0.05$) and total number of reflux ($p < 0.001$), whereas BIBP showed a non-significant reduction in AET and reflux events but similar to HVs patterns (Table 1).

Conclusion: HRM verified that different bariatric techniques produced different modification of IGP and GEPG, leading to different reflux exposure. Only GB and SG can negatively impact on esophageal function and reflux exposure, and they should be avoided in obese patients with pre-existing GERD.

Introduction: The modern understanding of gastroesophageal reflux disease (GERD) pathogenesis includes Th1/Th2 immune response imbalance that can be determined as phenotype of macrophages (M1 or M2). Studies using high-resolution manometry (HRM) with 22-channel water-perfused catheter have shown that esophageal motility disorders frequently occur in patients with gastroesophageal reflux disease (GERD).
Aims and Methods: The aim of the present study was to investigate the role of esophageal motility disorders and immune response in diagnosis GERD phenotypes. To determine correlation between esophageal motility disorders, immune response and diagnosis of nonerosive reflux disease (NERD), erosive reflux disease (ERD), Barrett's esophagus (BE). 68 patients with GERD were studied: 28 (14 men, 45.74 ± 2.23 yr) NERD, 22 (15 men, 45.0 ± 3.24 yr) ERD and 18 (13 men, 47.22 ± 2.95 yr) BE. All the patients were performed HRM with 22-channel water-perfused catheter (Solar GI MMS, The Netherlands). We analyzed distal contractile integral (DCI). Monocytes were isolated from the patients' blood samples and cultured to macrophages in standard conditions – RPMI1640 medium, 10% FBS, 37oC, 5% CO2. Pooled analysis of macrophage and monocyte derived macrophages included typical M1/M2 surface macrophage CD markers (CD25, CD80 and CD163, CD206, respectively) performed by flow cytometry (Beckman Coulter FC500). The statistical analysis was done using SPSS Statistics 17.0.
Results: In NERD patients median DCI was 991 [104;3759], in ERD – 570 [41;2462], in BE – 505 [0;1933] mm Hg *c*cm. DCI in NERD patients was significantly higher than in ERD and BE ($\chi2 = 2.81$, $p = 0.03$ and $\chi2 = 3.13$, $p = 0.076$, respectively). DCI in patients with BE tended to be lower than in patients with ERD, although without statistical significance. In NERD patients median expression of surface M1/M2 macrophage CD markers was CD25–37.2 [6.1;69.4], CD80–19.6 [2.8;49.3], CD163–15.7 [2.7;37.2], CD206–10.5 [0.4;21.6], in ERD was CD25–34.7 [13.1;59.6], CD80–22.8 [6.1;43.6], CD163–17.4 [0.6;37.2], CD206–12.6 [0.3;30.6], in BE was CD25–39.2 [16.3;67], CD80–21.9 [8.3;41.6], CD163–14.9 [18;34], CD206–8.9 [0.5;25.9]. We determined negative correlation between NERD and expression of CD25 ($P = -0.402$, $P = 0.001$) and positive correlation between BE and expression CD25 ($P = 0.338$, $P = 0.005$). In GERD patients there were no significant correlation between expression CD25 and DCI.
Conclusion: Analysis of monocyte derived macrophages phenotype showed the prevalence of expression CD25 marker in all groups patients that characterizes M1 pro-inflammatory activated macrophages (Th1). These results suggest that type of immune response may play a major role in the pathogenesis of esophageal inflammation in GERD. We observed that NERD patients have a significantly higher DCI than ERD and BE. Patients with BE had a lower DCI than patients with ERD. This study points to a clear association between esophageal dysmotility and GERD.

P1150 CARDIAC ARRHYTHMIA AND GERD IN CHILDREN

T. Zimnytska[1], T. Golovko[1], I. Bulich[1]
[1]*VN Karazin Kharkiv National University, Department of pediatrics N2, Kharkiv, Ukraine*

Contact E-Mail Address: zim01tv@gmail.com
Introduction: Gastroesophageal reflux disease (GERD) is a digestive disorder that is caused by gastric acid flowing from the stomach into the esophagus. Prevalence of GERD in children ranges from 8.5% to 20% (Amy Wu, *Pharm D*, 2015). Among 1-year-old children the incidence is 1.48 per 1000 person-years, it increased to a maximum at 16–17 years of 2.26 per 1000 person-years for girls and 1.75 per 1000 person-years (A. Ruigómez et al, 2009).
Except typical esophageal complaints such as heartburn, acid regurgitation, dysphagia, pain behind the sternal bone, there are atypical (extraesophageal) symptoms in children with GERD (laryngitis, bronchoobstructive syndrome, sinusitis, chronic cough, heart rhythm disorders). Presence of heart rhythm disorders can be explained that inflammation of the esophageal mucosa affects local receptors that may induce afferent-efferent reflex mechanisms of the cardiac rhythm, which can lead to secondary stimulation of the vagal nerves (M Floria, V Liviu, 2015; Cuomo R, DE Giorgi F, 2016).
Aims and Methods: The aim of investigation is to determine the frequency of heart rhythm disorders in children with GERD.
82 patients with GERD within the age of 10–17 years were investigated. The diagnosis was established according to ICD -10 (K. 21, K. 21.9). Group I included 26 patients, who had GERD with esophagitis and group II included 56 patients who had GERD without esophagitis. Diagnosis was verified by upper endoscopy (with using the Los Angeles Classification of Oesophagitis). Electrocardiogram (ECG) was done for each patient.
Results: Sinus tachicardia was observed in 4 children (15.4%) with GERD with esophagitis (I group). It exceeded ($p < 0.05$) same parameters in children without esophagitis (II group) (2 persons; 3.6%). 3 children (11.5%) from group I and 2 children from group II (7.3%) had sinus bradycardia. There was no statistical difference in the indices of the study groups ($p > 0.05$). 3 children (11.5%) from group I had short PQ interval on ECG. It was higher ($p < 0.05$) than in children from group II (2 persons; 3.6%).
Conclusion: Frequency of disorders of rhythm is higher ($p < 0.05$) in children with GERD with esophagitis (14 persons; 53%) than in children with GERD without esophagitis (8 persons; 14.2%).
Frequency of sinus tachycardia and short PQ interval is higher ($p < 0.05$) in children with GERD with esophagitis than in children with GERD without esophagitis.

Contact E-Mail Address: nilaydanis17@gmail.com
Introduction: In Western countries, response rates for proton pump inhibitors (PPIs) are about 60–70% and higher in heartburn than regurgitation. The differences between response rates in phenotypes have not been adequately investigated. We evaluated PPI response rates of Barrett's esophagus (BE), erosive esophagitis (EE), nonerosive (NERD), esophageal hypersensitivity esophagus (EH) phenotypes and functional heartburn (FH), and success rates according to the different diagnostic techniques.
Aims and Methods: The aim of this trial is to investigate PPIs response rates of erosive, nonerosive (NERD), hypersensitive esophagus and functional pyrosis fenotypes that are diagnosed by only history, diagnosed by history and upper gastrointestinal endoscopy (UGE), diagnosed by history, UGE, esophageal monometry and 24 h intraesophageal pH-impedance. Patients were randomly chosen among the patients from the database of Ege University Reflux outpatient clinic who were on continue PPIs. Among 1233 patients, 510 patients who accepted to response phone survey were included. Exclusion criteria were medications which other than PPIs and influence the study, upper gastrointestinal surgeries, cholecystectomy, major comorbidity, pregnancy. Subjects were evaluated with a validated questionnaire consisted of 28 questions. Pollsters were medical school students who had been educated for face to face and phone interview techniques.
Results: 54 of those patients were diagnosed with only history. 151 patients were evaluated with history and UGE. 305 patients were underwent to UGE, HRM and 24 h intraesophageal MII-pH (off-PPI). Last group was classified into EE (117), NERD (94), EH (16), FH (58) BE (20). Response rate under 50% for either heartburn and/or regurgitation was accepted as unresponsive (Table). Cumulative response rates for heartburn and regurgitation were 85.3% and 82.2% respectively. When the effect of advanced diagnostic modalities on response rates for heartburn and regurgitation among phenotypes were evaluated, the highest rate was in history + UGE group (91.4%, 85.4% respectively).
Conclusion: We found a higher PPIs response rate than Western populations in all GERD patients. Response rate was not different in regurgitation compared to heartburn. When it is investigated according to the groups, response rate was highest in EE and lowest in EH and FH. Interestingly, response rates were similar between EE and NERD. It should be noted that these results were belong to a single/tertiary referral center with difficult to treat cases. Probably due to this reason, response rates of patients who were diagnosed by using all diagnostic modalities are lower than those who were diagnosed with only history and UGE.

	Erosive Esophagitis	NERD	Esophageal Hypersensitivity	Functional Heartburn
Heartburn	88%*	85.1%	68.8%*	72.4%
Regurgitation	87.2%*	84%	62.5%*	74.1%

P1152 THE NEW P-CAB X482 WAS SAFE, TOLERABLE AND PROVIDED 24H INTRAGASTRIC CONTROL, AFTER SINGLE ORAL DOSES IN HEALTHY VOLUNTEERS

K. Andersson, P. Unge
Cinclus Pharma AG, Basel, Switzerland

Contact E-Mail Address: kjell@cinclusphara.com
Introduction: Erosive GERD (eGERD), a subgroup within the GERD family, is a chronic disorder with prevalence in North America and Europe of more than 10%. Epidemiology data suggest a lower but increasing prevalence in Asia. Available PPIs have a mediocre effect in severe forms of eGERD leaving 20–40% of patients unhealed after 4–8 weeks. A new class of molecules, potassium-competitive acid blockers (P-CABs), represents a different mode of action and the PK profile may allow full acid control both day and night after a single dose. Animal studies of X842, a prodrug of linaprazan, show a slower uptake, lower Cmax and a longer plasma residence time, resulting in a prolonged control of intragastric acidity compared to the main metabolite linaprazan.

Aims and Methods: The first-in-man Phase 1 study of X842 in healthy volunteers comprised a Single Ascending Dose (SAD) part in which four subjects were included in each cohort. The primary objective was to determine the safety and tolerability of X842. The secondary objectives were to determine PK characteristics and PK/PD relationship of X842 and main metabolite. PD was assessed using an intragastric 24h pH-metry and sequential dose levels were tested. All available safety, tolerability, PK and PD data were reviewed prior to proceeding to the next cohort. The initial dose of X842 was 0.08 mg/kg. Standard safety assessments were applied. The Full Analysis Set (FAS) consists of all subjects who had received at least one dose of X842.
Results: X842 was safe and well tolerated. No serious or severe adverse events were reported. A clear dose-linearity was observed both for PK and for PD. Full control of 24h intragastric pH was obtained after a single dose of X842. Seventy-two minutes after administration of 2 mg/kg, the intragastric pH value presented as the mean of the 10 minutes median intervals was 4.5. The subsequent pH data showed 100% control of intragastric acidity. All means of the 10 minute median intervals for all four subjects showed pH >4 throughout the 24 h assessment time.
Conclusion: X842 was safe, well tolerated and provided full 24h intragastric pH control. The results warrant further investigations with X842 in patients with acid-related disorders.

Introduction: Intact esophageal mucosal integrity is important to prevent symptoms during gastroesophageal reflux events. Recently, we performed in vitro experiments in human esophageal mucosa, showing topical protectant effect of solutions containing alginates and cashew gum. *Gracilaria caudate,* a marine algae rich in sulfated polysaccharides, has shown some gastroprotective and antiinflammatory effects.
Aims and Methods: The present study aims to evaluate an in vitro topical protective effect of sulfated polysaccharide from *Gracilaria caudate* in esophageal biopsies obtained from patients with heartburn. We studied biopsies from patients with heartburn without erosions (n = 19), median age 42 years (range: 21–63, 6M:13F), and patients with esophagitis (n = 18), median age 47 years (range: 21–70, 7M:11F). Biopsies were mounted in mini-Ussing chambers to measure basal transepithelial electrical resistance (TER). The effect of mucosal exposure to acid solution (pH 2 + pepsin 1mg/ml, TDC 5mM) on TER was analyzed with and without pre-coating the mucosa with sulfated polysaccharide from *Gracilaria caudata* in different concentrations (0.1, 0.3 and 1%).
Results: Basal esophageal mucosal electrical resistance was significantly lower in biopsies from patients with esophagitis (TER = 114.4 ± 5.4 Ω/cm^2) compared to biopsies from patiets without erosion (TER = 163.2 ± 8.19 Ω/cm^2, $p < 0.01$). Pre-coated with sulfated polysaccharide from *Gracilaria caudate* (1%) significantly prevented acidic solution (pH 2+pepsin+TDC) induced TER drop in heartburn without erosions (unprotected = 27.21 ± 2.4%, protected 4.06 ± 4.08%, $p < 0.01$), but this effect was not observed in biopsies from patients with esophagitis (unprotected = 19.92 ± 1.7%, protected = 20.83 ± 3.50%).
Conclusion: Sulfated polysaccharide from *Gracilaria caudate* has an in vitro topical esophageal mucosal protectant effect in patients with NERD but not in patients with esophagitis. This finding suggests that degree of inflammation might influence topical protection, perhaps interacting with bio-adhesivity of the compound. The positive effect in patients with NERD should be further explored in development of a topical approach heartburn patients without esophagitis. Financial support: CAPES- Brazil, CNPq- Brazil.

Introduction: Acid suppression with proton-pump inhibitors (PPIs) is considered the standard treatment for erosive esophagitis (EE), despite inadequate treatment outcomes. Vonoprazan (TAK-438) belongs to the novel class of potassium-competitive acid blockers, which, unlike PPIs such as lansoprazole, reversibly inhibits the gastric hydrogen potassium enzyme ATPase responsible for gastric acid secretion, independently of pH. We conducted a phase 3, double-blind, multicentre study that demonstrated the non-inferior efficacy of vonoprazan 20 mg versus (vs) lansoprazole 30 mg in healing EE in non-Japanese Asian patients (pts) during 2, 4, and 8 weeks (wks) of treatment. In this sub-analysis we report the efficacy and safety of vonoprazan 20 mg vs lansoprazole 30 mg in healing EE in the Chinese sub-cohort.
Aims and Methods: Pts were aged ≥18 years with endoscopically-confirmed EE (Los Angeles [LA] classification grade A-D); proportion of pts with EE of LA classification grade C or D was planned to be ≥30%. Pts were stratified by baseline LA classification grade A/B vs C/D. Following a 28-day screening phase, pts were randomized 1:1 to receive vonoprazan 20 mg or lansoprazole 30 mg once daily for up to 8 wks. The primary endpoint was the EE endoscopic healing rate during 8 wks of treatment. The secondary efficacy endpoints were EE endoscopic healing rates during 2 and 4 wks of treatment. Assuming an 8-wk healing rate of 94.7% in both treatment arms, it was estimated that 240 pts per group would provide 90% power to establish non-inferiority with a 10% margin using a two-sided 95% confidence interval (CI). Safety endpoints included treatment-emergent adverse events (TEAEs).
Results: In the China sub-cohort a total of 143 pts received vonoprazan and 131 pts received lansoprazole treatment. Generally, baseline characteristics were comparable between arms (Table 1). The 8-wk EE healing rate was 92.0% with vonoprazan and 89.0% with lansoprazole (difference [95% CI]: 3.0% [-4.103, 10.092]); the non-inferiority of vonoprazan vs lansoprazole was therefore demonstrated. The 2-wk EE healing rate with vonoprazan (77.9%) also demonstrated non-inferiority to lansoprazole (72.0%) (difference [95% CI]: 5.9% [-4.572, 16.454]), as did the 4-wk EE healing rate with vonoprazan (83.9%) vs lansoprazole (83.5%) (difference [95% CI]: 0.5% [-8.442, 9.396]). In patients with baseline LA classification grade C/D, 2-, 4- and 8-wk EE healing rates were slightly higher with vonoprazan vs lansoprazole (63.5% vs 56.8%, difference [95% CI]: 6.6% [-12.991, 26.278]; 69.8% vs 68.9%, difference [95% CI]: 0.9% [-17.400, 19.245]; and 83.0% vs 77.8%, difference [95% CI]: 5.2% [-10.562, 21.044], respectively). TEAE rates were similar between the vonoprazan arm (44.8%) and lansoprazole arm (42.0%).
Conclusion: Findings demonstrated the non-inferior efficacy of vonoprazan vs lansoprazole in achieving EE healing at Wk 8 in this Chinese sub-cohort. Safety outcomes were similar between both treatment arms.

Introduction: The proton pump inhibitors (PPIs) are used to the upper gastrointestinal disorder, such as heartburn, and belch in the patients with gastroesophageal reflux disease (GERD). However, some patients are incomplete response to PPI therapy in these symptoms. Hangeshashinto (HST), a traditional Japanese (Kampo) medicine, has been widely prescribed to relieve chemotherapy-induced diarrhea and stomatitis[1)] in Japan. One of the mechanisms of HST has been reported to have anti-inflammatory effect via inhibition of prostaglandin E_2 production[2)]. HST is used empirically for dyspepsia and heartburn, but has not been fully elucidated. Taken together, these reports and empirical use suggested that HST can be a promising agent for the upper gastrointestinal disorder patients. We investigated the efficacy of HST in patients with PPI refractory GERD.
Aims and Methods: We conducted the randomized, multicenter exploratory study for the efficacy of HST in gastroesophageal reflux disease (GERD) patient refractory to PPIs. All patients were diagnosed with GERD with a frequency scale for the symptoms of gastroesophageal reflux disease (FSSG) total score ≥ 8 following treatment with PPIs for a more than 4 weeks. Patients were randomly allocated to HST 7.5g/day with a standard-dose of rabeprazole10mg/day (HST group) or a double-dose of rabeprazole 20mg/day (PPI double-dose group).
The gastrointestinal symptoms were evaluated by FSSG and Gastrointestinal Symptom Rating Scale (GSRS). The primary endpoint was to determine the change in total score FSSG after 4 weeks treatment to estimate the difference between the two treatment groups. The secondly endpoint was the changes in GSRS, and also was assessed using the each symptom questionnaires prior to and 4 weeks following treatments. Additionally, the subpopulation analysis based on patient background factors was performed.
Results: Of a total 78 patients were enrolled in this study, 70 subjects of effective analysis (HST group 38, double-dose group 32) were examined. The change in FSSG total score was significantly improved after 4 week treatment in both groups. However, there were no significant differences between two groups. The total score FSSG was significantly decreased after 4 week treatment in both groups (HST group: from 19.5 ± 9.6 to 9.8 ± 7.6, $p < 0.001$, PPI double-dose group: from 16.3 ± 6.2 to 10.1 ± 7.1, $p < 0.001$). HST group was showed improvement of acid related dysmotility (ARD) score after 1 week treatment, meanwhile double-dose group showed a significant improvement effect of ARD three weeks after administration. There were no significant differences in the improvement degrees of GSRS scores between the two groups after 4 week treatment, but the GSRS score was significantly improved compared to pretreatment in both groups. By factor analysis for the change in the improvement degrees of FSSG score, it is found that having an abdominal symptom, a history of allergic and being treated with a combination of HST and standard dose PPI therapy were significant factors for decreasing FSSG score.
Conclusion: There is no difference in treatment of combination therapy (HST and standard dose PPI) and double dose PPI. However, these results suggest that combination therapy may be an effective therapeutic option for the treatment of PPI-refractory GERD patients, though detailed clinical study required to clarify clinical efficacy of the HST.

Introduction: The main precursor condition of Esophageal Adenocarcinoma (EAC) is Barrett's Esophagus (BE). BE is mainly attributed to inflammation due to chronic reflux of gastric and bile acid. Risk of progression to EAC correlates with obesity and a western-style diet, which further affects the gut microbiome. In previous studies on our L2-IL-1ß (IL-1ß) overexpressing BE mouse model it was shown that treatment with bile acids, especially deoxycholic acid (DCA), accelerated tumorigenesis in the mice (1).
Aims and Methods: We are aiming to clarify the effect of bile acid exposure and the associated nuclear bile acid receptor Farnesoid-X-Receptor (FXR) in coherence with diet and gut microbiome on the development of BE and EAC. Thus, we analyzed cohorts of IL-1ß mice with & without FXR whole body knockout and with & without a high fat diet (HFD) through histology, gene expression and a characterization of the microbiome. Effects of an FXR agonist (obeticholic acid (OCA)) were analyzed on 3D organoid cells before testing on IL-1ß mice fed control (CD) or high fat diet (HFD). In organoids, mice and human patients, analyses including flow cytometry, 16s- sequencing, gene expression- and serum bile acid analyses were performed.
Results: Gene expression analyses demonstrate that FXR, a key regulator in bile acid-metabolic and inflammatory signaling, was upregulated in BE but downregulated in EAC in humans and mice. A germline knockout of FXR in IL-1ß mice accelerated malignant progression of BE with increased DNA damage, stem cell numbers and cellular dedifferentiation, suggesting a protective function of FXR in BE. Importantly, OCA, a selective FXR agonist, had a protective function and eliminated the toxic effect of DCA in organoids. In IL-1ß mice, resembling human western-style diet, high-fat diet (HFD) causes a change in the gut microbiome including distinct bile acid metabolizing bacteria and accelerates malignant progression, which correlates with changes in circulating bile acid levels in the serum. In these mice, OCA increases differentiation in the metaplastic tissue, suggesting it to suppress malignant progression. An ongoing analysis of the microbiome of the human study cohort will lead to a better understanding of the postulated coherences.
Conclusion: In summary we propose that the gut microbiome, which is altered by a HFD is partly metabolizing primary bile acids leading to altered bile acid metabolites in the blood. The nuclear bile acid receptor, FXR, on metaplastic BE cells seems to be an important player to regulate the inflammatory effects of bile acid exposure and the differential potential of progenitor cells at the gastro-esophageal junction, suggesting a protective function that could be activated through OCA treatment. Thus, we provide evidence for a novel mechanism how secondary bile acids accelerate esophageal carcinogenesis and how FXR activation could be used for preventive or therapeutic approaches in BE and EAC patients.

Introduction: Circumferential endoscopic submucosal dissection (ESD) allows to treat large esophageal superficial neoplasia, however with high occurrence of severe esophageal stricture. In a previous work we demonstrated that the application of a prototype of self-assembling peptide (SAP) matrix on esophageal wounds after a circumferential-ESD delayed the onset of esophageal stricture in a porcine model (1). The aim of this work was to consolidate these results using the commercialized version of this SAP matrix, a short peptide "RADA16" (4 [Arg-Ala-Asp-Ala]), currently used as a hemostatic agent.
Aims and Methods: Eleven pigs underwent a 5 centimetres-long circumferential esophageal ESD under general anesthesia. Five pigs were used as a control group and six were treated with the SAP. In the experimental group, 3.5 ml of the SAP matrix were immediately applied on the ESD wound with a dedicated catheter. At day 14, an endoscopy and an esophagogram were realized. Animals were then euthanized and underwent necropsy with *en bloc* esophagectomy. Pathology with Hematoxylin Eosin Saffron coloration and immunohistochemistry with the use of Collagen I and III, and Alpha smooth muscle actin antibodies were performed.
Results: At D14, two animals in the treated group had an esophageal stricture without any symptom versus all animals in the control group who had a symptomatic stenosis (33 vs. 100%, $p = 0.045$). In the treated group, the mean esophageal diameter at day 14 was 9.5 ± 0.98 millimeters vs. 4 ± 0.6 mm in the control group ($p = 0.004$). Histologically, the neoepithelium was longer in the SAP treated group vs. the control group (3075 µm vs. 1155µm, $p = 0.014$). On immunohistochemistry, the staining of Alfa smooth muscle actin was significantly greater in the SAP treated group vs. the control group.

Conclusion: Apposition of a self-assembling peptide matrix immediately after a circumferential esophageal ESD reduced by 67% the occurrence of a stricture at day 14, by promoting re epithelialisation of the resected area.
The authors would like to thank 3D Matrix Europe for their material support.

Introduction: Barrett's Esophagus (BE) is a premalignant condition occurring as gastroesophageal reflux disease (GERD) complication. GERD symptoms are observed in approximately 20% of the developed countries population. On the other hand, hydrogen sulfide (H_2S) has been shown to prevent gastric mucosa injury induced by NSAIDs, topical irritants or stress. However, the role of H_2S in the pathogenesis of BE has not been elucidated.
Aims and Methods: We investigated if the enzymatic pathway of H_2S biosynthesis is involved in the development of BE and if the treatment with H_2S precursor (L-cysteine) or donors (NaHS or GYY4137) prevents BE progression in vivo and in vitro. An anastomosis between the gastroesophageal junction and the duodenum on its anterior mesenteric border was created to induce mixed duodenogastroesophageal reflux in Wistar rats. Next, animals were treated daily for 8 weeks with water (vehicle), NaHS (0.1–20 mg/kg), GYY4137 (5 mg/kg), L-cysteine (1–50 mg/kg) or D,L-propargylglycine (PAG, 1–30 mg/kg), inhibitor of cystathionine-g-lyase (CTH). Esophageal lesions/metaplasia index (ELMI) was assessed macroscopically and microscopically using H&E and PAS staining. Esophageal blood flow (EBF) was measured by laser flowmetry. Expression of mRNA for proinflammatory iNOS and COX-2 was determined in esophageal mucosa by real-time PCR. H_2S production in esophageal mucosa was assessed using methylene blue method. CTH or CBS gene knock-outs were induced using CRISPR/Cas9 technique in human-derived non-neoplastic Barrett's epithelial cells (BAR-T), esophageal keratinocytes (EPC2) and squamous esophageal epithelial cells (HET-1A).
Results: Chronic reflux led to esophagitis, metaplasia, fall in EBF, and upregulation of iNOS, COX-2 and decreased H_2S production. NaHS and GYY4137 but not L-cysteine significantly decreased ELMI, mucus production, iNOS and COX-2 expression and increased EBF. PAG (15 or 30 mg/kg/day) increased ELMI, mucus generation, mRNA expression of iNOS, COX-2 and decreased EBF. CTH or CBS gene knock-out did not affect BAR-T, HET-1A and EPC2 viability.
Conclusion: We conclude that decreased H_2S production in esophageal mucosa exposed to GERD could be involved in the development of BE metaplasia. CTH/CBS genes are not essential for the maintenance of BAR-T, EPC2 or HET-1A viability. Treatment with NaHS or GYY4137 prevents BE development by the compensation of decreased H_2S production. This effect involves vasodilatory and anti-inflammatory properties of H_2S. [Funding source: National Science Centre, Poland (UMO-2016/23/D/NZ4/01913)].

P1159 IMPROVING BARRETT'S SURVEILLANCE PRACTICE THROUGH THE USE OF PRAGUE CLASSIFICATION OR LENGTH OF BARRETT'S OESOPHAGUS – A RETROSPECTIVE STUDY IN A DISTRICT GENERAL HOSPITAL

A.A. Shivarajan, **J. Stevenson**, R. Raja Shariff, W. Jafar, C. Kong
Stockport NHS Foundations Trust, Gastroenterology, Manchester, United Kingdom

Contact E-Mail Address: jason.stevenson@nhs.net
Introduction: Barrett's Oesophagus (BO) surveillance is recommended in the presence of columnar epithelium visible at or more than 1cm above the gastroesophageal junction (GOJ), with histological confirmation of intestinal metaplasia.[1] The risk of developing oesophageal adenocarcinoma in patients with BO supports the rationale for repeat endoscopic surveillance, with quadrantic biopsies taken for every 2 cm of BO as per the British Society of Gastroenterology (BSG) guidelines.[2] The Prague Classification was introduced in 2004 by the International Working Group as a standardized method of measuring and recording BO.[3] It has now become widely accepted as the universal standard.[1,4]
Aims and Methods: In this retrospective study we aim to assess whether implementation of compulsory basic data input of Prague Classification or length of BO improves adherence to the BSG guidelines for Barrett's surveillance. Data was collected from endoscopy reports from May to Sept 2014 (5 months). The list of patients were obtained from the Barrett's surveillance programme on the endoscopy reporting system "Unisoft". Prague classification or the length of Barrett's was implemented as compulsory basic data input for endoscopy reporting of BO in 2016 and a re-audit was conducted with data collected from Nov 2017 to May 2018 (5 months). Exclusion criteria were incorrect Prague classification used or no length of Barrett's documented. The two cohorts were not overlapping as the 2014 cohort would have been followed up for repeat endoscopy by 2016, whereas the second cohort commenced from Nov 2017. The length of BO, Prague classification and number of biopsies taken were obtained from each report. The endoscopy was deemed non-adherent to the guidelines if no reason was provided as to why quadrantic biopsies were not taken. The data was entered onto a Microsoft Excel 2010 spreadsheet and the Chi square test of Independence was applied.
Results: 174 reports were retrieved from 2014 of which 26 were excluded from the study. Of the 148 reports, 45% (66) adhered to the BSG guidelines. In the re-audit, 212 reports were collected, with 73 excluded. Of the 139 reports collected from 2017, 76% (106) adhered to the BSG guidelines. Thus, the implementation of compulsory basic data input of Prague classification, or length of Barrett's was found to correlate significantly with the correct number of biopsies taken ($p < 0.001$). Prague classification was documented in 68% (95) of the 2016 cohort and in none of the 2014 cohort. Potential confounding factors were the endoscopists' increased awareness of Barrett's surveillance after the first audit cycle which could not be measured.
Conclusion: This study found that the implementation of compulsory basic data input of Prague classification or length of Barrett's in reporting, significantly improves Barrett's surveillance[5, 6]. It is postulated that compulsory data input of Prague classification or length of BO, helps to assist the endoscopist's thought process of adhering to the guidelines. Therefore, adjustments to software used to document findings of Barrett's surveillance may help to improve adherence to the BSG guidelines and as a result the quality of surveillance.

Introduction: Alterations in the human gut microbiome have been linked to health and disease including metabolic syndrome, autoimmunity, and IBD. In addition, microbes and their metabolic byproducts have been linked to gut neoplasia. We hypothesized that alterations in mucosa-adherent Barrett's microbiota could be a link to risk factors for neoplasia
Aims and Methods: We sought to detect significant differences in Barrett's esophagus (BE) with and without neoplasia and paired squamous mucosa associated microbiota. Taxa were considered one-by-one using a generalized linear model based on the negative binomial distribution and the log link function as designed by the functions of the R Bioconductor package edgeR. We identified 53 patients who were enrolled in an IRB-approved protocol for research biopsies (Normal controls-10, Intestinal metaplasia (IM) -10, Low-grade dysplasia (LGD) -10, High-grade dysplasia (HGD) -10, Esophageal adenocarcinoma (EAC)-12). Biopsies of the Barrett's, EAC and normal esophagus (3 cm cephalad) were obtained for mucosa-associated bacteria along with gastric secretions for 16S rRNA V4 DNA sequencing.

Results: We analyzed the microbe composition of paired mucosa-associated microbes comparing changes in bacteria in samples representing progression of disease from intestinal metaplasia to LGD to HGD to adenocarcinoma. We found significant increases in phyla Synergistetes, OP8, and Chlamydiae and significant decreases in the archaean Crenarchaeota ($p < 0.05$, FDR corrected). At the genus level, Pyramidobacter, Plesiocystis, Synergistes, and Paenibacillus were the microbes most significantly increased and Siphonobacter, Propionivibrio, and Sphingobacterium among those most significantly decreased. Overall the significant changes either up or down are in genera that represent $<10\%$ of the entire bacterial community.
Conclusion: There are significant changes in specific bacterial genera, both increased and decreased, in esophageal biopsies representing the presumed progression of Barrett's mucosa toward neoplasia. Further study will be needed to establish the biologic plausibility of the effects on the epithelium induced by these microbes that could contribute to protection from or induction of dysplasia.

Introduction: The endoscopic detection and characterization of early Barrett's cancer can be challenging, especially for endoscopists with limited Barrett experience. The evaluation of Barrett's esophagus with the help of computer-aided diagnosis (CAD) may be a valuable adjunctive tool for endoscopists managing patients with Barretts esophagus. As of date, there is only limited experience in the use of deep learning for computer-aided diagnosis of early Barrett's cancer[1].
Aims and Methods: A CAD system was trained using deep learning and then tested for sensitivity and specificity using 33 endoscopic images of histologically confirmed early Barrett's cancer and 41 images of Barrett's mucosa without dysplasia. All endoscopic images were collected prospectively at the Klinikum Augsburg and included near-focus white light and narrow band Images. Early Barrett's cancer was limited to the mucosa or superficial submucosa (sm1 $\leq$ 500 µm). Histology was the gold standard with which the test results of the CAD system was compared. Training of the system included training patch generation, image augmentation, adjustment of a convolutional neural network, patch probability computation and finally image classification.
Results: After training of the CAD system, sensitivity and specificity was 97% and 88% for white light images and 94% and 80% for narrow band images respectively.
Conclusion: CAD can be trained to classify Barrett's cancer using a deep learning approach with excellent diagnostic performance. A much larger pool of images is needed to improve the ability of the CAD system. However, if developed further, CAD using deep learning could become a useful adjunctive tool for endosocpists in the evaluation of Barrett's esophagus.

Introduction: Oesophageal adenocarcinoma (OAC) incidence has increased dramatically over the last four decades. Barrett's oesophagus (BO) is the most important risk factor to develop OAC. Clinical guidelines recommend surveillance and, if there is an indication, endoscopic eradication therapy (EET) of BO patients. However, an important policy-practice gap exists between recommended and observed intervals for BO surveillance.
Aims and Methods: We aimed to determine how current practice of surveillance of BO patients in the Netherlands affects costs and benefits of the surveillance programme, compared to the recommended policy in the Dutch guideline. We used the Microsimulation Screening Analysis (MISCAN) model to simulate a 60-year-old Dutch BO cohort and evaluated 4 different surveillance strategies. In the first strategy, surveillance was simulated according to the Dutch guideline: non-dysplastic BO (NDBO) patients underwent surveillance every 3–5 years, low-grade dysplasia (LGD) patients every 6 months to 1 year, and patients with T1a, HGD, or persistent long-segment LGD received EET. The other three strategies simulated a more intensive surveillance strategy for either NDBO (every 2–3.5 years), LGD patients (every 3–6 months), or both in accordance with intervals observed in practice. For each strategy, we computed number of OAC cases, life-years gained, and costs. Also, we calculated the difference between Dutch guideline strategy and the more intensive strategies.
Results: In the Dutch guideline strategy, the costs for surveillance and treatment were €6.5 million per 1,000 patients, while 35 OAC cases (excluding T1a) were prevented (Table 1). The more intensive surveillance practice for NDBO, resulted in 26% higher costs (+€1.7 million) compared to the Dutch guideline strategy, while only 8 more cases (+23%) were prevented and 42 more (+19%) quality-adjusted life-years (QALY) were gained. The more intensive surveillance for LGD increased costs by a half million and prevented only 2 more OAC cases (+6%) resulted in gaining 4 more QALYs (+2%). In the more intensive surveillance practice for both NDBO and LGD, the costs increased by 37% (+€2.4 million) compared to the Dutch guideline strategy. Only 11 more OAC cases were prevented (+31%) and 51 more QLAYs (+23%) per 1,000 BO patients were gained. As a consequence, the incremental cost-effectiveness ratio of all these non-adherent strategies exceeded €40,000 per QALY compared to the Dutch guideline strategy.
Conclusion: Our findings indicate that the policy-practice gap in BO surveillance intervals leads to up to 50% higher costs for BO surveillance for less than 25% increase in QALY gained. The actual impact of the policy-practice gap in BO management is likely to be even higher, because other deviations from the guideline, such as adherence to the biopsy protocol, were not considered. It is important to develop incentives to eliminate this policy-practice gap so that the burden of BO management on health care resources can be reduced.

Strategy	Dutch guideline	More intensive for NDBO[1]		More intensive for LGD[1]		More intensive for NDBO and LGD[1]

Introduction: According to current guidelines, endoscopically visible columnar metaplasia <1 cm does not qualify as Barrett's esophagus (BE). However, Barrett's neoplasia [high-grade dysplasia (HGD) and early esophageal adenocarcinoma (EEA)] is still encountered in many of these patients.
Aims and Methods: Our aim was to evaluate the long-term outcomes and safety of endoscopic eradication of Barrett's neoplasia in patients with ultra-short (US) BE. Data on patients with histology proven HGD\EEA undergoing endoscopic eradication was collected prospectively. Consecutive endoscopic resection (EMR) combined with radio-frequency ablation (RFA) were performed until endoscopic and histologic eradication of dysplasia and metaplasia was achieved.
Results: Between 2004 and 2017, 511 patients underwent endoscopic eradication for HGD\EEA, of which 83(16%) patients had an US ($\leq$1cm) segment of BE. Eighteen patients were found to have high-risk histological features and were referred for surgical consultation. In the remaining 65 patients, 71% had EEA and 29% had HGD. Complete eradication of neoplasia and intestinal metaplasia (IM) was achieved in 92%(60/65) and 74% (48\65) of patients, respectively. After a median follow-up of 9.9 months following the first negative endoscopy control, neoplasia recurred in 10% and IM in 6%. Esophageal dilation was required in 38.5% (median 3 dilations) at a median follow-up of 23 months.
Conclusion: Routine biopsies and surveillance is not recommended in BE less than 1cm in length. However, a significant proportion of our patients were found to have neoplastic BE within an US segment. In these patients, endoscopic therapy consisting of EMR and RFA was found to be highly effective and safe.

Introduction: Endoscopic therapy is recommended for removal of dysplastic Barrett's oesophagus (BO) to prevent progression to oesophageal adenocarcinoma. Hybrid Argon Plasma Coagulation (HAPC) is an upcoming ablative technique, however, only limited data are available. HAPC can be performed using a standard electrosurgical unit that is available in most hospitals. It is therefore more widely available with reduced equipment cost compared to Radio Frequency Ablation.

Aims and Methods: The primary aim of this feasibility study is to assess efficacy of HAPC for ablation of dysplastic BO. The secondary aim was to assess adverse event rates.

This was a prospective single-arm study including patients with histologically confirmed low-grade dysplasia, high-grade dysplasia or T1a adenocarcinoma. Patients with a BO segment >13cm, previous oesophageal ablative therapy and presence of endoscopically visible abnormalities at initial treatment were excluded. Submucosal injection of a sodium chloride 0.9% fluid cushion followed by APC treatment using a flexible HAPC probe and ERBE waterjet™ was performed. HAPC therapy was performed at 8-week intervals until complete endoscopic removal of BO had been achieved upon inspection with high-resolution endoscopy and (virtual) chromoendoscopy. Biopsies were taken after eradication of BO. If BO was detected additional HAPC sessions were performed, to a maximum of 5 sessions. After each session adverse events were assessed by phone call at 24 hours and during follow-up visit in clinic 2 weeks post treatment. Patients underwent follow-up endoscopy after treatment at 3, 6, 12, 18, 24, 30, 42, 48, 54 and 60 months.

Results: In total 8 patients [75% male, mean age 66 +/− 6 years;] were enrolled. Currently, 3 patients have achieved histologically complete eradication after a median of 3 treatments (IQR 2–4 treatments). All patients tolerated the procedure well and BO was successfully eradicated using HAPC. None of the patients required the maximum number of 5 sessions at this stage. Five patients are currently being treated with HAPC sessions and are awaiting complete eradication. Median procedure time of all procedures was 12 minutes (IQR 5–18.5 minutes). No treatment-related complications or post-procedural adverse events have been reported to date.

Conclusion: Our interim analysis shows that HAPC is effective and safe for removal of dysplastic BO in a small patient group. Further data will follow on cost-effectiveness of this treatment that is more widely available to patients than the current standard of care.

Introduction: The role of ESD on Barrett's esophagus (BE) neoplasia has been studied in some small series with suboptimal results, mainly due to positive lateral margins (LM). We started ESD for neoplastic BE on 2011. Due to early suboptimal results because of positive lateral margins (LM), we decided to perform wide-field ESD of Barrett's neoplasia from 2015. With the new approach resection is performed, as described for wide-field colorectal EMR, with wider (5–10mm) free margins, after careful BE assessment. Our aim was to evaluate the feasibility, safety and efficacy of wide field ESD (WF-ESD) for resection of BE neoplasia comparing it to conventional ESD (C-ESD).

Aims and Methods: Patients, tumors and ESD procedures characteristics were assessed, and a comparison between c-ESD with WF-ESD was performed. In order to reduce stricture risk, oral steroids were used in patients with more than 3/4 resection of all circumferential lumen of the esophagus. The primary outcomes were the rates of *en bloc*, R0 and curative resection rates. The secondary outcomes were the rates of negative LM and adverse events rate such as bleeding, perforation and stricture. This study was approved by the Stockholm Regional Ethical Committee and all patients were discussed in multidisciplinary conference before inclusion.

Results: In total, 72 consecutive ESDs of Barrett's neoplasia were performed in 57 patients in our center between 01.2011–12.2014 and 01.2015–03.2018. The mean age was 67.1 ± 9.9 vs 67.6 ± 10.1 and the male/female ratio was 13/6 vs 33/6, in c-ESD and WF-ESD, respectively ($p > 0.05$). The resected specimen size was 43.7 ± 26.0 vs 51.1 ± 24.4 and lesion size was 18.4 ± 19.1 vs 23.3 ± 17.7 in c-ESD and WF-ESD, respectively ($p > 0.05$). Considering primary outcomes, en-block resection rate was 91.3 vs 100% (21/23 vs 49/49), R0 resection rate was 69.6 vs 85.7% (16/23 vs 42/49), curative resection rate was 56.5 vs 73.5% (13/23 vs 36/49) in c-ESD and WF-ESD, respectively. Considering secondary outcomes, positive LM rate was 26.1 vs 4.1% (6/23 vs 2/49), adverse event rate including perforation and bleeding was 4.3 vs 8.3% (1/23 vs 4/48) and stricture rate was 26.1 vs 6.1% (6/23 vs 3/49) in c-ESD and WF-ESD with $p < 0.05$ for LM and stricture rate. All complications were managed endoscopically.

Conclusion: Wide-field ESD is associated with improved efficacy and good safety profile, with marked decrease in positive lateral margins. Moderate increase in curative resection is related with more advanced lesions treated with ESD in the second cohort as a consequence of technique's efficacy and safety, and considering high morbidity of the alternative treatment (surgery) in that setting.

Introduction: Gastric adenocarcinoma of fundic gland type (GAFG) is newly added as a special type cancer in Japanese classification of gastric carcinoma, the 15th Edition (1). GAFG is an uncommon variant of gastric adenocarcinoma which has a distinct clinicopathological, immunohistochemical, and endoscopic features (2–4). GAFG is defined by positive immunohistochemical staining for pepsinogen-I (a marker of chief cells) and/or H+K+-ATPase (a marker of parietal cells) and is not associated with *H. pylori* infection. Histopathologically, GAFG is classified into pure GAFG and gastric adenocarcinoma of fundic gland mucosal type (GAFGM) which exhibited differentiation toward gastric foveolar epithelium in addition to fundic gland differentiation and is suspected as an aggressive type of pure GAFG. Endoscopically, the most common features with white light image (WLI) were submucosal tumor shape, whitish color, dilated vessels with branching architecture and background mucosa without atrophic change (3). The most frequent features with magnifying endoscopy with NBI (ME-NBI) were indistinct line of demarcation between lesion and surrounding mucosa, dilatation of crypt opening, dilatation of intervening part between the crypts and microvessels without distinct irregularity (4). However, the color and morphological classification of GAFG has not been established, and the clinicopathological features of GAFG according to the classification have not been well investigated.

Aims and Methods: The aim of this study was to establish the color and morphological classification of GAFG and elucidate the clinicopathological features of GAFG according to the classification. A total of 40 patients with 46 GAFGs were retrospectively evaluated from January 2008 to December 2017. All GAFGs were classified into 4 types according to color and morphology, as follows: Type 1. whitish protruded type (n = 23), Type 2. whitish flat/depressed type (n = 12), Type3. reddish protruded type (n = 7), Type 4. reddish flat/depressed type (n = 4). We then compared them via a clinicopathological evaluation and endoscopic features which we have reported (3,4).

Results: All GAFGs were classified into 37 pure GAFGs and 9 GAFGMs, Type 1. (n = 23, 21: 2), Type 2. (n = 12, 11: 1), Type3. (n = 7, 3: 4), Type 4. (n = 4, 2: 2). The frequency of GAFGM was significantly higher in Type 3 (4/7) and Type 4 (2/4) than in Type 1 (2/23) and Type 2 (1/12) ($p < 0.01$). There were no significant differences between the 4 types in the following findings: location of lesion, method of treatment, depth of invasion, lymph node metastasis, proliferative activity, p53 protein overexpression, and H. pylori infection. The average of tumor size (8.7 vs. 7.3 vs. 10 vs. 23.8mm, $p < 0.05$) was significantly greater and the rates of lymphatic invasion (0/23 vs. 1/12 vs. 0/7 vs. 2/4, $p < 0.05$) was significantly higher in Type 4 than in other Types. Endoscopically, the frequency of dilated vessels with branching architecture in WLI (17/23 vs. 9/12 vs. 1/7 vs. 1/4, $p < 0.05$) and indistinct line of demarcation between lesion and surrounding mucosa in ME-NBI (16/17 vs. 9/11 vs. 2/6 vs. 2/3, $p < 0.05$) were significantly higher in Type 1 and 2 than in Type 3 and 4. Furthermore, the background mucosa with atrophic change was more often seen in Type 4 (2/4, $p = 0.05$).

Conclusion: The reddish GAFGs (Type 3 and 4) has higher frequency of GAFGM than the whitish GAFG (Type1 and 2), and present atypical endoscopic features. Additionally, Type 4 may have a high malignant potential, and background mucosa with atrophic change may be related to the tumor progression.

Introduction: There is rare report for the effect of body mass index (BMI) on gastric cancer mortality. We evaluated gastric cancer mortality by age, sex, and BMI.
Aims and Methods: Patients with gastric cancer diagnosed from 2005 to 2013 in a single tertiary center were enrolled and followed up until December 2017. To evaluate gender-specific gastric cancer mortality by age and BMI, they were categorized. Age groups: <50yr, 50–60, 60–70, and ≥70yr. BMI groups by Asian-Pacific guideline; <18.5, 18.5–23, 23–25, 25–30, and ≥30 kg/m^2. Cox regression analysis using hazard ratios (HRs) and 95% confidence intervals (CIs) was performed to assess gender-specific mortality by age and BMI.
Results: A total of 6005 gastric cancer patients (4007 men and 1998 women) underwent ESD (n = 1056, 17.6%), gastrectomy with or without chemotherapy (n = 4529, 75.4%), or palliative chemotherapy only (n = 420, 7.0%). In adjusted analysis, mortality was higher in advanced stage (HR, 3.39; 95% CI, 3.16–3.67) and increased by aging (HR, 1.69; 95% CI, 1.57–1.82). Mortality was higher in low BMI (HR, 0.78; 95% CI, 0.72–0.84) and male sex (HR, 1.59; 95% CI, 1.36–1.85).
Conclusion: Gastric cancer mortality increased by aging and was higher in low BMI and male sex.

Introduction: Signet ring cell carcinoma (SRC) is a poorly differentiated cancer of the stomach. Recent studies imply that early gastric SRCs can be well managed by endoscopic resection. Unfortunately, unlike differentiated cancers, the endoscopic features of early gastric SRCs have not been well studied. We not only evaluated the endoscopic features of early gastric SRC, but also the risk factors regarding submucosal (SM) invasion through this study.
Aims and Methods: The medical records of patients from 7 tertiary hospitals (Daejeon and Chungcheong province), who underwen surgery or endoscopic resection from January 2011 to December 2016, were reviewed to examine endoscopic findings and clinical data. The patients were divided into two groups (derivation group and validation group), in order to develop an endoscopic scoring system for SM invasion. Two endoscopists analyzed the endoscopic images separately.
Results: In total, 331 patients (129 patients, derivation group; 202 patients, validation group) were enrolled in the this study. In the derivation group, the risk factors for SM invasion, namely fold convergence, nodular mucosal change, and deep depression were risk factors of SM invasion determined by logistic regression analysis (OR = 3.4, 5.9, 6.0, p < 0.05). A depth-prediction score was created by assigning 1 point for fold convergence and 2 points for other factors. When validation lesions of 0.5 points or more were diagnosed as SM invasion, the sensitivity and the specificity were 76.8%-78.6% and, 61.6%-74.7%, respectively.
Conclusion: Fold convergence, nodular mucosal change, and deep depression are the risk factors for SM invasion in early gastric SRCs. Our depth prediction scoring system may be useful for differentiating SM cancers.

P1170 CLINICAL SUBMUCOSAL INVASIVE GASTRIC CANCER: IS SURGERY THE ONLY OPTION?

H.D. Lee[1], H. Chung[1], S.G. Kim[1], J. Kim[1], H.C. Jung[1]
[1]*Seoul National University Hospital, Department of Internal Medicine and Liver Research Institute, Seoul, Korea (Republic of)*

Contact E-Mail Address: hyundeok.lee@gmail.com
Introduction: The current standard treatment modality for clinical submucosal invasive (cT1b) gastric cancer is surgery. However, there are discrepancies in T staging between pre- and post-operative findings and especially in some cases of overestimation, patients may lose the opportunity to preserve the stomach.
Aims and Methods: The aim of this study is to analyze surgical outcomes of cT1b gastric cancer and to determine the favoring factors for endoscopic submucosal dissection (ESD).
From January 2010 to December 2014, we retrospectively reviewed 466 patients who underwent curative gastrectomy for cT1b gastric cancer with differentiated type histology and 3cm or less in diameter. According to final surgical pathologic results, two groups were classified: the group of patients whose pathologic results were qualified for ESD (ESD qualified group, n = 205) and the group of patients whose pathologic results were not suitable for ESD (ESD disqualified group, n = 261). The preoperative clinical characteristics were compared between two groups.
Results: Forty-four percent of the patients (205/466) who underwent gastrectomy for cT1b gastric cancer was qualified for the ESD; their size of endoscopic lesion tended to be smaller than 2cm (1cm < size≤2cm, odd ratio[OR] = 0.499, 95% confidence interval[CI] = 0.313–0.796, P = 0.003; size≤1cm, OR = 0.267, 95% CI = 0.144–0.495, P = 0.000) and located to the distal part of stomach (middle third, OR = 0.531, 95% CI = 0.279–1.010, P = 0.054; lower third, OR = 0.362, 95% CI = 0.206–0.637, P = 0.000). In addition, ESD qualified group showed significantly higher proportion of well-differentiated adenocarcinoma (OR = 0.565, 95% CI = 0.379–0.843, P = 0.005) in endoscopic biopsy. (Table 1)

	Odd ratio [OR]	95% Confidence interval [CI]	P-value
Endoscopic lesion size			
2cm < size ≤ 3cm	1		
1cm < size ≤ 2cm	0.499	0.313–0.796	0.003
size ≤ 1cm	0.267	0.144–0.495	0.000
Endoscopic location			
Upper third	1		
Middle third	0.531	0.279–1.010	0.054
Lower third	0.362	0.206–0.637	0.000
Pathology of endoscopic biopsy			
Moderate-differentiated adenocarcinonma	1		
Well-differentiated adenocarcinonma	0.565	0.379–0.843	0.005

[Table 1. Logistic regression analysis of favoring factors for endoscopic submucosal dissection]

Conclusion: Forty-four percent of the patients with cT1b gastric cancer who underwent gastrectomy had a chance to preserve the stomach by ESD. Factors such as smaller endoscopic size (≤ 2cm), distal tumor location (middle or lower third) and well-differentiated adenocarcinoma were the important clinical indicators for ESD in cT1b gastric cancer.
Disclosure: Nothing to disclose

P1171 THE CLINICAL CHARACTERISTICS AND THERAPEUTIC OUTCOMES OF NON AMPULLARY DUODENAL NEUROENDOCRINE TUMOR(NADNET): MULTICENTER, RETROSPECTIVE STUDY

Introduction: Duodenal neuroendocrine tumors (DNETs) are rare tumors and found occasionally during upper endoscopic examination. The incidence of DNETs are increasing. However, the data regarding the treatment outcome are not sufficient.
Aims and Methods: The aim of this study was to evaluate the treatment outcomes of non ampullary DNETs which were resected endoscopically or surgically.
We searched medical records of patients diagnosed as non ampullary DNET from 2004 to 2017 in seven university hospitals. We analyzed clinical characteristics and compared therapeutic outcomes according to endoscopic lesion size and treatment methods retrospectively.
Results: We enrolled 50 non ampullary DNET patients who received endoscopic treatment and 11 patients who received surgical treatment. In endoscopically treated patients, the mean lesion size was 8.2 mm and surgical treatment group was 13.9 mm. En bloc resection, endoscopic complete resection and pathologic complete resection (CR) rate was 88%, 92 % and 50% respectively in endoscopic treatment group. Endoscopic treatment group was divided into 3 group (1–5mm, 6–10mm,≥11 mm). The pathologic CR rate was significantly low in the lesion size ≥ 11 mm (0%, p < 0.05). The lymphovascular invasion was significantly high

(33%, $p < 0.05$) in lesion size ≥11 mm in endoscopic treatment group. The pathologic CR of surgical treatment group was higher (90.9%) than endoscopic treatment group (50%) ($P < 0.05$).
Conclusion: In endoscopic treatment group, the group of lesion size ≥ 11mm had low pathologic CR rate and elevated risk of lymphovascular invasion. Surgical treatment was more effective than endoscopic treatment in lesion size ≥ 11mm.
Disclosure: Nothing to disclose

P1172 CLINICAL RISK FACTORS OF NON-CURATIVE RESECTION BY ENDOSCOPIC SUBMUCOSAL DISSECTION FOR THE PATIENTS WITH EXPANDED INDICATION OF INTESTINAL-TYPE EARLY GASTRIC CANCER (CT1), AN ANCILLARY ANALYSIS OF MULTI-INSTITUTIONAL, SINGLE-ARM, CONFIRMATORY TRIAL (JCOG0607)

Introduction: The multi-institutional, single-arm, confirmatory trial (JCOG0607) showed excellent efficacy and safety of endoscopic submucosal dissection (ESD) for the expanded indication of intestinal-type early gastric cancer (GC)[1]. However, the proportion of non-curative resection (NCR) was as high as 32% of all resected lesions (152/469) for which additional surgeries were required. In order to reduce the proportion of NCR, it is important to improve the diagnostic accuracy of clinical factors of intestinal-type early GC. The aim of this ancillary analysis is to evaluate the clinical factors associated with NCR of ESD for intestinal-type early GC using the data from JCOG0607.
Aims and Methods: The major inclusion criteria of JCOG0607 were as follows: 1) histologically proven intestinal-type adenocarcinoma; 2) cT1aN0M0; 3) lesion without clinical finding of ulcer (cUL (-)) and >2 cm in size, or cUL (+) and ≤ 3 cm in size; 4) age 20–75. The NCR was defined as not meeting any of the following 4 criteria of complete curative resection (CCR): 1) pT1a without ulcer, pT1a with ulcer and ≤ 3 cm in size, or minute invasion to the submucosal layer (SM) (<500 μm) and ≤ 3 cm, 2) intestinal-type dominant with no presence of diffuse-type cancer cells in SM, 3) no lymphovascular infiltration, 4) negative vertical and lateral margin confirmed in the en block resected specimen. Excluding the 4 patients with multiple-fragments resection from the 470 patients enrolled in JCOG0607, we investigated clinical factors associated with NCR in each cUL (-) and cUL (+) groups using log-linear model.
Results: The subjects of this analysis were 260 patients with cUL (-) GC and 206 patients with cUL (+) GC. The incidences of NCR were 33.8% (88/260) in cUL (-) group and 29.6% (61/206) in cUL (+) group. In both groups, the most frequent reason that was not met the criteria of CCR was minute invasion to SM (<500 μm). For cUL (-) GC, a multivariable analysis demonstrated that clinical moderately-differentiated predominant histology (vs papillary or well-differentiated) and lower tumor location (vs upper) were independent factors significantly associated with NCR (histology, risk ratio (RR) 1.93, 95% CI 1.34–2.77; location, RR 0.57, 95% CI 0.34–0.97). Meanwhile, for cUL (+) GC, female (vs male) and >2 cm clinical tumor size (vs ≤ 2 cm) were independent factors associated with NCR (sex, RR 1.62, 95% CI 1.07–2.44; size, RR 1.78, 95% CI 1.22–2.58).
Conclusion: ESD should be applied carefully for the lesions with moderately differentiated adenocarcinoma and/or located in upper of the stomach body in case of cUL (-), and GC >2cm in size in case of cUL (+).

P1173 USEFULNESS OF LINKED COLOR IMAGING FOR RECOGNITION OF EARLY GASTRIC CANCER AND ADENOMA —COMPARISON WITH WHITE LIGHT&INDIGO CARMINE&BLUE LASER IMAGING

T. Yasuda, Y. Nakahata, T. Kurobe, Y. Yasuda, T. Omatsu, A. Obora, T. Kojima, N. Yagi
Asahi University Hospital, Gastroenterology, Gifu, Japan

Contact E-Mail Address: everyday.enjoy29@gmail.com
Introduction: Linked Color Imaging (LCI) is a novel color enhancement feature available by using LASEREO endoscopy systems (FUJIFILM Co., Tokyo, Japan), which can enhances the slight difference in mucosal color. Recently we reported that color enhancement of the diffuse redness in gastric mucosa by LCI mode was significantly useful for the diagnosis of active *H. pylori* infection. We expected that LCI facilitate the endoscopic recognition of early gastric cancer and gastric adenoma by enhancing its color difference between normal and atypical mucosa. Furthermore, light source of LCI consist of normal white light and short-wavelength narrowband light, which is used to obtain more detailed mucosal surface and microvessel patterns. Therefore, we expected LCI to facilitate the endoscopic recognition of early gastric cancer and adenoma by emphasizing its color difference as well as slight uneveness on the mucosal surface.
Aims and Methods: The aim of this study was to evaluate the usefulness of LCI for recognition of early gastric cancer and adenoma compared to conventional white light imaging mode (WLI), WLI with indigo carmine contrast (IC) and blue laser imaging bright mode (BLI-brt). We used LASEREO system with EG-L590ZW or EG-L600ZW endoscope (FUJIFILM Co., Tokyo, Japan). We retrospectively analyzed 84 lesions in 76 patients who were examined by all four imaging (WLI, IC, BLI-brt and LCI) before endoscopic submucosal dissection at Asahi University Hospital from June 2014 to March 2018. Both subjective and objective evaluation methods were adopted to quantify the recognition of early gastric cancer and adenoma. Subjective evaluation was performed by three endoscopists. Each lesion was assigned the recognition score (RS) from 3 (excellent visibility) to 0 (no visibility). Objective evaluation was performed with the L*a*b* color space-based color difference scores (CDS) between inside and outside of the lesion (40 × 40 pixels), which was calculated by using CIE76 formula (defined by commission internationale de l'éclairage, Vienna, Austria).
Results: The overall mean RS of LCI was significantly higher ($p < 0.01$) than that of WLI/IC/BLI-brt (2.41 ± 0.71 vs. $1.77 \pm 0.74/2.16 \pm 0.86/1.83 \pm 0.81$). The overall mean CDS of LCI was significantly higher ($p < 0.01$) than that of WLI/IC/BLI-brt (23.94 ± 9.53 vs. $14.38 \pm 7.53/18.54 \pm 8.61/14.73 \pm 7.94$). Subgroup analysis based on tumor type revealed that both RS and CDS of LCI for type 0-IIb or 0-IIc lesions (44 lesions) were significantly higher ($p < 0.05$) than those of WLI/ IC/BLI-brt. On the other hand, regarding type 0-IIa lesions or adenomas (40 lesions), both RS and CDS of LCI, as well as IC, were significantly higher ($p < 0.05$) than those of WLI, however, no significant difference was seen between LCI and IC.
Conclusion: The LCI mode was significantly useful for recognition of flat- or depressed-type early gastric cancer compared to WLI, IC, and BLI-brt.

Introduction: The natural history of different neoplasms is influenced by Inflammation, immunity and nutritional status. Asian studies have proven neutrophil-to-lymphocyte and C-reactive protein (CRP)-to-albumin ratios to be related with mortality in patients with gastric adenocarcinoma. This study aimed to investigate this relationship in Western patients.
Aims and Methods: Patients with gastric adenocarcinoma submitted to R0 resection surgery from January/2013 to December/2017 were included. The study consisted of: registration of neutrophil, lymphocyte, CRP and albumin values within 3 months before surgery; calculation of neutrophil-to-lymphocyte and CRP-to-albumin ratios; evaluation of their relationship with gender, age, tumor size, T, N, M, stage (TNM), presence of lymphatic, vascular and perineural invasion; evaluation of the relationship between these ratios and mortality.
Results: One hundred and twenty-seven patients with leukocyte formula (age 67.6 ± 12.4 years old, 52% male) were included, of whom 70 had preoperative CRP and albumin evaluation (age 70.5 ± 11.9 years old, 58.6% male). The average follow-up time was greater than 24 months.
The neutrophil-to-lymphocyte ratio and the number of neutrophils were unrelated to tumor characteristics and did not predict mortality ($AUC = 0.562$, $p = 0.327$ and $AUC = 0.470$, $p = 0.635$, respectively). The number of lymphocytes correlated with tumor size ($p = 0.005$). Based on the ROC curve analysis, it was established 1667 lymphocytes as a cutoff value, with shorter survival times in patients below this cutoff ($p = 0.003$).
CRP and CRP-to-albumin ratio correlated with tumor size ($p = 0.042$ and $p = 0.046$ respectively), with shorter survival times when CRP≥10.2 mg/L or CRP/albumin≥0.28 ($p = 0.002$ and $p = 0.003$, respectively). Albumin values were unrelated to the studied variables and had no value predicting mortality ($AUC = 0.606$, $p = 0.162$).
Conclusion: In this study, the number of lymphocytes and CRP were related to tumor size and survival in patients with gastric adenocarcinoma. There was no additional benefit in using neutrophil-to-lymphocyte and CRP-to-albumin ratios.

Introduction: Autoimmune atrophic gastritis (AAG) is an autoimmune condition that affects patients of all ages causing atrophy of the corpus-fundus mucosa of the stomach, with subsequent vitamin B12 and iron deficiency. AAG may be associated with a number of autoimmune disorders, namely type I diabetes mellitus, vitiligo, Hashimoto's thyroiditis, and Addison's disease. It has been hypothesised that the presence of concomitant autoimmune disorders may be associated with the development of type I neuroendocrine tumours (NET).
Aims and Methods: Aim of the study was to assess the prevalence of autoimmune disorders in relation to the development of NETs in patients with AAG diagnosed in two Italian tertiary referral centres for gastrointestinal disorders (Pavia and Aviano). Over the last twenty years, both centres consecutively enrolled and followed-up all patients diagnosed with AAG (corpus/fundus atrophy with antrum sparing and positivity to anti-parietal cells antibody, according to the Sydney-Houston classification). We therefore analysed the association of autoimmune disorders with the presence of NETs.
Results: Overall, 448 patients suffering from AAG (mean age 63 ± 16 years; F:M ratio 2.3:1) have been evaluated in the two centres. At least one concomitant autoimmune disorder was present in 244/448 patients (54.4%; mean age 60.3 ± 15 years, F:M ratio 2.4:1), whereas at least two autoimmune disorders were present in 51/448 (11.3%; mean age 62.4 ± 14 years, F:M ratio 1.9:1). The most common autoimmune disorders were as follow: 175/448 (39.1%) Hashimoto's thyroiditis, 45/448 (10.0%) connective tissue disorder, 32/448 (7.1%) type I diabetes mellitus, 24/448 (5.3%) vitiligo, 17/448 (3.8%) Grave's disease, 13/448 (2.9%) psoriasis and/or psoriatic arthritis, 11/448 (2.5%) coeliac disease, 10/448 (2.2%) rheumatoid arthritis. Moreover, 64/448 (14.2%) patients were also diagnosed with a neuroendocrine tumour, 39/448 (8.7%) of which at the time of diagnosis. The overall prevalence of NETs did not differ between patients with or without autoimmune comorbidities ($p = 0.685$), nor it was increased in patients with two or more concomitant autoimmune diseases ($p = 0.584$).
Conclusion: Over half of patients with AAG present at least one concomitant autoimmune disorder, namely thyreopaties, connective tissue disorders, type I diabetes mellitus, vitiligo, and rheumatic disorders. The presence of autoimmune comorbidities does not increase the risk of developing NETs. The not negligible proportion of NETs in our AAG cohort warrants a proper endoscopic follow-up.

Introduction: A biopsy-based histologic diagnosis is a critical factor for determining treatment strategy in early gastric cancer (EGC). There were some studies about histological discrepancies between initial forcep biopsy and endoscopic resection (ER) pathology. However, there was no study to investigate the role of biopsy to determine treatment including ER and surgery in EGC.
Aims and Methods: The aim was to compare between histologic diagnosis from biopsy sample and final diagnosis from ER and surgical specimens. In addition, we tried to find predictive factors related to discrepancy. 1,043 patients with a biopsy diagnosis of gastric adenocarcinoma were treated by ER or surgery. To compare the histological discrepancy rate, we checked the histologic diagnosis from the biopsy sample and the final diagnosis from the ER and surgical specimen. Clinicopathologic characteristics were also analyzed.
Results: 44% of EGC patents were treated by ER, and 56% of EGC patients were treated by surgery. Among patients who received ER, subjects with histologic discrepancies (Group 1) was 10.3%. Subjects with differentiated EGC (D-EGC) based on biopsy and undifferentiated EGC (UD-EGC) on ER pathology was 84% of Group 1. Among them, curative resection (CR) was 33.3%, and non-curative resection (non-CR) was 66.6%. Subjects with UD-EGC on biopsy and D-EGC on ER pathology was 16% of Group 1, and all of them were diagnosed with CR. In surgery group, subjects with histologic discrepancy were 11.0%. Among histologic discrepancy group (Group 2), subjects with D-EGC on biopsy, and UD-EGC on pathology was 22.1%. All of them were included in beyond expanded indication (EI) for ER. Subjects with UD-EGC on biopsy and D-EGC on pathology was 17.4% of Group 2. Among them, patients who were diagnosed with absolute indication (AI) of ER was 13.3%, EI was 40%, and beyond EI of ER was 46.7% according to final pathology. In patients with D-EGC on biopsy and UD-EGC on final pathology (ER and surgery), age, size, tumor location in the upper-third segment of the stomach, and submucosal 2 invasion were significant predictive factors. Patients with this group were more likely to have elevated gross appearance, but did not reach statistical significance. In patients with UD-EGC on biopsy and D-EGC on final pathology (ER and surgery), elevated gross appearance of tumor was significant predictive factor.
Conclusion: In retrospective view, unfavorable treatment decisions were made in some cases due to histological discrepancies. There were patients who could be treated by ER, but had surgery. In contrary, there were patients whose initial treatment regimen should be surgery not ER. To determine the treatment strategy for EGC more properly, not only biopsy but also endoscopic characteristics should be considered especially for lesions with predictive factors.

Introduction: Accurate assessment of depth of invasion in early gastric cancer (EGC) has critical importance when selecting appropriate endoscopic treatment for patients [1]. EGC of deep submucosal invasion (more than 500μm: SM2) should be treated by surgery, whereas EGC with only intramucosal cancer (M) or superficial submucosal invasion (within 500μm from the musclaris mucosa: SM1) should be considered for endoscopic resection (ER).
Aims and Methods: In this study, we evaluated the diagnostic accuracy of endoscopic ultrasound (EUS) to differentiate the M-SM1 and SM2 of EGC that had been initially suspected as SM2 by conventional endoscopic diagnosis.
We retrospectively reviewed electronic medical records, endoscopic and histological reports of 250 EGCs with a suspected endoscopic diagnosis of SM2 and subsequently had EUS between April 2008 and July 2017. We further retrospectively reclassified lesions into M-SM1 or SM2 by reviewing conventional endoscopy (CE) and EUS reports individually. A 20 MHz miniature probe was used for EUS examination with water filling method. Endoscopic findings such as location, morphology, size, estimation of depth by CE and EUS, and histological findings such as histological type of differentiation, an ulcer finding, and depth were evaluated. The histological staging was confirmed by the endoscopically or surgically resected specimens. Logistic regression was used to analyze the factors that affected the EUS diagnosis.
Results: Diagnostic sensitivity, specificity and accuracy of EUS in differentiating M-SM1 and SM2 lesions was 75.9%, 71.4% and 74.0% respectively, in comparison to CE which was 69.0%, 45.7% and 59.2% respectively. In the multivariate analysis, factors associated with under-estimation of depth of invasion by EUS was the anterior wall of the stomach ($p = 0.02$), whereas over-estimated lesions included the lesions with ulcer findings ($p = 0.05$).
Conclusion: The diagnostic performance using EUS was superior to that of CE of early gastric cancers suspicious for SM2 invasion. The lesion with ulcer findings or located anterior wall may lead to misdiagnosis in those lesions.

Introduction: Missed gastric cancer (MGC) at upper gastrointestinal endoscopy (UGE) is a poorly documented entity in Western populations.
Aims and Methods:
1. To assess the rate, predictors and survival of MGC.
2. To compare MGC and non-MGC and detect factors associated with negative UGE.
Retrospective-cohort study conducted at 4 tertiary Spanish hospitals. Gastric adenocarcinomas diagnosed between 2008–2015 were included. Patients referred for treatment from other centers ($n = 64$) or without follow-up ($n = 21$) were excluded. MGC was defined as a cancer detected within 36 months after a negative UGE for malignancy. Demographic, clinical, endoscopic, histological and survival data were recorded. Statistics: Unconditional binomial logistic regression and Kaplan-Meier with the log-rank test.

Abstract No: P1178
Table 1: Baseline characteristics. Initial negative endoscopy in MGC patients vs Diagnostic endoscopy in Non-MGC patients

	Initial negative endoscopy in MGC patients (n = 61)	Diagnostic endoscopy in Non-MGC patients (n = 1228)	Univariant (P values)	
Age years, (mean)	69.3	74.3	0.0007	OR = 0.96 (CI 95%: 0.94–0.98), p = 0.001
Male sex	60.6%	61.6%	0.88	
PPI therapy	78.7%	46.3%	< 0.001	OR = 5.72 (CI 95%: 2.9–11.1), p < 0.001
H. pylori infection	73.7%	62.3%	0.082	NS
Family history of gastric cancer	3.9%	7.6%	0.42	
Elective endoscopy	87.3%	86.6%	1	
High-definition	36.1%	40.7%	0.47	
Sedation	26.2%	33%	0.27	
Endoscopist experience (< 5 years)	24.6%	21%	0.5	

Results: 123,395 UGE were performed during the study period, and 1374 GC were diagnosed (1.11%). 1289 patients with GC were finally included in the analysis.
Mean age was 74.1 years (SD: 11.2) and 62% were males. Global MGC rate was 4.73% (61/1289, CI 95%: 3.7–6 %), without significant differences across centers (p = 0.23). Median time between negative UGE and MGC diagnosis was 13.1 months (range: 3.1–35.2). The median number of negative UGEs in MGC group was 1 (range:1–3). Gastritis (51%), intestinal metaplasia (41%), gastric atrophy (31%) and gastric ulcers (29.5%) were the most common findings at negative UGE. These ulcers were benign at histology and were not endoscopically monitored. Compared to confirmed malignant ulcers in Non-MGC group (n = 610), ulcers at negative UGE were smaller (median: 10 vs 30 mm, p = 0.02) and less frequently biopsied (median: 1 vs 3.5, p < 0.001).
At multivariate analysis, negative UGE was independently associated with younger age (OR: 0.96, p = 0.001), PPI therapy (OR: 5.72, p < 0.001), previous Billroth II surgery (OR: 5.2, p = 0.002) and absence of alarm symptoms (OR 0.21, 47.5% vs 78.5%, p < 0.001) (Table 1).
The gastric body (52.4%) and intestinal-type (55.6%) were the most common location and histological subtype of MGC, respectively, without differences with Non-MGC. Compared to Non-MGC, MGC were smaller (31 vs 41 mm, p = 0.04), more frequently flat-depressed (49.2% vs 29%, p = 0.003) and diagnosed at an earlier stage (Stage I-II: 47.4% vs 28.3%, p = 0.023). Overall 2-year survival rate was similar for MGC (34%) and Non-MGC (35.3%) (log-rank p = 0.59).
Conclusion: MGC is frequent and associated with poor 2-year survival.
Our study found independent factors associated with MGC and negative UGE that may be helpful for clinical practice.
High-quality UGE may help to reduce MGC incidence.

Introduction: New parameters complementary to clinical TNM classification are needed to orient preoperatively about the possibility of a R0 gastric resection. Blood neutrophil/lymphocyte ratio (N/L) reflects the systemic antitumoral inflammatory response in patients and it has been related with post-operative survival in Asiatic studies. Nevertheless, there are few data concerning pretreatment predictive value of these N/L ratio and radical tumor resection
Aims and Methods: We aimed to analyse the potential predictive value of an elevated blood neutrophil/lymphocyte ratio (N/L) in relation to R0 tumoral resectability.
Observational retrospective study of 257 consecutive gastric cancers, without haematological diseases or neoadjuvant treatment. The optimal cut-off of N/L was: < 5 (ROC curves). Frequency of R0 resection was compared between the group of "normal" N/L ratio: < 5 vs "high" N/L ratio ≥ 5. Multivariate analysis (logistic regression, determining odds ratio (OR) and 95% confidence interval (CI95%) of R0 resectability was performed according to N/L ratio, with the following adjustment variables: preoperatory ASA (1–4), tumoral differentiation grade (well, moderate, poor, undifferentiated) and presurgical TNM stage.
Results: A radical R0 resection was performed in 139 gastric carcinomas (54.1%). A "high" N/L ratio was registered in 46 cases (17.9%). R0 resectability was higher in patients with a N/L ratio < 5: 59.7%, compared to patients with N/L ≥ 5: 28.6% [p < 0.0001; OR = 3.76; CI95% = (1.78–8.04)]. The relation between N/L ratio < 5 and the frequency of R0 resection was maintained in the multivariate analysis: [p = 0.017; OR = 3.46; CI95% = (1.25–9.59)], independently of ASA: [p = 0.004; OR = 2.44; CI95% = (1.33–4.49)], differentiation grade: [p = 0.020; OR = 1.71; CI95% = (1.09–2.67)] and presurgical TNM: [p < 0.0001; OR = 5.60; CI95% = (3.56–8.80)].
Conclusion: 1.- The presence of a "normal" N/L ratio < 5 at the diagnosis of a gastric carcinoma is significantly related with a higher frequency of R0 tumoral resection.
2.- In our series, this higher proportion of R0 resection is independent of presurgical ASA, tumoral differentiation grade and presurgical TNM.

Introduction: Young patients with gastric cancer reportedly have a worse prognosis than older patients owing to delayed diagnosis and more aggressive tumor behavior. However, it is unclear whether this applies to early gastric cancer (EGC), for which endoscopic resection is indicated. We aimed to investigate the association between age and lymph node metastasis (LNM).
Aims and Methods: We identified 4,055 patients diagnosed with EGC of differentiated histology who underwent surgery. The association between age and LNM was examined using logistic regression for each T stage separately with adjustments for multiple covariates. We compared LNM rates for each of the Japanese Endoscopic Resection Guidelines criteria in younger (< 40 years) and older patients (≥40 years).
Results: The median number of lymph nodes examined was the same for T1a and T1b stages (n = 34). The median number of lymph nodes examined was not significantly different within T1a stage (P-value = 0.093), but within T1b stage, the number of lymph nodes examined was significantly different (P-value = 0.019), with the highest number between 50 and 59 years (median = 37), and the lowest number in the 20 to 49 and over 70 age brackets (median = 34). LNM rate and age were not significantly associated within each stage (P-values 0.269, 0.783 for T1a and T1b, respectively). Among patients fulfilling endoscopic resection criteria, the LNM rate in younger patients was lower than in older patients.
Conclusion: In differentiated-type EGC, young age at diagnosis was not associated with LNM rate. Therefore, endoscopic resection criteria for early gastric cancer can be applied to younger patients.

Introduction: PPIs are commonly prescribed for a long period of time. Therefore, the long-term safety issue was raised. There are some adverse events including: bone fractures, enteric infections, community-acquired pneumonia and nutritional deficiencies. As PPIs inhibit acid production atrophic gastritis could be worse, a precursor of gastric adeno-carcinoma. Two recent wide health database reports reported a higher risk for gastric cancer (GC) among PPIs long term user (HR 2.44, SIR 3.38) which increased with the duration of PPIs use (1,2). PPIs were proved to be more effective than placebo for the improvement of symptoms and quality of life in Functional Dyspepsia (FD), Epigastric Stress type.
Aims and Methods: We aimed to bridge the gap between evidence and decision making by formulating a decision analysis model focusing on patients with FD

treated by PPI), to address the question whether the improvement in quality of life rationalizes continuity of the PPI treatment despite the risk of GC.
