## 18 19 **Abstract**

20 The spike protein of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) has been identified  
21 as the prime target for vaccine development. The spike protein mediates both binding to host cells and  
22 membrane fusion and is also so far the only known viral target of neutralizing antibodies. Coronavirus  
23 spike proteins are large trimers that are relatively instable, a feature that might be enhanced by the  
24 presence of a polybasic cleavage site in the SARS-CoV-2 spike. Exchange of K986 and V987 to prolines  
25 has been shown to stabilize the trimers of SARS-CoV-1 and the Middle Eastern respiratory syndrome  
26 coronavirus spikes. Here, we test multiple versions of a soluble spike protein for their immunogenicity  
27 and protective effect against SARS-CoV-2 challenge in a mouse model that transiently expresses human  
28 angiotensin converting enzyme 2 via adenovirus transduction. Variants tested include spike protein with  
29 a deleted polybasic cleavage site, the proline mutations, a combination thereof, as well as the wild type  
30 protein. While all versions of the protein were able to induce neutralizing antibodies, only the antigen  
31 with both a deleted cleavage site and the PP mutations completely protected from challenge in this  
32 mouse model.

## 33 34 **Importance**

35 A vaccine for SARS-CoV-2 is urgently needed. A better understanding of antigen design and attributes  
36 that vaccine candidates need to have to induce protective immunity is of high importance. The data  
37 presented here validates the choice of antigens that contain the PP mutation and suggests that deletion  
38 of the polybasic cleavage site could lead to a further optimized design.

## 39 40 41 42 43 **Introduction**

44  
45 Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) emerged in late 2019 in China and has  
46 since then caused a coronavirus disease 2019 (COVID-19) pandemic (1-3). Vaccines are an urgently  
47 needed countermeasure to the virus. Vaccine candidates have been moved at unprecedented speed

48 through the pipeline with first Phase III trials already taking place in summer 2020, only half a year after  
49 discovery of the virus sequence. From studies on SARS-CoV-1 and the Middle Eastern respiratory  
50 syndrome CoV (MERS-CoV), it was clear that the spike protein of the virus is the best target for vaccine  
51 development (4-6). Most coronaviruses (CoVs) only have one large surface glycoprotein (a minority also  
52 have a hemagglutinin-esterase) that is used by the virus to attach to the host cell and trigger fusion of  
53 viral and cellular membranes. The spike protein of SARS-CoV-2, like the one of SARS-CoV-1, binds to  
54 human angiotensin receptor 2 (ACE2) (7-9). In order to be able to trigger fusion, the spike protein has to  
55 be cleaved into the S1 and S2 subunit (10-12). Additionally, a site in S2 (S2') that has to be cleaved to  
56 activate the fusion machinery has been reported as well (13). While the spike of SARS-CoV-1 contains a  
57 single basic amino acid at the cleavage site between S1 and S2, SARS-CoV-2 has a polybasic motif that  
58 can be activated by furin-like proteases (10-12), analogous to the hemagglutinin (HA) of highly  
59 pathogenic H5 and H7 avian influenza viruses. In addition, it has been reported that the activated spike  
60 protein of CoVs is relatively instable and multiple conformations might exist of which not all may  
61 present neutralizing epitopes to the immune system. For SARS-CoV-1 and MERS-CoV stabilizing  
62 mutations – a pair of prolines replacing K986 and V987 in S2 – have been described (14) and a beneficial  
63 effect on stability has also been shown for SARS-CoV-2 (9). Here, we set out to investigate if including  
64 these stabilizing mutations, removing the cleavage site between S1 and S2 or combining the two  
65 strategies to stabilize the spike would increase its immunogenicity and protective effect in a mouse  
66 model that transiently expressed hACE2 via adenovirus transduction (15). This information is important  
67 since it can help to optimize vaccine candidates, especially improved versions of vaccines that might be  
68 licensed at a later point in time.

69

## 70 **Results**

71

### 72 **Construct design and recombinant protein expression**

73

74 The sequence based on the S gene of SARS-CoV-2 strain Wuhan-1 was initially codon optimized for  
75 mammalian cell expression. The wild type signal peptide and ectodomain (amino acid 1-1213) were  
76 fused to a T4 foldon trimerization domain followed by a hexa-histidine tag to facilitate purification. This  
77 construct was termed wild type (WT). Additional constructs were generated including one in which the  
78 polybasic cleavage site (RRAR) was replaced by a single alanine (termed  $\Delta$ CS), one in which K986 and  
79 V987 in the S2 subunit were mutated to prolines (PP) and one in which both modifications were  
80 combined ( $\Delta$ CS-PP) (**Figure 1A-C**). The proteins were then expressed in a baculovirus expression system  
81 and purified. At first inspection by sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-  
82 PAGE) and Coomassie staining, all four constructs appeared similar with a major clean band at  
83 approximately 180kDa (**Figure 1E**). When a Western blot was performed, additional bands were  
84 detected in the lanes with the WT, PP and  $\Delta$ CS-PP constructs, suggesting cleavage of a fraction of the  
85 protein. For WT, the most prominent detected smaller band ran at 80 kDa, was visualized with an  
86 antibody recognizing the C-terminal hexa-histidine tag and likely represents S2 (**Figure 1F**). The two  
87 constructs containing the PP mutations also produced an additional band at approximately 40 kDa  
88 (**Figure 1E**), potentially representing a fragment downstream of S2'. While in general these bands were  
89 invisible on an SDS PAGE and therefore are likely only representing a tiny fraction of the purified spike  
90 protein, they might indicate vulnerability to proteolytic digest of the antigen *in vivo*. All constructs were  
91 also recognized in a similar manner by mAb CR3022 (16, 17), an antibody that binds to the RBD (**Figure**  
92 **1F**).

93

### 94 **All versions of the recombinant spike protein induce robust immune responses in mice**

95

96 To test the immunogenicity of the four spike constructs, all proteins were used in a simple prime-boost  
97 study in mice (**Figure 2A**). Animals were injected intramuscularly (i.m.) with 3 $\mu$ g of spike protein  
98 adjuvanted with AddaVax (a generic version of the oil-in-water adjuvant MF59) twice in a 3 week  
99 interval. A control group received an irrelevant immunogen, recombinant influenza virus hemagglutinin  
100 (HA), also expressed in insect cells, with AddaVax. Mice were bled three weeks after the prime and four  
101 weeks after the boost to assess the immune response that they mounted to the vaccine (**Figure 2B**). To  
102 determine antibody levels to the RBD, we performed enzyme-linked immunosorbent assays against  
103 recombinant, mammalian cell expressed RBD (18, 19). All animals made anti-RBD responses after the  
104 prime but they were higher in the  $\Delta$ CS and  $\Delta$ CS-PP groups than in the WT or PP groups (**Figure 2C**). The  
105 booster dose increased antibodies to the RBD significantly but the same pattern persisted (**Figure 2D**).  
106 Interestingly, the  $\Delta$ CS-PP group showed very homogenous responses compared to the other groups  
107 where there was more spread between the animals. In addition, we also performed cell-based ELISAs  
108 with Vero cells infected with SARS-CoV-2 as target. While all groups showed good reactivity, a similar  
109 pattern emerged in which  $\Delta$ CS and  $\Delta$ CS-PP groups showed higher reactivity than WT and PP groups  
110 (**Figure 2E**). Finally, we performed microneutralization assays with authentic SARS-CoV-2 (20). Here, the  
111 WT, PP and  $\Delta$ CS groups showed similar levels of neutralization while the  $\Delta$ CS-PP group animals had  
112 higher serum neutralization titers (**Figure. 2F**).  
113

#### 114 **Vaccination with recombinant S protein variants protects mice from challenge with SARS-CoV-2**

115

116 In order to perform challenge studies, mice were sensitized to infection with SARS-CoV-2 by intranasal  
117 (i.n.) transduction with an adenovirus expressing hACE2 (AdV-hACE2), using a treatment regimen  
118 described previously (**Figure 2A**) (15, 21, 22). They were then challenged with 10<sup>5</sup> plaque forming units  
119 (PFU) of SARS-CoV-2 and monitored for weight loss and mortality for 14 days. Additional animals were  
120 euthanized on day 2 and day 4 to harvest lungs for histopathological assessment and  
121 immunohistochemistry, and on day 2 and day 5 to measure virus titers in the lung. After challenge, all  
122 groups lost weight trending with the negative control group (irrelevant HA protein vaccination), except  
123 for the  $\Delta$ CS-PP group which displayed minimal weight loss (**Figure 3A**). Only on days 4-6 the WT, PP and  
124  $\Delta$ CS groups showed a trend towards less weight loss than the control group. However, all animals  
125 recovered and by day 14 and no mortality was observed. Lung titers on day 2 suggested low virus  
126 replication in the WT, PP and  $\Delta$ CS groups with some animals having no detectable virus and no presence  
127 of replication competent virus in the  $\Delta$ CS-PP (**Figure 3B**). Two of the control animals showed high virus  
128 replication while virus could not be recovered from the third animal. No virus could be detected in any  
129 of the vaccinated groups on day 5 while all three controls still had detectable virus in the 10<sup>4</sup> to 10<sup>5</sup>  
130 range (**Figure 3C**).  
131

#### 132 **Lung immunohistochemistry and pathology**

133

134 Lungs were harvested on days 2 and 4 post challenge. Samples from both days were used for  
135 immunohistochemistry to detect viral nucleoprotein antigen. Viral antigen was detectable in all groups  
136 on day 2 as well as day 4 post infection (**Figure 3D**). However, the  $\Delta$ CS-PP group showed very few  
137 positive cells, especially on day 4 while antigen was detected more widespread in all other groups.  
138 These results correlate well with the viral lung titers shown above. The samples were also hematoxylin  
139 and eosin (H&E) stained and scored for lung pathology by a qualified veterinary pathologist using a  
140 composite score with a maximum value of 24 (**Figure 4A and C**). At D2 post-infection with SARS-CoV-2,  
141 all mice were determined to exhibit histopathological lesions typical of interstitial pneumonia, with  
142 more severe alveolar inflammation in the WT group. Alveolar congestion and edema were also more  
143 pronounced in S vaccinated groups as compared with the irrelevant control HA immunogen. At this

144 time-point, the overall pathology score was lowest for the irrelevant HA control group, followed by  $\Delta$ CS-  
145 PP<PP< $\Delta$ CS<wild type (**Figure 4A**). On day 4 all groups showed mild to moderate pathology scores,  
146 reduced in severity as compared with D2. Observations included perivascular, bronchial and alveolar  
147 inflammation, as well as mild to moderate congestion or edema. Scores were slightly higher in  
148 vaccinated than control animals which may reflect the infiltration of CoV-2 antigen-specific immune cells  
149 into the lung, which would be absent in the irrelevant HA immunized control mice (**Figure 4C and D**).

150

## 151 Discussion

152

153 The spike protein of SARS-CoV-2 has been selected early on as a target for vaccine development, based  
154 on experience with SARS-CoV-1 and MERS CoV (6). The coronavirus spike protein is known to be  
155 relatively labile, and in addition to this inherent property the SARS-CoV-2 spike also contains a polybasic  
156 cleavage site between S1 and S2. Work on SARS-CoV-1 and MERS CoV had shown that introducing two  
157 prolines in positions 986 and 987 (SARS-CoV-2 numbering) improves stability and expression (14). In  
158 addition, removal of polybasic cleavage sites has been shown to stabilize hemagglutinin (HA) proteins of  
159 highly pathogenic influenza viruses. In this study, we tested different versions of the protein either  
160 lacking the polybasic cleavage site or including the stabilizing PP mutations or both. While vaccination  
161 with all constructs induced neutralizing antibodies and led to control of virus replication in the lung, we  
162 observed notable differences. Removing the polybasic cleavage site did increase the humoral immune  
163 response in ELISAs. Since we did not observe cleavage of the majority of protein when purified (although  
164 some cleavage could be observed), even with the polybasic cleavage site present, we speculate that  
165 removal of the site might make the protein more stable *in vivo* post vaccination. Longer stability could  
166 lead to stronger and potentially more uniform immune responses. The combination of deleting the  
167 polybasic cleavage site plus introducing the PP mutations performed best, also in terms of protection of  
168 mice from weight loss. It is important to note that all versions of the protein tested had a third  
169 stabilizing element present, which is a trimerization domain. This trimerization domain might have also  
170 increased stability and immunogenicity.

171 Current leading vaccine candidates in clinical trials include virus vectored and mRNA vaccines. The  
172 ChAdOx based vaccine candidate that is developed by AstraZeneca is using a wild type version of the  
173 spike protein (23), while Moderna's mRNA vaccine is based on a spike construct that includes the PP  
174 mutations but features a wild type cleavage site (24). It is currently unclear, if addition of the  
175 modifications shown here to enhance immunogenicity of recombinant protein spike antigens would also  
176 enhance immunogenicity of these constructs. However, it might be worth testing if these vaccine  
177 candidates can be improved by our strategy as well. Of note, one study in non-human primates with  
178 adenovirus 26-vectored vaccine candidates expressing different versions of the spike protein also  
179 showed that a  $\Delta$ CS-PP (although including the transmembrane domain) performed best and this  
180 candidate is now moving forward into clinical trials (25). Similarly, Novavax is using a recombinant spike  
181 construct that features  $\Delta$ CS-PP and, when adjuvanted, induced high neutralization titers in humans in a  
182 Phase I clinical trial (26).

183 While vaccination with all constructs led to various degrees of control of virus replication,  
184 histopathology scores, especially on day 2 after challenge were above those of the negative controls  
185 animals. We do not believe that this is a signal of enhanced disease as it has been observed in some  
186 studies for SARS-CoV-2 but the hallmark of an antigen-specific immune response. This is also evidenced  
187 by significantly reduced weight loss in the  $\Delta$ CS-PP group as well as complete control of virus replication  
188 despite having increased lung histopathology scores. However, future studies with recombinant protein  
189 vaccines that are routed for clinical testing, as outlined below, will need to assess this increase in lung  
190 pathology in more detail.

191 Recombinant protein vaccines including the spike ectodomain (27, 28), membrane extracted spike (29)  
192 as well as S1 (30) and RBD (31) have been tested for SARS-CoV-1 and several studies show good efficacy  
193 against challenge in animal models. It is, therefore, not surprising that similar constructs for SARS-CoV-2  
194 also provided protection. While our goal was not vaccine development but studying the effect of  
195 stabilizing elements on the immunogenicity of the spike protein, Sanofi Pasteur has announced the  
196 development of a recombinant protein based SARS-CoV-2 vaccine and a second recombinant protein  
197 candidate is currently being developed by Seqirus. Our data shows that this approach could be effective.

198  
199

## 200 **Materials and methods**

201

202 **Cells and viruses.** Vero.E6 cells (ATCC CRL-1586-clone E6) were maintained in culture using Dulbecco's  
203 Modified Eagle Medium (DMEM; Gibco) which was supplemented with Antibiotic-Antimycotic (100 U/ml  
204 penicillin- 100 µg/ml streptomycin- 0.25 µg/ml Amphotericin B) (Gibco; 15240062) and 10% fetal bovine  
205 serum (FBS; Corning). SARS-CoV-2 (isolate USA-WA1/2020 BEI Resources, NR-52281) was grown in  
206 Vero.E6 cells as previously described and was used for the *in vivo* challenge (20). A viral seed stock for a  
207 non-replicating human adenovirus type-5 (HAdV-C5) vector expressing the human ACE2 receptor was  
208 obtained from the Iowa Viral Vector Core Facility. High titer Ad-hACE2 stocks were amplified in TRex™-  
209 293 cells, purified by CsCl ultracentrifugation and infectious titers determined by tissue-culture  
210 infectious dose-50 (TCID<sub>50</sub>), adjusting for plaque forming unit (PFU) titers using the Kärber statistical  
211 method, as described previously (32).

212 **Recombinant proteins.** All recombinant proteins were expressed and purified using the baculovirus  
213 expression system, as previously described (18, 33, 34). Different versions of the spike protein of SARS-  
214 CoV-2 (GenBank: MN908947.3) were expressed to assess immunogenicity. PP indicates that two  
215 stabilizing prolines were induced at K986 and K987. ΔCS indicates that the cleavage site of the spike  
216 protein was removed by deletion of the arginine residues (RRAR to just A). The HA was also produced in  
217 the baculovirus expression system similar to the spike variants.

218 **SDS-PAGE and Western blot.** One µg of each respective protein was mixed at a 1:1 ratio with 2X  
219 Laemmli buffer (Bio-Rad) which was supplemented with 2% β-mercaptoethanol (Fisher Scientific). The  
220 samples were heated at 90°C for 10 minutes and loaded onto a 4-20% precast polyacrylamide gel  
221 (BioRad). The gel was stained with SimplyBlue SafeStain (Invitrogen) for 1 hour and then de-stained with  
222 water for a few hours. For Western blot, the same process was used as mentioned above. After the gel  
223 was run, the gel was transferred onto a nitrocellulose membrane, as described previously (33). The  
224 membrane was blocked with phosphate buffered saline (PBS; Gibco) containing 3% non-fat milk  
225 (AmericanBio, catalog# AB10109-01000) for an hour at room temperature on an orbital shaker. Next,  
226 primary antibody was prepared in PBS containing 1% non-fat milk using anti-hexahistidine antibody  
227 (Takara Bio, catalog #631212) at a dilution of 1:3000. The membrane was stained with primary antibody  
228 solution for 1 hour at room temperature. The membrane was washed thrice with PBS containing 0.1%  
229 Tween-20 (PBS-T; Fisher Scientific). The secondary solution was prepared with 1% non-fat milk in PBS-T  
230 using anti-mouse IgG (whole molecule)-alkaline phosphatase (AP) antibody produced in goat (Sigma-  
231 Aldrich) at a dilution of 1:3,000. The membrane was developed using an AP conjugate substrate kit,  
232 catalog no. 1706432 (Bio-Rad).

233 **ELISA.** Ninety-six well plates (Immulon 4 HBX; Thermo Fisher Scientific) were coated with recombinant  
234 RBD at a concentration of 2 ug/ml with 50µl/well overnight. The RBD protein was produced in 293F cells  
235 and purified using Ni-NTA resin and this procedure has been described in detail earlier (19). The next  
236 morning, coating solution was removed and plates were blocked with 100µls of 3% non-fat milk  
237 (AmericanBio, catalog# AB10109-01000) prepared in PBS-T for 1 hour at room temperature (RT). Serum  
238 samples from vaccinated mice were tested on the ELISA starting at a dilution of 1:50 and three-fold  
239 subsequent dilutions were performed. Serum samples were prepared in PBS-T containing 1% non-fat  
240 milk and the plates were incubated with the serum samples for 2 hours at RT. Next, plates were washed  
241 with 200µls of PBS-T thrice. Anti-mouse IgG conjugated to horseradish peroxidase (Rockland, catalog#  
242 610-4302) was used at a concentration of 1:3000 in PBS-T with 1% non-fat milk and 100 µl was added to  
243 each well for 1 hour at RT. Plates were then washed again with 200 uls of PBS-T and patted dry on paper  
244 towel. Developing solution was prepared in sterile water (WFI, Gibco) using SIGMAFAST OPD (o-  
245 phenylenediamine dihydrochloride; Sigma-Aldrich, catalog# P9187) and 100 µls was added to each well  
246 for a total of 10 mins. Next, the reaction was stopped with 50 µls of 3M hydrochloric acid and  
247 absorbance was measured at 490 nm (OD<sub>490</sub>) using a Synergy 4 (BioTek) plate reader. Data was analyzed  
248 using GraphPad Prism 7 and are under the curve (AUC) values were measured and graphed (18). An AUC  
249 Of 0.05 was assigned to negative values for data analysis purposes.

250 To perform an ELISA on infected cells, Vero.E6 cells were seeded at 20,000 cells per well in a 96-well cell  
251 culture plate a day before and infected at a multiplicity of infection of 0.1 for 24 hours with SARS-CoV-2  
252 (isolate USA-WA1/2020 BEI Resources, NR-52281). The cells were fixed with 10% formaldehyde  
253 (Polysciences) for 24 hours after which the ELISA procedure mentioned above was performed using  
254 serum from each vaccinated animal.

255 **Mouse vaccinations and challenge.** All animal procedures were performed by adhering to the  
256 Institutional Animal Care and Use Committee (IACUC) guidelines. Six to eight week old, female, BALB/c  
257 mice (Jackson Laboratories) were immunized intramuscularly with 3 µg of recombinant protein per  
258 mouse with an adjuvant, AddaVax (Invivogen) in a volume of 50 ul. Three weeks later, mice were again  
259 immunized, via intramuscular route, with 3 µg of each respective protein with adjuvant. Mice were bled  
260 3 weeks after the prime regimen and were also bled 4 weeks after the boost regimen. Another four  
261 weeks later, 2.5x10<sup>8</sup> PFU/mouse of AdV-hACE2 was administered intranasally to each mouse in a final  
262 volume of 50µL sterile PBS. Adhering to institutional guidelines, a mixture containing 0.15 mg/kg  
263 ketamine and 0.03 mg/kg xylazine in water was used as anesthesia for mouse experiments and  
264 intranasal infection was performed under anesthesia.

265 Five days post administration of the AdV-hACE2, mice were infected with 10<sup>5</sup> PFUs of SARS-CoV-2. On  
266 day 2 and day 5, mice were sacrificed using humane methods and the whole lung was dissected from  
267 each mouse. Mice were sacrificed for measuring viral titers in the lung as well as to see pathological  
268 changes in the lungs. Lungs were homogenized using BeadBlaster 24 (Benchmark) homogenizer after  
269 which the supernatant was clarified by centrifugation at 14,000 g for 10 mins. Experimental design was  
270 adapted from earlier reported work (15, 35). The remaining mice were weight daily for 14 days.

271 **Micro-neutralization assays.** We used a very detailed protocol that we published earlier for measuring  
272 neutralizing antibody in serum samples (18, 20). Briefly, Vero.E6 cells were seeded at a density of 20,000  
273 cells per well in a 96-well cell culture plate. Serum samples were heat-inactivated for 1 hour at 56 C.  
274 Serial dilutions starting at 1:10 were prepared in 1X (minimal essential medium; MEM) supplemented

275 with 1% FBS. The remaining steps of the assay were performed in a BSL3 facility. Six-hundred TCID<sub>50</sub> of  
276 virus in 80µls was added to 80 uls of each serum dilution. Serum-virus mixture was incubated at room  
277 temperature for 1 hour. After 1 hour, media from the cells was removed and 120 µls of serum-virus  
278 mixture was added onto the cells. The cells were incubated for 1 hour in a 37°C incubator. After 1 hour,  
279 all of the serum-virus mixture was removed. One hundred uls of each corresponding serum dilution was  
280 added onto the cells and 100 uls of 1X MEM was added to the cells as well. The cells were incubated at  
281 37°C for 2 days. After 2 days, cells were fixed with 10% formaldehyde (Polysciences). The next day, cells  
282 were stained with an anti-nucleoprotein antibody (ThermoFisher; Catalog # PA5-81794) according to our  
283 published protocol (20). The 50% inhibitory dilution (ID<sub>50</sub>) for each serum was calculated and the data  
284 was graphed. Negative samples were reported as half of the limit of detection (ID<sub>50</sub> of 5).

285 **Plaque assays.** Four-hundred thousand Vero.E6 cells were plated the day before the plaque assay was  
286 performed. All assays using SARS-CoV-2 were performed in the BSL3 following institutional guidelines.  
287 To assess viral titer in the lung, plaque assays were performed using lung homogenates. Dilutions of lung  
288 homogenates were prepared starting from 10<sup>-1</sup> to 10<sup>-6</sup> in 1X MEM supplemented with 2% FBS. Media  
289 was removed from cells and each dilution was added to the cells. The cells were incubated in a  
290 humidified incubator at 37°C for 1 hour. Next, the virus was removed, and cells were overlaid 2X MEM  
291 supplemented with 2% oxoid agar (final concentration of 0.7%) as well as 4% FBS. The cells were  
292 incubated at 37°C for 72 hours after which cells were fixed with 1 ml of 10% formaldehyde  
293 (Polysciences) was added for 24 hours to ensure inactivation of virus. Crystal violet was used to visualize  
294 the plaques. Only 5 or more plaques were counted and the limit of detection was 250.

295 **Histology and immunohistochemistry.** Mice were subjected to terminal anesthesia and euthanasia  
296 performed by exsanguination of the femoral artery before lungs were flushed/inflated with 10%  
297 formaldehyde by injecting a 19 gauge needle through the trachea on day 4 for immunohistochemistry.  
298 Fixed lungs were sent to a commercial company, Histowiz for paraffin embedding, tissue analysis and  
299 scoring by an independent veterinary pathologist. Hematoxylin and eosin (H&E) and  
300 immunohistochemistry (IHC) staining was performed. IHC staining was performed using an anti-SARS-  
301 CoV nucleoprotein antibody (Novus Biologicals cat. NB100-56576). Histology and IHC for day 2 samples  
302 was performed on only half of the lung which was dissected and cut in half from sacrificed mice. The  
303 other half of the lung was used for quantification of virus, as mentioned above.

304 Scores were assigned by the pathologist based on six parameters: perivascular inflammation,  
305 bronchial/bronchiolar epithelial degeneration/necrosis, bronchial/bronchiolar inflammation,  
306 intraluminal debris, alveolar inflammation and congestion/edema. A 5-point scoring system was used  
307 ranging from 0-4, with 0 indicating no epithelial degeneration/necrosis and inflammation while 4  
308 indicating severe epithelial degeneration/necrosis and inflammation.

309  
310 **Statistics.** Statistical analysis was performed in Graphpad Prism using one-way ANOVA corrected for  
311 multiple comparisons.

## 312 **Acknowledgments**

313  
314 We thank Randy A. Albrecht for oversight of the conventional BSL3 biocontainment facility. This work  
315 was partially supported by the NIAID Centers of Excellence for Influenza Research and Surveillance  
316 (CEIRS) contract HHSN272201400008C (FK, AG-S), Collaborative Influenza Vaccine Innovation Centers  
317

318 (CIVIC) contract 75N93019C00051 (FK, AG-S), , NIAID R21AI157606 (L.C), a supplement to NIAD adjuvant  
319 contract HHSN272201800048C (FK, AG-S) and the generous support of the JPB foundation, the Open  
320 Philanthropy Project (#2020-215611 to AG-S) and other philanthropic donations. We thank Susan  
321 Stamnes, Kaylee Murphy (Iowa Viral Vector Core) and Dr. Paul B. McCray Jr (University of Iowa) for  
322 making the AdV-hACE2 virus rapidly available to us.

323

#### 324 **Conflict of interest**

325

326 The Icahn School of Medicine at Mount Sinai has filed patent applications regarding SARS-CoV-2  
327 vaccines.

458

459 **Figure 1. Spike construct design and protein characterization.** (A-D) described the wild type,  $\Delta$ CS, PP  
460 and  $\Delta$ CS-PP constructs used in this study. (B) shows the four antigens on a SDS-PAGE stained with  
461 Coomassie blue, while (C) shows the same protein on a Western blot developed with an antibody to the  
462 C-terminal hexahistidine tag. While all four proteins are detected as clean, single bands on the SDS-  
463 PAGE, the Western blot reveals a small fraction of degradation products at approximately 80 kDa for the  
464 wild type and PP variants and of approximately 40 kDa for the PP and  $\Delta$ CS-PP constructs. (D) shows  
465 binding of mAb CR3022 to the constructs in ELISA. Data for the negative control mAb and the blank were  
466 combined for the different substrates.

467  
468 **Figure 2. Immunogenicity of different spike variants in the mouse model.** (A) shows the vaccination  
469 regimen used for the five groups of mice and (B) shows the timeline. Animals were bled 3-weeks post  
470 prime (C) and 4 weeks post-boost (D) and antibody levels to a mammalian-cell expressed RBD were  
471 measured. Post-boost sera were also tested in cell-based ELISAs on cells infected with authentic SARS-  
472 CoV-2. Finally, post-boost sera were tested in a microneutralization assay against SARS-CoV-2.

473  
474 **Figure 3. Challenge of mice with SARS-CoV-2.** Animals sensitized by transient expression of hACE2 via  
475 adenovirus transduction were challenged with  $10^5$  PFU or SARS-CoV-2 and weight loss was monitored  
476 over a period of 14 days (A). (B) and (C) shows day 2 and day 5 lung titers respectively, while (D) shows  
477 lung immunohistochemistry staining for SARS-CoV-2 nucleoprotein on days 2 and 4 post challenge.  
478 Representative images from two animals each are shown at 5-fold magnification. Scale bar = 500  $\mu$ m.

479  
480 **Figure 4: Lung pathology.** (A) shows a histopathological composite score for animals on day 2 post  
481 infection, (B) shows representative H&E stained tissue images from 2 animals per group. (C) and (D)  
482 show the same but for day 4 post challenge. Scale bar = 500  $\mu$ m.
