Abstract

Background: Most patients with COVID-19 experience mild illness, which can be managed in a home environment. This study was done to assess the perception, awareness, and practices regarding home-based management of COVID-19 among the general population in India.

Methods: This cross-sectional study was done in May and June 2021. Data were collected using a Google Form.

Results: Mean age of the 294 participants was 36.6 ± 12.1 years. Of these participants, 45 (15.3%) were diagnosed with COVID-19 anytime in the past. Among them, 37 (82.2%) underwent home-based management for COVID-19. Monitoring body temperature and oxygen saturation were performed just once a day by 15.2% and 5.9% of COVID-19 patients respectively. Self-medication was practiced by 11 (29.7%) patients.

Disposable face masks were worn by 23 (62.2%) patients beyond eight hours of continuous usage. The disposable type of face mask was not discarded despite becoming wet, and cloth masks were worn by eight (21.6%) patients. Disposable gloves were only worn by 14 (37.8%)

Any reports and responses or comments on the

caregivers of COVID-19 patients. As many as 10 (27%) patients were tested for COVID-19 after completion of home isolation. Awareness of all mild symptoms and signs of the disease was known to only 19 (6.5%) participants. Normal oxygen saturation in the blood was known to 40 (13.6%) participants. Just six (2%) participants were aware of the correct duration of home isolation in a symptomatic patient with COVID-19. The recommended duration of handwashing with soap and water was known to 102 (34.7%) participants. As many as 17.4% and 32.7% of participants were not confident in using thermometer and pulse oximeter respectively.

Conclusion: Practices, awareness, and perception regarding certain essential measures in COVID-19 home management were found lacking among several participants. These need to be addressed by suitable training programs among the general population.

Introduction

The coronavirus disease 2019 (COVID-19) is an emerging disease that continues to be a pandemic throughout the world. India is currently recovering from the second wave and is on the verge of a third wave in the months to come (<https://timesofindia.indiatimes.com/>). During the second wave, the country faced a severe shortage of medical facilities and hospital beds (<https://reliefweb.int/>). Fortunately, most patients with COVID-19 experience mild illness and can therefore be managed in the home setting (MoH & FW, 2021 (<https://www.mohfw.gov.in/>); Public Health Unit, 2020 (<https://www.un.org/>)). Apart from the commonly known clinical presentation of COVID-19, the various psychological problems among those affected by COVID-19 are gaining importance. A study carried out in China reported that anxiety disorders and depression are common among COVID-19 patients managed in the hospital settings.¹ A study in USA stated that anxiety disorders were not only common among COVID-19 patients but were also self-rated as severe.² Isolation of patients in a home environment with the support of family members may help to alleviate these psychological problems.

An Italian study reported that home management of COVID-19 patients following a standard prevention algorithm reduced the risk of hospitalization and thereby the cost of medical care by more than 90%.³ On the contrary, if home management is not practised as per guidelines, the transmission of the disease to other household members could be disastrous. Monitoring of the vital parameters by patients or their caregivers and identifying and reporting of any danger signs helps in the timely hospital admission of patients developing complications during home isolation. Therefore, this study was done to assess the practices, perception, and awareness of home-based management of COVID-19 patients among the general population in an urban area in south India.

Methods

This cross-sectional study was done during the second wave of COVID-19 in Mangalore city in May and June 2021. Mangalore is located between the Arabian sea and the Western Ghats, and it is the only city in Karnataka state, India, with all four modes of transport namely, road, rail, air, and sea. This makes the local population highly susceptible to COVID-19 infection.

The population of Mangalore city in the year 2021 is estimated to be 724,159 (<https://worldpopulationreview.com/>). In May 2021, as many as 31,090 cases and 156 deaths due to COVID-19 were reported in Mangalore city, according to the records of Mangalore City Corporation.

In the study conducted in USA², 88.9% of COVID-19 patients undergoing home-based management monitored their blood pressure. Using this proportion, the sample size using the formula $N = 4PQ/d^2$ comes to 200 at 95% CI and 5% relative precision. Adding 20% as the non-response rate, the minimum sample size was taken as 240 participants. Data collection was carried out from May 29th, 2021 to June 7th, 2021. It was stopped after completing the stipulated data collection period of ten days.

Data were collected using an anonymous semi-structured questionnaire designed as a Google Form.⁴ It was content validated with the help of a subject expert from the Department of Internal Medicine, Kasturba Medical College, Mangalore. It was later pilot tested among a group of ten people who were later excluded from the main study.

The link to the questionnaire was then circulated among the local population using WhatsApp. This was done to minimize exposure with the study participants during the data collection process in the background of the ongoing COVID-19 pandemic. The questionnaire is available as an extended data.⁴

The study information sheet and the consent form constituted the first page of the questionnaire. Participants not willing to participate in this research study were given the option to decline consent leading to termination and submission of an empty questionnaire. Participants below 18 years of age were also excluded from this study.

The questionnaire was prepared using an extensive literature search. The websites of the World Health Organization, Centers for Disease Control and Prevention, Ministry of Health and Family Welfare Government of India, Indian Council of Medical Research, Government of Karnataka state, and previously published research articles related to the research topic were referred for preparing a comprehensive questionnaire. It had four sections to obtain information regarding socio demographic variables, practices, perception, and awareness of respondents regarding home-based COVID-19 management. Only one eligible participant per household was instructed to complete the questionnaire. This was possible because an instruction stating that only one member from the same household is supposed to fill this form was mentioned at the start of the questionnaire.

Socio economic status (SES) of participants were assessed using the Modified BG Prasad classification of 2020.⁵

Submitted responses were extracted from the Google form entered in Microsoft Excel 2016, and transferred to SPSS version 25.0, Armonk, New York for data analysis.

The reliability of the data collection tool was calculated using Cronbach's alpha value. Its value was calculated from the responses to questions and was found to be 0.81 indicating good internal consistency.

Approval was obtained from the institutional ethics committee of Kasturba Medical College, Mangalore before starting this study. The approval number was IEC KMC MLR 06-2021/205.

Results

The mean age of the 294 participants was 36.6 ± 12.1 years. The majority of participants were female [160 (54.4%)] and the majority were graduates [132 (44.9%)] SES could be assessed among 165 participants. Among them, 87(52.7%) belonged to Class I SES (Table 1).

Out of the total participants, 45 (15.3%) were diagnosed with COVID-19 at any time in the past. Among them, 32 (71.1%) were diagnosed using the RT-PCR test, five (11.1%) using the rapid antigen test, and eight (17.8%) using both the tests. One underwent a CT scan and was also tested with a D-dimer assay. The majority [30 (66.7%)] of COVID-19 diagnosed patients were females. Three patients were diagnosed with COVID-19 on more than one occasion. Usage of substances of abuse was reported among eight (17.8%) patients. Among them, seven were alcoholics, three were current smokers, and three were current tobacco chewers. Six (13.3%) patients had long-standing illnesses: all of them were hypertensive, three had diabetes mellitus, and two had cancer.

Out of the 45 patients with COVID-19, eight were managed at a hospital. The rest [37 (82.2%)] underwent home-based management for COVID-19. Reasons for hospital-based admission were due to the severity of the disease in five and due to a request by the patients to avoid the spread of the disease among other family members in three. Out of the five patients who had severe COVID-19, two developed complications. One had breathlessness, persistent cough, and very low oxygen saturation, while the other had telogen effluvium and developed adverse drug reactions.

The monitoring of body temperature and oxygen saturation was performed just once a day by 15.2% and 5.9% of COVID-19 patients respectively. Monitoring of respiratory rate and capillary refill time was practised by just 35.1% and 5.4% of patients respectively (Table 2).

Systemic steroids were prescribed to two patients, and they were started on the first day of diagnosis. Self-medication was practised by 11 (29.7%) patients. The various drugs taken during self-medication were vitamin C tablets by five, paracetamol by four, multivitamin syrup by one and ivermectin tablets by one patient. Eight patients tried an alternative system for COVID-19 management. Among them, six tried Ayurveda. Three out of these six patients who tried Ayurvedic preparations for COVID-19 found it to be very effective (Table 2).

Ten (27%) patients who underwent home isolation had to call their doctors for various reasons. The various reasons stated for telephonic consultation were to discuss the various symptoms experienced (by four), for associated fear (by one), for more information regarding self-monitoring practices (by one), to confirm the period of home isolation (by one), to enquire regarding medications to be taken (by two) and to enquire about medications to be continued after the completion of home isolation (by one).

All 37 patients undergoing home-based COVID-19 management used N95 or triple-layered surgical masks. However, 23 (62.2%) of them wore the disposable mask beyond eight hours of continuous usage. The disposable face mask was not discarded despite becoming wet by eight (21.6%) patients. At times, a cloth mask was worn by eight (21.6%)

*Multiple responses.

COVID-19 patients during home isolation. All 37 patients placed under home management had a single caregiver. Disposable gloves were worn by only 14 (37.8%) caregivers (Table 3).

Thirty-two (86.5%) patients performed steam inhalation, and 11 (34.4%) of them reported that it was the most effective intervention providing relief compared to other conservative methods. Surfaces frequently touched by COVID-19 patients were not disinfected at least once a day by five (13.5%) patients or their caregivers (Table 3).

Home visits by health care professionals were reported by 12 (32.4%) COVID-19 patients. The type of service rendered by personnel visiting the houses of COVID-19 patients was: monitoring of vital signs (by four), supply of medicines (by four), providing health education advice and home-based sanitization practices (by three), and performing clinical examination (by two) (Table 3). As many as 10 (27%) patients were tested for COVID-19 after completion of home isolation (Table 3).

Awareness of all the mild symptoms and signs of the disease was known to 19 (6.5%) participants. Two hundred and thirteen (72.4%) participants knew that home-based management is recommended for the mild stage of the disease. Normal oxygen saturation in the blood was known to 40 (13.6%) participants (Table 4). Only six (2%) participants knew

Table 4. Awareness of COVID-19 among the participants.

Characteristics	Number	Percentages
Awareness of mild symptoms and signs of COVID-19*		
Fever	182	61.9

the correct duration of home isolation in a symptomatic patient with COVID-19. In terms of exercise, 235 (79.9%) had heard about proning, and the majority of them [166 (56.5%)] obtained this information from social media sources. Of all the participants, 209 (71.1%) had heard about COVID-19 self-testing kits. The recommended duration of handwashing with soap and water was known to 102 (34.7%) participants (Table 5).

Out of the total participants, 210 (71.4%) had a thermometer, 195 (66.3%) had a pulse oximeter, 144 (49%) had a weighing machine, 128 (43.5%) had an electronic sphygmomanometer, 86 (29.2%) had a stethoscope, 40 (13.6%) had a mercury sphygmomanometer and 20 (6.8%) had an oxygen concentrator at their homes. As many as 17.4% and 32.7% of participants were not confident in using thermometer and pulse oximeter respectively (Table 6).

Discussion

Screening and therapeutic care practices among COVID-19 patients

The proportion of participants who had previously had COVID-19 in this study was 15.3%. Among them, 66.7% were female, and 6.7% were current smokers. A Turkish study observed that 58.5% of COVID-19 patients were female, and 46.3% were current smokers.⁶ It indicates that a greater proportion of female patients developed COVID-19.

Table 5. Awareness of COVID-19 management practices among the participants.

Characteristics	Number	Percentages
Period of home isolation in a COVID-19 patient with symptoms		
Ten days from the date of the positive test result and thereafter three days as asymptomatic	6	2.0

*Multiple responses.

In the present study, close to 90% of COVID-19 patients or their caregivers monitored blood oxygen saturation and body temperature. The frequency of monitoring body temperature was at least once a day among all patients. These findings were in accordance to the WHO framed international recommendations, which state that all COVID-19 patients isolated at home need to be monitored at least once a day for these vital signs (WHO, 2021). Hence, the presence of a pulse oximeter and thermometer is essential for home-based COVID-19 care. However, monitoring of respiratory rate and capillary refill time was practised by just 35.1% and 5.4% of patients respectively in this study. Therefore healthcare workers need to take the initiative and train patients and their caregivers to measure these parameters daily (MoH & FW, 2021). In a similar study done in USA, all COVID-19 patients managing their symptoms at home recorded their body

Table 6. Perception of participants regarding various COVID-19 protective measures.

Characteristics	Number	Percentage
Confident in self-testing with Coviself self-testing kit (n = 209)	104	49.8
Confident in performing the procedure of recording body temperature using a thermometer	243	82.6
Confident in interpreting the results while using a thermometer	176	59.9
Confident in performing the procedure of recording oxygen saturation using a pulse oximeter	198	67.3
Confident in interpreting the results while using a pulse oximeter	158	53.7
Steam inhalation is an effective protective measure in COVID-19	196	66.7
Gargles with salt and turmeric are effective protective measures in COVID-19	178	60.5
Breathing exercises can improve oxygen levels in the blood

Total	294	100.0

temperature and oxygen saturation levels, 88.9% recorded their blood pressure and 55% their heart rate.² This means that if patients are trained, they can monitor their vital parameters and support self-care.

Approximately one-third of the patients in this study practised home-based exercises during home isolation, and more than half of them performed these exercises daily. This needs to be promoted in COVID-19 patients as physical activity at least once a day boosts the body's immunity (Michigan Psychiatry Resource, 2021). In a Spanish study, 87% of COVID-19 patients found home-based exercises easy or very easy to perform. However, 73% of these patients contacted their physiotherapist, which was more frequent during the first week of isolation.⁷ Physiotherapy in the home environment involving positioning the body, manoeuvres to help clear secretions in the respiratory tract, strengthening deconditioned muscle and de-stressing the mind is beneficial in COVID-19 care. It also teaches self-management techniques to help patients independently carry out their day-to-day activities.⁸

In the present study, two patients who experienced a fall in oxygen saturation performed proning exercise and found it beneficial. Proning exercises improve breathing and oxygenation among patients facing a drop in oxygen saturation levels (MoH & FW guidelines on proning, 2021).

More than one-third of the patients in this study during the home isolation were prescribed ivermectin and other antiviral drugs. In a Turkish study, 65.8% of COVID-19 patients in home-based care were taking anti-viral drugs, which was more than the observations of the present study.⁶ This was against WHO guidelines which advise against antimicrobial treatment for patients with mild COVID-19 (WHO, 2020). Two patients in this study were put on steroids within the first week of diagnosis of COVID-19. According to Indian government guidelines, systemic steroids are usually not indicated in mild COVID-19, and even if indicated, they need to be started beyond seven days of the onset of symptoms (MoH & FW, 2021). An Italian study reported that steroids were prescribed in 30% of patients experiencing persistent symptoms of low oxygen saturation but after seven days following the onset of symptoms.³ Therefore, guidelines for home-based treatment need to be strictly adhered to, and these aspects need to be emphasized during periodic training programmes for medical professionals at the setting.

Self-medication was practised by 29.7% of patients in this study. One of these patients had even self-medicated ivermectin. This was against the government recommendation, which states that the decision to start an anti viral drug is to be made only by a qualified medical professional (MoH & FW, 2021). People therefore need to be educated about the hazards of self-medication as a part of home-based COVID-19 care.

None of the patients in this study experienced worsening of their health condition during home isolation compared to 9.8% in the Turkish study who were hospitalized following home-based COVID-19 management.⁶

Preventive care practices among COVID-19 patients

All patients under home isolation reported that they were placed in a well-ventilated room. This ensures adequate cross ventilation as per the government recommendations (MoH & FW, 2021). In the present study, the majority of participants wore N95 face masks followed by triple-layered surgical masks. However, about one-fourth of the patients (21.6%) at times also reported that they wore a cloth-type mask during home isolation. This is a dangerous practice as cloth masks are not as effective as disposable masks to prevent virus transmission. According to government guidelines, COVID-19 positive patients should always wear at least a triple layer surgical mask during the home isolation period (MoH & FW, 2021). As many as 62.1% of the patients undergoing home isolation in this study wore a disposable mask beyond eight hours of continuous usage. According to recommendations, disposable masks must be discarded after eight hours of continuous use and earlier if soiled or wet (MoH & FW, 2021; Bhatia, 2021). These masks should be disinfected with chemicals like 1% sodium hypochlorite before disposal (MoH & FW, 2021). This is another area where information needs to be provided.

All 37 patients undergoing home care in this study had a single caregiver. This is in accordance with government recommendations where only one person in the family should be allocated as a caregiver (Bhatia, 2021). Among the caregivers, 81.1% wore N95 masks, and the rest 18.9% wore a triple-layered surgical mask. However only 37.8% of them wore disposable gloves. As per the government recommendations, caregivers should wear a double mask or an N95 and should maintain a one-metre distance or more while taking care of COVID-19 patients (Bhatia, 2021).

More than three-quarters of the patients in this study took steam inhalation, drank hot fluids, and performed saltwater gargles. As per the national recommendations, steam inhalation and performing warm water gargles are desirable twice a day in COVID-19 care (MoH & FW, 2021).

The practice of immersing laundry items in hot water before washing was followed on every occasion by 48.7% of patients. As per WHO recommendations, clothes, bed linen, and bath towels of COVID-19 patients need to be immersed in water at 60 to 90 °C, washed with soap or detergent, and later dried thoroughly (WHO & UNICEF, 2020). As many as 86.5% of patients or their caregivers in this study practiced disinfection of frequently touched surfaces in their houses at least once a day in accordance with WHO guidelines (WHO & UNICEF, 2020). Disinfectants like 0.1% sodium hypochlorite need to be used for disinfecting surfaces.

Home visits by health care professionals were reported by close to one-third of COVID-19 patients in this study. They act as the primary point of contact between patients and health care facilities. This helps address immediate concerns among patients that have not been resolved during telephone conversations. Provision of a contact number of a health caregiver or establishment, to every patient under home isolation is a prerequisite in home-based COVID-19 management, as per national guidelines (MoH & FW, 2021). Community health workers can monitor and train patients or their caregivers to monitor vital signs and recognize danger signs of poor oxygen saturation during home visits (<https://www.cdc.gov/coronavirus/>). They also have an opportunity to offer psychological and social support to both patients and their families with the help of various training modules (ICMR, 2021). This will help reduce the burden on the local health care delivery system. According to national guidelines, the district health authorities need to ensure that all patients under home isolation in their jurisdiction are strictly monitored (MoH & FW, 2021). Home-based management for mild COVID-19 was reported to be safe and effective in a study in Pakistan. The study reported that by close monitoring, particularly of oxygen saturation with a pulse oximeter, the hospitalization rate among the home isolated patients was minimal, and there was no incident of any mortality.⁹

More than one-quarter of the patients were tested for COVID-19 after completion of home isolation in this study. In comparison, in a Turkish study, a COVID-19 PCR test was repeated among 87.8% of patients undergoing home isolation.⁶ However, according to Indian government recommendations, there is no need to re-test patients after completion of the suggested period of home isolation. This should be made known to all health caregivers (MoH & FW, 2021).

Awareness of COVID-19 and its management among participants

Symptoms of upper respiratory tract infection without breathlessness or without a drop in normal oxygen saturation in COVID-19 positive patients suggest a mild form of this disease (MoH & FW, 2021). This fact was known only to 6.5% of the total participants in this study.

The risk factors of the severe form of COVID-19 as stated in literature are age above 60 years, an immunosuppressive state, the presence of co-morbidities like diabetes mellitus, hypertension, cancer, cerebrovascular and cardiovascular disease, chronic lung and renal diseases, and habits like smoking and alcohol consumption (WHO Scientific Brief, 2020).

In a study done in Iraq, among severe COVID-19 patients managed in a home environment, as many as 72.5% had at least one co-morbidity.¹⁰

Less than 40% of the participants in this study were aware that the presence of cancer and renal diseases and being alcoholic are risk factors for the severe form of COVID-19. None of the participants were aware that the presence of cerebrovascular disease was also a risk factor for developing severe COVID-19.

The national and international guidelines state that medical attention needs to be given immediately if a patient with COVID-19 on home isolation experiences: a drop in normal oxygen saturation, difficulty in breathing, chest pain, mental confusion, feels drowsy, develops bluish discolouration of nail beds, lips or skin (MoH & FW, 2021; CDC, 2021). The majority of the participants in this study were unaware that mental confusion, drowsiness, and bluish discolouration of body parts are red flags for hospital admission in COVID-19 patients placed under home isolation. Patients and their caregivers need to be made aware of these symptoms.

Every COVID-19 patient needs to isolate for 10 days after symptom onset, followed by three days without symptoms (MoH & FW, 2021). This fact was known to a mere 2% of the participants in this study. Awareness of this guideline is essential to prevent the transmission of COVID-19 in the community.

More than three-quarters of participants in the present study had heard about proning exercises. More than seventy percent of them obtained this information from social media sources. Videos have been extensively circulated and used to train people in COVID-19 care.¹¹ This method can be used to train patients to perform proning, other chest expansion, and breathing exercises and active limb exercises.⁷ This training approach has been successful in helping people perform these exercises correctly.⁷

According to international guidelines, the recommended duration of hand washing with soap and water for 20 seconds was known to little more than one-third of the participants in this study (Mayoclinic, 2021). This is an essential information for people to learn. This should therefore be emphasized during any awareness sessions held in the community.

The need for COVID-19 re-testing after completing home isolation is not recommended as per state guidelines (Government of Karnataka, 2020). This fact was known to only 56 (19%) participants in this study. Along with the health caregivers, the patients also need to be made aware of this to minimize anxiety and unnecessary wastage of resources like COVID-19 testing kits.

Perception of participants regarding COVID-19 protective measures

The confidence in performing and interpreting results of body temperature and blood oxygen saturation recording were found lacking among several participants in this study. This also needs to be addressed in future training programmes.

Strengths of this study

This study has comprehensively assessed the practices, awareness, and perception among the general population regarding home-based management in COVID-19. It has highlighted several grey areas that need to be addressed by local health authorities and policymakers.

Limitations of this study

The participants in this study were enrolled using an online selection method considering the prevailing pandemic situation. Therefore, the sample chosen may not represent the entire population of Mangalore. There is also a possibility of non-reporting of information by the participants in this study.

Conclusion

Practices, awareness, and perception regarding certain essential measures in COVID-19 home management were found lacking among several participants in this study. The local health authorities need to address these inadequacies by implementing suitable training programmes among the general population in this setting.

This is an important study carried out among individuals in Mangalore, South India on practices, awareness, and perceptions regarding home-based COVID management. The study presents new information but does have the limitation of online selection of a limited number of respondents. The respondents selected may or may not be reflective of the general population. My specific comments are shown below.

- Methods section: I did not understand the mention of the use of monitoring blood pressure in a United States study to calculate the sample size.
- The repetition between the Results and the Discussion can be reduced. The authors can share the questionnaire used in the appendix.
- The method of questionnaire development should be mentioned in greater detail.
- Are patients briefed about the criteria mentioned and the guidelines to be followed before they undergo home quarantine?
- The title should be modified to reflect the fact that the study was conducted only in one city in South India and may not reflect the entire population of the region.
- The standard of written English is good but may require some modifications in certain areas. Are there more studies dealing with home-based COVID management in the literature?
- The authors can consider the use of long paragraphs. There are many lone sentences in the manuscript.
- At the end of the Discussion, the authors should add a section on the strengths and limitations of the study.

Is the work clearly and accurately presented and does it cite the current literature?

Yes

Is the study design appropriate and is the work technically sound?

Yes

Are sufficient details of methods and analysis provided to allow replication by others?

Partly

If applicable, is the statistical analysis and its interpretation appropriate?

Yes

Are all the source data underlying the results available to ensure full reproducibility?

Yes

Are the conclusions drawn adequately supported by the results?

Yes

Competing Interests: No competing interests were disclosed.

Reviewer Expertise: Rational use of medicines, COVID-19

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard, however I have significant reservations, as outlined above.

Author Response 11 Mar 2022

Nitin Joseph, Kasturba Medical College, Mangalore, Manipal Academy of Higher Education, Manipal, Karnataka, India, Manipal, India

Original comments of the reviewer: The study has the limitation of online selection of a limited number of respondents. The respondents selected may or may not be reflective of the general population.

Reply by the author(s): This statement has been added under the limitation section.

Original comments of the reviewer: I did not understand the mention of the use of monitoring blood pressure in a United States study to calculate the sample size.

Reply by the author(s): One of the study objectives was to assess the practices of patients during the home management of COVID-19. One of the essential practices recommended among COVID-19 patients is the monitoring of vital parameters on a day-to-day basis during home management. Hence, the proportion of patients monitoring their blood pressure in a study done in USA was used to calculate the sample size in the present study.

Original comments of the reviewer: The repetition between the Results and the Discussion can be reduced.

Reply by the author(s): The last paragraph under the discussion section, which was a repetition of the results section, has been completely deleted.

Original comments of the reviewer: The authors can share the questionnaire used in the appendix.

Reply by the author(s): Unfortunately, F1000 do not offer appendices on their articles, so the questionnaire is supplied as extended data.

Original comments of the reviewer: The method of questionnaire development should be mentioned in greater detail.

Reply by the author(s): In order to make a comprehensive questionnaire, several websites of national and international bodies along with previously published research articles related to the research topic were referred by the investigators. The details of the same have been added under the methods section as suggested.

Original comments of the reviewer: Are patients briefed about the criteria mentioned and the guidelines to be followed before they undergo home quarantine?

Reply by the author(s): Yes, all patients under home isolation or home quarantine are briefed at the beginning about the criteria mentioned and the guidelines to be followed during the home isolation period.

Original comments of the reviewer: The title should be modified to reflect the fact that the study was conducted only in one city in South India and may not reflect the entire population of the region.

Reply by the author(s): The title has been changed as per the suggestion.

Original comments of the reviewer: The standard of written English is good but may require some modifications in certain areas. The authors can consider the use of long paragraphs. There are many lone sentences in the manuscript.

Reply by the author(s): The entire manuscript has been language edited as per the suggestion. The paragraph breaks have also been edited as per the suggestion.

Original comments of the reviewer: Are there more studies dealing with home-based COVID management in the literature?

Reply by the author(s): Findings from two recent studies on home-based COVID-19 care done in two developing countries in Asia have been added to the discussion section. (Reference 9 and 10)

Original comments of the reviewer: At the end of the Discussion, the authors should add a section on the strengths and limitations of the study.

Reply by the author(s): These sections have been added at the end of the discussion section as suggested.

Competing Interests: None declared

Reviewer Report 10 January 2022

<https://doi.org/10.5256/f1000research.78279.r102501>

Department of Preventive and Social Medicine, Jawaharlal Institute of Postgraduate Medical Education and Research (JIPMER), Puducherry, India

In light of the ongoing 3rd wave of COVID-19 which is being witnessed in most parts of the world, this study is very relevant and well-written in all the parts of the study. The majority of patients currently infected with Omicron have mild illness and are recommended isolation in a home environment. This research study brings out the current understanding of the general population regarding steps to be followed during home isolation for COVID-19 management and the grey areas that need to be addressed by policymakers and health care providers.

Some comments:

- Introduction -1st sentence may be modified as - possible verge of the start of a third wave.
- How one member from a family is selected may be mentioned in the methods section.

Is the work clearly and accurately presented and does it cite the current literature?

Yes

Is the study design appropriate and is the work technically sound?

Yes

Are sufficient details of methods and analysis provided to allow replication by others?

Yes

If applicable, is the statistical analysis and its interpretation appropriate?

Yes

Are all the source data underlying the results available to ensure full reproducibility?

Yes

Are the conclusions drawn adequately supported by the results?

Yes

Competing Interests: No competing interests were disclosed.

Reviewer Expertise: Mental health, Maternal and Child health

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.

Author Response 11 Mar 2022

Nitin Joseph, Kasturba Medical College, Mangalore, Manipal Academy of Higher Education, Manipal, Karnataka, India, Manipal, India

Original comments of the reviewer: 1st sentence may be modified as - possible verge of the start of a third wave

Reply by the author(s): The third wave of COVID-19 started in the last week of November 2021 and continued to rise thereafter. Currently, in March 2022, there is a decline in the daily number of COVID-19 new cases. Hence, the statement has been left as it is.

Original comments of the reviewer: How one member from a family was selected may be mentioned in the methods section.

Reply by the author(s): An instruction stating that only one member from the same household is supposed to fill this form was mentioned at the start of the questionnaire.

Competing Interests: None declared

The benefits of publishing with F1000Research:

- Your article is published within days, with no editorial bias
- You can publish traditional articles, null/negative results, case reports, data notes and more
- The peer review process is transparent and collaborative
- Your article is indexed in PubMed after passing peer review
- Dedicated customer support at every stage

For pre-submission enquiries, contact research@f1000.com
