Received 29 May 2009; accepted 4 June 2009

 Key indicators: single-crystal X-ray study; $T = 295$ K; mean $\sigma(\text{C}-\text{C}) = 0.002$ Å;
 R factor = 0.030; wR factor = 0.079; data-to-parameter ratio = 11.3.

The title compound, $\text{C}_8\text{H}_9\text{N}_5\text{O}$, was synthesized by the reaction of ethyl 2-(benzotriazol-1-yl)acetate with hydrazine hydrate in ethanol. In the amide group, the C–N bond is relatively short [1.3283 (16) Å], suggesting some degree of electronic delocalization in the molecule. In the crystal structure, molecules are linked into infinite chains along the a axis by intermolecular O–H...N hydrogen bonding.

2-(1*H*-Benzotriazol-1-yl)acetohydrazide

Y.-X. Zhang and Z.-Q. Shi

Comment

In our previous papers (Shi *et al.*, 2007a; Shi *et al.*, 2007b; Ji *et al.*, 2008;), we have reported a number of Schiff-bases by the reaction of benzotriazol-1-yl-acetic acid hydrazide with relevant aldehyde or ketone. As a part of a more general study of multiple-hydrogen-bonding N-heterocyclic systems as potential supramolecular reagents (Portalone, 2007; Portalone & Colapietro, 2007, 2008), the title compound, (I), was synthesized and its crystal structure determined. The asymmetric unit of the (I) comprises one independent molecule. In (I) (Fig. 1), the bond lengths and angles are in good agreement with the expected values (Allen *et al.*, 1987). In the crystal structure (Fig. 2), the molecules are linked into infinite chains by O—H \cdots N hydrogen bond.

Experimental

The title compound was synthesized by the reaction of benzotriazol-1-yl-acetic acid ethyl ester (1 mmol) with hydrazine hydrate 85% (1.1 mmol) in ethanol (20 ml) under reflux conditions (348 K) for 24 h. The solvent was removed and the solid product recrystallized from tetrahydrofuran. After four days colorless crystals suitable for X-ray diffraction study were obtained.

Refinement

All H atoms were placed in idealized positions (C—H = 0.93—0.97 Å, N—H = 0.86 Å) and refined as riding atoms. For those bound to C, $U_{\text{iso}}(\text{H}) = 1.2$ or $1.5U_{\text{eq}}(\text{C})$, while for those bound to N, $U_{\text{iso}}(\text{H}) = 1.2 U_{\text{eq}}(\text{N})$.

Figures

Fig. 1. The molecular structure of (I), with displacement ellipsoids drawn at the 30% probability level.

Fig. 2. The structure of the infinite chains formed *via* hydrogen bonds, H atoms have been omitted for clarity. The dashed lines indicate hydrogen bonds.

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -

factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R - factors based on ALL data will be even larger.
