ABSTRACT

Introduction Globally, one in two people needing insulin lack access. High prices and poor availability are thought to be key contributors to poor insulin access. However, few studies have assessed the availability, price and affordability of different insulin types in low-income and middle-income countries in a systematic way.

Methods In 2016, 15 insulin price and availability surveys were undertaken (using an adaptation of the WHO/Health Action International medicine price and availability measurement methodology) in Brazil, China (Hubei and Shaanxi Provinces), Ethiopia, Ghana, India (Haryana and Madhya Pradesh States), Indonesia, Jordan, Kenya, Kyrgyzstan, Mali, Pakistan, Russia (Kazan Province) and Uganda. Data were collected in three sectors (public, private pharmacies and private hospitals/clinics) in three regions per survey. Insulin prices were standardised to 10 mL 100 IU/mL in US dollars (\$). Data were also collected for four comparator medicines.

Results Mean availability was higher for human (55%–80%) versus analogue insulins (55%–63%), but only short-acting human insulin reached 80% availability (public sector). Median government procurement prices

were \$5 (human insulins) and \$33 (long-acting analogues). In all three sectors, median patient prices were \$9 for human insulins. Median patient prices for analogues varied between the public sector (\$34) and the two private sectors (\$44). Vials were cheaper than pens and cartridges. Biosimilars, when available, were mostly cheaper than originators. A low-income person had to work 4 and 7 days to buy 10 mL human and analogue insulin, respectively. For isophane human insulin, only three countries meet the WHO target of 80% availability of affordable essential medicines for non-communicable diseases in any sector.

Conclusion Improving insulin availability and affordability needs to be addressed through national and global actions, including prioritising the supply of more affordable human insulin, increasing competition through the use of lower priced quality-assured biosimilars, negotiating lower prices from manufacturers and improving distribution systems.

Key questions

What is already known?

- Despite being discovered nearly 100 years ago, one in every two people globally needing insulin lack access to this life-saving medicine.
- The global insulin market is dominated by only three companies, but it is estimated that increased competition with biosimilar insulin could lead to large price reductions.

What are the new findings?

- In low-income and middle-income countries, insulin availability in outlets is poor, and treatment is unaffordable for those on low wages having to pay out of pocket.
- Biosimilar insulins are mostly (but not always) cheaper than originator brands, and analogue insulins, in particular, are far higher priced than estimated costs of production including profit.

What do the new findings imply?

- High insulin prices and poor availability need to be addressed through national and global actions.

BACKGROUND

By 2045, an estimated 629 million people will have diabetes. This constitutes a 48% increase over the 2017–2045 period.¹ Currently, one in two people needing insulin lack access to this life-saving medicine. To address this, in 2013, the WHO published its Global Action Plan for the Prevention and Control of Non-communicable Diseases 2013–2020 (GAP).² One of GAP's objectives is to strengthen health systems, which includes improving access to affordable medicines to treat non-communicable diseases (NCDs). The GAP includes a voluntary target of 80% availability of affordable essential medicines, including generics, required to treat major NCDs in both public and private facilities by 2025. Data have shown that few essential medicines for diabetes have met the GAP target.³

In the public sector in low-income, lower middle income and upper middle income countries 17%, 21% and 45%, respectively, of diabetes medicines were both available (80% or greater availability in outlets) and affordable (requiring no more than 1 day's wages of the lowest paid unskilled government worker

to purchase 30 days' treatment). In the private sector, it was 28%, 23% and 32%.³

Insulin is a life-saving medicine for people with type 1 diabetes and is used to manage an increasing number of people with type 2 diabetes. Serious complications result from suboptimal treatment, including blindness, amputations and premature death. Therefore, access to insulin is vital.

Studies in 2003–2009 by the International Insulin Foundation in seven low-income and middle-income countries (LMICs) found a variety of barriers to insulin access, including high prices.^{4–13} Availability was also suboptimal, for example, in Mali and Mozambique, insulin was present in only 20% of public sector outlets. In 2010, a snapshot survey by Health Action International (HAI) of 60 countries found patient prices of regular insulin were highly variable across the world.¹⁴ A snapshot 2015 survey (43 countries) showed insulin patient prices were generally high, and treatment was unaffordable for those on low incomes.¹⁵ Human insulins were lower priced than analogues in public sector outlets (median US\$7.64 vs \$45.03 for 10 mL 100 IU/mL) and private pharmacies (median US\$16.65 vs \$39.35), with prices highly variable between countries. Insulin vials were cheaper than insulin cartridges and prefilled pens for all human insulins, but not all analogues. On average, 2.5–9.5 days' wages were needed, by those on a low wage, to buy 10 mL depending on the insulin type and sector. Government procurement prices were, on average, US\$5.99 for human insulin and US\$34.20 for analogues.¹⁵ A recently published study showed insulin availability in pharmacies was poor in LMICs, and 63% of households in low-income countries could not afford insulin.¹⁶

This article reports the findings from a comprehensive survey undertaken in 2016 as part of the Addressing the Challenge and Constraints of Insulin Sources and Supply (ACCISS) Study on the availability, price and affordability of insulin, and four comparator medicines, in the public and private sectors of 13 LMICs.

METHODS

Sampling

Fifteen surveys were undertaken in 13 countries: Brazil, China (Hubei and Shaanxi provinces), Ethiopia, Ghana, India (Haryana and Madhya Pradesh states), Indonesia, Jordan, Kenya, Kyrgyzstan, Mali, Pakistan, Russia (Kazan province) and Uganda. Three sectors were surveyed: public hospitals (outpatients dispensary), private retail pharmacies and private hospitals/clinics. Data were collected in three areas per survey: including the capital or major urban city, the province closest to this city with the largest provincial hospital and the district closest to the province with the largest district hospital. In each area, the largest public hospital and private hospital/clinic were sampled, plus five private retail pharmacies (a large pharmacy and four randomly chosen from those within 5 km of the public hospital). In some countries,

there were no private hospitals/clinics in the district. See online supplementary appendix table 1 for the number of outlets sampled per survey.

The latest government procurement (tender) prices were collected from the national procurement office or central medical stores. In Brazil, India Madhya Pradesh, Pakistan and Russia Kazan, where medicine procurement is decentralised, procurement prices were collected in the public hospitals surveyed.

Medicines

Patient price and availability data were collected for all insulins found in the outlets and for four comparator medicines. Two comparators are commonly used to treat type 2 diabetes: metformin 500 mg tablets/capsules and gliclazide 80 mg tablet/capsules. Enalapril 10 mg tablets/capsules (used to treat hypertension) and ceftriaxone 1 g vials (the most commonly used injectable antibiotic in LMICs) were also surveyed. In Brazil and Kyrgyzstan, gliclazide was not surveyed as no products in the specified strength and dosage form have marketing authorisation.

For the comparators, prices were collected on the highest and lowest unit prices in the outlet (irrespective of whether they were originator brands or generics). All data were entered into customised Excel spreadsheets.

Data collection, entry and quality assurance

In each country, the Ministry of Health endorsed the survey. The outlets gave verbal consent to data collection.

National investigators experienced in conducting medicine price surveys (including using the WHO/HAI methodology¹⁷) trained their survey personnel. The authors reviewed and analysed the data. Insulin types, brands, volumes of insulin per presentation and so on were checked against the manufacturer's website. Where a product list was not provided, websites of major distributors were used. Brands of comparator medicines were also checked to confirm the active ingredient, strength and dosage form.

Patient and public involvement

No patients or the general public were involved in the survey.

Data analysis

The insulins were categorised by time of action that is, short-acting and intermediate-acting human insulin, mixed human insulin, rapid-acting and long-acting analogue insulin, mixed analogue insulin and animal insulin (see online supplementary appendix table 2).

Availability was assessed as the percentage of outlets that stocked the medicine on the day of data collection. In the public sector, the level of health facility (primary, secondary or tertiary-level hospitals/health centres) at which the medicine is legally permitted to be dispensed, and hence should be available, was considered. Whether the medicine was on the National Essential Medicines List (NEML) was also considered. Mean availability per sector of each insulin category, plus originators versus

Figure 1 Median prices of insulin by category and sector, 10 mL 100 IU/mL in US dollars (any presentation).

biosimilars, and the comparators was assessed across the surveys.

Insulin prices were standardised to 10 mL of 100 IU/mL. Both insulin and comparator prices were converted to US dollars (\$) using the exchange rate of the first day of data collection according to OANDA (www.oanda.com/currency/converter).

For each survey, median prices for each insulin category, type and presentation were assessed per outlet and per sector. Insulin prices were also compared between the originators (manufactured by Novo Nordisk A/S (Novo Nordisk), Eli Lilly and Company (Lilly), Sanofi S.A. (Sanofi)) and independent biosimilar manufacturers (including biosimilars made by the originator companies). For each comparator, median prices were assessed for the highest and lowest price. In this article, only availability and affordability data are reported for comparators.

Affordability was based on median treatment prices and expressed as the number of days the lowest paid unskilled government worker has to work to purchase 10 mL of insulin (approximately 30 days' supply), 90 tablets metformin, 30 tablets gliclazide, 30 tablets enalapril and 1 vial of ceftriaxone. The GAP target did not define affordability, so the WHO/HAI threshold of not more than 1 day's wage of the lowest paid unskilled government worker to purchase 30 days' supply was used.

FINDINGS

Government procurement prices

Government procurement prices were obtained in all countries except Kenya. For six surveys, insulin was procured from only one manufacturer, in three surveys

from two manufacturers, for four surveys from three manufacturers and in one from six manufacturers.

Median procurement prices of human insulins across the countries (any presentation) were similar, ranging from \$4.56 (short acting) to \$5.30 (mixed human) (figure 1 and online supplementary appendix table 3). Large price variations were seen across the countries. For example, short-acting and intermediate-acting human insulins ranged from \$1.45 (Ethiopia) to approximately \$24 (Hubei, China).

Six countries had at least one analogue on their NEML (Russia, Kyrgyzstan, Indonesia, China, Jordan and Ghana). Of these, all but Ghana had purchased analogues. Long-acting analogues had the highest median price (\$33.36) and the largest price variation (\$21.56 (Indonesia) to \$106.52 (Hubei, China)).

In most countries, there were large price differences between human and analogue insulins. The Kyrgyzstan government, for example, paid \$3–\$4 for human insulins and \$24–\$32 for analogues. By contrast, in Indonesia, the price differential was smaller (human insulin \$15–\$19 and analogues \$22–\$28). The highest prices were found in the two Chinese provinces; median prices of human insulins were approximately \$24, and rapid-acting and long-acting analogues were approximately \$38 and \$100, respectively.

For short-acting and mixed human insulins, median prices of originator brands (\$5.90) were higher than biosimilars (\$3.55), whereas they were similar for intermediate-acting human insulin (\$5.90 vs \$5.79). Only the Shaanxi provincial government in China purchased biosimilar analogues. For matched pairs of human insulins (same insulin, strength and presentation) assessed

Table 1 Paired government procurement prices, originator and biosimilar insulins, 1000 IU in US dollars

Survey	Human insulin, strength, presentation	Originator(s)	Biosimilar(s)	Difference biosimilar to originator
Pakistan	Regular, isophane and mixed 30/70, 100 IU/mL vial	\$2.38 N	\$2.00 G	16% ↓
Kazan, Russia	Regular 100 IU/mL vial	\$6.07 N	\$6.65 P	10% ↑

Hubei, China	Mixed 50/50 100 IU/mL cartridge	\$28.35 N	\$25.05 U; \$26.96 D	5%–12% ↓
	Regular 40 IU/mL vial	\$20.70 N	\$17.71 D	14% ↓
	Isophane 40 IU/mL vial	\$20.76 N	\$17.71 D	14% ↓
	Mixed 30/70 40 IU/mL vial	\$21.39 N	\$17.94 D	16% ↓
	Regular 100 IU/mL cartridge	\$26.51 L; \$26.53 N	\$23.18 Li; \$23.62 D; \$27.41 Bt	3% ↑–13% ↓
	Isophane 100 IU/mL cartridge	\$26.20 L; \$27.47 N	\$23.35 Li; \$24.24 D; \$28.11 Bt	7% ↑–15% ↓
	Mixed 30/70 100 IU/mL cartridge	\$26.44 L; \$26.66 N	\$22.56 Li; \$23.80 D; \$27.84 Bt	5% ↑–15% ↓
	Mixed 50/50 100 IU/mL cartridge	\$27.78 N	\$22.09 Li; \$26.23 D	6%–20% ↓

Originator companies: L, Lilly; N, Novo Nordisk.

Biosimilar companies: Bt, Bioton; D, Tonghua Dongbao; G, Getz; Li, Lianbang; P, Pharmstandard; U, United.

for Pakistan, Russia Kazan and the two Chinese provinces, biosimilars were no more than 20% lower priced than originators (table 1). In a few cases, the biosimilar was higher priced, for example, 10% higher in Russia Kazan (regular insulin in vials) and 3%, 5% and 7% in Hubei, China, for regular, mixed 30/70 and isophane cartridges, respectively.

Only Hubei, China, was purchasing animal (porcine) insulin. Prices were \$9.20, \$10.12 and \$13.29 for short-acting, intermediate-acting and mixed porcine insulins, respectively. These were lower than median prices of the human insulins procured.

Availability in outlets

In the public sector, mean availability of human insulins was 55%–80% depending on the country (see online supplementary appendix figure 1). Analogue availability was 55%–63% in the six countries with them on their NEML plus Kenya (found but not in the NEML). In private pharmacies, availability was lower at 45%–53% (human) versus 27%–36% (analogue), and in private hospitals, it was 54%–71% (human) versus 35%–51% (analogue).

While Pakistan had good availability of the three types of human insulin in all three sectors (95%–100%), this was not the case in other countries. For example, in Haryana, India, where insulin is free in the public sector, no human insulin was found in the provincial and district public hospitals, and only short-acting insulin was in stock in the teaching hospital in the state capital. Availability

was higher in private pharmacies and private hospitals, where people have to pay out of pocket.

Mean availability of biosimilars was lower than originators in the public (17% versus 51%), private pharmacy (8% versus 40%) and private hospital (10% vs 52%) sectors. Biosimilars of human insulins had higher availability (11%–36% depending on type and sector) than analogues (0%–17%). Most analogue biosimilars were glargine (made by Biocon, Gan&Lee, Getz and Lilly). In the public sector, the availability of biosimilars exceeded that of originators only for human insulins and only in a few countries, that is, India Haryana (regular), Ethiopia and Pakistan (regular and isophane), Uganda (regular, isophane and mixed human insulin) and India Madhya Pradesh (regular and mixed human insulin). There was only one case in private pharmacies (in Uganda for glargine) and one case in private hospitals (Ethiopia, mixed human insulin).

The mean availability of metformin and ceftriaxone was similar to, or higher than, human and analogue insulin availability in all sectors. A mixed picture was seen for gliclazide and enalapril, depending on the sector and insulin category.

Patient prices

Overall

Insulin was provided free of charge in the public sector in India, Kyrgyzstan, Pakistan, Uganda, Russia (registered users only from public hospitals) and Brazil. Where people pay out of pocket, median prices were \$9.36 for

human insulin versus \$29.39 for analogues in the public sector, \$9.65 (human insulin) versus \$43.81 (analogues) in private pharmacies and \$9.02 (human insulin) versus \$45.26 (analogues) in private hospitals/clinics.

By insulin category and country

In the public sector, median patient prices ranged from \$8.78 to \$10.15 for human insulin and \$31.27–\$47.46 for analogues, depending on the type (figure 1). In private pharmacies and private hospitals/clinics, prices ranged from \$8.36 to \$14.52 and from \$8.07 to \$11.11, respectively, for human insulins, and \$33.00–\$60.05 and \$39.44–\$59.96, respectively, for analogues.

The largest price variations were seen for long-acting analogues. In private pharmacies, which had the greatest number of price points, glargine ranged from \$13.42 in Madhya Pradesh, India, to \$131.27 in Brazil (median \$59.94). Prices for detemir ranged from \$27.22 in Kazan, Russia, to \$116.36 in Shaanxi, China (median \$59.70). In private pharmacies, degludec was only found in Brazil (\$117.57).

By presentation

In private pharmacies (greatest number of data points), median prices of vials of short-acting, intermediate-acting and rapid-acting insulin, and mixed human, were lower than insulin in pens and cartridges (see online supplementary appendix figure 2). For example, mixed human insulin in vials, pens and cartridges had median prices of \$6.76, \$18.16 and \$14.42, respectively. For long-acting analogues, vials were higher priced; for mixed analogues, prices were similar across presentations. Note: this was not a paired analysis, and there were limited data for some presentations and insulin categories.

Originators versus biosimilars

Of the 49 matched pairs of originators and biosimilars by presentation, biosimilars had lower median prices in 36 cases (18 vials and 18 cartridges), were identical in three (all vials) and had higher prices in 10 cases (6 vials and 4 cartridges) (table 2). Matched data for pens was available for only one outlet (Indonesian private pharmacy) where the biosimilar was 12% cheaper.

In the public sector, median biosimilar prices were all cheaper (by 7%–26% for vials; 2%–25% for cartridges) than originators except for one case in Ethiopia. In private pharmacies, biosimilars were cheaper (by 3%–45% vials; 11%–26% cartridges) than originators in 16/26 cases, the same price in 2/26 cases and higher priced in 8/26 cases (by 1%–26% vials; 1%–83% cartridges). In private hospitals, biosimilars were all cheaper (by 13%–40% vials; 4%–38% cartridges) than originators except for two cases in Madhya Pradesh.

Affordability

Based on median prices, the lowest paid unskilled government worker has to work 3.5–3.9 days (human) versus 6.1–7.9 days (analogue) to purchase 10 mL 100IU/mL of insulin in the public sector, depending on type.

In private pharmacies, it was 2.2–4.3 (human) versus 6.6–15.6 (analogues) days' wages. In private hospitals, 3.7–5.0 (human) versus 6.7–14.3 (analogues) days' wages were needed (table 3). Long-acting analogues were least affordable, requiring 7.9, 15.6 and 14.3 days' wages in the public sector, private pharmacies and private hospitals, respectively.

Insulin was less affordable than the four comparators in all sectors. For example, a month's supply of metformin (first-line treatment for type 2 diabetes), purchased in the public sector, requires a median of 1.3 (lowest priced) to 2.4 (highest priced) days' wages, whereas insulin requires 3.5 to 7.9 days' wages depending on the type of insulin. Gliclazide, also used in the management of type 2 diabetes, was also more affordable than insulin, even for highest priced products.

Figure 2 shows the availability and affordability of isophane (intermediate acting) human insulin by country and sector. Only the public sector in Brazil, Kyrgyzstan and Pakistan (where insulin is free of charge) and private hospitals in Brazil achieved the GAP target, although a few other countries came close. Glargine (long-acting analogue) did not achieve the target in any country/sector (see online supplementary appendix figure 3). By comparison, the number of countries meeting the target for metformin in the public, private and private hospital sectors were 5, 9 and 6 (based on lowest prices) and 4, 6 and 5 (highest prices), respectively.

DISCUSSION

Of the different countries studied, only the public sector in Brazil, Kyrgyzstan and Pakistan (where insulin is free of charge) and private hospitals in Brazil achieved the GAP target. This study found insulin availability was generally higher in the public sector than the private but still suboptimal and lower than the comparator medicines. Although the causes were not investigated, a prior WHO/HAI study¹⁸ reported poor medicine availability can be due to a combination of factors including inadequate funding, inability to forecast accurately, lack of incentives for maintaining stocks and inefficient distribution systems. Outlets may regard the need for refrigeration, higher procurement prices and lower demand compared with other medicines as barriers to stocking insulin.

A key issue in accessing insulin is its price. Several price trends were seen in this study. First, governments were paying highly variable prices for the same insulin, such as \$1.45 (Ethiopia) to \$24.72 (Shaanxi, China) for isophane human insulin. Even identical products had variable procurement prices. For example, Lantus pens ranged from \$21.56 (Indonesia) to \$106.52 (Hubei, China). Second, analogues were substantially higher priced than human insulin in all sectors. For example, people on insulin paid about \$9.50 for human insulin, but \$29.39 and \$43.81 for analogues in the public and private sectors, respectively. The third trend was that insulins in

				CS	\$32.63 L, N (3)	\$29.17 D, U (2)	11% ↓
				KE	\$61.89 S (1)	\$38.70 Bc (1)	37% ↓

Number in brackets=number of outlets where found.

Country surveys: CH, Hubei, China; CS, Shaanxi, China; ET, Ethiopia; GH, Ghana; IH, Haryana, India; IP, Madhya Pradesh, India; KE, Kenya; PK, Pakistan; RU, Kazan, Russia; UG, Uganda.

Originator companies: L, Lilly; N, Novo Nordisk; S, Sanofi.

Biosimilar companies: Bc, Blocon; Bt, Bioton; D, Tonghua Dongbao; G, Getz; Ge, Geropharm; GL, Gan&Lee; H, Highnoon; J, Julphar; Li, Lianbang; M, Medisintez; P, Pharmstandard; Pe, PharmEvo; Sh, Shreya; U, United; W, Wockhardt.

vial form (excluding long-acting and mixed analogues) were cheaper than when in pens and cartridges.

Some LMICs are able to provide insulin for free to their populations, which is an essential step in improving diabetes care. However, in countries where people had to pay for insulin, it was not affordable for those on low wages, requiring 2.2–15.6 days' wages to purchase 10 mL. The comparator medicines were far more affordable at 0.4–2.4 days' wages.

There are different possible areas where individuals and governments could decrease expenditure on insulin. First, the use of analogues is rising and already exceeds human insulin use in upper middle and high-income countries.¹⁹ This trend should concern all governments facing growing expenditure on medicines for diabetes and other NCDs. On two occasions (2011 and 2017), WHO's Expert Committee on the Selection and Use of Essential Medicines rejected proposals to include analogues in the model list due to their higher price and modest benefit compared with human insulin.²⁰ It was again proposed at the 2019 meeting of the Expert Committee, with the outcome unknown at the time of publication of this article. Purchasing human insulin reduces overall expenditure, with the government of Kyrgyzstan potentially saving nearly half a million US dollars annually if only human insulin was purchased.¹⁵ This trend was seen in an earlier study.¹⁵ These trends on a global level impact affordability for both governments, when they provide free or subsidised insulin, and people when paying out of pocket. Thus, the provision of human insulin should be promoted.

In late 2018, Gotham and colleagues²¹ conservatively estimated that manufacturers' selling prices (covering production costs, profit, transport and other costs) should be \$3.29 to \$4.93 for biosimilar human insulin and \$5.32 to \$9.13 for most analogues. Our study found governments were paying far more, particularly for analogues (but also for human insulins in some countries), showing scope for price reductions while still providing a profit for the manufacturer. This means that, both globally and nationally, pressure is needed on the manufacturers to lower the actual prices at which they sell their insulin.

Efforts are needed to increase competition through the use of lower priced quality-assured biosimilars.²² Encouraging biosimilar insulin manufacturers to bid to supply insulin in a country requires procurement agencies knowing who manufactures insulin globally and encouraging them to submit product dossiers for evaluation to the country's medicines regulatory authority. A review of regulatory processes for biosimilar insulins found assessments for these products are more complicated than for chemical medicines, resulting in inconsistent approaches across countries and, in some countries, additional studies being required.²³ Improvements could be achieved by WHO providing greater guidance combined with building the capacity of national regulators, the inclusion of biosimilar insulin in the WHO prequalification process (WHO have announced they are willing to

Table 3 Median affordability (days' wages) of insulin and comparator medicines across countries

	Public sector		Private retail pharmacies		Private hospitals/clinics	
	Median days' wages (range)	N	Median days' wages (range)	N	Median days' wages (range)	N
Insulins (10 mL 100 IU/mL)						
Short-acting human	3.9 (0.3–6.8)	9	3.7 (1.2 to 20.2)	14	4.2 (0.7–21.7)	12
Intermediate-acting human	3.6 (1.6–4.8)	6	4.3 (1.3 to 30.4)	13	5.0 (0.5–21.7)	12
Mixed human	3.5 (0.5–6.5)	8	2.2 (1.2 to 7.5)	13	3.7 (1.3–22.1)	11
Rapid-acting analogue	6.3 (4.9–7.4)	4	6.6 (2.7 to 50.9)	13	6.8 (3.1–14.0)	6
Long-acting analogue	7.9 (4.5–17.3)	5	15.6 (4.6 to 94.2)	15	14.3 (4.5–43.1)	9
Mixed analogue	6.1 (2.8–8.8)	6	7.9 (3.2 to 43.5)	14	6.7 (3.3–14.0)	8
Comparator medicines
