The asymmetric unit of the title compound, C<sub>42</sub>H<sub>24</sub>, contains two almost identical molecules. The molecules have approximate D<sub>2</sub> symmetry. They show a largely twisted double bond, the molecular halves enclosing dihedral angles of 62.86 (4) and 61.22 (3)<sup>o</sup>. The crystal studied was twinned by non-merohedry.

## Structure description

Benzoannulated fulvenes attract chemists because of their electronic properties (Bergmann *et al.* 1953*a,b*), their intense colour, the question of aromaticity and the participation of radical character in their ground state (Kanawati *et al.*, 2012; Wentrup *et al.*, 2016). In the overcrowded alkene, steric strain prevents the molecule from being planar; a single line in the ESR spectrum (Franzen & Joschek, 1961) and a simulated torsion angle of 52° (based on diffraction data, Beck *et al.*, 1994) between the two pentacyclic halves give evidence for a significant contribution of a radical species. The unit cell is filled with 16 molecules, eight molecules of type A (Fig. 1) and eight of type B. The two independent molecules, A and B, are nearly identical. A packing diagram shows their mutual orientation in the unit cell (Fig. 2). Molecule A consists of two planes, A1, A2, connected *via* the central C1A–C22A bond. The maximum deviation of carbon atoms from the mean planes are –0.254 (4) Å for C2 (A1) and 0.162 (4) Å for C39 (A2). The dihedral angle between these planes is 62.86 (4)° and the length of the central C1A–C22A bond is 1.408 (5) Å. The values for molecule B are very similar: maximum deviations from the mean planes are –0.293 (4) Å for C5 (B1) and 0.170 (4) Å for C26 (B2). The dihedral angle amounts to 61.22 (3)° and the length of the central C1B–C22B bond is 1.395 (5) Å. Whereas the length of the twisted and elongated bond connecting the two halves of molecules A and B [1.408 (5) and 1.395 (5) Å, respectively] correlates very well with the calculated value of 1.408 Å, the calculated torsion angle of 52° is about 10° too small. The solid material gives a very weak single ESR signal.

### Synthesis and crystallization

The dark-green title compound was prepared according to literature procedures (Magidson, 1925; Detert & Schollmeyer, 2019). Single crystals of the title compound were obtained by slow evaporation of a saturated solution in chloroform-*d*<sub>1</sub>.

### Refinement

Crystal data, data collection and structure refinement details are summarized in Table 1. The crystal was twinned by non-merohedry. The fractional contribution of the minor twin component refined to 0.4648 (15).

### Acknowledgements

The authors are grateful to Professor D. Lenoir for invaluable discussions and to Professor M. Baumgarten for measuring the ESR spectrum.

#### Special details

**Geometry.** All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

**Refinement.** Hydrogen atoms attached to carbons were placed at calculated positions and were refined in the riding-model approximation with C–H = 0.95 Å, and with  $U_{\text{iso}}(\text{H}) = 1.2 U_{\text{eq}}(\text{C})$ . Refined as a two-component twin.
