Background: Obesity was a recognized risk factor for the development and progression of hepatocellular carcinoma (HCC). However, the effects and mechanisms by which obesity promotes HCC metastasis remain poorly understood.

Materials and methods: We cultured adipocyte induced by preadipocyte 3T3-L1 in vitro and established HCC metastasis model in obesity mouse in vivo to mimic the tumor microenvironment in obese status. The mechanisms underlying obesity-associated miR-27a upregulation promoting HCC metastasis were investigated.

Results: In this study, we showed that miR-27a was upregulated in adipocytes, obese mouse model and clinical samples, and the increased miR-27a level promoted migration and invasion in HCC cells, increased the number of metastasis nodes in obese mouse model, and was associated with poor clinical outcomes. Overexpressed secreted frizzled-related protein 1 in HCC cells and tissues significantly alleviated the upregulation of β -catenin and matrix metalloproteinase-7 induced by high level of miR-27a. Meanwhile, the E-cadherin expression decreased and Vimentin expression increased, linking with high level of β -catenin in high-fat group.

Conclusion: Taken together, our results have elucidated the critical role of extracellular miR-27a as a pro-metastatic factor in HCC and revealed that obesity-associated miR-27a upregulation promoted HCC metastasis through activated Wnt/ β -catenin signaling by suppressing secreted frizzled-related protein 1. Our findings shed light on the novel mechanism underlying HCC metastasis and provided miR-27a as a promising target for obese liver cancer therapy.

Keywords: obesity, miR-27a, SFRP1, β -catenin, hepatocellular carcinoma

Introduction

Obesity has become an important public health challenge in recent decades all over the world. It is reported that there were more than 1.9 billion overweight adults in 2014, of whom over 600 million were obese.¹ Moreover, obesity is recognized as a common risk factor for many chronic diseases, including type 2 diabetes, cardiovascular diseases, and cancers.² Numerous experimental studies and meta-analyses have shown that obesity was directly associated with the risk of cancers, such as breast, endometrium, kidney, thyroid, esophagus, gastric cardia, pancreas, gallbladder, colon, liver, and so on.³ In addition, obesity can also lead to poor prognosis and result in higher cancer-related mortality.⁴⁻⁶

Hepatocellular carcinoma (HCC) is the fifth most common malignancy and the third leading cause of cancer-related deaths in the world.⁷ In recent years, although the treatment of HCC has improved, the prognosis of patients and the overall survival rate remain rather disappointing.⁸ Metastasis and local recurrence are responsible for

the majority of HCC-related deaths,⁹ which have become the major obstacle in the treatment of patients with liver cancer.¹⁰ Most cases of HCC (70%–90%) development are associated with chronic liver disease backgrounds, such as the infection with hepatitis B virus or hepatitis C virus and alcoholic liver disease.¹¹ While a substantial number of cases cannot be explained by these etiologies, HCC is increasingly being diagnosed among obese individuals.¹² Many studies have indicated that the link between obesity and increased incidence of HCC has been globally verified.^{13–15} The molecular mechanisms underlying the higher risk of HCC in obesity are currently attributed to adipose tissue remodeling with pro-inflammatory adipokine secretion, cell growth stimulation by insulin and insulin-like growth factors, and liver lipotoxicity due to ectopic lipid accumulation. Moreover, diet, gut microbiome, and genetic factors are also involved.^{16–18} Studies mostly focused on obesity-related hepatocarcinogenesis up to now; however, the correlation between obesity and metastasis of HCC, as well as the molecular mechanisms are unknown.

In our previous work, we addressed a hypothesis that miR-27a, which is characteristically overexpressed during obesity, altered HCC microenvironment and promoted tumor progression.^{19,20} Herein, we first demonstrated that adipose tissue-secreted miR-27a is upregulated in obese liver cancer tissues. Next, we established the co-culture system of 3T3-L1 cells transfected with a miR-27a overexpress plasmid with HepG2 cells *in vitro* and confirmed that miR-27a promoted HCC cell migration and invasion under obesity condition. Finally, we established an animal model to investigate the effect of obesity-related upregulation of miR-27a on metastasis of HCC and revealed the mechanism in our current study. We found that miR-27a promoted migration and invasion of HCC cells and activated Wnt/ β -catenin signaling by suppressing secreted frizzled-related protein 1 (SFRP1) *in vitro* and *in vivo*. In addition, epithelial–mesenchymal transition (EMT) may induce obesity-related metastasis of HCC.

Materials and methods

Human tissue samples

Twenty-five frozen HCC samples were obtained from the tissue specimen bank of our hospital. The clinical information of these cases was collected, which were divided into the normal (n=15) and the obesity (n=10) group based on the body mass index (BMI).²¹ This work was approved by the Ethics Committee of Jilin University and written informed consent was obtained from all patients for this study.

Cell culture

The mouse embryo 3T3-L1 cell line, the HCC cell line HepG2, and the mouse hepatoma cell line Hepa1-6 were obtained from the American Type Culture Collection (Manassas, VA, USA). The cells were grown in DMEM (Gibco, Carlsbad, CA, USA) with high glucose content, supplemented with 10% fetal bovine serum (FBS) (Gibco), 100 units/mL penicillin, and 100 g/mL streptomycin. All the cells were incubated at 37°C in a humidified chamber containing 5% CO₂. The primary antibodies against SFRP1 (rabbit, Cat. no. ab4193, Abcam, Cambridge, UK), β -catenin (rabbit, Cat. no. ab32572, Abcam), matrix metalloproteinase-7 (MMP7) (rabbit, Cat. no. ab5706, Abcam), Vimentin (rabbit, Cat. no. ab92547, Abcam), E-cadherin (mouse, Cat. no. ab76055, Abcam), and β -actin (mouse, Cat. no. sc-47778, Santa Cruz Biotechnology, Dallas, TX, USA) were diluted according to their instructions.

Differentiation of 3T3-L1 cell lines

To acquire adipocyte simulating obese model in cells, 3T3-L1 preadipocytes were seeded in 24-well plates at a density of 1×10^5 per well and incubated when they reached about 80% confluence, and then the cells were differentiated by DMEM containing 10% FBS and cocktail (MDI, 0.5 mM isobutyl-1-methylxanthine, 1 μ M dexamethasone, 10 μ g/mL insulin) for 3 days. The medium was replaced by DMEM with 10% FBS and 10 μ g/mL insulin, and the cells were incubated for another 3 days. The medium was then replaced with DMEM containing 10% FBS, and the cells continued to be cultured, waiting for a completion of differentiation. Adipocytes were only used for experiment when at least 95% of the cells showed an adipocyte phenotype with accumulation of lipid droplets.

Transient transfection of plasmids

The miR-27a expression plasmid, miR-27a inhibitor plasmid, SFRP1 overexpression plasmid, and the control vector were constructed by Shanghai GenePharma (Shanghai, China). The 3T3-L1 cells in exponential phase of growth were plated in plates at 2×10^5 cells/mL and cultured for 16 h, then transfected with the miR-27a expression plasmid, miR-27a inhibitor plasmid, and the control vector using Lipofectamine 2000 (Invitrogen, Carlsbad, CA, USA) according to the manufacturer's protocol. Successful and stable transfection was ensured by flow cytometry (Figure S1). The efficiency of transfection was examined by quantitative reverse transcription polymerase chain reaction (qRT-PCR). HepG2 cells transfected with the SFRP1 plasmid and the control vector in

the same way, and the efficiency of transfection was detected by Western blot analysis.

qRT-PCR analysis

Total RNA was isolated from cells, tissues, serums and culture media with TRIzol reagent (Invitrogen). RNA was reverse transcribed into cDNA with TransScript First-Strand cDNA synthesis supermix (Invitrogen), following the manufacturer's instructions. qRT-PCR was performed using a FastStart Universal STBR Green Master (Rox) from Roche (Basel, Switzerland). Primers of miR-27a and U6 were obtained from Ribobio (Guangzhou, China). The expression of miR-27a was normalized with U6 using the $2^{-\Delta Ct}$ method. The miRNA expression levels were defined based on the threshold cycle (Ct), and the relative expression levels were calculated as $2^{-(Ct \text{ of miR-27a} - [Ct \text{ of U6}])}$.

Cell migration and invasion assays

The transwell 24-well Boyden chamber (Corning, Corning, NY, USA) with 8.0 μm pore size poly-carbonate membrane was used for the migration and invasion assay according to the manufacturer's protocol. For migration assay, 3T3-L1 cells were trypsinized and seeded in the lower chamber at a density of 1×10^5 cells/well. After cell differentiation, the medium was replaced with 600 μL of complete medium while 1×10^5 HepG2 cells were seeded in the upper chamber in 100 μL of serum-free medium and the migration during 12 h toward the lower chamber. Cells remaining at the upper surface of the membrane were removed with cotton swabs and cells on the lower surface of the membrane were fixed with 4% paraformaldehyde, stained with crystal violet solution and counted in 5 randomly chosen high-power fields (100 magnification). Cell invasion assay was carried out similarly, except that 100 μL of 1:8 DMEM-diluted Matrigel (Becton Dickinson, Franklin Lakes, NJ, USA) was added to each well at 37°C for 6 h before cells were seeded onto the membrane, followed by incubation for 12 h.

Western blot analysis

The total proteins of cells and tissues were lysed in PIPA lysis buffer containing 10 mM Tris-HCl, 0.25 M sucrose, 10 mM NaCl, 1 mM ethylenediaminetetraacetic acid, 1% sodium dodecyl sulfate (SDS), and protease inhibitor cocktail (Roche), pH 7.5. The lysates were centrifuged at 12,000 g for 15 min at 4°C and the supernatant obtained was labeled as total protein extract. The protein concentration was determined by BCA protein assay kit (Beyotime Institute of Biotechnology,

Shanghai, China). Equal quantities of protein (20 μg) were loaded onto 12% SDS polyacrylamide gel electrophoresis (SDS-PAGE) gels. The electrophoresis was carried out first at 80 V for 20 min and followed by 160 V for 60–85 min. The separated proteins were transferred to polyvinylidene fluoride membranes (Bio-Rad Laboratories, Hercules, CA, USA). The membranes were blocked with 5% non-fat milk in Tris-buffered saline containing 0.05% Tween-20 for ~2 h at room temperature and then were probed with primary antibodies against SFRP1 (1:250 dilution), β -catenin (1:5,000 dilution), MMP7 (1:1,000 dilution), Vimentin (1:1,000 dilution), E-cadherin (1:1,000 dilution), and β -actin (1:1,000 dilution) overnight at 4°C. The membranes were then washed and incubated with the horseradish peroxidase (HRP)-conjugated goat anti-rabbit secondary antibody (1:5,000 dilution, Cat. no. SA00001-1; ProteinTech Group, Rosemont, IL, USA) or HRP-conjugated goat anti-mouse secondary antibody (1:5,000 dilution, Cat. no. SA00001-2; ProteinTech Group) at room temperature for 1 h. Bands were visualized by an ECL Western blotting detection system (Tanon 4200, Shanghai, China) and analyzed by Quantity-one software (Bio-Rad).

Establishment of obesity mouse model

Male C57BL/6J mice (18–20 g, 6 weeks) were purchased from the Animal Research Center (Beijing, China) and kept in environment-controlled specific-pathogen-free room (20°C \pm 2°C, humidity of 40%–60%, 12-h light/dark cycle) following Chinese government guidelines. All mice were given free access to food and water throughout the study. All animal experimental protocols were approved by the Institutional Animal Care and Use Committee of Jilin University. The experimental manipulation of mice was conducted in accordance with the National Institute of Health Guide for the Care and Use of Laboratory Animals and the approval of the Scientific Investigation Board of Science and Technology of Jilin Province (Changchun, China).

Mice were randomly divided into 2 groups and fed either a control diet containing 10% kcal fat (D12450B, Research Diets, New Brunswick, NJ, USA) or high-fat (HF) diet containing 60% kcal fat (D12492i, Research Diets). During the experimental period, their body weights were measured twice per week. After 10 weeks, 6 mice were selected from each group randomly and sacrificed. Serum was collected after centrifuging the whole blood at 3,000 rpm for 15 min. Livers, lungs, and epididymal adipose tissues were resected and weighed. Half part of the organs was fixed in a 4% paraformaldehyde solution overnight and processed for

paraffin sections followed by H&E stain and immunohistochemistry (IHC) stain, and the other half was stored in -80°C immediately for qRT-PCR and Western blot analysis.

Establishment of HCC metastasis mouse model

After the obesity model was established, mice of both groups received the surgery for orthotopic transplantation. Mice were anesthetized with a mixture consisting of ketamine at 100 mg/kg (Heng Rui, China) and xylazine at 25 mg/kg (Sigma-Aldrich, St Louis, MO, USA) via intraperitoneal injection and a small subxiphoid midline incision was made to expose the left lateral lobe of the liver. Hepa1-6 cells (5×10^5 in 50 μL PBS medium with 50% Matrigel) then were injected into the left lateral lobe. Following the injection, the liver surface at the site of needle tract should be covered with a drop of matrigel (Becton Dickinson) to avoid any possible early peritoneal seeding of the HCC cells. After 20 days, the mice were sacrificed. Lungs, livers, and epididymal adipose tissues were dissected and photographed. Serum was collected after centrifuging the whole blood at 3,000 rpm for 15 min. At necropsy, the pulmonary metastasis colonies on the surface of the lungs were counted. Then, a half part of the organs was fixed in a 4% paraformaldehyde solution overnight and processed for paraffin sections followed by H&E and IHC stains, and the other half was stored in -80°C immediately for qRT-PCR and Western blot analysis.

IHC

The tissue sections were dewaxed in xylene and dehydrated in alcohol. Antigen retrieval was done by incubating the slides in citric acid buffer for 10 min. After blocking with 3% hydrogen peroxide for 15 min and 5% bovine serum albumin, the slides were incubated overnight at 4°C with the antibody against SFRP1 (1:800 dilution). After rinsing with PBS, the sections were incubated with a HRP anti-rabbit IgG antibody (Cowin Bioscience, Beijing, China) for 30 min at room temperature. The expression was visualized by diaminobenzidine tetrahydrochloride solution (DAB, Cowin Bioscience) staining. The sections were finally counterstained with hematoxylin for 5 min. All slides were observed under a light microscope at a magnification of 100 \times and 400 \times .

Statistical analysis

Statistical analysis was performed using Graphpad prism software 6.0 (GraphPad Software, La Jolla, CA, USA). All data were expressed as mean \pm SD. Statistical significance ($p < 0.05$) was evaluated using Student's *t*-test when

only 2 groups were compared. If more than 2 groups were compared, evaluation of significance was performed using one-way analysis of variance, followed by Bonferroni's post hoc test. Kaplan–Meier survival method was performed to assess the prognostic significance of obesity and the difference of resulting curves was analyzed by the log-rank test. Spearman correlation coefficients were performed to determine the association between SFRP1 and miR-27a expression. A value with $p < 0.05$ was considered as statistically significant.

Results

miR-27a promotes migration and invasion of HCC cells in vitro

Our previous study found that miR-27a promoted HCC cell proliferation through the downregulation of FOXO1.¹⁹ To determine whether miR-27a from adipose tissue influences the migration and invasion of the HCC, we established a co-culture transwell chamber system of differentiated adipocyte 3T3-L1 cells with HepG2 cells. As shown in Figure 1, qRT-PCR analysis confirmed that 3T3-L1 cells could secrete miR-27a into culture media and increase the miR-27a level of HepG2 cells. To enhance or eliminate the expression of miR-27a, we transfected miR-27a expression plasmids and miR-27a inhibitor plasmids into 3T3-L1 cells and obtained the expected results in 3T3-L1 adipocytes (lower chamber), culture medium, and HepG2 cells (up chamber) (Figure 1). Transwell assays showed that more HepG2 cells migrated or invaded into the lower chamber when they were co-cultured with 3T3-L1 cells (Figure 2). Moreover, overexpression of miR-27a in 3T3-L1 cells clearly enhanced the migration and invasion of HepG2 cells, whereas the opposite result was observed in the miR-27a inhibitor group.

miR-27a activates Wnt/ β -catenin signaling by suppressing SFRP1 in vitro

The Wnt/ β -catenin signaling pathway is involved in HCC cell migration and invasion.²² Several studies have shown that SFRP1, a member of Wnt inhibitors, is negatively regulated by miR-27a.^{23,24} Western blot showed that overexpression of miR-27a in 3T3-L1 cells clearly suppressed SFRP1 in HepG2 cells and that inhibition of miR-27a did the opposite (Figure 3C), which was consistent with previous reports. To determine whether SFRP1 participates in secretory miR-27a from adipocytes-driven migration and invasion of HCC cells, we overexpressed SFRP1 in HepG2 cells. It was shown that SFRP1 protein level in HepG2 cells

increased three-fold after transfection (Figure 3A). But the migration and invasion of HepG2 cells co-cultured with 3T3-L1 in a miR-27a-enriched environment were substantially attenuated upon SFRP1 overexpression (Figure 3B). To further confirm the relationship between SFRP1 and the Wnt/ β -catenin signaling pathway in metastasis of HCC cells communication with adipocytes through secretory miR-27a, the related important protein levels were detected by western blot, including SFRP1, β -catenin, and its downstream MMP7. Overexpression of miR-27a in 3T3-L1 cells induced β -catenin and its downstream MMP7 expression level, and inhibition of miR-27a increased their expression (Figure 3C). Meanwhile, the induction of β -catenin and MMP7 by the secretory miR-27a from 3T3-L1 cells were reversed by overexpression of SFRP1 (Figure 3C), which confirmed the efficacy of SFRP1-inhibiting Wnt/ β -catenin signaling pathway. In addition, the expression of SFRP1 was increased

through inhibiting the expression of miR-27a. Moreover, the expression of β -catenin and MMP-7 was also changed compared with control group. Taken together, our result suggested that secretory miR-27a could promote the metastasis of HCC cells through the degradation of SFRP1, of which could further activate Wnt/ β -catenin signaling pathway.

miR-27a was upregulated in metastasis of HCC in vivo

To investigate the profile of miR-27a in an obese individual in vivo, we established the HF diet-induced obese model of C57BJ mice. Mouse model of HCC metastasis was established by orthotopic syngeneic tumor transplantation in obese C57BJ mice mentioned previously. Twenty days after tumor transplantation, more visible metastasis nodes were observed on lung tissue compared with that of the control group (16.33 ± 3.091 vs 34.17 ± 6.149 ; Figure 4A).

Figure 2 Secretory miR-27a promotes migration and invasion of HCC cells in vitro.

Notes: (A) Transwell assays were employed to evaluate the migratory and invasive ability of HepG2 cells under co-culture alone, or with 3T3-L1, miR-27a overexpressing 3T3-L1, miR-27a inhibitor 3T3-L1 and 3T3-L1 transfected with empty vector co-culture. The original magnification is $\times 40$, with a scale of 1:200 μm . (B, C) Quantitative results for the migratory and invasive ability of each group are shown as the number of cells. Each bar represents the mean \pm SD of 3 replicates. * $p < 0.05$ and ** $p < 0.01$.

Abbreviation: HCC, hepatocellular carcinoma.

The miR-27a levels of adipose tissue, liver, and serum were also significantly higher in the HF group than the control group (Figure 4B). To study the molecular mechanisms of the HCC metastasis under obesity condition, the protein expression of SFRP1, β -catenin, and MMP7 were detected in liver tumor tissue. Western blot and IHC showed that SFRP1 expression was suppressed significantly compared with the control group (Figure 5A and B). Moreover, the protein levels of β -catenin and MMP7 were increased in HF group, which indicated the activation of Wnt/ β -catenin pathway in HCC may contribute distal metastasis. EMT-associated proteins Vimentin and E-cadherin were also detected to further elucidate the mechanisms of the HCC metastasis under obesity condition. Upregulation of Vimentin and downregulation of E-cadherin in protein expressions shown in HF group were compared with that of control group, which suggested that EMT was involved in HCC metastasis under obesity condition (Figure 5B). Collectively, these data demonstrated that

miR-27a was upregulated in metastasis of HCC in vivo and suppressed SFRP1. Activation of the Wnt/ β -catenin pathway, as well as induction of EMT may participate in HCC metastasis under obesity condition.

SFRP1 expression is negatively associated with the expression of miR-27a in human HCC tissues

To analyze miR-27a–SFRP1 interactions in human HCC, we detected the expression of miR-27a using qRT-PCR and SFRP1 using Western blot in 25 frozen human HCC tissues (Figure 6A). The results showed that miR-27a was upregulated and that SFRP1 was downregulated in the obesity group, compared with the normal group. The inverse correlation between miR-27a and SFRP1 protein levels in human HCC were further illustrated using Spearman's correlation scatter plots (Figure 6B). Besides, we also detected the relationship between obesity and clinical outcome.

Follow-up data showed that the overall survival of HCC patients with high BMI were shorter than those with normal BMI (Figure 6C).

Discussion

Many studies revealed that obesity was one of the risk factors for various cancers, including HCC.³ Obesity not only increased the incidence of HCC but also resulted in impaired drug treatment efficacy and poor prognosis of HCC.^{16,18}

However, the mechanism underlying obesity promoting the development and progression of liver cancer is unclear. Recently, the tumor microenvironment in association with endocrine modifications provided by the unique adipose tissue, promoting the initiation, proliferation, invasion, and metastatic progression of tumor, has been extensively discussed. Besides adipokine and cytokine (leptin, adiponectin, interleukin [IL]-6, tumor necrosis factor alpha, and IL-1 β), adipogenic microRNA became a new class of regulatory

molecules that influence carcinoma initiation and metastatic progression.^{25,26} miR-27a has been linked with cancer progression, such as renal carcinoma, colon carcinoma, gastric adenocarcinoma, pancreatic cancer and lung cancer.^{27–31} Our

previous work showed that miR-27a was overexpressed in obese HCC patients than patients with normal body weight in both serums and tissues.¹⁹ We repeated the work with 25 human samples and found that patients with obesity had high

levels of miR-27a and poor clinical outcomes. In the present study, we cultured differentiated 3T3-L1 cells with HepG2 cells in vitro and set up HCC metastasis model in obesity mouse in vivo to mimic the tumor microenvironment in obese status. MiR-27a expression is consistently upregulated in culture medium of 3T3-L1 with transfection of miR-27a plasmid, as well as adipose tissue, liver, and serum in HCC metastasis model based on obesity. We found that secretory miR-27a promotes migration and invasion of HCC cells in vitro, and we also observed more visible metastasis nodes on lung tissue from orthotopic liver transplantation tumor in obese. Our results confirmed that miR-27a plays a critical role on HCC metastasis, particularly in obesity HCC patients.

Numerous signaling pathways are deregulated during the initiation and progression of HCC, including Wnt/ β -catenin, JAK/STAT, PI3K/Akt/mTOR, Ras/Raf/MEK/ERK, as well as Hedgehog pathways.³² It is reported that miR-27a promoted gastric cancer cell metastasis by activating Wnt/ β -catenin signaling pathway³³ and miR-27a regulated Wnt/ β -catenin signaling through directly targeting SFRP1 in glioma.²⁴ SFRP1, which is located at chromosome 8p12-11.1, is a 35-kDa glycoprotein that acts as a member of negative regulators of Wnt.³⁴ After it is released into the extracellular space, SFRP1 can block the activation of Wnt signaling pathway by competitively binding to the frizzled receptors.³⁵ The epigenetic silencing of SFRP1 was observed in HCC and loss of SFRP1 expression is associated with poor prognosis.^{34,36,37} These studies provide a clue to investigate whether miR-27a promote HCC metastasis by targeting SFRP1, which is further involved in Wnt/ β -catenin pathway. To determine whether the miR-27a regulates HCC progression via SFRP1, we overexpressed SFRP1 in HepG2 cells, co-culturing with adipocyte 3T3-L1 transfected miR-27a plasmid. It was seen that the expressing of SFRP1 prevented the migration and invasion of HCC in vitro. Meanwhile, the obesity mouse model revealed upregulation of miR-27a accompanied by the loss of SFRP1 expression in HF group. The decreased SFRP1 expression was closely related with the elevated number of lung metastatic nodes in tumor metastasis model of obese mice. We further verified the inverse correlation between miR-27a and SFRP1 protein levels in human HCC tissues. In addition, the loss of SFRP1 resulted in Wnt proteins binding to the frizzled receptor, which led to β -catenin accumulation in the cytoplasm by escaping from degradation and translocated into the nucleus, where it interacted with its downstream transcription factors lymphoid-enhancing factor/T-cell factor.²² Our results showed that overexpressed miR-27a upregulated the protein

level of β -catenin and MMP7; this effect was cut down by overexpression of SFRP1 in HCC cells. This tendency reappeared in tumor tissues of the HF group, compared with that of control group. Our study pointed that SFRP1 may act as a direct target gene of miR-27a and can negatively modulate Wnt/ β -catenin pathway in HCC metastasis progression.

The EMT is a crucial developmental event in embryonic tissue formation and regeneration and is also hijacked by carcinomas during solid tumor progression.³⁸ It is characterized by loss of the epithelial homotypic adhesion molecule E-cadherin and the gain of mesenchymal markers, such as Vimentin, which promotes tumor invasion and metastasis.³⁹ EMT is accompanied by the activation of Wnt/ β -catenin pathway. β -catenin is an essential molecule both in cadherin-mediated cell adhesion and canonical Wnt signaling. Our results showed that the increased expression of Vimentin and the decreased E-cadherin expression was linked with high level of β -catenin in HF group, and the opposite tendency was observed in the control group. This suggested a possible link between obesity and EMT through Wnt/ β -catenin signaling, but the mechanism needs to be further investigated.

Conclusion

Our study suggested that obesity-associated miR-27a may promote HCC metastasis by suppressing SFRP1, subsequently activating Wnt/ β -catenin signaling, and to some extent, involvement of EMT. Our findings shed light on the mechanism the HCC metastasis in obese individuals and provided miR-27a as a promising target for liver cancer therapy in obese patients.

Acknowledgments

This work is sponsored by Natural Science Foundation of Jilin Province (20160101203JC), the Education Department of Jilin Province grant (2016, No 452), the Undergraduate Innovative Program of Jilin University (2016B79690, 2015741102), and Norman Bethune Program of Jilin University (2015224). Most of the experiments were carried out at the Nanomedicine Engineering Laboratory of Jilin Province.

Supplementary material

Figure S1 FACS analysis of transfection efficacy.

Notes: (A) 3T3-L1 cells transfected with the empty vectors, the miR-27a inhibitor plasmids, and the miR-27a expression plasmids. (B) HepG2 cells transfected with the empty vectors and the miR-27a expression plasmids. Each transfection experiment was performed 3 times.

Abbreviations: FACS, fluorescence activated cell sorting; SFRP1, secreted frizzled-related protein 1.
