Introduction: Programmed cell death 1 ligand 1 (PD-L1) can be upregulated in cancer cells via interferon gamma (IFN γ) in the tumor microenvironment. IFN γ /PD-L1 signaling is associated with the response to immune checkpoint blockade in melanoma patients. Our previous investigation indicated that the microsatellite instability-high (MSI-H) cell line might exhibit selective hyperresponsiveness to IFN γ treatment, which contributes to increased PD-L1 expression and may be a mechanism of response to anti-PD-1 therapy in colorectal cancer.

Methods: The present study evaluated the expression of PD-L1 in a set of MSI and microsatellite stability (MSS) cell lines with IFN γ treatment. The differential signaling molecules associated with signal transducer and activator of transcription (STAT) contributing to hyperresponsiveness to IFN γ exposure were also investigated. Furthermore, we established a coculture assay containing CT26 cells with higher expression of PD-L1 and peripheral blood mononuclear cells (PBMCs) in vitro. Changes in cancer cell viability as well as apoptosis status in response to anti-PD-1 therapy were demonstrated. We further observed changes in the percentage of CD4⁺ and CD8⁺ lymphocytes after PD-1 immunotherapy in the coculture assay. Finally, the average extent of inflammation and adaptive immunity factors in the assay was also investigated.

Results: This in vitro study revealed that the MSI cell line might exhibit hyperresponsiveness to IFN γ exposure, and IFN γ induced upregulation of PD-L1 mainly through increased STAT1 and decreased STAT3 signaling. IFN γ /PD-L1 signaling participated in the response to anti-PD-1 therapy mainly through the CTL profile.

Discussion: Our findings reinforce previous knowledge of the fact that the response to immune checkpoint blockade occurs mainly in patients with a preexisting intratumoral IFN γ /PD-L1 signal, thus suggesting potential therapeutic strategies to enhance responsiveness to PD-1 blockade immunotherapy in most patients with colorectal cancer.

Keywords: IFN γ , PD-L1, CTL, colorectal cancer

Introduction

Colorectal cancer (CRC) is the third most common cancer in the world.¹ With the aging of the population and changes in lifestyle, the incidence of colorectal cancer in China has gradually increased.² Tumor surgery and chemotherapy are the main treatments for patients with colorectal cancer.³ However, innumerable side effects induced by chemotherapy-based treatment cannot be ignored. Currently, growing numbers of targeted drugs are also available to treat metastatic/progressed colorectal cancer,⁴ including

epidermal growth factor receptor (EGFR)-targeted therapy, vascular endothelial growth factor receptor (VEGFR)-targeted therapy and immune checkpoint (IC) inhibitor immunotherapy. These monoclonal antibodies targeting IC have drawn much attention and displayed promising therapeutic effects in the field of solid tumor therapy.⁵⁻⁷

Programmed cell death 1 ligand 1 (PD-L1) is a critical IC molecule. After binding to its receptor, programmed death (PD-1), PD-L1 delivers a suppressive signal to T cells and an anti-apoptotic signal to tumor cells, leading to T cell dysfunction and tumor survival. Blockade of PD-1/PD-L1 results in the preferential activation of T cells with specificity for cancer and restoration of antitumor activity.⁸ PD-1 inhibitors have become the second-line or third-line treatment recommended by the National Comprehensive Cancer Network guidelines for patients with advanced colorectal cancer who display mismatch repair deficiency (dMMR)/microsatellite instability-high (MSI-H). However, only 5% to 15% of colorectal cancers display the MSI-H genotype,⁹ which leaves the majority of patients with CRC of the microsatellite stability (MSS) genotype, without immunotherapy options.^{10,11} If the mechanism for the heterogeneity of the responses to anti-PD-1 therapy is elucidated, it could guide clinicians to identify other potentially targetable factors and determine therapeutic strategies to enhance responsiveness to PD-1 blockade immunotherapy in most CRC patients.

PD-L1 may be induced by oncogenic signals or can be upregulated via interferon gamma (IFN γ). In the tumor microenvironment, tumor-infiltrated lymphocytes produce IFN γ and drive PD-L1 expression in cancer cells; however, the extent of PD-L1 induction is not uniform.¹²⁻¹⁴ IFN γ /PD-L1 signaling is an important marker for predicting the response to immune checkpoint blockade in NSCLC and melanoma patients.¹⁵ Defects in the IFN γ signaling pathway are one of the main mechanisms of resistance to anti-PD-1 immunotherapy.^{16,17} It is currently accepted that differential expression of the PD-L1 protein exists between MSI-H and MSS genotypes for CRC patients.¹⁸⁻²⁰ There seems to be some evidence to indicate that PD-L1 expression shows more signals of antitumor activity during PD-1 blockade therapy.^{21,22} Our previous investigation²³ indicated that an MSI cell line might exhibit selective hyperresponsiveness to IFN γ treatment, which contributes to increased PD-L1 expression and may be a mechanism of the response to anti-PD-1 therapy in colorectal cancer. Furthermore, the differential molecular mechanisms associated with the signal transducer and activator of transcription (STAT) signaling

pathway contributing to the high PD-L1 expression induced by IFN γ exposure were not investigated in the MSI cell line, and the profiles of adaptive immunity factors for PD-L1 overexpression treated with PD-1 blockade, in general, remain to be determined.

Accordingly, the present study investigated partial differential signaling molecules associated with STATs contributing to hyperresponsiveness to IFN γ exposure in an MSI cell line. The profiles of adaptive immunity factors for PD-L1 overexpression treated with PD-1 blockade in a coculture assay *in vitro* were also observed. Our results provide novel insights into the mechanism by which anti-PD-1 therapy focuses on IFN γ /PD-L1 signaling, thus suggesting potential therapeutic strategies to enhance responsiveness to PD-1 blockade immunotherapy in most patients with CRC.

Materials and Methods

Cell Line Culture and IFN γ Treatment *in vitro*

Human colorectal cancer cell lines of the MSI genotype (HCT116, LOVO, HCT15) and MSS genotype (SW480, SW620, SW1116) were obtained from the Institute of Zoology, Chinese Academy of Sciences (Kunming, China), and mouse colorectal cancer CT26 cells were purchased from the Cell Bank of the Chinese Academy of Sciences (Shanghai, China). The PD-L1-overexpressing CT26 cell line was generated as previously described.²³ In brief, the cDNA sequence of the mouse PD-L1 was generated by PCR using 5'-CCGGAATTCGCCACCATGAGGATATTTGCTGGCATTATATTC-3' as the forward primer and 5'-CCGCTCGAGTTACGTCTCCTCGAATTGTGTATCA-3' as the reverse primer. Lentiviruses were produced by transient transfection of 293T cells using PGMLV-GTP-PD-L1 constructed plasmid. After transfection, virus samples were harvested and concentrated. Transduction of CT26 cells was performed by 6 h of exposure to dilutions of the viral supernatant in the presence of polybrene (5 μ g/mL). The above-mentioned cell lines were plated in 6-well plates at a density of 2×10^5 cells/well and cultured in the presence of IFN γ (100 IU/mL, PeproTech, USA).

Isolation and Activation of Peripheral Blood Mononuclear Cells

PBMCs were isolated out of blood from healthy donors, which was obtained from the blood transfusion center in Kunming, Yunnan. A total of 10 mL of EDTA-

anticoagulant peripheral blood was collected. The source of peripheral blood was mouse. Peripheral blood mononuclear cells (PBMCs) were isolated using Ficoll-Hypaque (Sigma, St. Louis, MO, USA) density gradient centrifugation from anticoagulant peripheral blood samples. PBMCs were activated by the addition of 1% PHA (Sigma, St. Louis, MO, USA) and IL-2 (2000 IU/mL, PeproTech, USA) to cultures.

Cancer Cells and PBMC Coculture Experiments

IFN γ pretreated cancer cells were seeded in a 96-well plate (5×10^4 per well) in complete RPMI and cocultured with activated PBMCs (1×10^5 per well). The PD-1 antibody was used at a final concentration of 10 μ g/mL to block the PD-1/PD-L1 interaction.

Cell Proliferation Viability Assay

Cell proliferation viability was measured using Cell Counting Kit-8 (CCK-8; Beyotime, China) according to the manufacturer's instructions. Cell viability (%) = $\frac{\text{OD}_{450}(\text{experiment}) - \text{OD}_{450}(\text{No-treatment control})}{\text{OD}_{450}(\text{Conditional control}) - \text{OD}_{450}(\text{No-treatment control})} \times 100\%$.

RT-qPCR

Total cell RNA was extracted using TRIzol reagent (Thermo, USA) and then reverse transcribed with the Revert First Strand cDNA Synthesis Kit (Thermo, USA) according to the manufacturer's instructions. Reverse-transcription quantitative polymerase chain reaction (RT-qPCR) was performed using ABI-7500 (Applied Biosystems, USA). The primer sequences are described as previously.²³

Western Blot

The cell lysates (80 μ g) were harvested, separated and then transferred onto PVDF membranes as previously described.²³ The membranes were blocked with 5% bovine serum albumin for 1 h at room temperature before the addition of 5 mL of primary antibody. The antibodies used in this study included anti-PD-L1 (1:500; Proteintech) and anti- β -actin (1:2000; Abmart). The membrane was then washed with PBS and incubated with rabbit anti-HRP-conjugated secondary antibody (1:2000; Abmart) for 1 h at room temperature. The bands were visualized using a chemiluminescence reagent (Millipore, USA).

Flow Cytometry

The following antibodies were used for FACS analysis: CD274-PE, CD4-FITC, and CD8-FITC (eBioscience). The carboxyfluorescein succinimidyl ester (CFSE) for the proliferation assays was purchased from eBioscience. Cell samples were harvested, washed and stained with 5 μ L of antibody for 30 min to avoid light exposure. Cells were washed, resuspended in 500 μ L of PBS and transferred to FACS tubes for analysis. Cells were analyzed using a Canto II (BD Biosciences) FACS machine.

TUNEL Assay

TUNEL staining was performed using an in situ cell death detection kit (Roche), and nuclei were stained with DAPI for 10 min. The number of TUNEL-positive cells (red color) and total number of cells (blue color) were captured with a fluorescence microscope (Olympus). The rate of cell apoptosis was measured by the number of red cells divided by the number of blue cells.

Statistical Analysis

All statistical analyses were performed using SPSS software version 21.0. Values are given as the mean \pm SDs, and the differences were assessed with 2-sided tests. Statistical significance was set at p values less than 0.05.

Results

IFN γ Induced a Higher Intensity of PD-L1 Expression in MSI Cell Lines

To investigate whether IFN γ responsiveness is related to MSI status, we evaluated the expression of PD-L1 in different cell lines induced by IFN γ via RT-qPCR, Western blot and FCM. The basic level of PD-L1 oncogenic expression in CRC cell lines was extremely low. Treatment with the same concentrations of IFN γ in MSI (HCT116, LOVO, HCT15) cell lines displayed a higher intensity of PD-L1 expression compared with MSS (SW480, SW620, SW1116) status (Figure 1).

Upregulation of PD-L1 by IFN γ in CRC Cell Lines Was Mainly Associated with STAT1 Activation, and STAT3 Signaling Molecules Might Contribute to Hyporesponsiveness to IFN γ in MSS Cell Lines in vitro

PD-L1 expression levels may be associated with intrinsic oncogenic changes and exogenous cytokine induction. We

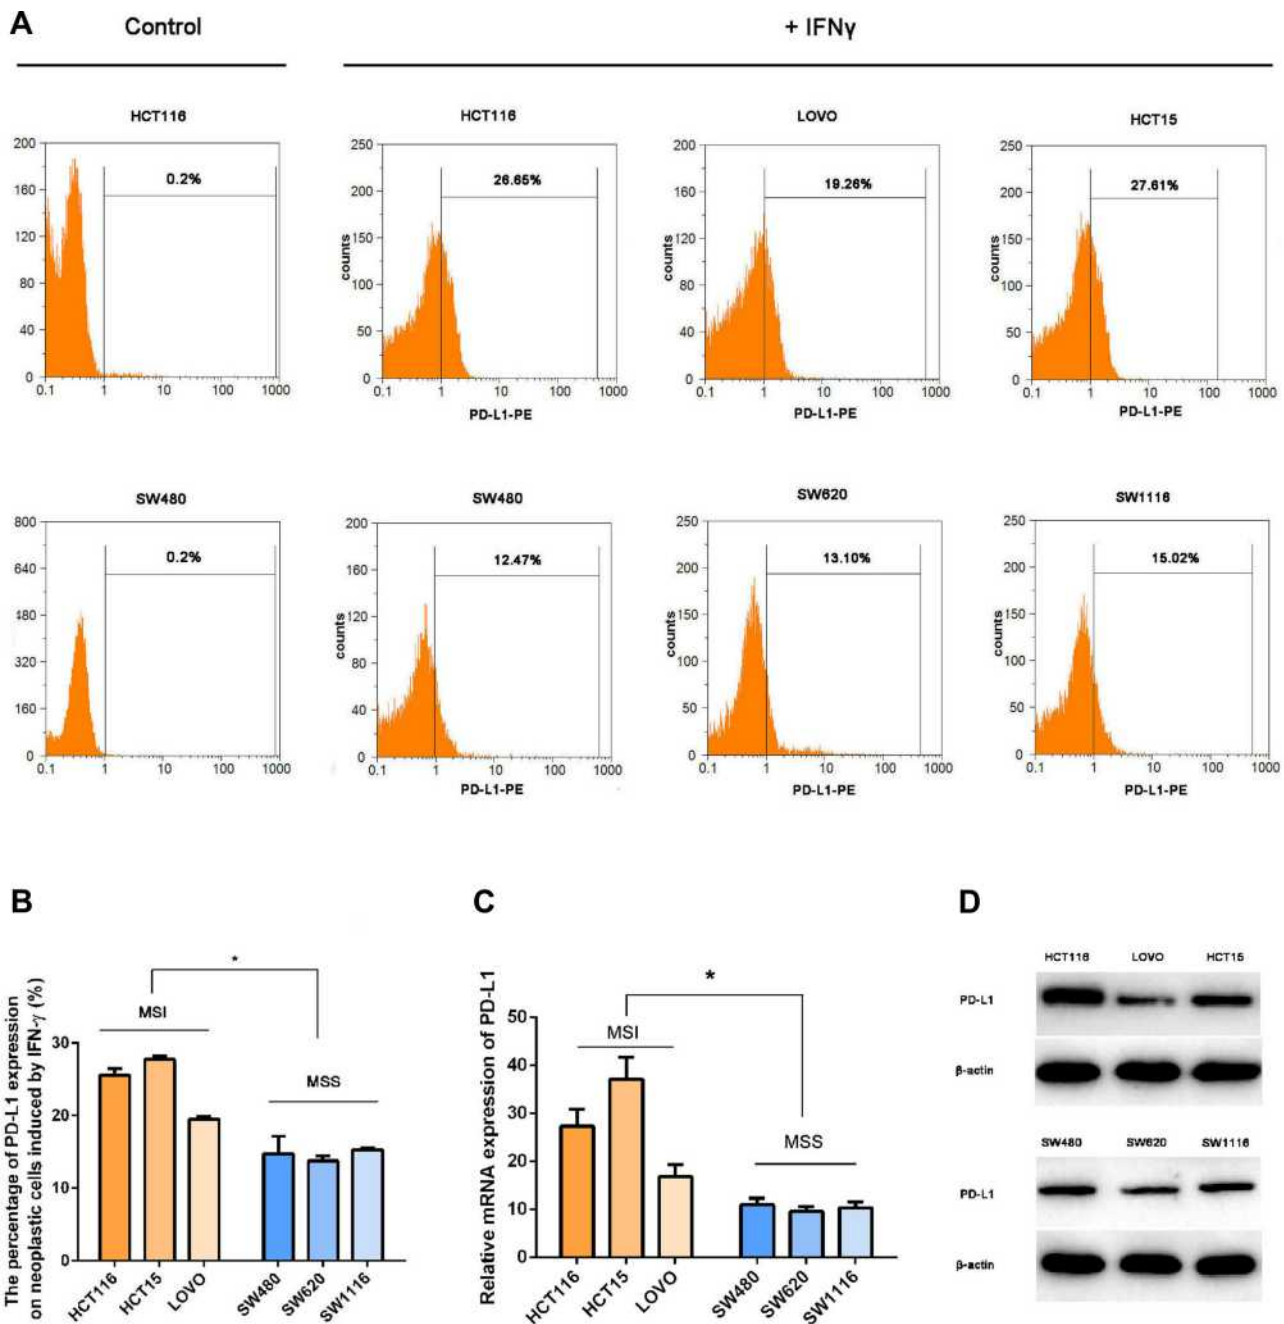

Figure 1 IFN γ induced a higher intensity of PD-L1 expression in MSI cell lines. To investigate whether IFN γ responsiveness is related to MSI status, we evaluated the expression of PD-L1 in different cell lines induced by IFN γ via RT-qPCR, Western blot and FCM. **(A and B)** PD-L1 expression was measured by flow cytometry in MSI (the upper line: HCT116, LOVO and HCT15) and MSS (the lower line: SW480, SW620 and SW1116) cell lines 12 h after treatment with 100 IU/mL IFN γ . DMSO was used as a negative control (* $P < 0.05$). **(C)** PD-L1 mRNA relative expression induced by IFN γ (100 IU/mL IFN γ for 12 h) was measured by qPCR (* $P < 0.05$). **(D)** Expression levels of the PD-L1 protein stimulated with 100 IU/mL IFN γ for 12 h.

observed that the basic level of PD-L1 oncogenic expression was extremely low, and IFN γ treatment induced high level of PD-L1 expression on neoplastic cells. Therefore, the expression induced by exogenous cytokines including IFN γ , was the main source of expression of PD-L1 on CRC cells. It is well known that PD-L1 expression stimulated by IFN γ was mainly controlled by the JAK-STAT, MAPK or PI3K-AKT

pathways. Therefore, we used the ERK1/2 inhibitor PD98059 (APEX-BIO, 50 μ mol/L), the AKT inhibitor wortmannin (APEX-BIO, 10 μ mol/L), or the STAT1 inhibitor fludara (APEX-BIO, 50 μ mol/L) to explore the signaling mechanism of PD-L1 expression induced by IFN γ (100 IU/mL) in HCT15 and SW620 cells. We evaluated the expression of PD-L1 in human colorectal cancer cells pretreated

with the ERK1/2 inhibitor PD98059 (APExBIO, 50 $\mu\text{mol/L}$), the AKT inhibitor wortmannin (APExBIO, 10 $\mu\text{mol/L}$), or the STAT1 inhibitor fludara (APExBIO, 50 $\mu\text{mol/L}$) by FCM. As shown in [Figure 2](#) in detail, PD-L1 expression was significantly downregulated in cell lines with differential MSI status when pretreated with fludara. With $\text{IFN}\gamma$ treatment, both MSI and MSS cell lines displayed significant phosphorylation of STAT1. Twelve hours later, the expression of STAT1 in both types of CRC cell lines significantly increased ([Figure 2D](#)). In contrast, there was no significant alteration in STAT3 expression after treatment with $\text{IFN}\gamma$ in HCT116 and HCT15 cell lines that displayed the MSI genotype. Interestingly, only MSS cell lines (SW480 and SW620) displayed obviously enhanced expression of STAT3 signaling molecules after $\text{IFN}\gamma$ exposure, which showed significantly increased phosphorylation and protein levels, respectively.

PD-L1 Expression Influenced Neoplastic Cells in Response to PD-1 Blockade

To investigate whether PD-L1 expression influences the response of PD-1 blockade immunotherapy *in vitro*, we performed two different profiles with higher PD-L1 expression in a coculture assay: PD-L1 transduced CT26 cell challenge (a higher extent of PD-L1 overexpression) and HCT116 enrolled (a lower degree of PD-L1 overexpression). As shown in [Figure 3](#), higher PD-L1 expression in the PD-L1-transduced CT26 coculture system exhibited obviously enhanced neoplastic cell viability as well as decreased cell apoptosis. No significant difference was observed between the HCT116 and SW480 groups. Furthermore, immunotherapy with PD-1 blockade significantly inhibited cancer cell viability in line with enhanced cell apoptotic rate, especially in the coculture group enrolled with PD-L1 transduced CT26 cells ([Figure 3C](#)). All neoplastic cells in different coculture systems treated with PD-1 blockade displayed similar cell viability and apoptotic rates.

PD-L1 Overexpression on CT26 Cells Influenced PD-L1 Expression on CD4^+ and CD8^+ Lymphocytes

As shown in [Figure 4A](#) and [B](#), we observed that PD-L1 protein was also extensively expressed on CD4^+ and CD8^+ lymphocytes in the coculture assay. To investigate whether the higher PD-L1 expression on CT26 cells influenced PD-L1 expression on cocultured mononuclear cells, we further

performed fluorescence double staining for PD-L1 and CD4/CD8 by FCM analysis. The results demonstrated that PD-L1 expression on CD8^+ lymphocytes was clearly decreased when challenged with PD-L1 overexpression. However, an inverse increase in PD-L1 expression on CD4^+ lymphocytes was observed in the same coculture system.

PD-1 Blockade Induced Changes in CD4^+ or CD8^+ Cell Percentage

To observe changes in CD4^+ or CD8^+ cell percentage, we performed FCM analysis for CD4 or CD8 expression in the two coculture system, as shown in [Figure 4A](#) and [C](#). PD-L1 overexpression on CT26 cells significantly decreased the percentage of CD8^+ lymphocytes in line with increased CD4^+ cells in the coculture assay. As expected, the percentage of CD8^+ lymphocytes clearly increased in response to PD-1 blockade. However, the expression of CD4^+ cells was interestingly decreased after anti-PD-1 immunotherapy ([Figure 4](#)). After PD-1 blockade, PD-L1 overexpression on CT26 cells did not influence the percentage of CD4^+ or CD8^+ cells in those coculture systems.

PD-L1 Overexpression Influenced Inflammation and Adaptive Immunity in Response to Anti-PD-1 Immunotherapy

To observe the effect of PD-L1 overexpression on the average extent of adaptive immunity in response to PD-1 blockade, we performed RT-qPCR for selected genes encoding signature T cell cytokines as well as core transcription factors for the major T helper subsets CD4, Th1/Tc1 (TBX21 and $\text{IFN}\gamma$), CTL (CD8A, GZMB, PRF1, IL21), Th17 (IL-17A, RORC, IL23A) and Treg (IL10, TGF- β 1). The sets of genes associated with proinflammatory factors (IL1B, IL16, IL6, IL12A, TNF- α) were also analyzed ([Figure 5](#)). In response to immunotherapy with PD-1 mAb, genes encoding CD8, Th17 and pro-inflammatory factors were prominently enhanced, especially in cells harvested from the PD-L1 overexpression assay. However, associated genes of CD4, Th1/Tc1 and Treg were mostly decreased when challenged with anti-PD-1 immunotherapy.

Discussion

In this study, we found that cancer cell lines with the MSI genotype displayed higher PD-L1 expression induced by $\text{IFN}\gamma$ *in vitro*. Here, $\text{IFN}\gamma$ responsiveness is related to MSI status, and this result is also consistent with most clinical

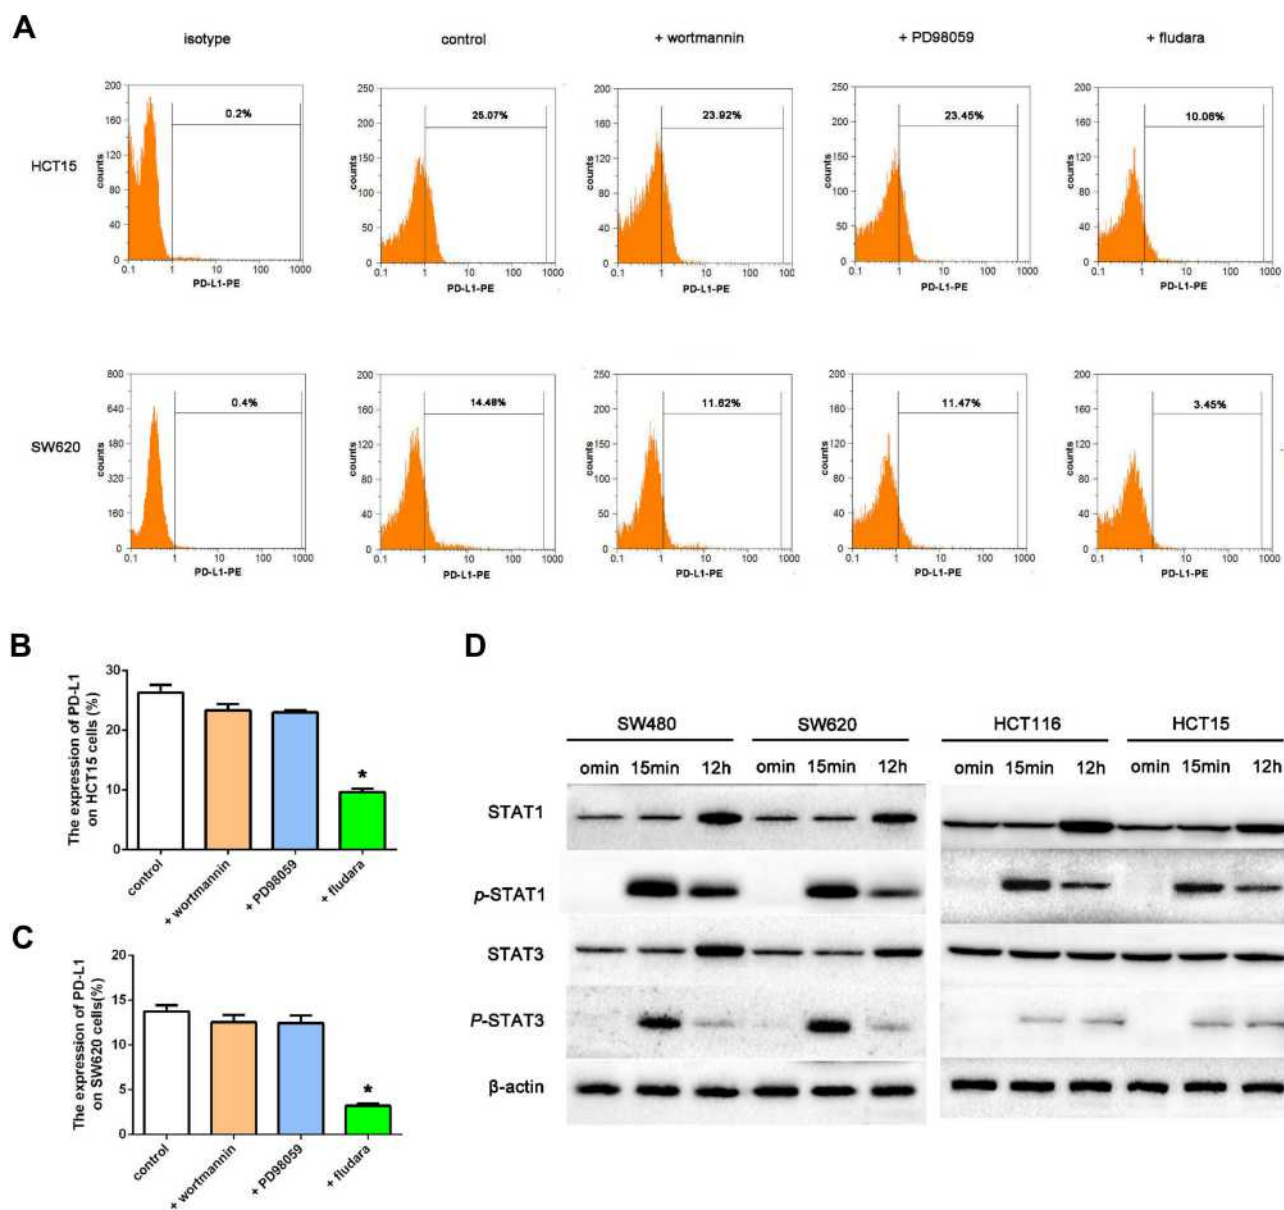

Figure 2 Effects of IFN γ and kinase inhibitors on PD-L1 expression in the MSI and MSS cell lines. **(A–C)** PD-L1 expression was measured by flow cytometry in HCT15 (the upper line) and SW620 (the lower line) cell lines 12 h after treatment with 100 IU/mL IFN γ , with 1 μ mol/L wortmannin (AKT inhibitor), 50 μ mol/L PD98059 (ERK1/2 inhibitor), or 50 μ mol/L fludara (STAT1 inhibitor). DMSO was used as a vehicle and negative control (* P < 0.05 vs cells treated with IFN γ and DMSO). **(D)** Expression levels of STAT1, p-STAT1, STAT3 and p-STAT3 in MSI cell lines (HCT116 and HCT15) as well as MSS cell lines (SW480 and SW620) with 100 IU/mL IFN γ for 15 min and 12 h, respectively.

investigations that show that MSI patients have a significantly higher rate of positivity for PD-L1 expression.^{22,24} Recent investigation²⁵ have suggested that IFN γ treatment converts immunologically quiet tumors into “hot” tumors and works in concert with anti-PD1 therapy to provide patient benefit. The mechanism may be partly associated with the increased expression of PD-L1 on tumor cells.

PD-L1 expression on tumor cells may be generally induced by oncogenic signals^{26,27} or can be upregulated

via IFN γ .^{28–30} Considering the similar low PD-L1 expression on CRC cells without IFN γ exposure in vitro, we then explored whether IFN γ /PD-L1 signaling molecules may have different effects on the response to IFN γ treatment in MSI cell lines. In our experiment, IFN γ exposure in vitro induced increased PD-L1 mRNA expression in line with the enhanced protein expression, which demonstrated that the upregulated PD-L1 molecules on CRC cell lines may be the result of IFN γ /PD-L1 signaling activation and new mRNA transcription, rather than translocation of

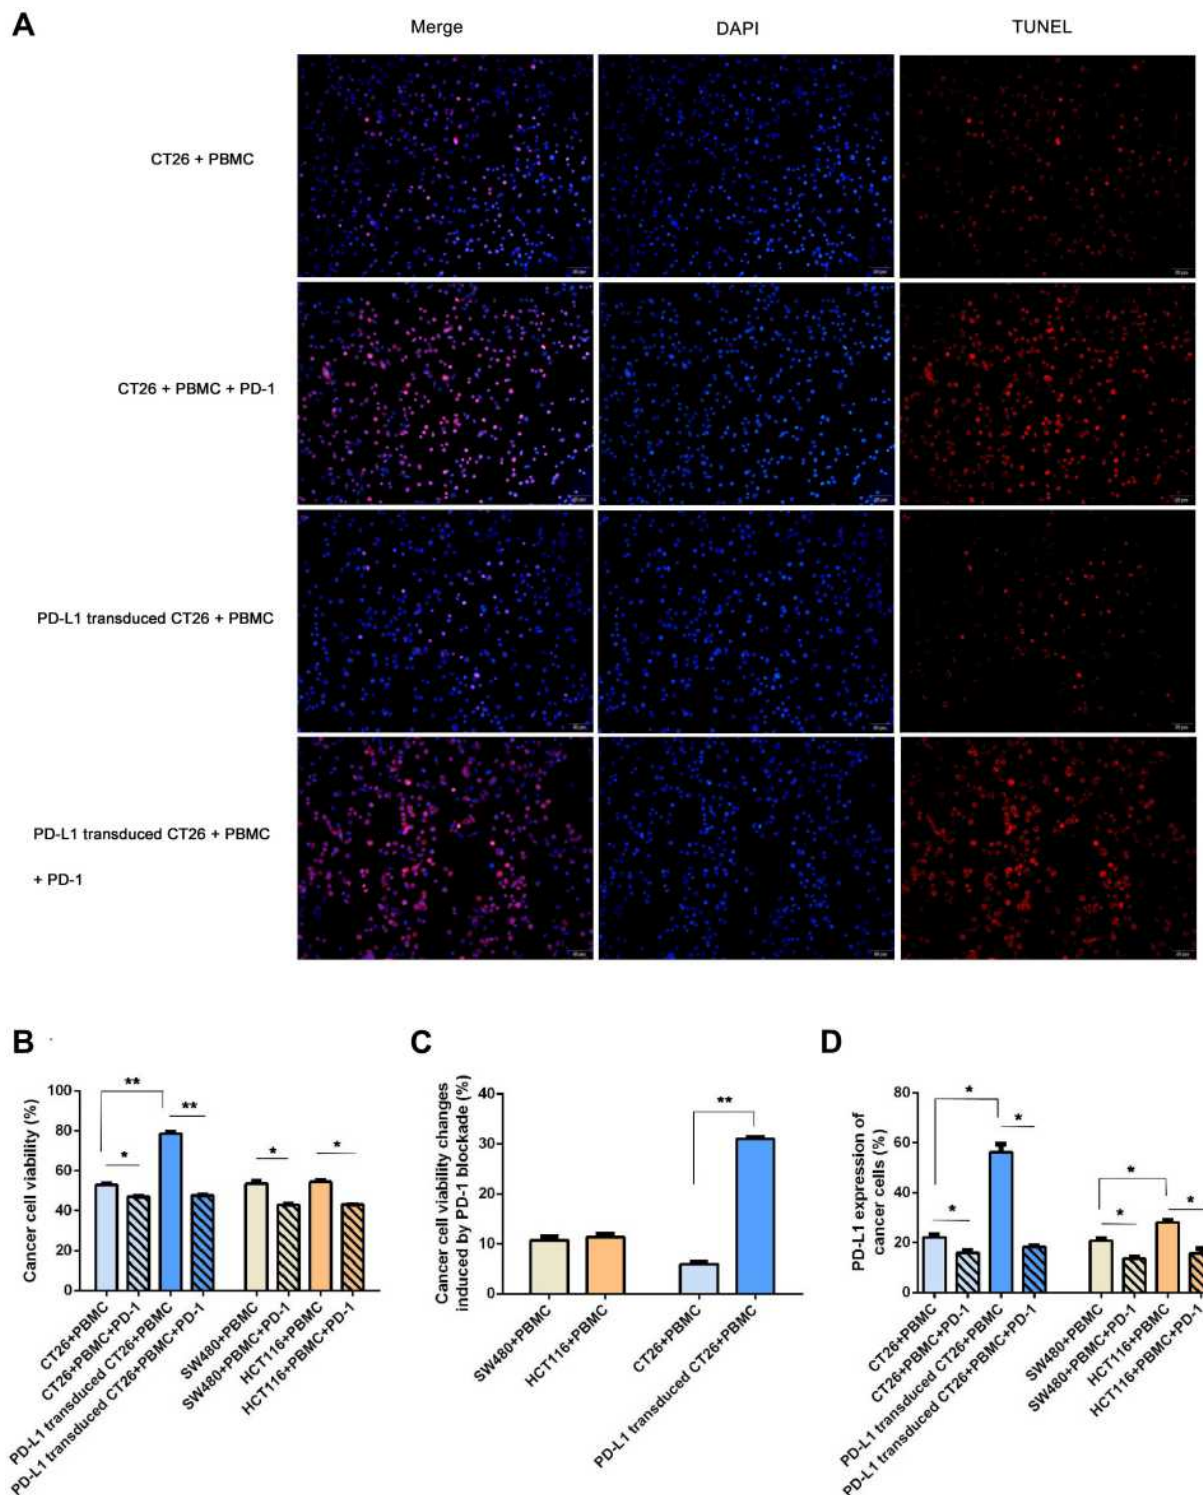

Figure 3 PD-L1 expression influenced neoplastic cells in response to PD-1 blockade. To investigate whether PD-L1 expression influences the response of PD-1 blockade immunotherapy in vitro, we performed two different profiles with higher PD-L1 expression in a coculture assay: PD-L1 transduced CT26 cell challenge (a higher extent of PD-L1 expression) and HCT116 enrolled (a lower degree of PD-L1 expression). **(A)** Cell apoptosis shown by TUNEL staining ($\times 40$, scale bar is $20\ \mu\text{m}$) in the four coculture assays. Shown by fluorescence microscopy, red indicates apoptotic cells stained by TUNEL, and blue indicates nuclei stained by DAPI. The number of TUNEL-positive cells (red color) and total number of cells (blue color) were captured with a fluorescence microscope. The rate of cell apoptosis was measured by the number of red cells divided by the number of blue cells. The apoptotic rate was $(26.00\pm 3.61)\%$ in group 1 (CT26+PBMC), $(12.33\pm 3.21)\%$ in group 2 (PD-L1 transduced CT26+PBMC), $(90.33\pm 2.52)\%$ in group 3 (CT26+PBMC+PD-1), and $(92.00\pm 2.65)\%$ in group 4 (PD-L1 transduced CT26+PBMC+PD-1). The apoptosis rate of group 3 was significantly decreased compared with that of group 1 ($p=0.001$). PD-1 blockade significantly induced an increased apoptosis rate in CT26-challenged ($p=0.003$), or PD-L1-transduced CT26 cell-exposed ($p=0.000$). No significant difference was observed among the two PD-1 blockade groups. **(B and C)** Effect of PD-1 blockade on viability of CT26, PD-L1 transduced CT26, SW480 and HCT116 cells. Cells were treated with IFN γ plus PD-1 blockade for 12 hours. Cell proliferation viability was measured using Cell Counting Kit-8 assay. Data represented as mean \pm SE of three independent experiments made in three replicates ($^*P < 0.05$, $^{**}P < 0.001$). **(D)** Effect of PD-1 blockade on PD-L1 expression of CT26, PD-L1 transduced CT26, SW480 and HCT116 cells. Cells were treated with IFN γ plus PD-1 blockade for 12 hours. PD-L1 expression of cancer cells was measured using flow cytometry ($^*P < 0.05$, $^{**}P < 0.001$).

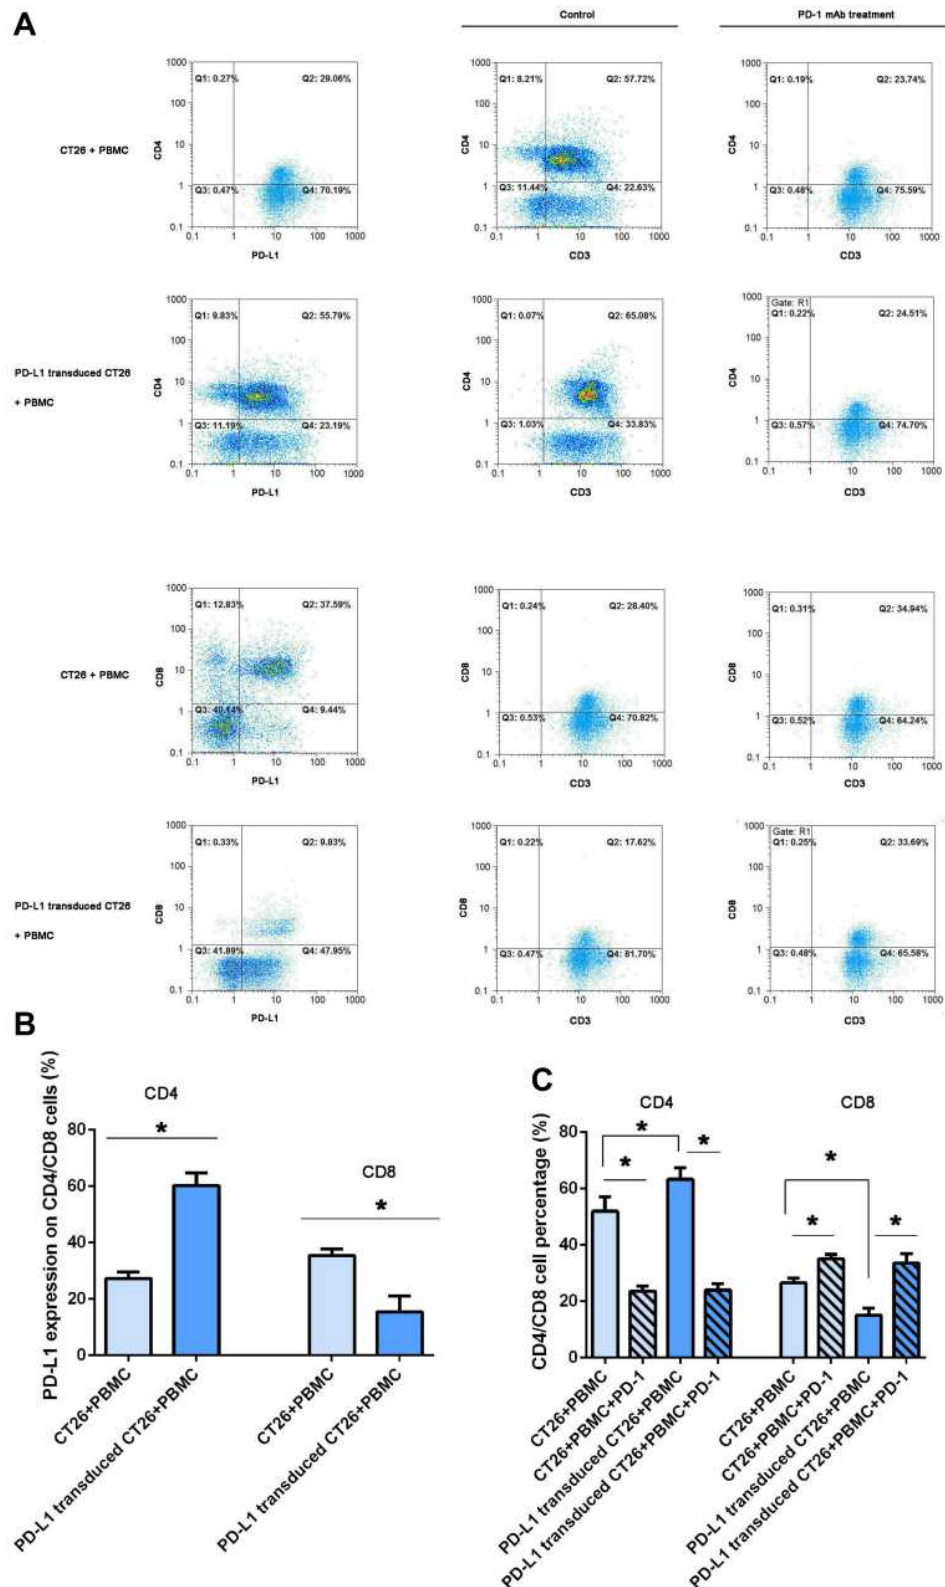

Figure 4 PD-L1 overexpression on CT26 cells influenced PD-L1 expression on CD4⁺/CD8⁺ lymphocytes and PD-1 blockade induced changes in CD4⁺/CD8⁺ cell counts. Analysis of PD-L1 expression on lymphocytes in a coculture assay and CD4⁺/CD8⁺ T cells by flow cytometry. **(A)** After 12 h following activation in the presence of 100 IU/mL IFN γ in the two coculture assays, the mononuclear cells were collected and PD-L1 expression was assessed by flow cytometry (the left column). CD4 and CD8 expression was, respectively, detected in the two coculture assays treated with IFN γ plus PD-1 blockade for 12 hours (the right column). One representative sample of three is shown. **(B)** The frequency of CD4⁺PD-L1⁺ and CD8⁺PD-L1⁺ T cells, and the frequency of CD4⁺CD3⁺ and CD8⁺CD3⁺ T cells **(C)** in different coculture assays was statistical analyzed (**P* < 0.05).

Figure 5 Immune-related gene expression profiles were assessed using RT-qPCR for selected genes. Sets of genes were defined by functional relevance: CD₄, Th1/Tc1, CTL, Th17, Treg and pro-inflammation related gene. To analyze the different responses to PD-1 blockade in a coculture assay with CT26 enrolled (the legend is "CT26", blue) or PD-L1 overexpressing CT26 challenged (the legend is "PD-L1 transduced CT26", red), we calculated the fold change in gene expression using the $2^{-\Delta\Delta C_t}$ method. *Indicates statistically significant differences, $p < 0.05$; **indicates $p < 0.001$.

preexisting intracellular PD-L1 protein stores to the cell surface. We also showed that IFN γ induces the expression of PD-L1 by increasing STAT1 signaling in all CRC cell lines. This raises the possibility that drugs targeting STAT1 might improve IFN γ -induced PD-L1 expression and enhance the efficiency of anti-PD-1 immunotherapy.

As shown in the current report, only MSS cell lines displayed obviously enhanced expression of STAT3 signaling molecules after IFN γ exposure. IFN γ decreased cytokine-induced activation of STAT3 while increasing STAT1 signaling.^{14,31–33} STAT1 may compete for STAT binding sites on the receptor, thereby interfering with the activation of STAT3. This demonstration of the involvement of distinct signaling pathways in driving PD-L1 expression in MSS genotype cells suggests new strategies for targeting STAT3 to improve the responsiveness of anti-PD-1 therapy in colorectal cancer. The broad spectrum of biological roles for STAT1/3 suggests that it could be difficult to target this factor specifically or selectively in MSS tumor cells, but these theoretical mechanisms should be kept in mind in future studies.

A literature review³⁴ highlighted that blockade of PD-1/PD-L1 ligation results in the preferential activation of

T-cells with specificity for cancer, restoring antitumor T cell activity. It is currently accepted that PD-1 blockade immunotherapy might play a remarkable role in tumor rejection through activated CD8⁺ cytotoxic T lymphocytes (CTLs). In our experiment, anti-PD-1 immunotherapy in the PD-L1-overexpressing CT26 cell coculture system in vitro displayed the highest extent of cancer cell viability rejection, in line with the increased apoptosis of CT26 cells, enhanced expression of CTL genes, Th17 genes and proinflammatory genes, and higher levels of CD8⁺ lymphocytes, compared with the CT26 cell coculture models treated with the same blockade. Consistent with our formal studies²³ in vivo, the experiment suggested that experimental PD-L1 overexpression on CT26 cells might play a remarkable role in tumor cell viability rejection in response to PD-1 immunotherapy, possibly through infiltrating cytotoxic T lymphocytes as well as proinflammatory factors, which promote cell apoptosis in the colorectal cancer microenvironment. Extremely elevated enhancement of CTL genes was not observed in the PD-L1-overexpressing CT26 cell coculture system after PD-1 blockade. Furthermore, it was a bit depressed that neither terminal neoplastic cell viability

nor apoptotic rate in coculture assays could be influenced by experimental PD-L1 overexpression on CT26 cells in the course of PD-1 blockade, which partly associated with the limited infiltrating cytotoxic T lymphocytes in the coculture assays in vitro. However, to the best of our knowledge, our present study is the first report observed that PD-1 blockade immunotherapy in PD-L1 higher-expression neoplastic cell interestingly displayed the higher extent of cancer cell viability rejection compared with the CT26 cell coculture models treated with the same blockade. Furthermore, the expression of Th17-associated genes also displayed an enhanced profile after PD-1 immunotherapy, especially in the PD-L1-overexpressing CT26 cell coculture assay. Published data³⁵ have shown that the IL-17A level is increased in the tumor tissues of CRC patients. Interestingly, PD-1 blockade increased the expression of Th17-associated genes. The paradoxical tendency induced by anti-PD-1 therapy might be partly associated with the decreased expression of Treg-associated genes. Lessening Treg immunity is favorable for eliminating neoplastic cells that have undergone PD-1 immunotherapy. In response to PD-1 blockade, experimental PD-L1 overexpression on CT26 cells induced prominently enhanced expression of genes encoding Th17, in line with the significantly decreased level of Treg-associated genes. It is probably concluded that PD-L1 overexpression on CT26 cells has little effect on maintaining the balance of Th17/Treg cells in the coculture assay, which responds to PD-1 blockade.

On the other hand, we observed that experimental PD-L1 overexpression on CT26 cells in the coculture assay was accompanied by a decreased amount of CD8⁺ lymphocytes in line with enhanced CD4⁺ lymphocytes. Recently, investigations³⁶ in gastric cancer patients demonstrated that positive PD-L1 status in tumor cells (tPD-L1) was associated with a higher density of CD8⁺ TILs. Nevertheless, tPD-L1 was associated with an increased number of CD4⁺ TILs only in the nonmetastasis group. The discrepancy in CD8⁺ cell changes might be partly attributed to the profile of higher PD-L1 expression on cancer cells. These data suggest that experimentally overexpressed PD-L1 in CT26 cells probably acted like a high-level molecular shield, resulting in anti-apoptosis of cells as well as decreased CD8⁺ lymphocytes. Although recent studies³⁷ were compelling as to whether the higher density of PD-L1 expressed in tumor cells or in tumor-infiltrating myeloid cells in the stroma was featured more prominently in anti-PD-1 therapy in CRC, this study also

extensively observed PD-L1 expression on CT26 neoplastic cells and CD4⁺/CD8⁺ lymphocytes in a coculture system in vitro. Specifically, PD-L1 expression on CD4⁺/CD8⁺ lymphocytes might be associated with changes in the number of lymphocytes.

In conclusion, this in vitro study revealed that the MSI cell line might exhibit hyperresponsiveness to IFN γ exposure, and IFN γ induced upregulation of PD-L1 mainly through increased STAT1 and decreased STAT3 signaling. Furthermore, IFN γ /PD-L1 signaling also participated in the response to anti-PD-1 therapy mainly through the CTL profile. Our findings reinforce previous knowledge of the fact that the response to immune checkpoint blockade occurs mainly in patients with a preexisting intratumoral IFN γ /PD-L1 signal. Understanding the complex mechanisms will open new opportunities for developing pharmaceutical targeted combination therapies to enhance the effects of anti-PD-1 immunotherapy.

Cell Line Authentication

Human CRC cell lines were obtained from the Institute of Zoology, Chinese Academy of Sciences (Kunming, China), and rat CRC CT26 cells were purchased from the Cell Bank of the Chinese Academy of Sciences (Shanghai, China). Cell Bank, Type Culture Collection, Chinese Academy of Sciences (CBTCCAS) can provide the Certificate of STR Analysis.

OncoTargets and Therapy

Dovepress

Publish your work in this journal

OncoTargets and Therapy is an international, peer-reviewed, open access journal focusing on the pathological basis of all cancers, potential targets for therapy and treatment protocols employed to improve the management of cancer patients. The journal also focuses on the impact of management programs and new therapeutic

agents and protocols on patient perspectives such as quality of life, adherence and satisfaction. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
